DOCA Documentation v3.3.0

Table of Contents

1 DOCA Framework 80
1.1 Introduction 80
1.2 DOCA Packages 80
1.2.1 DOCA-Host 81
1.2.2 BlueField-Bundle (BF-Bundle) 81
1.2.3 BlueField-Firmware Bundle (BF-FWBundle) 81
1.3 BlueField Devices 82
2 DOCA SDK 83
2.1 DOCA Overview 83
2.1.1 Introduction 83
2.1.2 Installation 86
2.1.3 API 86
2.1.4 Programming Guides 87
2.1.5 Applications 87
2.1.6 Tools 87
2.1.7 Services 87
2.2 DOCA Release Notes 88
2.2.1 Introduction 88
2.2.2 Installation Notes 88
2.2.3 Supported Device Speeds 89
2.2.4 Technical Support 90
2.2.5 Changes and New Features 90
2.2.5.1 DOCA Framework New Features and Updates 90
2.2.5.2 DOCA-Host and DOCA Drivers New Features and Updates 92
2.2.5.3 BlueField-3 Firmware Changes and New Features 94
2.2.5.4 BlueField-2 Firmware Changes and New Features 95
2.2.5.5 API Changes 95
2.2.5.6 Customer Affecting Changes 96
2.2.5.6.1 Changes in This Release 96
2.2.5.6.2 Changes Planned for Future Releases 97
2.2.5.6.3 Changes from Earlier Releases 98
2.2.5.6.4 Discontinued Features 102
2.2.5.7 Declared Unsupported Features 102
2.2.6 General Support 102
2.2.6.1 Supported Platforms and NIC Firmware Versions 102
2.2.6.2 Embedded DOCA Firmware Components - BlueField 103
2.2.6.3 Embedded DOCA Drivers 103

2.2.6.4 DOCA Packages 106
2.2.6.5 BlueField Operating System 106
2.2.6.6 Supported Host OS per DOCA-Host Installation Profile 107
2.2.6.7 Storage Supported DOCA-Host Operating Systems 110
2.2.6.8 DOCA-Host Version Interoperability 111
2.2.6.9 Supported Devices 112
2.2.7 Bug Fixes in This Version 112
2.2.7.1 DOCA Framework Bug Fixes 112
2.2.7.2 DOCA-Host and DOCA Drivers Bug Fixes 114
2.2.7.3 BSP Bug Fixes 115
2.2.7.4 BMC Bug Fixes 116
2.2.7.5 BlueField-3 Firmware Bug Fixes 116
2.2.7.6 BlueField-2 Firmware Bug Fixes 118
2.2.8 Known Issues 118
2.2.8.1 DOCA Framework Known Issues 118
2.2.8.2 DOCA-Host and DOCA Drivers Known Issues 126
2.2.8.3 BlueField-3 Firmware Known Issues 129
2.2.8.4 BlueField-2 Firmware Known Issues 133
2.2.9 BlueField Firmware Cables 135
2.2.9.1 BlueField-3 Validated and Supported Cables and Modules 136
2.2.9.1.1 Cables Lifecycle Legend 136
2.2.9.1.2 NDR / 400GbE Cables 136
2.2.9.1.3 HDR / 200GbE Cables 139
2.2.9.1.4 EDR / 100GbE Cables 144
2.2.9.1.5 FDR / 56GbE Cables 148
2.2.9.1.6 25GbE Cables 150
2.2.9.1.7 10GbE Cables 151
2.2.9.1.8 1GbE Cables 152
2.2.9.1.9 Supported 3rd Party Cables and Modules 152
2.2.9.2 BlueField-2 Validated and Supported Cables and Modules 160
2.2.9.2.1 Cables Lifecycle Legend 160
2.2.9.2.2 NDR Cables 161
2.2.9.2.3 HDR / 200GbE Cables 164
2.2.9.2.4 EDR / 100GbE Cables 167
2.2.9.2.5 FDR / 56GbE Cables 168
2.2.9.2.6 50GbE Cables 169
2.2.9.2.7 40GbE Cables 169
2.2.9.2.8 25GbE Cables 171
2.2.9.2.9 10GbE Cables 172
2.2.9.2.10 1GbE Cables 173
2.2.9.2.11 Supported 3rd Party Cables and Modules 174
2.3 BlueField and DOCA User Types 178
2.3.1 Introduction 178

2.3.2 DOCA Components 179
2.3.3 BlueField Networking Platform User Types 181
2.3.3.1 BlueField Administrator 181
2.3.3.2 DOCA Developer 182
2.4 DOCA EULA 182
2.4.1 End-User License Agreement 182
2.4.2 DOCA Legal Notices and 3rd Party Licenses 189
3 Quick Start for BlueField Developers 192
3.1 DOCA Developer Quick Start Guide 192
3.1.1 Introduction 192
3.1.2 Install BlueField Networking Platform 192
3.1.3 Install DOCA Software Package 193
3.1.4 Access BlueField 193
3.1.5 Run Reference DOCA Application 193
3.1.6 More Information 194
4 Installation and Setup 195
4.1 DOCA Profiles 195
4.1.1 Introduction 195
4.1.2 Which Profile to Install? 196
4.1.3 Profile Details 197
4.1.3.1 doca-all 197
4.1.3.2 doca-networking 197
4.1.3.3 doca-ofed 198
4.1.3.4 doca-roce 198
4.1.3.5 doca-host-basic 198
4.1.4 Supported Devices 198
4.1.5 Profile Installation Notes 199
4.1.6 MLNX_OFED to DOCA-OFED Transition Guide 199
4.1.6.1 Introduction 199
4.1.6.2 What is DOCA-Host? 199
4.1.6.3 What is DOCA-OFED? 200
4.1.6.4 Why Switch to DOCA-OFED and DOCA-Host? 200
4.1.6.5 Switching to DOCA-OFED and DOCA-Host 200
4.1.6.5.1 Installation Example of DOCA-OFED from Online Repo 201
4.1.6.5.2 Installation Example of DOCA-OFED Offline Repo 201
4.1.6.6 MLNX_EN Transition 201
4.1.6.7 Transition Timeline 201
4.1.6.8 Summary 203
4.2 BlueField Modes of Operation 204

4.2.1 Introduction 204
4.2.1.1 NIC Mode 204
4.2.1.2 DPU Mode 205
4.2.1.2.1 DPU Mode Architecture 205
4.2.1.2.2 InfiniBand in DPU Mode 206
4.2.1.3 DPU Mode in Zero Trust 206
4.2.2 Moving Between Operation Modes 207
4.2.2.1 Identifying Which Mode BlueField is Currently Operating In 209
4.2.2.2 Changing Mode 211
4.2.2.2.1 Using External Host Command Line 211
4.2.2.2.2 Using External Host UEFI Menu 212
4.2.2.2.3 Using Arm OS Command Line 214
4.2.2.2.4 Using Arm UEFI Menu 215
4.2.2.2.5 Using DPU-BMC Redfish 216
4.2.2.2.6 Using Platform-BMC NC-SI OEM Commands 217
4.3 DOCA Installation Guide for Linux 218
4.3.1 Introduction 218
4.3.2 Supported Networking Platforms 218
4.3.3 Hardware Prerequisites 219
4.3.4 DOCA Packages 219
4.3.5 Supported Host OS per DOCA-Host Installation Profile 219
4.3.6 Setting Up Build Environment for Developers 219
4.3.7 Available BF-Bundle Installation and Upgrade Methods 219
4.3.8 DOCA-Host Installation and Upgrade 220
4.3.8.1 Uninstalling Software from Host 221
4.3.8.2 Installing Software on Host 221
4.3.8.3 Upgrading Software on Host 223
4.3.8.4 Package and Kernel Module Signing 223
4.3.8.4.1 Package Signing 223
4.3.8.4.2 Kernel Module Signing 224
4.3.8.5 DOCA Extra Package and doca-kernel-support 224
4.3.8.6 Storage Installation 227
4.3.8.6.1 VMA Installation 227
4.3.8.6.2 XLIO Installation 228
4.3.8.7 Installing Proprietary Packages 228
4.3.8.7.1 Download and Install MFT and Firmware 229
4.3.8.8 DOCA-Host Installation and DKMS Management Guide 229
4.3.8.8.1 Introduction 229
4.3.8.8.2 Understanding DKMS 229
4.3.8.8.3 Supported Platforms and Profiles 230
4.3.8.8.4 Installation Procedure 230
4.3.8.8.5 Secure Boot and Package Signing 231

4.3.9 BF-Bundle Installation and Upgrade 231
4.3.9.1 Installing DOCA-Host 232
4.3.9.2 Installing Software on BlueField Using BF-Bundle 232
4.3.9.2.1 Option 1 – No Pre-defined Password 232
4.3.9.2.2 Option 2 – Set Pre-defined Password 233
4.3.9.3 Upgrading BlueField Using Standard Linux Tools 235
4.3.9.3.1 DEB-based 236
4.3.9.3.2 RPM-based 238
4.3.9.4 Installing Multiple BlueField Devices with DOCA Installer Tool 241
4.3.9.4.1 Prerequisites 241
4.3.9.4.2 DOCA Installer Operation Modes 242
4.3.9.4.3 Configuration File Options 243
4.3.9.4.4 Logs and Debuggability 244
4.3.9.4.5 DOCA Installer Standalone Flags 245
4.3.9.4.6 BlueField-2 Limitation 248
4.3.9.5 Building Custom BFB Installation Image 248
4.3.10 Additional SDKs for DOCA 249
4.3.10.1 Installing CUDA on NVIDIA Converged Accelerator 249
4.3.10.1.1 Configuring Operation Mode 249
4.3.10.1.2 Downloading and Installing CUDA Toolkit and Driver 250
4.3.10.1.3 GPUDirect RDMA 251
4.3.10.2 Installing Rivermax on BlueField 251
4.3.10.2.1 Downloading Rivermax Driver 251
4.3.10.2.2 Installing Rivermax Driver 252
4.3.10.2.3 Installing Rivermax Libraries from DOCA 252
4.4 DOCA Developer Guide 252
4.4.1 Introduction 253
4.4.2 Developing Using BlueField Networking Platform 254
4.4.2.1 Setup 254
4.4.2.2 Development 255
4.4.2.3 Testing 256
4.4.2.4 Publishing 256
4.4.3 Developing Without BlueField Networking Platform 256
4.4.3.1 Setup 254
4.4.3.2 Development 255
4.4.3.3 Testing 258
4.4.3.4 Publishing 256
5 DOCA Programming Guide 260
5.1 DOCA Programming Overview 260
5.1.1 Hardware Architecture 260
5.1.1.1 Arm Cores 261
5.1.1.2 Accelerated Programmable Pipeline 261

5.1.1.3 Data-Path Accelerator 261
5.1.2 DOCA SDK Architecture 262
5.1.2.1 Device Subsystem 262
5.1.2.1.1 Device Abstraction 262
5.1.2.1.2 DOCA Device Types 262
5.1.2.2 Memory Management Subsystem 263
5.1.2.3 Execution Model 265
5.1.2.3.1 Task and Event Model 265
5.1.2.3.2 Progress Engine – Managing Asynchronous Processing 265
5.2 DOCA Compatibility Policy 266
5.2.1 Introduction and Purpose 267
5.2.2 Defining Compatibility 267
5.2.2.1 Layers 267
5.2.2.2 Type of Compatibility 267
5.2.2.3 Direction of Compatibility 268
5.2.3 Software Release and Versioning Policy 268
5.2.4 DOCA Compatibility Policy Types 268
5.2.5 DOCA Dependency Compatibility Policy 269
5.2.5.1 Key Objectives 269
5.2.5.2 DOCA Dependency Policy Levels 269
5.2.5.2.1 Level 1: Perpetual Dependency Compatibility 269
5.2.5.2.2 Level 2: Limited Dependency Compatibility 270
5.2.5.3 Application of Policies 270
5.2.5.4 Update Methodology 270
5.2.6 DOCA SDK Compatibility Policy 271
5.2.6.1 DOCA SDK Versioning 271
5.2.6.2 DOCA SDK API Backward Compatibility 271
5.2.6.2.1 Source Compatibility 272
5.2.6.2.2 Binary Compatibility 272
5.2.6.2.3 Behavioral Compatibility 273
5.2.6.3 Backward Compatibility for Non-Opaque Structs Using CTSD 273
5.2.6.3.1 Library Version Management 273
5.2.6.3.2 User Responsibility 273
5.2.6.4 DPA SDK Compatibility Considerations 274
5.2.6.5 DOCA SDK Protocol Compatibility 274
5.2.6.6 DOCA SDK Dependencies Compatibility 275
5.3 DOCA Development Best Practices 275
5.3.1 Capability Checking 275
5.3.1.1 Device Capability 275
5.3.1.2 Library Capability 276
5.3.1.3 Core Capability 276
5.3.2 Debuggability 277

5.3.2.1 Return Values 277
5.3.2.2 SDK Logging 277
5.4 DOCA Libraries 277
5.4.1 DOCA Common 278
5.4.1.1 DOCA Core 279
5.4.1.1.1 Introduction 279
5.4.1.1.2 Prerequisites 280
5.4.1.1.3 Changes From Previous Releases 281
5.4.1.1.4 Architecture 281
5.4.1.1.5 DOCA Core Samples 322
5.4.1.1.6 Backward Compatibility of DOCA Core doca_buf 327
5.4.1.1.7 Sync Event 327
5.4.1.1.8 Mmap Advise 345
5.4.1.2 DOCA Log 351
5.4.1.2.1 Log Verbosity Level Enumerations 351
5.4.1.2.2 Logging Backends 351
5.4.1.2.3 Enabling DOCA SDK Libraries Logging 352
5.4.1.2.4 Enabling DOCA Application Logging 353
5.4.1.2.5 Logging DOCA Application Messages 353
5.4.1.2.6 Controlling Verbosity Level of Loggers 354
5.4.2 DOCA Flow 354
5.4.2.1 Introduction 355
5.4.2.2 Prerequisites 356
5.4.2.3 Architecture 356
5.4.2.4 Steering Domains 357
5.4.2.4.1 List of Steering Domains 357
5.4.2.4.2 Domains in VNF Mode 358
5.4.2.4.3 Domains in Switch Mode 359
5.4.2.5 API 360
5.4.2.6 Flow Life Cycle 360
5.4.2.6.1 Initialization Flow 360
5.4.2.6.2 Start Point 365
5.4.2.6.3 Port Operation State 366
5.4.2.6.4 Create Pipe and Pipe Entry 368
5.4.2.6.5 Teardown 404
5.4.2.7 Metadata 405
5.4.2.7.1 Metadata Actions 405
5.4.2.7.2 Behavior and Usage Considerations 406
5.4.2.7.3 Metadata Field Breakdown 406
5.4.2.7.4 Pipe Design Consideration 406
5.4.2.7.5 Scratch Area Usage by Pipe Type 407
5.4.2.7.6 Supported Metadata Fields per Hardware and Mode 407
5.4.2.8 Custom Header 408

5.4.2.8.1 Network Header Properties 408
5.4.2.8.2 IPv4 Header Definition Example 409
5.4.2.8.3 GENEVE Header Definition Example 410
5.4.2.8.4 GENEVE Option Definition Example 410
5.4.2.8.5 UDP Header Definition Example 411
5.4.2.8.6 Custom Header Lifecycle 412
5.4.2.8.7 Match and Actions Fields 414
5.4.2.8.8 Known Limitations 414
5.4.2.8.9 NIC Configuration for Custom Header Support 415
5.4.2.9 Packet Processing 416
5.4.2.10 Debug and Trace Features 417
5.4.2.10.1 Installation 417
5.4.2.10.2 Using Trace Libraries 417
5.4.2.10.3 Trace Features 418
5.4.2.11 DOCA Flow Samples 418
5.4.2.11.1 Sample Prerequisites 418
5.4.2.11.2 Running the Sample 419
5.4.2.12 Field String Mapping 420
5.4.2.12.1 Field String Supported Actions 420
5.4.2.12.2 Non-Matchable Field Strings 428
5.4.2.13 DOCA Flow Connection Tracking 429
5.4.2.13.1 Introduction 429
5.4.2.13.2 Architecture 429
5.4.2.13.3 Prerequisites 431
5.4.2.13.4 Actions 433
5.4.2.13.5 Changeable Forward 435
5.4.2.13.6 API 436
5.4.2.13.7 DOCA Flow Connection Tracking Samples 441
5.4.2.14 DOCA Flow Tune Server 442
5.4.2.14.1 Introduction 442
5.4.2.14.2 Prerequisites 443
5.4.2.14.3 Configuration 443
5.4.2.14.4 API 444
5.4.3 DPA Subsystem 445
5.4.3.1 Multiple Processes on Multiple Execution Units 447
5.4.3.2 DPA RTOS 447
5.4.3.3 DPA Memory and Caches 447
5.4.3.4 DPA Access to NIC Accelerators 448
5.4.3.5 DPA Development 448
5.4.3.5.1 Overview 448
5.4.3.5.2 Flex IO SDK 463
5.4.3.5.3 DPA Application Authentication 479
5.4.3.5.4 Distribution of Execution Units Across Multiple Applications 499
5.4.3.5.5 Known Limitations 500

5.4.3.6 DOCA DPA 501
5.4.3.6.1 Introduction 501
5.4.3.6.2 Prerequisites 502
5.4.3.6.3 Library Changes From Previous Releases 502
5.4.3.6.4 Development Flow 503
5.4.3.6.5 Software Architecture 505
5.4.3.6.6 Hello World Example 528
5.4.3.6.7 Samples 531
5.4.3.7 DOCA PCC 540
5.4.3.7.1 Introduction 540
5.4.3.7.2 Prerequisites 541
5.4.3.7.3 Changes From Previous Releases 542
5.4.3.7.4 Dependencies 542
5.4.3.7.5 Architecture 542
5.4.3.7.6 API 545
5.4.3.8 DOCA DPA Comms 556
5.4.3.8.1 Introduction 556
5.4.3.8.2 Architecture 556
5.4.3.9 DOCA DPA Verbs 560
5.4.3.9.1 Overview 560
5.4.3.9.2 Deployment 561
5.4.3.9.3 Architecture 561
5.4.3.9.4 Core Concepts 563
5.4.3.9.5 API Reference 564
5.4.3.9.6 Integration with Host-side DOCA RDMA Verbs 569
5.4.3.9.7 Usage Patterns 571
5.4.3.9.8 Optimizing Performance with Compile-Time Constants 572
5.4.4 DOCA DMA 573
5.4.4.1 Introduction 573
5.4.4.2 Prerequisites 573
5.4.4.3 Library Changes From Previous Releases 573
5.4.4.3.1 Changes in 2.9.0 573
5.4.4.4 Environment 574
5.4.4.5 Architecture 574
5.4.4.5.1 Objects 575
5.4.4.6 Configuration Phase 575
5.4.4.6.1 Configurations 576
5.4.4.6.2 Device Support 576
5.4.4.6.3 Buffer Support 576
5.4.4.7 Execution Phase 576
5.4.4.7.1 Tasks 577
5.4.4.7.2 Events 578
5.4.4.8 State Machine 578
5.4.4.8.1 Idle 578

5.4.4.8.2 Starting 578
5.4.4.8.3 Running 579
5.4.4.8.4 Stopping 579
5.4.4.9 Alternative Datapath Options 579
5.4.4.9.1 GPU Datapath 580
5.4.4.10 DOCA DMA Samples 580
5.4.4.10.1 Running the Samples 580
5.4.4.10.2 Samples 581
5.4.5 DOCA Comch 583
5.4.5.1 Introduction 583
5.4.5.2 Prerequisites 584
5.4.5.3 Changes From Previous Release 584
5.4.5.4 Environment 585
5.4.5.5 Architecture 585
5.4.5.5.1 Objects 586
5.4.5.5.2 Security Considerations 587
5.4.5.5.3 Initialization Flow 587
5.4.5.5.4 Teardown Flow 590
5.4.5.5.5 MsgQ (DPA Communication) 591
5.4.5.6 Configuration Phase 592
5.4.5.6.1 Configurations 592
5.4.5.6.2 Device Support 594
5.4.5.6.3 Buffer Support 594
5.4.5.7 Execution Phase 594
5.4.5.7.1 Tasks 595
5.4.5.7.2 Events 598
5.4.5.8 State Machine 600
5.4.5.8.1 Idle 600
5.4.5.8.2 Starting 600
5.4.5.8.3 Running 601
5.4.5.8.4 Stopping 601
5.4.5.9 Alternative Datapath Options 602
5.4.5.9.1 DPA Support 602
5.4.5.9.2 GPU Datapath Support 605
5.4.5.10 DOCA Comch Samples 606
5.4.5.10.1 Running the Samples 607
5.4.5.10.2 Samples 607
5.4.6 DOCA UROM 609
5.4.6.1 Introduction 609
5.4.6.2 Prerequisites 610
5.4.6.3 Architecture 611
5.4.6.3.1 UROM Deployment 611
5.4.6.3.2 UROM Framework 611
5.4.6.3.3 UROM Installation 613

5.4.6.4 API ... 615

8.11.3.9.1 Configuration File Examples 2652
8.11.3.9.2 Configuration Parameters 2653
8.11.3.10 Appendix – Frequently Asked Questions 2655
8.11.3.10.1 How do I enable SNAP? 2655
8.11.3.10.2 How do I configure SNAP to support VirtIO-blk? 2655
8.11.3.10.3 How do I configure SNAP to work with both ports (for the same or for multiple targets)? 2656
8.11.3.10.4 How do I configure offload mode? Which protocols are supported? 2657
8.11.3.10.5 How do I configure Firmware for SNAP? 2657
8.11.3.10.6 Can I work with custom SPDK on Arm? 2657
8.11.3.10.7 Can I replace my backend storage at runtime? 2658
8.11.3.10.8 I'm suffering from low performance after updating to latest mlnx-snap. How can I fix it? 2658
8.11.3.11 SNAP-3 Release Notes 2659

1 DOCA Framework

> DOCA v3.3.0 is tested as part of Spectrum-X reference architecture release version 2.1. For a list of approved releases, refer to the NVIDIA Spectrum-X Validated Solution Stack.

This page provides an overview of the NVIDIA DOCA Framework including details on its architecture, installation packages, and software components.

1.1 Introduction

The DOCA Framework provides a comprehensive software suite that includes drivers, libraries, tools, and low-level software for interacting with hardware devices and the default operating system installed with BlueField.

Rather than being a single installation package, the DOCA Framework is a collection of DOCA-related software components, distributed through two primary packages: DOCA-Host and BlueField-Bundle.

The framework consists of two main parts:

DOCA SDK	Enables developers to quickly build applications and services on NVIDIA® BlueField® networking platforms, leveraging industry-standard APIs and the power of NVIDIA BlueField DPUs and SuperNICs. DOCA SDK documentation is available here.
BlueField Platform Software	Provides the essential components for booting and configuring BlueField devices, including bootloaders, firmware, and the official Ubuntu-based reference Linux distribution. It contains the ATF/UEFI, BMC firmware, and BlueField NIC firmware. BlueField platform software documentation is available here.

1.2 DOCA Packages

To ensure an optimal installation of DOCA on your host and device, DOCA provides the installation packages presented in the following subsections.

1.2.1 DOCA-Host

DOCA-Host is the software package installed on the host server to support NVIDIA devices, including BlueField and ConnectX.

DOCA-Host offers multiple installation profiles, each tailored to specific use cases:

- doca-all
- doca-networking
- doca-ofed

See details on installation profiles and supported host operating systems here.

1.2.2 BlueField-Bundle (BF-Bundle)

The BlueField software bundle (BF-Bundle) is installed on the BlueField Arm cores to provide a complete DOCA experience on the BlueField networking platform. BlueField devices are shipped with BF-Bundle preinstalled.

BF-Bundle includes:

- DOCA SDK libraries, drivers, and tools
- BlueField Platform Software
- The default operating system for BlueField Arm cores (Ubuntu 22.04)

1.2.3 BlueField-Firmware Bundle (BF-FWBundle)

The BlueField Firmware Bundle (BF-FWBundle) is a minimal software package installed on the BlueField Arm cores. It provides only the management interface required for external provisioning and software loading.

BF-FWBundle includes:

- ATF
- UEFI
- BlueField NIC Firmware
- BMC Firmware
- eROT Firmware

BF-FWBundle does not include:

- DOCA SDK
- An operating system for BlueField Arm cores

1.3 BlueField Devices

BlueField user manuals provide detailed instructions on installation, supported interfaces, specifications, and troubleshooting.

2 DOCA SDK

This section contains the following pages:

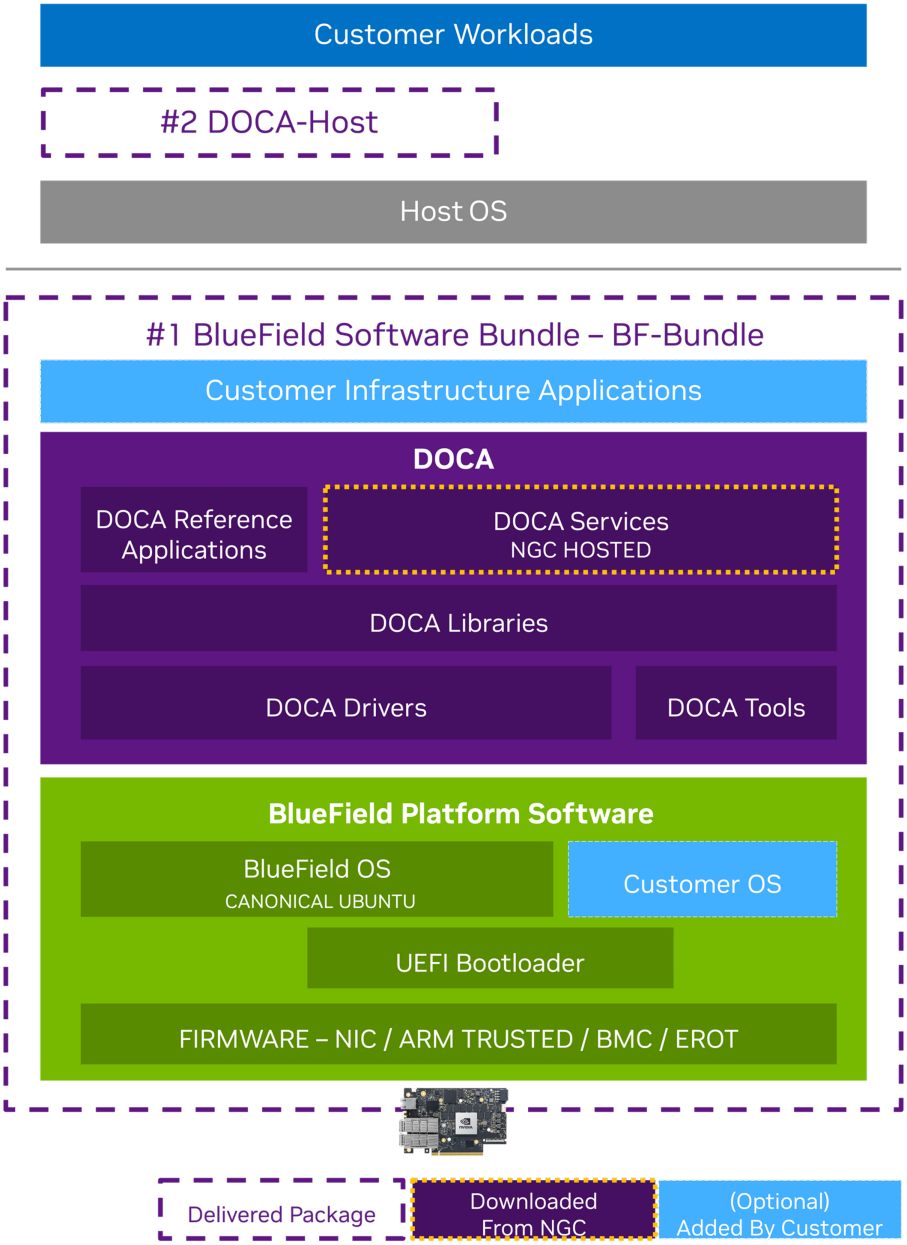
- DOCA Overview
- DOCA Release Notes
- BlueField and DOCA User Types
- DOCA EULA

2.1 DOCA Overview

This is an overview of the structure of NVIDIA DOCA documentation. It walks you through DOCA's developer zone portal which contains all the information about the DOCA toolkit from NVIDIA, providing all you need to develop NVIDIA® BlueField®-accelerated applications and the drivers for the host.

2.1.1 Introduction

The NVIDIA DOCA™ Framework enables rapidly creating and managing applications and services on top of the BlueField networking platform, leveraging industry-standard APIs. With DOCA, developers can deliver breakthrough networking, security, and storage performance by harnessing the power of NVIDIA's BlueField data-processing units (DPUs) and SuperNICs. Installing DOCA on your host provides all the necessary drivers and tools to manage NVIDIA® BlueField® and NVIDIA® ConnectX® devices.



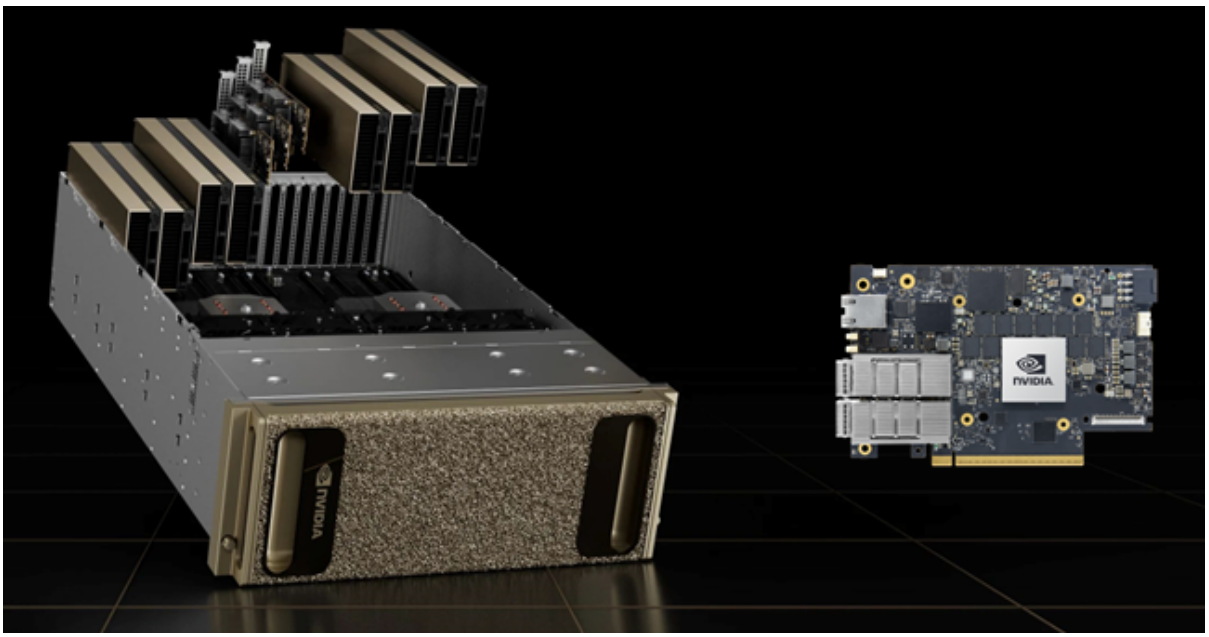
DOCA Framework includes the DOCA-Host package and the BlueField Software Bundle for BlueField Arm:

- BlueField Software Bundle (BF-Bundle) is the software package installed on the BlueField Arm cores
- DOCA-Host is the software package installed on the host server which includes different DOCA installation profiles

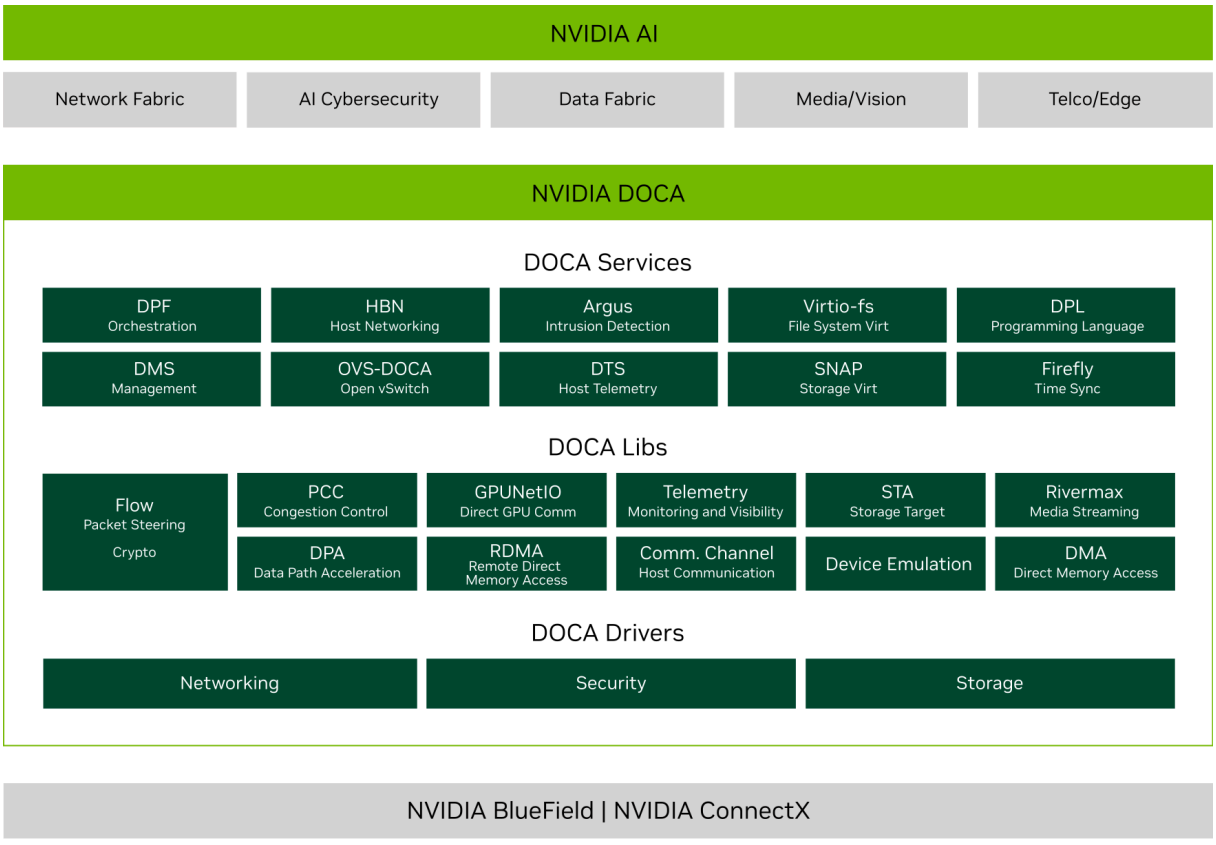
The BlueField Software Bundle includes:

- The DOCA runtime drivers and libs installed on top of the BlueField Platform
- The OS installed on the BlueField Platform
- The BlueField Platform Software (i.e., firmware and UEFI bootloader)

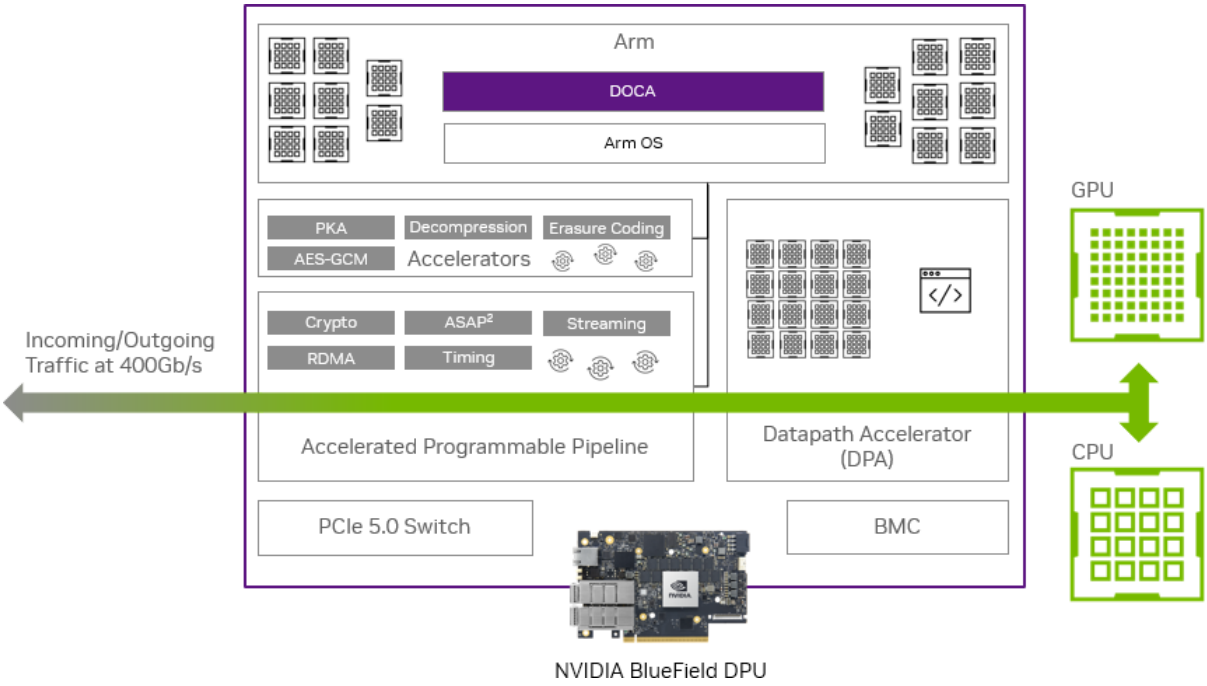
DOCA provides all the required libraries and drivers for hosts that include NVIDIA Networking platforms (i.e., BlueField and ConnectX) with a dedicated DOCA-Host package installation.



DOCA contains a runtime and development environment, including libraries and drivers for device management and programmability, for the host and as part of a BlueField Platform Software.



DOCA is the software infrastructure for BlueField's main hardware entities:



2.1.2 Installation

Installation instructions for both host and BlueField image can be found in the DOCA Installation Guide for Linux.

Whether DOCA has been installed on the host or on the BlueField networking platform, one can find the different DOCA components under the `/opt/mellanox/doca` directory. These include the traditional SDK-related components (libraries, header files, etc.) as well as the DOCA samples, applications, tools and more, as described in this document.

2.1.3 API

The DOCA SDK is built around the different DOCA libraries designed to leverage the capabilities of BlueField. Under the Programming Guide section, one can find a detailed description of each DOCA library, its goals, and API. These guides document DOCA's API, aiming to help develop DOCA-based programs.

The API References section holds the Doxygen-generated documentation of DOCA's official API.

2.1.4 Programming Guides

DOCA programming guides provide the full picture of DOCA libraries and their APIs. Each guide includes an introduction, architecture, API overview, and other library-specific information.

Each library's programming guide includes code snippets for achieving basic DOCA-based tasks. It is recommended to review these samples while going over the programming guide of the relevant DOCA library to learn about its API. The samples provide an implementation example of a single feature of a given DOCA library.

For a more detailed reference of full DOCA-based programs that make use of multiple DOCA libraries, please refer to the Reference Applications.

2.1.5 Applications

Applications are a higher-level reference code than the samples and demonstrate how a full DOCA-based program can be built. In addition to the supplied source code and compilation definitions, the applications are also shipped in their compiled binary form. This is to allow users an out-of-the-box interaction with DOCA-based programs without the hassle of a developer-oriented compilation process.

Many DOCA applications combine the functionality of more than one DOCA library and offer an example implementation for common scenarios of interest to users such as application recognition according to incoming/outgoing traffic, scanning files using the hardware RegEx acceleration, and much more.

For more information about DOCA applications, refer to DOCA Reference Applications.

2.1.6 Tools

Some of the DOCA libraries are shipped alongside helper tools for both runtime and development. These tools are often an extension to the library's own API and bridge the gap between the library's expected input format and the input available to the users.

For more information about DOCA tools, refer to DOCA Tools.

2.1.7 Services

DOCA services are containerized DOCA-based programs that provide an end-to-end solution for a given use case. DOCA services are accessible as part of NVIDIA's container catalog (NGC) from which they can be easily deployed directly to BlueField, and sometimes also to the host.

For more information about container-based deployment to the BlueField Platform, refer to the DOCA Container Deployment Guide.

For more information about DOCA services, refer to the DOCA Services.

For questions, comments, and feedback, please contact us at doca-feedback@nvidia.com.

2.2 DOCA Release Notes

NVIDIA DOCA SDK release notes contain information on new features, software interoperability, and known issues.

2.2.1 Introduction

The DOCA release notes contain the following subpages:

- Changes and New Features
- General Support
- Bug Fixes in This Version
- Known Issues
- BlueField Firmware Cables

2.2.2 Installation Notes

BlueField-3 devices are not supported with MLNX_OFED as the host driver. They must use DOCA-Host.

BlueField DPUs with the following SKUs require an 8-pin ATX power supply cable connection when powering up. Without this connection to the power supply cable, the device will not complete the power-on procedure and will not function properly.

- B3220 DPUs – 900-9D3B6-00CV-AA0 and 900-9D3B6-00SV-AA0
- B3240 DPUs – 900-9D3B6-00CN-AB0 and 900-9D3B6-00SN-AB0
- B3210 DPUs – 900-9D3B6-00CC-AA0 and 900-9D3B6-00SC-AA0
- B3210E DPUs – 900-9D3B6-00CC-EA0 and 900-9D3B6-00SC-EA0

Refer to the DOCA Installation Guide for Linux for information on:

- Setting up the DOCA SDK on your BlueField networking platform or SmartNIC
- Supported BlueField platforms

DOCA Runtime and DOCA Devel (SDK)

By default, installing DOCA profiles with standard Linux tools (yum, apt) installs both `doca-runtime` and `doca-devel` (previously `doca-sdk`).

- `doca-runtime` includes all components, libraries, drivers, and tools used in a production environment by a DOCA admin
- `doca-devel` includes all components, libraries, drivers, and tools used for development, including reference applications, compilers, etc.

2.2.3 Supported Device Speeds

Uplink/Adapter Card	Driver Name	Uplink Speed
BlueField-3	mlx5	• InfiniBand: SDR, FDR, EDR, HDR100, HDR, NDR200, NDR • Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE, 100GbE, 200GbE, 400GbE
BlueField-2		• InfiniBand: SDR, FDR, EDR, HDR • Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE [1], 100GbE [1]
BlueField		• InfiniBand: SDR, QDR, FDR, FDR10, EDR • Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE, 100GbE
ConnectX-8		• InfiniBand: SDR, FDR, EDR, HDR100, HDR, NDR200, NDR, XDR • Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE, 100GbE, 200GbE, 400GbE
ConnectX-7		• InfiniBand: EDR, HDR100, HDR, NDR200, NDR • Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE [1], 100GbE [1], 200GbE [2], 400GbE
ConnectX-6 Lx		• Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE [1]
ConnectX-6 Dx		• Ethernet: 10GbE, 25GbE, 40GbE, 50GbE [1], 100GbE [1], 200GbE [1]
ConnectX-6		• InfiniBand: SDR, FDR, EDR, HDR • Ethernet: 10GbE, 25GbE, 40GbE, 50GbE [1], 100GbE [1], 200GbE [1]
ConnectX-5/ ConnectX-5 Ex		• InfiniBand: SDR, QDR, FDR, FDR10, EDR • Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE, 100GbE
ConnectX-4 Lx		• Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE
ConnectX-4		• InfiniBand: SDR, QDR, FDR, FDR10, EDR • Ethernet: 1GbE, 10GbE, 25GbE, 40GbE, 50GbE, 56GbE [3], 100GbE

1. Speed that supports both NRZ and PAM4 modes in Force mode and Auto-Negotiation mode.
2. Speed that supports PAM4 mode only.
3. 56GbE is an NVIDIA proprietary link speed and can be achieved while connecting an NVIDIA adapter card to NVIDIA SX10XX switch series or when connecting an NVIDIA adapter card to another NVIDIA adapter card.

2.2.4 Technical Support

Customers who purchased NVIDIA products directly from NVIDIA can contact us through the following methods:

- E-mail: enterprisesupport@nvidia.com
- Enterprise Support Services: https://www.nvidia.com/en-us/support/enterprise

If you purchased NVIDIA M-1 Global Support Services, refer to your contract for technical support details.

Customers who purchased NVIDIA products through an NVIDIA-approved reseller should first seek assistance through their reseller.

2.2.5 Changes and New Features

2.2.5.1 DOCA Framework New Features and Updates

- **NVIDIA ConnectX-9 SuperNIC Support** – DOCA 3.3.0 introduces support for the NVIDIA ConnectX-9 SuperNIC, making it the first GA DOCA release to enable ConnectX-9
- DOCA 3.3 is validated with the following NVIDIA platforms: GB200, GB300, B300, B200
- **DMS**
  - Containerized DMS support
- **DOCA packages and components versioning**
  - DOCA components version change only when component includes changes
  - OFED Packaging: Remove obsolete knem module and replace it with xpmem
- **DOCA Logging**
  - doca-log users can control verbosity level per DOCA module
- **DOCA Host**
  - Adding DOCA PCC to DOCA Networking Profile
  - Adding doca-sosreport to DOCA-Host Profiles (DOCA OFED, RoCE)
  - Removing SHARP from DOCA-Host

    - Supporting RISC-V CPU Architecture on DOCA-Host DOCA-OFED profile
    - Removing support for EOL: Ubuntu 20.04 , Ubuntu 25.04, Azure Linux 2.0, OpenEular 20.03, Debian 10.13, Xenserver 8.2
- **DOCA Flow**
    - FlexParser [Beta] - allows acceleration of more complex/user-defined protocols
    - Allowing all IPv4/IPv6 encapsulation combinations (4 in 4, 6 in 6, 4 in 6, 6 in 4)
    - Enabling One-Way-Delay (OWD) calculation
- **DOCA Perftest**
    - To run from DPU supporting bare-metal and N-S flows such as inference and storage
- **DOCA Platform Framework (DPF)**
    - For more information see DPF Release Notes
- **DTS**
    - OVS Steering counters added to Multi-plane layer 2 solution
- **NVIDIA Network Operator**
    - SPC-X K8s Support for Single-plane deployment for BlueField-3 SuperNIC [GA]
    - SPC-X K8s Support for software Multi-plane deployment for ConnectX-8 SuperNIC [GA]
    - For more information see NVIDIA Network Operator Release Notes
- **OVS-DOCA**
    - OVS DOCA Added support for PTP link local traffic
    - OVS-DOCA upstream – basic acceleration support
    - IPv6 support improvements
    - Improved logging and troubleshooting for OVS DOCA
- **Platform**
    - Expanded DPU scalability to support multiple switch ports and up to 32 PFs
    - Aligned BlueField attestation capabilities with the NVIDIA RIM Service, enabling automated access to CoRIM files to support zero-trust measurement and validation processes
    - Replaced MLNX_DPDK with official upstream DPDK (v25.11+) across the BlueField ecosystem, updating OVS and DOCA components to support standard upstream APIs.
    - Added support for software-defined vBLK emulation, utilizing the DOCA TLP SDK to offload storage data paths while retaining flexibility for custom control plane implementations
    - Added Redfish OOB support for configuring NIC Host Restriction settings, enabling administrators to enforce Zero Trust policies (equivalent to `mlxprivhost`) without logging into the DPU OS.

2.2.5.2 DOCA-Host and DOCA Drivers New Features and Updates

> ⚠ NVIDIA® BlueField®-3 networking platforms must use DOCA-Host as the host driver. MLNX_OFED does not support BlueField-3 devices.

- **NVIDIA ConnectX-9 SuperNIC Support** – DOCA 3.3.0 introduces DOCA-Host support for the NVIDIA ConnectX-9 SuperNIC, making it the first GA DOCA release to enable ConnectX-9.
- **RS-FEC Histogram Statistics Reporting** – Adds support for reporting RS-FEC histogram statistics via ethtool. These IEEE 802.3–defined histograms reveal the distribution of corrected codewords by number of symbol errors corrected per block, improving link quality diagnostics and enabling earlier detection of signal degradation.
- **PTP Raw Cycle Counter Exposure** – Extends the PTP subsystem and driver to expose the raw free-running cycle counter of PTP hardware clocks, enabling user space to obtain (cycle, system-time) pairs via new ioctls and correlate hardware cycle timestamps with host time without requiring PHC synchronization.
- **TCP Header-Data Split Zero-Copy** – Exposes header–data split to the TCP layer to enable TCP zero-copy. This allows all headers up to and including TCP to be processed in software, while payload data is DMA-transferred directly from the NIC to the GPU without CPU involvement, achieving true zero-copy.
- **PCIe Congestion Event Counters** – PCIe congestion events are events generated by the firmware when the device side has sustained PCIe inbound or outbound traffic above certain thresholds. This feature adds support for receiving and exposing such events as ethtool counters.
- **PH and Steering Tags Support** – Enables the device to provide "hints" indicating where MR TLPs should be processed in system memory.
- **InfiniBand Service Record Resolution** – Introduces APIs that translate an InfiniBand service name or ID into destination address details and allow querying that resolved IB addressing information.
- **IPsec Offload for Active-Passive Bonding** – Active-passive bonding aggregates multiple network devices into a single logical interface for higher redundancy. While bonding already supported IPsec offload, this completes full support by adding correct IPsec GSO offload and fixing several race conditions around failover.
- **PSP Security Protocol** – PSP Security Protocol support is now integrated into the core subsystem, with corresponding support implemented in the mlx5 driver. This enables mlx5 devices to recognize and handle PSP-secured traffic using the common core infrastructure.

- **Validation of DOCA-Host on ESXi Hypervisor** – This feature validates that DOCA Host runs reliably in an ESXi hypervisor environment. It covers install/upgrade flows, correct device enumeration and passthrough configuration, and successful driver/module and service bring-up.
- **DOCA PCC inclusion in DOCA-Networking Profile** – The DOCA-Host DOCA-Networking profile now includes DOCA-PCC, FlexIO, and DPACC.
- **DOCA-Host Universal doca-sosreport Enablement** – Adds doca-sosreport to all DOCA-Host profile packages (RoCE, OFED, Networking, and All) so the same support data collection tool is always available, regardless of which DOCA flavor is installed. It standardizes how system and DOCA-related diagnostics are gathered (e.g., host OS details, driver/module status, configuration, and relevant logs), making it faster and more consistent to capture troubleshooting bundles for analysis and support.
- **Transition to Upstream DPDK Sourcing and Dependencies (DPDK 25.11+)** – As DOCA transitions from MLNX_DPDK to upstream DPDK, all package dependencies switch to the upstream versions, and DPDK sources should be pulled from the official upstream repository, starting with DPDK 25.11 and tracking the latest releases from there.
- **Querying Effective VF Bandwidth when in LAG Mode** – Currently, the mlx5 driver reports only the parent function's link speed to VFs, with no way to retrieve the VF's effective bandwidth in LAG and MPESW setups. As a result, user space and upper-layer software cannot obtain accurate bandwidth information, which can lead to suboptimal traffic decisions. This new capability allows user space applications to query the effective port speed and receive real-time notifications when it changes. In LAG configurations, each mlx5 port reports the aggregated transmit bandwidth available to it.
- **Extended DCB Traffic Class (TC) Rate Limiting** - Extended DCB Traffic Class (TC) Rate Limiting, significantly increases the maximum configurable TC bandwidth on high-speed NICs. Previously, the TC max-rate field was limited to 8 bits, capping the value at 255 Gbps. With compatible firmware, the mlx5 driver now supports TC rate limits up to 65,535 Gbps (≈ 6.5 Tbps) through capability detection, while maintaining backward compatibility on legacy hardware.

  The configured maximum must align with the limits supported by the specific hardware.

  Example configuration methods:

  - DCB utility

    ```
    dcb maxrate set dev eth2 tc-maxrate 0:0 1:0 2:0 3:0 4:0 5:0 6:0 7:300Gbit
    ```

  - mlnx_qos

```
mlnx_qos -i eth2 -r 5,0,0,10,0,0,7,320
```

2.2.5.3 BlueField-3 Firmware Changes and New Features

- **PCIe Attention Button Hotplug Support (virtio-net/virtio-blk)** – Added a new firmware capability that implements the PCIe-specification attention button hotplug/unplug flow for virtio-net and virtio-blk. This enables standards-compliant user-initiated device insertion/removal signaling and proper handling by the host stack for these virtio functions.
- **DOCA PCC** – The DOCA PCC NP application now enables the NIC to insert the RTT response transmit timestamp in hardware, reducing software-induced jitter and improving the accuracy and consistency of RTT measurements.
- **Fail-Safe DPU Identification via NC-SI** – Implemented a new NC-SI MLNX command, `get_host_info`, that allows software to reliably identify which DPU corresponds to a given physical machine/PCIe slot. This provides a fail-safe identification mechanism for inventory, provisioning, and troubleshooting workflows, especially in systems with multiple DPUs.
- **DPA Process Limit Update** – The system-wide limit for DPA processes has been reduced to **30**. This total includes both user processes across all GVMIs and internal ProgCC processes. The `max_dpa_processes` value reported to the user is calculated as: `max_dpa_processes=30-number_of_progcc_processes`
- **PLDM PDR Repository Change Event Support** – PLDM now supports the PDR Repository Change event type, enabling notification to the BMC when PDRs change. With this flow, the BMC can detect cable insertion/removal events. Refer to DSP0248 for details.
- **DOCA PCC API: DSCP Query for PCC Flows in QP Mode** – Introduces a DOCA PCC device API that enables retrieval of the DSCP value associated with a PCC flow when PCC operates in QP mode (for example, when `ROCE_CC_SHAPER_COALESCE_P1=2` and `ROCE_CC_SHAPER_COALESCE_P2=2` are configured via mlxconfig).
- **BlueField-3 DPU Mode VF Migration Support** – Introduced support for migrating Virtual Functions (VFs) in BlueField-3 DPU mode. It enables a VF's state and connectivity to be preserved across migration events, improving continuity for virtualized workloads and reducing disruption during maintenance operations such as host servicing, live migration, or recovery workflows.
- **Parallel Save/Load Support for VF Migration** – Added support for running save and load operations in parallel, enabling multiple contexts (e.g., multiple VFs) to be checkpointed and restored concurrently instead of serially. This reduces overall migration time and improves scalability in environments that need to migrate or recover many VFs at once.

- **NVGRE VSID Modify-Header Support** - Extended packet modify-header operations to support set and copy actions on the NVGRE VSID (Virtual Subnet Identifier). A new field, TUNNEL_HDR_DW_2 (0x84), enables dynamic VSID modification, adding header rewrite support for NVGRE tunnel traffic in addition to existing filtering capabilities.
- **Advanced SNAP NVMe Hot-Plug/Unplug Flow** - Advanced SNAP NVMe Hot-Plug/Unplug Flow introduces a recommended two-step flow for hot-plugging and unplugging emulated PCI PF devices. The device is first created in a POWER_OFF state, fully configured by DPU software, and only then exposed to the host PCI subsystem. This provides better control and visibility, makes the plug/unplug flows more symmetric, and helps avoid undefined PCI states.
- **SNAP NVMe Host-Aware/Host-Unaware Hot-Plug Mode** - Host awareness ensures the DPU tracks the host system state (e.g., boot, power-off, or power-cycle) and performs hotplug/hotunplug operations only when the host can safely handle PCIe changes. In host-aware mode, NVMe function hotplug/unplug explicitly gates these actions on host readiness; in host-unaware mode, these checks are skipped, which is unsafe and may lead to unpredictable behavior.

2.2.5.4 BlueField-2 Firmware Changes and New Features

- **PLDM PDR Repository Change Event Support** – PLDM now supports the PDR Repository Change event type, enabling notification to the BMC when PDRs change. With this flow, the BMC can detect cable insertion/removal events. Refer to DSP0248 for details.

2.2.5.5 API Changes

The following table details the API changes that were introduced in this version of DOCA:

Library	Change Description
TBD	TBD

To view API changes for previous DOCA versions, refer to the release notes of those archived versions.

2.2.5.6 Customer Affecting Changes

2.2.5.6.1 Changes in This Release

Category	Description	Customer Impact and Recommendation
DOCA-Host 3.3.0 (Jan 2026)	The GPG key used to sign the DOCA-Host Linux repository has been rotated to a new, stronger key. The key identity has also changed from "Mellanox Technologies" to "NVIDIA DOCA Host."	During installation or upgrade, users may be prompted to confirm and import the new repository key; once accepted, the process will proceed normally.
	DOCA-Host 3.3.0 no longer supports the end-of-life Ubuntu 20.04 , Ubuntu 25.04, Azure Linux 2.0, OpenEuler 20.03, Debian 10.13, Xenserver 8.2, BCLinux 21.10 SP2.	
	The SHARP package has been removed from all DOCA-Host deliverables.	
	The SYSFS interface for MR cache configuration will be deprecated and replaced by the `rdma` resource command.	Any users or scripts relying on this SYSFS interface must be updated to use the new `rdma` command API.
	The knem module has been deprecated and replaced by xpmem.	
DOCA-Host 3.3.0 (Jan 2026)	Transition to 2023 Microsoft UEFI Certificate Authority - To align with updated Microsoft UEFI Secure Boot requirements and the upcoming end-of-life of the 2011 Certificate Authority (CA), NVIDIA is transitioning to the 2023 CA. To ensure successful loading of the Expansion ROM (ExpROM) during the UEFI Secure Boot process, system BIOS and operating system trust stores must be updated to include the 2023 CA.	When performing a firmware update of ConnectX and BlueField devices the new certificate is required for Secure Boot. To continue supporting Secure Boot, systems must be updated to recognize the "Microsoft Option ROM UEFI CA 2023."
DOCA 3.3.0 (Jan 2026)	DPDK-based hardware acceleration in openvswitch and doca-openvswitch (also known as OVS-DPDK) will be deprecated and retired.	This change affects openvswitch packages in the BF-Bundle (BFB) and all DOCA Host Profiles. Recommendation: Customers using OVS-DPDK mode should either transition to DOCA-DPIF (recommended) or remain on the DOCA 3.2 LTS release.
DOCA 3.3.0 (Jan 2026)	MLNX_DPDK will be End-of-Life (EOL) and replaced by upstream DPDK (community LTS version 25.11). DOCA 3.2 (Oct 2025) will be the final LTS release to include MLNX_DPDK.	This transition applies to DOCA-HOST and BF-Bundle (BFB) packages for both ConnectX and BlueField adapters. There is no expected loss of functionality, as all MLNX_DPDK capabilities are included in the upstream version. DOCA Flow samples and reference applications have transitioned to use the upstream DPDK for packet acquisition. Customers may contact CPM for transition guide to adapt with the upstream version.

Category	Description	Customer Impact and Recommendation
DOCA Flow 3.3.0 (Jan 2026)	The `doca_flow_flags_type` enum has been refactored so that all values now represent proper bitwise flags. As part of this change, the enumeration has been renamed to better reflect its scope and usage.	Renamed `doca_flow_flags_type` to `doca_flow_entry_flags` and modified the bit values of `DOCA_FLOW_ENTRY_FLAGS_NO_WAIT` and `DOCA_FLOW_ENTRY_FLAGS_WAIT_FOR_BATCH`. **Users must recompile their applications.** No behavior change for the flags values from previous releases. These flags are described at the DOCA Flow programming guide section 6.4.17.
DOCA Flow 3.3.0 (Jan 2026)	The "Isolated" run mode argument (that was used to configure forwarding the miss packets to kernel) is deprecated and ignored.	Customers will not be able to run multiple processes on the same port when in VNF mode. It aligns the behavior with switch mode. To clarify, the default destination of packets missing the user's root pipe remains KERNEL.
DOCA Virtio-net 3.3.0 (Jan 2026)	The `mrg_rxbuf` and `packed_vq` parameters will no longer be supported in the `virtnet.conf` configuration file.	Configuration of the `mrg_rxbuf` and `packed_vq` features must now be performed using the CLI modify device option.

2.2.5.6.2 Changes Planned for Future Releases

Planned for Version	Description	Customer Impact and Recommendation
October 2027	ConnectX-6 Adapters and BlueField-2 DPU Adapters End-of-Life	October 2027 DOCA release will be the last to support Connect-X-6 and BlueField-2. This version will be an LTS version supported for 3 years. The following release (January 2028) will no longer support these devices.
DOCA 3.4 (April/ 26)	Virtio-net and virtio-blk support for BlueField-2 devices will be removed from DOCA GA release. BlueField-2 virtio-net will continue to be available in the current LTS branches (DOCA 2.9.x and DOCA 3.2.x).	BlueField-2 customers interested in using virtio-net should use one of the LTS branches.
DOCA 3.4 (April/ 26)	basic pipe actions - support in crypto actions will be removed from basic pipe.	for crypto functionality customers should moved to order list.

2.2.5.6.3 Changes from Earlier Releases

This section provides a list of changes that took place throughout the past two major releases that broke compatibility/interface or discontinued support for features or OS versions.

> For older changes, consult the DOCA documentation archive.

Introduced in Version	Description	Customer Impact and Recommendation
DPA 3.2.0	**DPA Application Attributes**: To enhance security, DPA application attributes are being introduced. Developers must now create a dpa-app-attributes file for each application, which declares the app's permissions and must be compiled with the application.	When updating the BF-Bundle (or ConnectX firmware), users must also update the corresponding DOCA Host components. Action Required: As part of this update, each DPA application must be rebuilt with its `dpa-app-attributes` file. ⚠ If a file is not supplied, a default manifest enabling all permissions will be applied automatically19.
	Undocumented and previously deprecated DPA/FlexIO APIs will be removed.	Users who utilized these APIs must remove them from their code and re-build their applications.
DOCA-Host 3.2.0	OpenSM support is removed from DOCA-Host for Xenserver operating systems.	No impact.
	The HCOLL and MPItests packages have been removed from all DOCA-Host deliverables.	No impact listed.
	The phy_stats sysfs counters are deprecated. • Deprecated: `/sys/class/net/<iface>/phy_stats/` • Replacement: Use `ethtool -S <iface>` and filter for `packets_phy` or `bytes_phy`.	No impact listed; recommendation is in the description.
	The has_smi sysfs entry is deprecated. • Deprecated: `/sys/class/infiniband/mlx5_0/ports/1/has_smi` • Replacement: Use the `ib_stat` tool	Recommendation: Users should parse the `ib_stat` output for the "Capability mask" value. • Bit #1 indicates `IsSM` • Bit #10 indicates `IsSMdisabled`

Introduced in Version	Description	Customer Impact and Recommendation
	The hfunc sysfs entry for setting/showing hash functions is deprecated. • Show (Deprecated): `cat /sys/class/net/<iface>/settings/hfunc` • Show (Replacement): `ethtool -x --show-rxfh <devname>` • Set (Deprecated): `echo [hfunc] > /sys/class/net/<iface>/settings/hfunc` • Set (Replacement): `ethtool -X --rxfh <devname> [hfunc FUNC]`	No impact listed; recommendation is in the description.
	The `pfc_stall_prevention` sysfs entry is deprecated. • Show (Deprecated): `cat /sys/class/net/<iface>/settings/pfc_stall_prevention` • Show (Replacement): `ethtool --get-tunable <iface> pfc-prevention-tout` • Set (Deprecated): `echo [default/auto] > /sys/class/net/<iface>/settings/pfc_stall_prevention` ℹ `default` is mapped to 8000 msec per critical prevention. `auto` is mapped to 100 msec per critical prevention. • Set (Replacement): `ethtool -X --set-tunable <devname> [pfc-prevention-tout N]`	No impact listed; recommendation is in the description.
	The sysfs entry for displaying VF statistics is deprecated. • Deprecated: `/sys/class/infiniband/mlx5_2/device/sriov/2/stats`	Recommendation: Users should use the ip command instead: `/opt/mellanox/iproute2/sbin/ip -s link show dev <VF-interface-name>`
	VGT+ capability will be unsupported as of October 2025.	No impact listed.
	The "Per Channel Statistics" `ethtool` private-flag will be unsupported as of October 2025.	No impact listed.
	The `commands_cache` sysfs entry is deprecated.	No impact listed.
	Dynamic Kernel Module Support (DKMS) is now integrated, allowing customers to build their own DOCA-Host packages.	As part of the DKMS build process, driver signing is removed. Customers must sign the drivers themselves.
	The `mlxdevm` tool, part of DOCA-Host, is deprecated.	Recommendation: Use the `devlink` tool, which is included in DOCA-Host. `mlxdevm` is redundant as it provides the exact same functionality.

Introduced in Version	Description	Customer Impact and Recommendation
	Backward compatibility with older MFT (NVIDIA Firmware Tools) versions 4.31.0-149 and 4.30.0-139 is no longer supported.	Using these unsupported MFT versions may lead to unexpected behavior or prevent device detection.
DOCA-Host 3.1.0	In the DOCA-OFED profile, the `openvswitch` component was deprecated and replaced with the `doca-openvswitch` component.	The content and features are identical, but customers using the `openvswitch` component must re-build their applications with the new `doca-openvswitch` package.
	The "Shared RQ" feature was replaced by the "memory consumption reduction for representors" feature.	As a result, the `esw_pet_insert` devlink parameter is no longer available, and setting `ALLOW_SHARED_RQ` in `/etc/mellanox/mlnx-bf.conf` has no effect.
DOCA-HOST 3.0.0 (April 2025)	The `mlxdevm` tool was aligned with `devlink` v6.12. In this version, a zero rate value indicates "unlimited" and is omitted from the display.	When using `mlxdevm port function rate show`, the `tx_rate` and `tx_max` fields are omitted if their value is zero. The driver also only accepts `tx_rate` and `tx_max` values that are multiples of 1 Mb/s.
	The `mlxdevm` tool was aligned with `devlink` v6.12 and conforms to its `man` page specifications.	To Set Rate: Use `port function rate set [DEV/PORT_INDEX | DEV/NODE_NAME] tx_max VALUE`
DOCA-HOST 2.10.0 (Jan 2025)	When Dynamic Interrupt Moderation (DIM) is enabled, static coalescing parameters cannot be set because the dynamic algorithm will override their values.	Recommendation: To set static coalescing parameters, you must first disable DIM.
	The ConnectX-4 adapter card family is no longer supported.	N/A
	Support was removed for several OS versions (e.g., RHEL 8.0, 8.1, 8.3, 8.5, 8.7, 9.1, 9.3, and OL 7.9).	N/A
DOCA-FLOW 2.10.0	Several features were temporarily unsupported in the 2.10 release, including ACL pipe, LPM pipe, CT pipe, `ordered_list` pipe, external send queue (SQ), and pipe resize.	Users needing these features were advised to use DOCA Flow 2.9.1.
	The requirement to use a `dummy_id` for IPsec encryption actions during pipe creation was removed.	When creating a pipe with a crypto action, `UINT32_MAX` now represents a changeable shared object, while a `crypto_id` between 0 and `UINT32_MAX` indicates a constant.
	Memory for "modify field" and "encap" actions must be allocated upfront on a per-port basis.	Recommendation: If these actions are used, the `doca_flow_port_cfg_set_actions_mem_size()` function must be called to configure the memory size.

Introduced in Version	Description	Customer Impact and Recommendation
	"Strict matching" is no longer supported.	The `doca_flow_pipe_cfg_set_enable_strict_matching()` function is deprecated. Users must use "relaxed matching".
	The entry aging mechanism no longer relies on DPDK. The `service_core=` and `svc_cycle_time=` DPDK arguments are no longer supported.	Recommendation: Users must use the new APIs: `doca_flow_port_cfg_set_service_threads_core()` and `doca_flow_port_cfg_set_service_threads_interval()`.
	The `doca_flow_parser_meta.random` field was changed to big-endian.	Users must update code to provide this value in big-endian format. The `DOCA_HTOBE16` macro is recommended.
	The RSS config API was refactored to align with other resource types.	Users must now specify whether the RSS resource is shared or non-shared.
	Values for the `doca_flow_l2_meta` and `doca_flow_meter_color` enums were changed.	Users must recompile their applications.
	The match fields `parser_meta.outer_l4_ok` and `parser_meta.inner_l4_ok` no longer validate the L4 checksum.	Recommendation: To check for a valid checksum, users must use `parser_meta.outer_l4_checksum_ok` and `parser_meta.inner_l4_checksum_ok`.
	Entry "life event" callback was previously invoked only on "entry add" and "entry removal".	The callback is now also invoked upon "port stop" during the removal of pipe entries. Therefore, the user context must still be defined at that stage.
DOCA-ETH 2.10.0	The `eth_rxq_managed_mempool_receive` and `eth_rxq_regular_receive` samples were not supported.	Users needing these samples were advised to use DOCA 2.9.1.
DOCA 2.9.0 (Oct 2024)	**DPA Outbox Blocking-Mode**: Due to a silicon issue (as of firmware v28.43.2026), the DPA outbox was set to non-blocking mode, causing requests to complete immediately without waiting for the actual operation to finish.	Action Required: The DPA stack must poll a "busy" bit before starting another operation. Users programming the DPA must update firmware to 28.43.2026+ and DOCA-Host to 2.9.x+.
	DPA Thread Context: As of firmware v28.43.2026, internal DPA stack API changes altered the DPA thread context, impacting the overlying DPA stack.	This requires the same action as the Outbox Blocking-Mode: update firmware to 28.43.2026+ and DOCA-Host to 2.9.x+.

2.2.5.6.4 Discontinued Features

List of features which are supported in previous generations of hardware devices.

N/A

2.2.5.7 Declared Unsupported Features

This section provides a list of features that are not supported in this release:

- ETS and VF rate limit (Cross E-Switch Scheduling)

2.2.6 General Support

2.2.6.1 Supported Platforms and NIC Firmware Versions

> ⚠ NVIDIA® BlueField®-2 and NVIDIA® ConnectX®-7 are the last generation of BlueField and ConnectX families that are supported by MLNX_OFED.

Adapter Card	Bundled Firmware Version
BlueField-3	32.48.1000
BlueField-2	24.48.1000
ConnectX-9	82.48.1000
ConnectX-8	40.48.1000
ConnectX-7	28.48.1000
ConnectX-6 Lx	26.48.1000
ConnectX-6 Dx	22.48.1000
ConnectX-6	20.43.8004
ConnectX-5/ConnectX-5 Ex	16.35.8008
ConnectX-4 Lx	14.32.1912

For official firmware versions, refer to Firmware Downloads.

2.2.6.2 Embedded DOCA Firmware Components - BlueField

Component	Version	Description
BlueField-3 NIC firmware	32.48.1000	Firmware is used to run user programs on the BlueField-3 which allow hardware to run
BlueField-2 NIC firmware	24.48.1000	Firmware is used to run user programs on the BlueField-2 which allow hardware to run
BMC firmware	26.01-2	BlueField BMC firmware
BlueField-3 eROT (Glacier)	00.02.0195.0000	BlueField-3 eROT firmware
BlueField-2 eROT (CEC)	04.0f	BlueField-2 eROT firmware
ATF	4.14.0-5-g6e80f22f0	Bootloader which initializes the Arm cores and manages the secure boot process
UEFI	4.14.0-8-ge7b6a89d9b	Standardized firmware interface for booting the system and initializing hardware before the OS loads
BSP	4.14.0.13878	Drivers and configurations required to initialize and support the BlueField platform's hardware

2.2.6.3 Embedded DOCA Drivers

Component	Version	Description	Licenses
clusterkit	1.15.475-1.20260211.db5c406.2601096	Multifaceted node assessment tool for high-performance clusters	BSD
collectx-clxapi	1.24.3-1	CollectX API library which allows any 3rd party to easily use CollectX functionality in their own programs	BSD-3-Clause
dpacc	2.1.0.16-1	High-level compiler for the DPA processor which compiles code targeted for the data-path accelerator (DPA) processor into a device executable and generates a DPA program	Apache-2.0 with LLVM exception and NVIDIA Proprietary License and GCC-exception-3.1
dpcp	1.1.59-1	Provides a unified flexible interface for programming IB devices using DevX	BSD-3-Clause
flexio-sdk	26.01.3154-0	SDK which exposes an API for managing the device and executing native code over the DPA processor	Proprietary
ibarr	2601.0.0-1	ip2gid address resolution and gid2lid path record resolution	(GPL-2.0 WITH Linux-syscall-note) OR BSD-2-Clause
ibdump	6.0.0-2	Dump of InfiniBand traffic; diagnostic tool	BSD2+GPL2

Component	Version	Description	Licenses
ibsim	0.12.1-4	Open-source InfiniBand fabric simulator	GPLv2 or BSD
ibutils2	2.1.1-0.22400.MLNX20260115 2019.ge04c0b67f	ibdiagnet scans the fabric using directed route packets and extracts all the available information regarding its connectivity and devices.	Mellanox Confidential and Proprietary
ibutils22	2.1.1-0.22400.MLNX20251030.g8c84ecb57.2510122	Utilities for InfiniBand	Proprietary
iser	26.01-OFED.26.01.0.9.6.1	Storage related drivers	GPLv2
isert	26.01-OFED.26.01.0.9.6.1	Storage related drivers	GPLv2
kernel-mft	4.35.0-159	Kernel part of MFT tools (for firmware burning, etc.)	Dual BSD/GPL
libvma	9.8.84-1	Accelerates latency-sensitive and throughput-demanding TCP and UDP socket-based applications by offloading traffic from the user-space directly to the NIC or HCA	GPLv2 or BSD
libxlio	3.61.2-1	Boosts the performance of TCP/IP applications based on NGINX (CDN, DoH, etc.) and storage solutions as part of the SPDK	GPLv2 or BSD
mft	4.35.0-159	Set of firmware management and debug tools for NVIDIA devices	Proprietary
mlnx-dpdk	25.11.0	Equivalent to DPDK upstream. The versioning of MLNX_DPDK indicates which upstream DPDK it is compatible with it (e.g., 22.11 is compatible with upstream DPDK 2022.11).	BSD, LGPLv2, and GPLv2
mlnx-ethtool	2601.0.2-1	Ethtool with optional MLNX adaptation	GPL
mlnx-iproute2	2601.0.5-1	IPRoute with optional MLNX adaptation	GPL
mlnx-libsnap	1.6.0-4	Library designed to assist common tasks for applications wishing to interact with emulated hardware over BlueField and take the most advantage from hardware capabilities	Proprietary
mlnx-nfsrdma	26.01-OFED.26.01.0.9.6.1	Storage related driver for NFS over RDMA	GPLv2
mlnx-nvme	26.01-OFED.26.01.0.9.6.1	Storage related driver for NVMe	GPLv2
mlnx-ofa_kernel	26.01-OFED.26.01.0.9.6.1	Kernel drivers for Ethernet InfiniBand together	GPLv2

Component	Version	Description	Licenses
mlnx-snap	3.8.0-13	BlueField SNAP for NVMe and virtio-blk enables hardware-accelerated virtualization of local storage	Proprietary
mlnx-tools	2601.0.1-1	Tools for loading modules, configurations, scripts, etc.	GPLv2 or BSD
mlx-steering-dump	1.0.0-1	Hardware/software steering dump parsing tools	GPLv2
mstflint	4.34.1-1	User space part of our MFT tools	GPL/BSD
multiperf	3.0-3.0.2601071	Linux tool for perf testing	BSD 3-Clause, GPL v2 or later
ofed-scripts	26.01-OFED.26.01.0.7.1	Scripts used to build OFED	GPL/BSD
openmpi	4.1.9a1-1.20260211.81d402c97a.2601096	MPI implementation (for RDMA/RoCE) with some improvements done by the HPC team	BSD
opensm	5.26.1-2026012 71032.8c07ef43 .2601071	InfiniBand Subnet Manager and Subnet Administrator based on OpenSM	GPLv2 or BSD
doca-openvswitch	3.3.0040-1	OVS (virtual switch), DPDK based	Proprietary
perftest	26.01.5-1	Test suite for performance	BSD 3-Clause, GPL v2 or later
rdma-core	2601.0.7-1	Implementation of the RDMA verbs	GPLv2 or BSD
rivermax	1:1.80.24	Optimized networking SDK for media and data streaming applications	Proprietary
rshim	2.6.6-0.g0ff6d20	User-space driver to access the BlueField SoC via the RShim interface, providing ways to push boot stream, debug the target, or login via the virtual console or network interface	GPLv2
sockperf	3.1-1	Network benchmarking utility over socket API UDP/TCP designed for testing network performance (latency and throughput)	BSD-3-Clause
spdk	23.01.5-30	Provides a set of tools and libraries for writing high performance, scalable, user-mode storage applications	Proprietary
srp	26.01-OFED.26.01.0.9.6.1	Storage-related driver for SCSI RDMA Protocol initiator	GPLv2
ucx	1.20.0-1.202602 11.d9a4f352d.2 601096	High-level application-oriented API for high-performance communication over RDMA networks	BSD

Component	Version	Description	Licenses
virtio-net-controller	26.01.8-1	Systemd service running on BlueField with a user interface front-end to manage the emulated virtio-net devices	Proprietary
xpmem	2601.0.7-1	Kernel module to enable inter-process mapping for memory copy in user space	GPLv2 and LGPLv2.1
xpmem-lib	2510.0.16-1	High-performance inter-process memory sharing	LGPLv2.1

2.2.6.4 DOCA Packages

Device	Component	Version	Description
Host	DOCA Devel	3.3.0	Software development kit package and tools for developing host software
	DOCA Runtime	3.3.0	Runtime libraries and tools required to run DOCA-based software applications on host
	DOCA Extra	3.3.0	Contains helper scripts (doca-info, doca-kernel-support)
	DOCA OFED	3.3.0	Software stack which operates across all NVIDIA network adapter solutions
Target BlueField DPU (Arm)	BlueField BSP	4.14.0	BlueField image and firmware
	DOCA SDK	3.3.0	Software development kit packages and tools for developing Arm software
	DOCA Runtime	3.3.0	Runtime libraries and tools required to run DOCA-based software applications on Arm

2.2.6.5 BlueField Operating System

The default operating system provided with the BlueField bundle (for DPU and SuperNIC) is Ubuntu 24.04 64k.

Primary BlueField operating systems are supported and require users to build their own BF-Bundle (BFB) with the binary DOCA package provided by NVIDIA. For instruction on how to build your own BF-Bundle please see bfb-build.

Primary OS supported with this DOCA release:

OS and version	Kernel
Ubuntu 22.04	5.15
Rocky Linux 9.2	5.14
Debian 13	6.12

OS and version	Kernel
Debian 12	5.15
OpenEular 22.03 SP3	5.10
Anolis 8.6	5.10
CTYunOS 23.01	5.10
RHEL 9.6	5.14
RH CoreOS	TBD

2.2.6.6 Supported Host OS per DOCA-Host Installation Profile

As of DOCA 3.3.0, NVIDIA will leverage DKMS to build and install host drivers from source on customer machines. Dynamic Kernel Module Support (DKMS) is a program/framework that enables generating Linux kernel modules whose sources generally reside outside the kernel source tree. This would affect the users as follows:

- NVIDIA no longer ships prebuilt and signed drivers, now only the source code for those drivers is provided and DKMS will build and install those drivers on the customers' machines during DOCA-Host installation.
- Furthermore, this means that NVIDIA no longer provides DOCA-Host for minor OS releases (e.g. RHEL9.X). We only provide major OS releases builds, and DKMS will handle the build and installation of the kernel modules for the different minor releases.
- Since kernel modules are built on client machines from source, NVIDIA can no longer sign the drivers.

The default operating system included with the BlueField bundle (for DPU and SuperNIC) is Ubuntu 24.04.

The supported operating systems on the host machine per DOCA-Host installation profile are the following:

⚠ Only the following generic kernel versions are supported for DOCA local repo package for host installation.

⚠ Dynamic Kernel Module Support (DKMS) in DOCA-Host includes the minor versions of Major versions with .x in the version. Minor versions that are EOL by the OS distribution are not support by DOCA.

OS	OS Version	Tested Kernel	Arch	doca-ofed/ doca-roce	doca-networking	doca-all

2.2.6.8 DOCA-Host Version Interoperability

The following versions were tested and verified in multi-version environments (environments with more than one `doca-ofed` version on host servers).

Current Version	Versions Verified for Interoperability	Release Type	Release Date
3.3.0 Jan 2026	DOCA-OFED 3.2.0	GA	October 2025
	25.10-1.7.1.0 LTS-DOCA-OFED	LTS-Update	November 2025
	24.10-4.1.4.0 LTS-DOCA-OFED	LTS-Update	January 2026
	23.10-6.1.6.1 LTS-DOCA-OFED	LTS-Update	January 2026
	5.8-7.0.6.1 LTS (EOS)	LTS-Update	June 2025

2.2.6.9 Supported Devices

For a complete list of supported devices, refer to the hardware user manuals.

2.2.7 Bug Fixes in This Version

2.2.7.1 DOCA Framework Bug Fixes

Ref #	Issue
4366800	Description: Creating a packet filtering rule with match criteria on certain unsupported fields (e.g., specific VXLAN-GPE flags) does not return an error as expected.
	Keyword: Packet filtering; DOCA Flow
	Detected in version: 3.2.0
4802407	Description: DOCA Flow does not support masked matching of the VXLAN Reserved 1 (RSVD1) field.
	Keyword: VXLAN RSVD1; Masked Matching; Hardware Offloading
	Detected in version: 3.2.0
4802408	Description: DOCA Flow does not support matching the ICMPv6 Identifier field in Echo Request and Echo Reply packets.
	Keyword: ICMPv6; echo request/reply; packet offloading
	Detected in version: 3.2.0
4636365	Description: The names of several telemetry counters and parameters in the Multi-Rack Connectivity (MRC) service are non-intuitive or ambiguous.
	Keyword: MRC Telemetry; counters; EV probes; ZTR RTTCC
	Detected in version: 3.2.0
4742653	Description: DOCA Argus (APSH) fails to enumerate Virtual Memory Areas (VMA) on Arm64 architectures.
	Keyword: Compatibility; enumeration; mm_struct
	Detected in version: 3.2.0
4704261	Description: OVS user space is not supported on RHEL 10.0.
	Keyword: Open vSwitch; DPDK EAL Panic; ovs-vsctl
	Detected in version: 3.2.0
4823654	Description: When running the NVQual test suite on Socket Direct (SD) systems using synthetic mode, the tool fails to correctly identify the BDF (Bus:Device.Function) of the upstream PCIe ports.
	Keyword: NVQual; Socket Direct; Synthetic Mode; PCIe BDF
	Detected in version:

Ref #	Issue
4687096	Description: The `doca_upf_accel` application is not supported on GB300 (ConnectX-8) systems, returning a `Failed to allocate dynamic extension table data` error.
	Keyword: GB300; SEGV; Dynamic Extension Table
	Detected in version: 3.2.0
4739125	Description: The `doca_gpunetio_verbs_write_bw` sample fails with a `DOCA_ERROR_DRIVER` error.
	Keyword: GPUNetIO; sample
	Detected in version: 3.1.0
4564535	Description: The DPU may fail to boot successfully after performing a firmware reset operation (`mlxfwreset`) following a software or firmware upgrade.
	Keyword: Hang; unresponsive; boot
	Detected in version: 2.9.4
4564535	Description: Under high flow-insertion rates on BlueField-3, pipe resize operations may time out (exceeding 10 seconds). This can cause OVS threads (`ovs_rcu`) to block, indicating a stall in the hardware offload process.
	Keyword: OVS; Pipe Resize; Timeout
	Detected in version: 3.1.0
4564538	Description: A pipe resize operation on BlueField-3, often triggered by dynamic flow limits, may fail. This can result in memory allocation errors and severe delays (10+ seconds), leading to a loss of network connectivity, such as BGP peering sessions dropping.
	Keyword: Pipe Resize; Flow Limit; Memory Allocation
	Detected in version: 3.1.0
4621473	Description: A race condition during flow deletion may cause application instability or incorrect counter values.
	Keyword: Flow; delete
	Detected in version: 3.1.0
4366800	Description: Creating a packet filtering rule with match criteria on certain unsupported fields (e.g., specific VXLAN-GPE flags) does not return an error as expected.
	Keyword: Packet filtering; DOCA Flow
	Detected in version: 3.1.0
4627850	Description: The RTC timestamp is not correctly parsed in the doca_telemetry_diag sample.
	Keyword: RTC; PTP; DOCA Telemetry
	Detected in version: 3.1.0
4548383	Description: The `doca_flow_header_ib_bth` structure includes fields for which match and action operations are not supported. Supported fields: • Match and action: `opcode`, `dest_qp` • Match only: `AckReq` (in `flags1`) • Action only: `psn`
	Keyword: DOCA Flow
	Detected in version: 3.1.0

Ref #	Issue
4560966	Description: Enabling the RX Rate flag in the ZTR RTTCC algorithm causes compilation to fail because the private DOCA PCC device header is not included.
	Keyword: DOCA PCC; Zero-touch RoCE; round-trip time congestion control
	Detected in version: 3.1.0
4223392	Description: CT miss pipe receives configured IP version only.
	Keyword: DOCA Flow
	Detected in version: 3.1.0

2.2.7.2 DOCA-Host and DOCA Drivers Bug Fixes

Ref #	Issue
4834414	Description: Fixed an issue on RHEL systems where installing chkconfig after mlnx-ofa_kernel (pulled in by packages such as doca-ofed and doca-host) could fail during installation. In this sequence, chkconfig may be installed indirectly as a dependency of a package that places init scripts under /etc/init.d, but the install would error out because /etc/init.d already existed as a directory (whereas chkconfig expects to manage it as a symlink). This fix prevents the /etc/init.d directory/symlink conflict that caused the RPM unpacking failure.
	Keyword: Installation
	Detected in version: 3.2.1
4743484 / 4563750	Description: Fixed an issue where, in LAG mode, a firmware reset race could cause the driver to hang during unload while waiting for UMR completion. The fix ensures sys_error notifications are registered early and kept through device unregister so error events reach the bond device during teardown.
	Keyword: LAG mode
	Detected in version: 3.2.0
4858587 / 4858692 / 4858693 / 4858694	Description: Fixed soft lockup warnings that could occur while releasing large UMEMs by periodically yielding the CPU during the release flow.
	Keyword: Soft lockup warnings
	Detected in version: 3.2.0
4742666 / 4070154 / 4237797 / NVbug 5672643	Description: Fixed a kernel crash that could occur if the devlink userspace process was terminated while switching the device to switchdev mode. In this scenario, the kernel could dereference invalid state and trigger an oops, potentially causing immediate node failure on GB300 systems.
	Keyword: devlink, switchdev mode
	Detected in version: 3.2.0
4426799 / 4491971 / NVbug 5253854	Description: Fixed an issue where devlink operations were not synchronized with fw_reset, which could lead to various failures. Added a mechanism to coordinate fw_reset with devlink operations.
	Keyword: devlink, fw_reset
	Detected in version: 3.2.0

Ref #	Issue
4775049 / 4540881 / 4777985 1 / 4777985 8 / 4830934 / 4865514	Description: Fixed an issue where the driver could incorrectly initialize polling-only CQs (e.g., ASO CQs), allowing them to receive EQ interrupts in rare cases. The CQ initialization flow was updated to prevent interrupts for polling-only CQs.
	Keyword: CQs, EQ
	Detected in version: 3.2.0
4802194	Description: Fixed an overflow issue where the max-rate value was stored in a unsigned 8-bit integer type, causing values above 255 to wrap (e.g., 257 became 1).
	Keyword: max-rate value
	Detected in version: 3.2.0
4830982 4748884	Description: Fixed an issue that prevented using more than 8 cores to set SF CPU affinity. This restriction has now been removed.
	Keyword: SF CPU affinity
	Detected in version: 3.2.0

2.2.7.3 BSP Bug Fixes

Ref #	Details
4845039	Description: MPI-dependent DOCA applications failed to compile on OpenEuler due to missing development tools.
	Keywords: OpenEuler; OpenMPI; compilation
	Detected in version: 4.13.0
4845039	Description: A kernel call trace could occur during BFB updates if the host-side ConnectX has a pending firmware upgrade.
	Keywords: Kernel
	Detected in version: 4.13.0
4829571	Description: The DELETE key does not remove characters following the cursor in both UEFI Shell and GRUB environments.
	Keywords: UEFI Shell; GRUB
	Detected in version: 4.13.0
4764682	Description: `mlnx-sf` fails to apply `-r` parameter (disable RoCE for SF) as it was removed from mlxdevm.
	Keywords: `mlnx-sf`; RoCE
	Detected in version: 4.13.0
4824650	Description: BFB installer (`bfb-install`) does not display error and warning messages during installation.

Ref #	Details
	Keywords: Bfb-install; warning messages; logging
	Detected in version: 4.13.0
4693948 4782014	Description: Installation of Ubuntu 24.04 on BlueField-3 eMMC devices is not supported in the 3.2.0 BFB release.
	Keywords: Installation; Ubuntu
	Detected in version: 4.13.0

2.2.7.4 BMC Bug Fixes

Ref #	Issue
4826162	Description: On systems equipped with multiple BlueField-3 DPUs, the `doca-installer --compare` command may intermittently fail to retrieve the CEC firmware version from one of the cards.
	Reported in version: 25.10

2.2.7.5 BlueField-3 Firmware Bug Fixes

Internal Ref.	Issue
4786813	**Description:** Fixed an issue where the DPA kernel used unsafe ICM access during process creation/modification, which could cause the DPA kernel to hang during FLR.
	Keywords: DPA kernel, FLR
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000
4804664 / 4806969	**Description:** Fixed an issue in the User Debugger “query caps” where it returned only the number of capabilities, not the capability bitmap.
	Keywords: User Debugger “query caps”
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000
4346373 / 4073037 / 4371711 / NBbug 5150535	**Description:** Fixed an issue where, after an unexpected cable removal, the current-limiter enable could assert unexpectedly, and a subsequent module removal could trigger an error message. The BlueField-3 PRS indication was updated to use Power Good instead of Over-Current.
	Keywords: virtio emulation, live migration, live update
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000

Internal Ref.	Issue
4819986 / 4827433 / 4832172 / 4832178	**Description:** Fixed an issue where the server could occasionally become stuck during live migration or while updating the Virtio emulation device.
	Keywords: virtio emulation, live migration, live update
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000
4484662	**Description:** Fixed an issue where mlxlink reported 0 values for SNR (media and host) due to incorrect local port mapping in firmware and an incorrect page number used by MFT.
	Keywords: mlxlink
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000
4450570 / 4780432 / 4780433	**Description:** Fixed an issue where the root complex sent MCTP-over-PCI messages before a BDF was assigned, causing responses to be sent with BDF 0. The fix ensures that MCTP messages routed by ID are ignored until a valid BDF is assigned.
	Keywords: MCTP-over-PCI, BDF, MCTP messages
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000
4809134 / 4824635	**Description:** Fixed an issue where the steering tables were not updated after enabling partial Spectrum-X capabilities (BTH.AR) via LLPD.
	Keywords: Steering tables, LLDP
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000
4773333 / 4711949	**Description:** Fixed an issue where, in older versions and under specific configurations, the MEMIC BAR size could be unaligned to 64 bytes. The software now treats the address as aligned down to a 64-byte boundary.
	Keywords: MEMIC BAR size
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000
4785853 / 4653684 / 4796563 / 4797987	**Description:** Fixed an issue where the virtio software controller could encounter an infinite FLR loop if the host shut down during the software live-upgrade procedure in configurations with separate power supplies (i.e., the DPU remains powered when the host is powered off).
	Keywords: Virtio, Software Live Upgrade, FLR
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000
4794198 / 4796352 / 4797985	**Description:** Fixed an issue where, in host-aware mode, the firmware did not block the hotplug FSM transition from HOTPLUG to HOTUNPLUG_PREPARE, which could cause a hotplug device to enter an unexpected state.
	Keywords: Hotunplug, Virtio
	Detected in version: 32.47.1026
	Fixed in Release: 32.48.1000

2.2.7.6 BlueField-2 Firmware Bug Fixes

Internal Ref.	Issue
4450570 / 4780432 / 4780433	**Description:** Fixed an issue where the root complex sent MCTP-over-PCI messages before a BDF was assigned, causing responses to be sent with BDF 0. The fix ensures that MCTP messages routed by ID are ignored until a valid BDF is assigned.
	Keywords: MCTP-over-PCI, BDF, MCTP messages
	Discovered in Version: 24.47.1026
	Fixed in Release: 24.48.1000

2.2.8 Known Issues

2.2.8.1 DOCA Framework Known Issues

Reference	Description
4871396 4849953	Description: The `dpa-ps` and `dpa-statistics` diagnostic tools are missing from the BlueField-3 BFB image for Oracle Linux 9 and Oracle Linux 8.
	Workaround: N/A
	Keyword: DPA; missing package
	Reported in version: 3.3.0
4833932 4833931	Description: The DMS container for x86 hosts is missing the `awk` utility dependency.
	Workaround: N/A
	Keyword: Container dependency; OS verify failure
	Reported in version: 3.3.0
4659016	Description: The `doca_spcx_cc` application does not support running multiple concurrent instances on the same network device.
	Workaround: N/A
	Keyword: DOCA PCC; FlexIO; QP Transition (RTR)
	Reported in version: 3.3.0
4761527	Description: The DOCA Flow ACL pipe (PIPE_ACL) does not currently support IPv6 matching.
	Workaround: N/A
	Keyword: IPv6 support; hardware steering (HWS); matcher failure
	Reported in version: 3.3.0

Reference	Description
4085538	Description: The `doca-bench` tool fails to initialize GPU acceleration, returning a `DOCA_ERROR_NOT_SUPPORTED` error.
	Workaround: N/A
	Keyword: doca-bench; GPUNetIO; `libdoca_bench_cuda_impl`
	Reported in version: 3.3.0
4774876	Description: The `dpa-resource-mgmt` tool fails to run on systems defaulting to Python 3.12, displaying the error `ModuleNotFoundError: No module named 'pkg_resources'`.
	Workaround: Execute the tool using Python 3.10 or older using one of the following methods: • Run explicitly with python3: `python3 /usr/bin/dpa-resource-mgmt <arguments>` • Modify the script header to point to the generic python3 executable: `sudo sed -i '1s|#!/usr/bin/python3.12|#!/usr/bin/python3|' /usr/bin/dpa-resource-mgmt`
	Keyword: FlexIO; Single Point of Resource Distribution; missing module
	Reported in version: 3.3.0
4401408	Description: When monitoring multiple PTP interfaces, the `ptp_ports` field in PTP Monitor logs incorrectly displays the same clock id for all interfaces. This clock ID corresponds to the first interface due to a bug in the ptp4l module. The port number, however, is correct.
	Workaround: N/A
	Keyword: DOCA Firefly; Logging; PTP
	Reported in version: 3.1.0
4549785	Description: DPA samples are not supported when running in switchdev mode from the host.
	Workaround: N/A
	Keyword: DOCA Core; switchdev
	Reported in version: 3.1.0
4540734	Description: OVS-DOCA live update is not supported over AML2.
	Workaround: N/A
	Keyword: OVS
	Reported in version: 3.1.0
4273101	Description: High PPS traffic on PF ports (>15Mpps) causes CPS degradation in OVS.
	Workaround: Apply a software meter to limit PPS on the PF port using `ovs-vsctl set interface <pf> options:sw-meter=pps:200000:32` then restart `openvswitch` for the setting to take effect.
	Keyword: Open vSwitch
	Reported in version: 3.1.0
4487794	Description: Upgrading to DOCA FW-Bundle 3.0.0 or later on a system with DOCA BF-Bundle (BFB) 2.10.0 or earlier is not supported. Full BF-Bundle (BFB) upgrade is required.
	Workaround: N/A

Reference	Description
	Keyword: Software update
	Reported in version: 3.1.0
4415267	Description: When DPA code running by Flex IO RPC or CMD-Q runs into a recoverable error, code execution does not resume from calling context, which results in a timeout.
	Workaround: N/A
	Keyword: DPA; Timeout; Flex IO SDK; RPC
	Reported in version: 3.0.0
4297489	Description: Due to incompatibility between DPA and host libraries, a DPA device application must be recompiled after updating DOCA to a newer version.
	Workaround: N/A
	Keyword: DPA; host library; update
	Reported in version: 2.10.0
4270602	Description: UEFI/ATF firmware does not upgrade as part of the Linux Standard Tool process when Secure Boot is disabled.
	Workaround: Remove PK key and initiate UEFI/ATF firmware upgrade again. To remove the PK key, use the UEFI menu to navigate to Device Manager → Secure Boot Configuration → Custom Secure Boot Options → PK Options → Delete Signature.
	Keyword: UEFI/ATF; PK; Secure Boot; EFI Capsule Authentication
	Reported in version: 2.10.0
4200690	Description: The fTPM trusted application is signed for testing proposes only (i.e., not securely) with a development key.
	Workaround: N/A
	Keyword: fTPM over OP-TEE
	Reported in version: 2.10.0
N/A	Description: Applications using DPA might not work with older firmware versions.
	Workaround: Full upgrade of all DOCA 2.9.0 components including the firmware (i.e., doca-host and BF-Bundle).
	Keyword: DPA; backward compatibility
	Reported in version: 2.9.0
N/A	Description: Applications using FlexIO SDK API may have missing symbols during runtime.
	Workaround: Re-compile FlexIO-based applications with the DOCA 2.9.0 release.
	Keyword: FlexIO; backward compatibility
	Reported in version: 2.9.0
4095728	Description: Corrupt create repo causes doca-kernel repo to not contain the repo data.
	Workaround: If repo data is missing after installing the doca-kernel repo, run `createrepo --help`. If no output is generated, then the createrepo is corrupted and must be removed and reinstalled.
	Keyword: Kernel; repo
	Reported in version: 2.9.0

Reference	Description
4049034	Description: On openEuler 22.03 SP3 and openEuler 20.03 SP1, it is not possible to do yum update after BFB installation.

	Workaround: To perform yum update with either openEuler 22.03 SP3 and openEuler 20.03 SP1, follow these procedures depending on the use case:
	1. To update DOCA only, disable ALL repos:
	`dnf --disablerepo='*' --enablerepo='kubernetes,doca' -y update`
	2. To update OS components, exclude `rdma-core` using one of the following options:
	• Option 1 – disable `rdma-core` from `dnf.conf` using `excludepkgs=rdma-core*oe2203sp3*`
	• Option 2 – disable `rdma-core` from `openEuler.repo` file under OS and everything using `exlude=rdma-core*`
	• Option 3 – run
	`yum update -x rdma-core`

	Keyword: openEuler
	Reported in version: 2.9.0
4046180	Description: PCIe data IDs that require `Node`, `PCIe index`, and `Depth` parameters in `doca_telemetry_diag`, the only valid values are 0, 0, 0.
	Workaround: N/A
	Keyword: DOCA Telemetry
	Reported in version: 2.9.0
4129715	Description: Compiling Rocky 9.2 may fail when using GCC with the "native" arch flag.
	Keyword: Upgrade to toolset 13 (gcc 13).
	Keyword: Linux; GCC
	Reported in version: 2.9.0
4035553	Description: `oper_sample_period` does not always reflect the correct sample period. In some cases, it will reflect the `admin_sample_period` instead.
	Workaround: N/A
	Keyword: Core
	Reported in version: 2.8.0
4022563	Description: OVS-DOCA connection tracking with E2E enabled is not supported.
	Workaround: N/A
	Keyword: OVS-DPDK; connection tracking; E2E
	Reported in version: 2.8.0
3844705	Description: In OpenEuler 20.03, the Linux Kernel version 4.19.90 is affected by an issue that impacts the discard/trim functionality for the BlueField eMMC device which may cause degraded performance of the BlueField eMMC over time.

Reference	Description
	Workaround: Upgrade to Linux Kernel version 5.10 or later.
	Keyword: eMMC discard; trim functionality
	Reported in version: 2.7.0

3877725	Description: During BFB installation in NIC mode on BlueField-3, too much information is added into RShim log which fills it, causing the Linux installation progress log to not appear in the RShim log.
	`echo "DISPLAY_LEVEL 2" > /dev/rshim0/misc`
	`cat /dev/rshim0/misc`

	Workaround: Monitor the BlueField-3 Arm's UART console to check whether BFB installation has completed or not for NIC mode.
	`[13:58:39] INFO: Installation finished`
	`...`
	`[14:01:53] INFO: Rebooting...`

	Keyword: NIC mode; BFB install
	Reported in version: 2.7.0
3855702	Description: Trying to jump from a steering level in the hardware to a lower level using software steering is not supported on `rdma-core` lower than 48.x.
	Workaround: N/A
	Keyword: RDMA; SWS
	Reported in version: 2.7.0

3855485	Description: When enabling the `PCI_SWITCH_EMULATION_ENABLE` NVconfig, the mlx devices, and potentially the RShim devices disappear. Also, looking at the kernel logs using `dmesg` shows the following messages:
	`pci 0000:29:00.0: BAR 0: no space for [mem size 0x0200 0000 64bit pref]`
	`pci 0000:29:00.0: BAR 2: no space for [mem size 0x0080 0000 64bit pref]`
	`...`

	Workaround: N/A
	Keyword: NVconfig; RShim; dmsg
	Reported in version: 2.7.0
3831230	Description: In OpenEuler 20.03, the Linux Kernel version 4.19.90 is affected by an issue that impacts the discard/trim functionality for BlueField eMMC device which may cause degraded performance of BlueField eMMC over time.
	Workaround: Upgrade to Linux Kernel version 5.10 or later.
	Keyword: eMMC discard; trim functionality
	Reported in version: 2.7.0
3743879	Description: `mlxfwreset` could timeout on servers where the RShim driver is running and INTx is not supported. The following error message is printed: `BF reset flow encountered a failure due to a reset state error of negotiation timeout`.

Reference	Description

	Workaround: Set `PCIE_HAS_VFIO=0` and `PCIE_HAS_UIO=0` in `/etc/rshim.conf` and restart the RShim driver. Then re-run the `mlxfwreset` command.
	If host Linux kernel lockdown is enabled, then manually unbind the RShim driver before `mlxfwreset` and bind it back after `mlxfwreset`:
	`echo "DROP_MODE 1" > /dev/rshim0/misc`
	`mlxfwreset <arguments>`
	`echo "DROP_MODE 0" > /dev/rshim0/misc`

	Keyword: Timeout; mlxfwreset; INTx
	Reported in version: 2.7.0
3678069	Description: If using BlueField with NVMe and mmcbld and configured to boot from mmcblk, users must create `bf.cfg` file with `device=/dev/mmcblk0`, then install the `*.bfb` as normal.
	Workaround: N/A
	Keyword: NVMe
	Reported in version: 2.5.0
N/A	Description: Execution unit partitions are still not implemented and would be added in a future release.
	Workaround: N/A
	Keyword: EU tool
	Reported in version: 2.5.0
3666160	Description: Installing BFB using `bfb-install` when `mlxconfig` `PF_TOTAL_SF` >1700, triggers server reboot immediately.
	Workaround: Change `PF_TOTAL_SF` to 0, perform a graceful shutdown, power cycle, then installing BFB.
	Keyword: SF; `PF_TOTAL_SF`; BFB installation
	Reported in version: 2.2.1
3594836	Description: When enabling Flex IO SDK tracer at high rates, a slow-down in processing may occur and/or some traces may be lost.
	Workaround: Keep tracing limited to ~1M traces per second to avoid a significant processing slow-down. Use tracer for debug purposes and consider disabling it by default.
	Keyword: Tracer FlexIO
	Reported in version: 2.2.1
3592080	Description: When using UEK8 on the host in DPU mode, creating a VF on the host consumes about 100MB memory on BlueField
	Workaround: N/A
	Keyword: UEK; VF
	Reported in version: 2.2.1

Reference	Description
3546202	Description: After rebooting a BlueField-3 DPU running Rocky Linux 8.6 BFB, the kernel log shows the following error: `[ 3.787135] mlxbf_gige MLNXBF17:00: Error getting PHY irq. Use polling instead` This message indicates that the Ethernet driver will function normally in all aspects, except that PHY polling is enabled.
	Workaround: N/A
	Keyword: Linux; PHY; kernel
	Reported in version: 2.2.0
3566042	Description: Virtio hotplug is not supported in GPU-HOST mode on the NVIDIA Converged Accelerator.
	Workaround: N/A
	Keyword: Virtio; Converged Accelerator
	Reported in version: 2.2.0
3546474	Description: PXE boot over ConnectX interface might not work due to an invalid MAC address in the UEFI boot entry.
	Workaround: On BlueField, create `/etc/bf.cfg` file with the relevant PXE boot entries, then run the command `bfcfg`.
	Keyword: PXE; boot; MAC
	Reported in version: 2.2.0
3561723	Description: Running `mlxfwreset sync 1` on NVIDIA Converged Accelerators may be reported as supported although it is not. Executing the reset will fail.
	Workaround: N/A
	Keywords: mlxfwreset
	Reported in version: 2.2.0
3306489	Description: When performing longevity tests (e.g., mlxfwreset, DPU reboot, burning of new BFBs), a host running an Intel CPU may observer errors related to "CPU 0: Machine Check Exception".
	Workaround: Add `intel_idle.max_cstate=1` entry to the kernel command line.
	Keywords: Longevity; mlxfwreset; DPU reboot
	Reported in version: 2.2.0
3534219	Description: On BlueField-3 devices, from DOCA 2.2.0 to 32.37.1306 (or lower), the host crashes when executing partial Arm reset (e.g., Arm reboot; BFB push; mlxfwreset).
	Workaround: Before downgrading the firmware: 1. Run: `echo 0 > /sys/bus/platform/drivers/mlxbf-bootctl/large_icm` 2. Reboot Arm.
	Keyword: BlueField-3; downgrade
	Reported in version: 2.2.0

Reference	Description

3462630	When trying to perform a PXE installation when UEFI Secure Boot is enabled, the following error messages may be observed:
	`error: shim_lock protocol not found.`
	`error: you need to load the kernel first.`

	Workaround: Download a Grub EFI binary from the Ubuntu website. For further information on Ubuntu UEFI Secure Boot PXE Boot, please visit Ubuntu's official website.
	Keyword: PXE; UEFI Secure Boot
	Reported in version: 2.0.2
3448841	Description: While running CentOS 8.2, switchdev Ethernet BlueField runs in "shared" RDMA net namespace mode instead of "exclusive".
	Workaround: Use `ib_core` module parameter `netns_mode=0`. For example: `echo "options ib_core netns_mode=0" >> /etc/modprobe.d/mlnx-bf.conf`
	Keyword: RDMA; isolation; Net NS
	Reported in version: 2.0.2
2706803	Description: When an NVMe controller, SoC management controller, and DMA controller are configured, the maximum number of VFs is limited to 124.
	Workaround: N/A
	Keyword: VF; limitation
	Reported in version: 2.0.2
3273435	Description: Changing the mode of operation between NIC and DPU modes results in different capabilities for the host driver which might cause unexpected behavior.
	Workaround: Reload the host driver or reboot the host.
	Keyword: Modes of operation; driver
	Reported in version: 2.0.2

3264749	Description: In Rocky and CentOS 8.2 inbox-kernel BFBs, RegEx requires the following extra huge page configuration for it to function properly:
	`sudo hugeadm --pool-pages-min DEFAULT:2048M`
	`sudo systemctl start mlx-regex.service`
	`systemctl status mlx-regex.service`
	If these commands have executed successfully you should see `active (running)` in the last line of the output.

	Workaround: N/A
	Keyword: RegEx; hugepages
	Reported in version: 1.5.1
3240153	Description: DOCA kernel support only works on a non-default kernel.
	Workaround: N/A
	Keyword: Kernel

Reference	Description
	Reported in version: 1.5.0
3217627	Description: The `doca_devinfo_rep_list_create` API returns success on the host instead of `Operation not supported`.
	Workaround: N/A
	Keyword: DOCA core; InfiniBand
	Reported in version: 1.5.0

2.2.8.2 DOCA-Host and DOCA Drivers Known Issues

Reference	Description
4639103	Description: OVS userspace modes DPDK and DOCA are not supported on RHEL 10.0, only kernel mode is supported.
	Workaround: N/A
	Keyword: OVS userspace modes, RHEL 10.0
	Reported in version: 3.2.0
4656429	Description: DOCA-Host installation caused CIFS to break in RHEL 8 and above. A dummy module was added so that CIFS will be disabled after DOCA-Host installation in RHEL 8 and above.
	Workaround: N/A
	Keyword: Installation, CIFS, RHEL 8 and above
	Reported in version: 3.0.0
4662007	Description: The same GCC version used to build the kernel must be used during module compilation to ensure compatibility.
	Workaround: N/A
	Keyword: GCC version
	Reported in version: 3.2.0
4694905	Description: The system requires DKMS version 3.2 or higher to be installed as a package. Please make sure that DKMS is properly installed and available on the system.
	Workaround: N/A
	Keyword: DKMS
	Reported in version: 3.2.0

Reference	Description
4662554	Description: DOCA-OFED compilation fails when CONFIG_XFRM_OFFLOAD is disabled in the kernel.
	Workaround: N/A
	Keyword: CONFIG_XFRM_OFFLOAD
	Reported in version: 3.1.0
4574425	Description: After shutting down a Xen VM with a PCI device attached, rebinding the device to mlx5_core may fail with the following error and can result in a leak of a command resourc.: `mlx5_core 0000:05:00.2: wait_func:1205:(pid 11034): ENABLE_HCA(0x104) timeout.`

	Workaround: Re-enable SR-IOV after the Xen VM shutdown issue, run the following commands:
	`# echo 0000:05:00.2 > /sys/bus/pci/drivers/pciback/unbind`
	`# echo 0 > /sys/class/infiniband/mlx5_0/device/sriov_numvfs`
	`# echo 2 > /sys/class/infiniband/mlx5_0/device/sriov_numvfs`
	`# echo 0000:05:00.2 > /sys/bus/pci/drivers/pciback/unbind`
	`# echo 0000:05:00.2 > /sys/bus/pci/drivers/mlx5_core/bind`

	Keyword: Xen VM, PCI device
	Reported in version: 3.2.0
4641515	Description: Starting with the October 2025 firmware release (32.47.1xxx), backward compatibility with older MFT versions (4.31.0-149 and 4.30.0-139) is no longer supported. Using these older versions may cause unexpected behavior or prevent device detection.
	Workaround: N/A
	Keyword: Firmware; MFT; compatibility
	Reported in version: 3.2.0
4542517	Description: `systemd-networkd` continuously monitors all network interfaces, including unmanaged ones. On systems with thousands of virtual interfaces (e.g., over 2,000), this behavior causes high CPU usage, slow network command responses, and timeouts. Since there is no option to disable statistics collection for unmanaged interfaces, the issue cannot be mitigated without risking loss of connectivity.
	Workaround: N/A
	Keyword: systemd-networkd
	Reported in version: 3.2.0
4545488	Description: When upgrading from DOCA with RShim version 2.1.13 and below, a missing support table prevents firmware version extraction from the image bundle, resulting in warning messages. Installation proceeds, but firmware versions are not verified post-installation.
	Workaround: N/A
	Keyword: Doca-installer; DOCA-Host; firmware extraction
	Reported in version: 3.1.0

Reference	Description
4405369	Description: Hash action is not supported concurrently with mirroring.
	Workaround: N/A
	Keyword: OVS; ECMP; tunnel mirroring
	Reported in version: 3.1.0
4522588	Description: Installing any profile on Amazon Linux fails due to two issues: incorrect priorities assigned to inbox repositories and an unsupported signing method.

	Workaround: Change the repository priority and disable GPG checks by updating `/etc/yum.repos.d/doca.repo` to the following:
	`[doca]`
	`name=DOCA 3.1.0-056000`
	`baseurl=file:///usr/share/doca-host-3.1.0/repo`
	`enabled=1`
	`gpgkey=file:///usr/share/doca-host-3.1.0/repo/RPM-GPG-KEY-doca`
	`priority=10`
	`gpgcheck=0`

	Keyword: Installation
	Reported in version: 3.1.0
43520000	Description: Modified ptp4l to limit LISTENING port prints to only occur on Best Master Clock (BMC) changes.
	Workaround: N/A
	Keyword: PTP sync
	Reported in version: 3.1.0
4446815	Description: Since `mlxdevm` does not yet support lightweight SFs, attempting to activate an SF after setting `max_io_eqs` to zero will fail with the following error: "alloc_netdev: Unable to allocate device with zero RX queues."
	Workaround: N/A
	Keyword: Lightweight SF, mlxdevm
	Reported in version: 3.1.0
4449280	Description: When one port on the switch is shut down, the driver does not update the LAG map.
	Workaround: To ensure proper ECMP behavior, set `ignore_routes_with_linkdown` to 1.
	Keyword: ECMP
	Reported in version: 3.1.0
4404719	Description: See DOCA-HOST 3.1.0 (July 2025) changes in section Customer Affecting Changes.
	Workaround: N/A
	Keyword: PCI information

Reference	Description
	Reported in version: 3.0.0
4273881	Description: PCI information is missing on RedHat p host.
	Workaround: Matching an interface name with its PCI address requires running: `ll /sys/class/net/ | grep <interface name>`
	Keyword: PCI information
	Reported in version: 3.0.0
4155701	Description: When offloading xfrm states to hardware, the offloading device is linked to the skb's secpath. If an skb is freed or deferred, an unregister netdevice operation may hang because the netdevice is still being reference-counted.
	Workaround: Remove the netdevice from the xfrm states when the netdevice is unregistered.
	Keyword: IPSec Crypto Offload
	Reported in version: 2.10.0

2.2.8.3 BlueField-3 Firmware Known Issues

Internal Ref.	Issue
4776492	**Description:** Occasionally, upgrading PLDM BFB from DOCA v3.2.0 to v3.2.1 may lead to an assert 0x7 in dmesg.
	Workaround: Install DOCA v3.2.1 bfb file using "bfb-install" command, and power cycle the server.
	Keywords: PLDM
	Detected in version: 32.47.1088
4604969	**Description:** Probe packets might be dropped at the transmission stage when multiple congestion control flows are active.
	Workaround: N/A
	Keywords: PCC, RTT, probe
	Detected in version: 32.47.1026
4683823	**Description:** Some diagnostic data counters share hardware resources and cannot be configured simultaneously since 64-bit counter formats (e.g., DIAG_DATA_PARAMS_CONTEXT.output_format set to FORMAT_0 or FORMAT_1) consume more hardware resources per counter.
	Workaround: If a NO_RESOURCES error occurs, use output_format FORMAT_2 to reduce resource usage.
	Keywords: DOCA Telemetry Diagnostics
	Detected in version: 32.47.1026

Internal Ref.	Issue
4685736	**Description:** Creating a DPA process that allocates a 128 MB data segment and loads a dynamic library may fail with syndrome 0xdc30ac.
	Workaround: Limit the DPA application's data segment size to 64 MB.
	Keywords: DPA
	Detected in version: 32.47.1026
4535791	**Description:** When running sync2 on an EP configuration, the following error may appear during the MLXFWReset sync2 operation: **ERROR: System Off: operation not handled**. Although sync2 is intended for use in a switch topology, it can technically run on an EP configuration. However, this is not the default mode, nor is it a typical or recommended use case.
	Workaround: N/A
	Keywords: sync2, EP configuration
	Detected in version: 32.46.1006
4534767	**Description:** In multi-probe mode, only one slot of IFA1 or IFA2 is allowed, although IFA1 and IFA2 can operate together.
	Workaround: N/A
	Keywords: PCC, IFA1, IFA2
	Detected in version: 32.46.1006
4394475	**Description:** The existing congestion control configuration applies globally, rather than on a per-priority basis.
	Workaround: Ensure that the configuration values for all priorities are aligned in either `mlxconfig ROCE_CC_PRIO_MASK_P$port` or `sysfs ecn/roce_rp/enable/$port`.
	Keywords: Congestion control, ROCE_CC_PRIO
	Detected in version: 32.45.1020
4422120	**Description:** Any BFB upgrade from the October GA (2.9.2) to the new BFB will trigger a 0x00b4 assert. Nonetheless, the update will complete successfully, and the customer can safely ignore the assert.
	Workaround: N/A
	Keywords: BFB upgrade
	Detected in version: 32.45.1020
4216761	**Description:** For all host-related counters, the buffers used by the Arm are the same as those used by the host. Buffer usage is tracked collectively, combining both ARM and host consumption.
	Workaround: N/A
	Keywords: Counters
	Detected in version: 32.45.1020
4125431	**Description:** The MKEY created by software (VirtIo.Net DPA App is created with a length of 1 byte and used to access L2 memory. Since the minimum translation size is 64 bytes, using a 1-byte MKEY results in a translation error and triggers an exception.
	Workaround: N/A
	Keywords: MKEY

Internal Ref.	Issue
	Detected in version: 32.45.1020
4303583	**Description:** The query_header_modify_pattern command may produce inaccurate results when specific fields are used.
	Workaround: N/A
	Keywords: query_header_modify_pattern command
	Detected in version: 32.45.1020
4296168	**Description:** Running mlxfwreset fails when the DPU is configured as the root complex for NVMe drives. This issue impacts the configuration use case where the DPU acts as the root complex for NVMe drives, rather than the BF-3 in the host functioning as a PCIe Switch for the NVMe.
	Workaround: To ensure the firmware reset works correctly, explicitly run the fwreset command from the host using the "--method 1" flag (hot reset).
	Keywords: mlxfwreset
	Detected in version: 32.45.1020
4193036	**Description:** The initial allocation of DPA_THREAD on group affinity allocates memory for all EUs, including stack, core dump, and other resources.
	Workaround: N/A
	Keywords: DPA
	Detected in version: 32.44.1036
4007228	**Description:** NC-SI pass-through requires the user to allocate a MAC address to the platform BMC.
	Workaround: N/A
	Keywords: NC-SI pass-through
	Discovered in Version: 32.41.1000
3787618	**Description:** NVIA register is not allowed for external host if any field of EXTERNAL_HOST_PRIV or EXTERNAL_HOST_PRIV_FAST TLVs is not set as the default.
	Workaround: N/A
	Keywords: Host privilege
	Discovered in Version: 32.41.1000
3636631	**Description:** When configuring BlueField-3 Arm cores as PCIe root-complex, all non-mlx5 devices must always set the BlueField-3's IOMMU to disabled or passthrough mode. Turning IOMMU "ON" requires special handling of interrupts in the driver or the use of polling. For further assistance, contact NVIDIA support.
	Workaround: N/A
	Keywords: IOMMU
	Discovered in Version: 32.39.2048
3614529	**Description:** The supported DDR5 link speed in SKU B3220, is 5200 MT/s.
	Workaround: N/A
	Keywords: DDR5 link speed
	Discovered in Version: 32.39.2048

Internal Ref.	Issue
3728450	**Description:** SW_RESET with a pending image is currently not supported.
	Workaround: N/A
	Keywords: SW_RESET
	Discovered in Version: 32.39.2048
3614288	**Description:** Occasionally, the device may hang when there a hot plug is performed from a unknown direction.
	Workaround: N/A
	Keywords: Hot-plug operation
	Discovered in Version: 32.39.2048
-	**Description:** The I²C clock fall time is lower than the 12ns minimum defined in the I2C-bus specification. For further information, refer to the I²C-bus Specification, Version 7.0, October 2021, https://www.i2c-bus.org/.
	Workaround: N/A
	Keywords: I²C clock
	Discovered in Version: 32.39.2048
3439438	**Description:** When connecting to a High Speed Traffic Generator in 400G speed, the linkup time may takes up to 3 minutes.
	Workaround: N/A
	Keywords: 400G linkup time
	Discovered in Version: 32.38.1002
3534128	**Description:** External flash access such as flash read using the MFT tools will fail if there is a pending image on the flash.
	Workaround: N/A
	Keywords: Flash access
	Discovered in Version: 32.38.1002
3534219	**Description:** On BlueField-3 devices, from DOCA 2.2.0 to 32.37.1306 (or lower), the host crashes when executing partial Arm reset (e.g., Arm reboot; BFB push; mlxfwreset).
	Workaround: Before downgrading the firmware, perform: • echo 0 > /sys/bus/platform/drivers/mlxbf-bootctl/large_icm • Arm reboot
	Keywords: BlueField-3; downgrade
	Discovered in Version: 32.38.1002
3547022	**Description:** When unloading the network drivers on an external host, sync1 reset may be still reported as 'supported' although it is not. Thus, initiating the reset flow may result in reset failure after a few minutes.
	Workaround: N/A
	Keywords: Sync1 reset
	Discovered in Version: 32.38.1002

Internal Ref.	Issue
3439438	**Description:** When connecting to a Spirent switch in 400G speed, the linkup time may takes up to 3 minutes.
	Workaround: N/A
	Keywords: Spirent, 400G, linkup time
	Discovered in Version: 32.38.1002
3178339	**Description:** PCIe PML1 is disabled.
	Workaround: N/A
	Keywords: PCIe PML1
	Discovered in Version: 32.38.1002
3525865	**Description:** Unexpected system behavior might be observed if the driver is loaded while reset is in progress.
	Workaround: N/A
	Keywords: Sync 1 reset, firmware reset
	Discovered in Version: 32.38.1002
3275394	**Description:** When performing PCIe link secondary-bus-reset, disable/enable or mlxfwreset on AMD based Genoa systems, the device takes longer then expected to link up, due to a PCIe receiver termination misconfiguration.
	Workaround: N/A
	Keywords: PCIe
	Discovered in Version: 32.37.1306
2878841	**Description:** The firmware rollback fails for the signature retransmit flow if the QPN field is configured in the mkey (as it only allows the given QP to use this Mkey) as the firmware rollback flow relies on an internal QP that uses the mkey.
	Workaround: N/A
	Keywords: Signature retransmit flow
	Discovered in Version: 32.37.1306
3412847	**Description:** Socket-Direct is currently not supported.
	Workaround: N/A
	Keywords: Socket-Direct
	Discovered in Version: 32.37.1306

2.2.8.4 BlueField-2 Firmware Known Issues

Internal Ref.	Issue
4394475	**Description:** The existing congestion control configuration applies globally, rather than on a per-priority basis.

Internal Ref.	Issue
	Workaround: Ensure that the configuration values for all priorities are aligned in either `mlxconfig ROCE_CC_PRIO_MASK_P$port` or `sysfs ecn/roce_rp/enable/$port`.
	Keywords: Congestion control, ROCE_CC_PRIO
	Detected in version: 24.45.1020
3754913	**Description:** PHYless Reset is currently not supported.
	Workaround: N/A
	Keywords: PHYless Reset
	Discovered in Version: 24.40.1000
3525865	**Description:** Unexpected system behavior might be observed if the driver is loaded while reset is in progress.
	Workaround: N/A
	Keywords: Sync 1 reset, firmware reset
	Discovered in Version: 24.39.2048
-	**Description:** When `tx_port_ts` is set to `"true"`, due to a compensation mechanism in the Tx timestamp available in some hardware Rx timestamp errors, a symmetrical error and no clock offset occur when using the timestamps to synchronize the device clock. This might also cause an error while using timestamps for delay measurements (e,g., delay measurements reported by a PTP daemon) and even negative delay measurements in some cases.
	Workaround: N/A
	Keywords: PTP path delay
	Discovered in Version: 24.38.1002
2878841	**Description:** The firmware rollback fails for the signature retransmit flow if the QPN field is configured in the mkey (as it only allows the given QP to use this Mkey) as the firmware rollback flow relies on an internal QP that uses the mkey.
	Workaround: N/A
	Keywords: Signature retransmit flow
	Discovered in Version: 24.37.1300
3329109	**Description:** MFS1S50-H003E cable supports only HDR rate when used as a split cable.
	Workaround: N/A
	Keywords: HDR, split cable, MFS1S50-H003E
	Discovered in Version: 24.37.1300
3267506	**Description:** CRC is included in the traffic byte counters as a port byte counter.
	Workaround: N/A
	Keywords: Counters, CRC
	Discovered in Version: 24.35.2000

Internal Ref.	Issue
3141072	**Description:** The "max_shaper_rate" configuration query via QEEC mlxreg returns a value translated to hardware granularity.
	Workaround: N/A
	Keywords: RX Rate-Limiter, Multi-host
	Discovered in Version: 24.34.1002
2870970	**Description:** GTP encapsulation (flex parser profile 3) is limited to the NIC domain. Encapsulating in the FDB domain will render a 0-size length in GTP header.
	Workaround: N/A
	Keywords: GTP encapsulation
	Discovered in Version: 24.34.1002
2870213	**Description:** Servers do not recover after configuring `PCI_SWITCH_EMULATION_NUM_PORT` to 32 followed by power cycle.
	Workaround: N/A
	Keywords: VirtIO-net; power cycle
	Discovered in Version: 24.33.1048
2855592	**Description:** When working with 3rd party device (e.g., Paragon) in 25GbE speed, the 25GbE speed must be configured in force mode.
	Workaround: N/A
	Keywords: Force mode, 3rd party devices, 25GbE
	Discovered in Version: 24.33.1048
2850003	**Description:** Occasionally, when rising a logical link, the link recovery counter is increase by 1.
	Workaround: N/A
	Keywords: Link recovery counter
	Discovered in Version: 24.33.1048
2616755	**Description:** Forward action for IPoIB is not supported on RX RDMA Flow Table.
	Workaround: N/A
	Keywords: Steering, IPoIB
	Discovered in Version: 24.33.1048

2.2.9 BlueField Firmware Cables

The firmware version included in this DOCA release supports the following cables.

- BlueField-3 Validated and Supported Cables and Modules
- BlueField-2 Validated and Supported Cables and Modules

2.2.9.1 BlueField-3 Validated and Supported Cables and Modules

The BlueField-3 firmware version included in this DOCA release supports the following cables.

2.2.9.1.1 Cables Lifecycle Legend

Lifecycle Phase	Definition
EOL	End of Life
LTB	Last Time Buy
HVM	GA level
MP	GA level
P-Rel	GA level
Preliminary	Engineering Sample
Prototype	Engineering Sample

2.2.9.1.2 NDR / 400GbE Cables

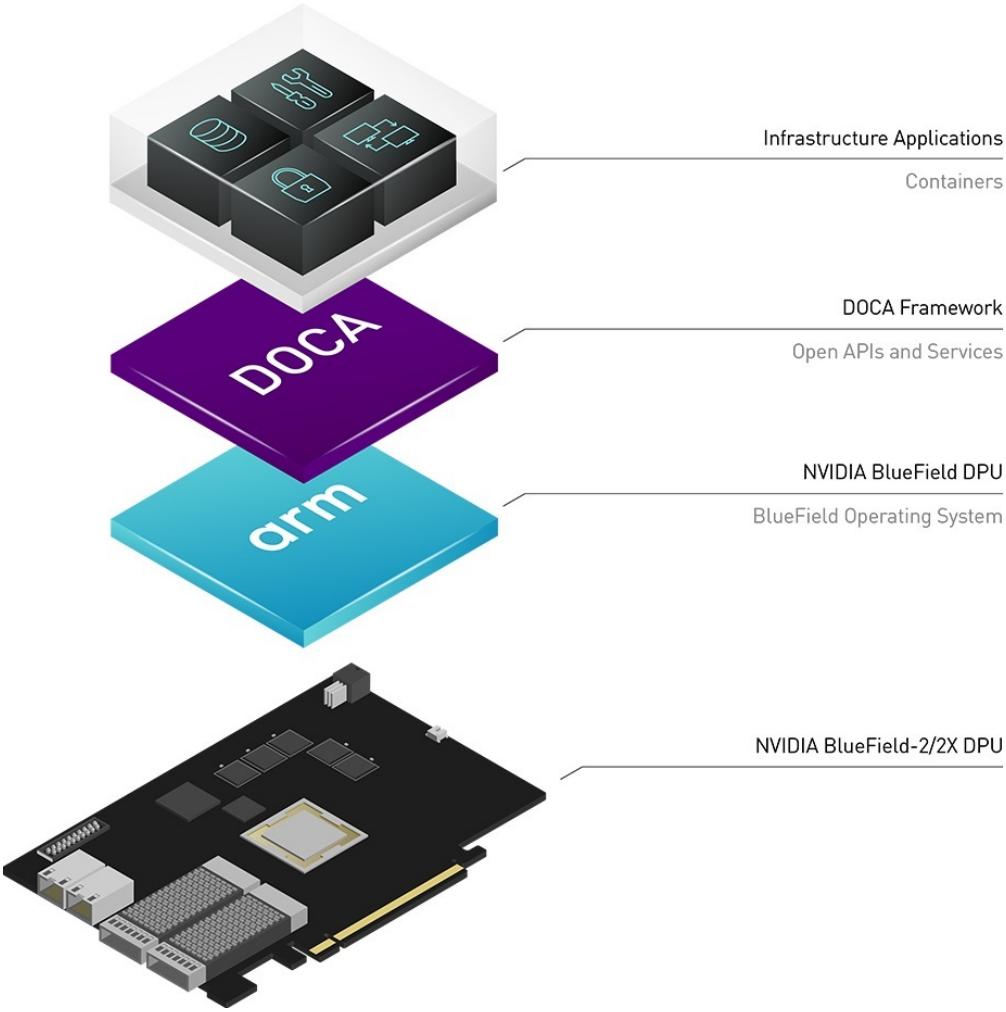
2.3 BlueField and DOCA User Types

This guide provides a quick introduction to the NVIDIA® BlueField® networking platform, its DOCA software components, and BlueField user types.

2.3.1 Introduction

The BlueField family of networking platforms includes data processing units (DPUs) and SuperNICs, and is optimized for traditional enterprise, high-performance computing (HPC), and modern cloud workloads, delivering a broad set of accelerated software-defined networking, storage, security, and management services. BlueField enables organizations to transform their IT infrastructures into state-of-the-art data centers that are accelerated, fully programmable, and armed with zero-trust security to prevent data breaches and cyber-attacks.

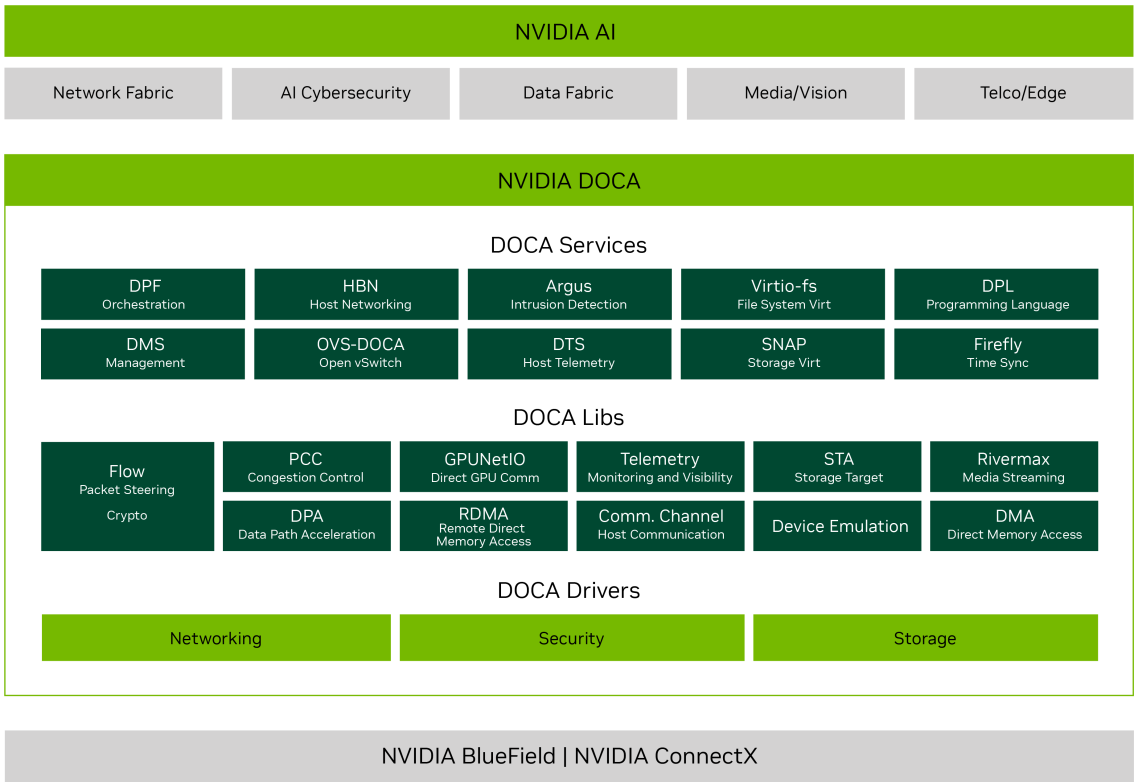
NVIDIA DOCA™ brings together a wide range of powerful APIs, libraries, and frameworks for programming and acceleration of the modern data center infrastructure. Like NVIDIA® CUDA® for GPUs, DOCA is a consistent and essential resource across all existing and future generations of BlueField products.



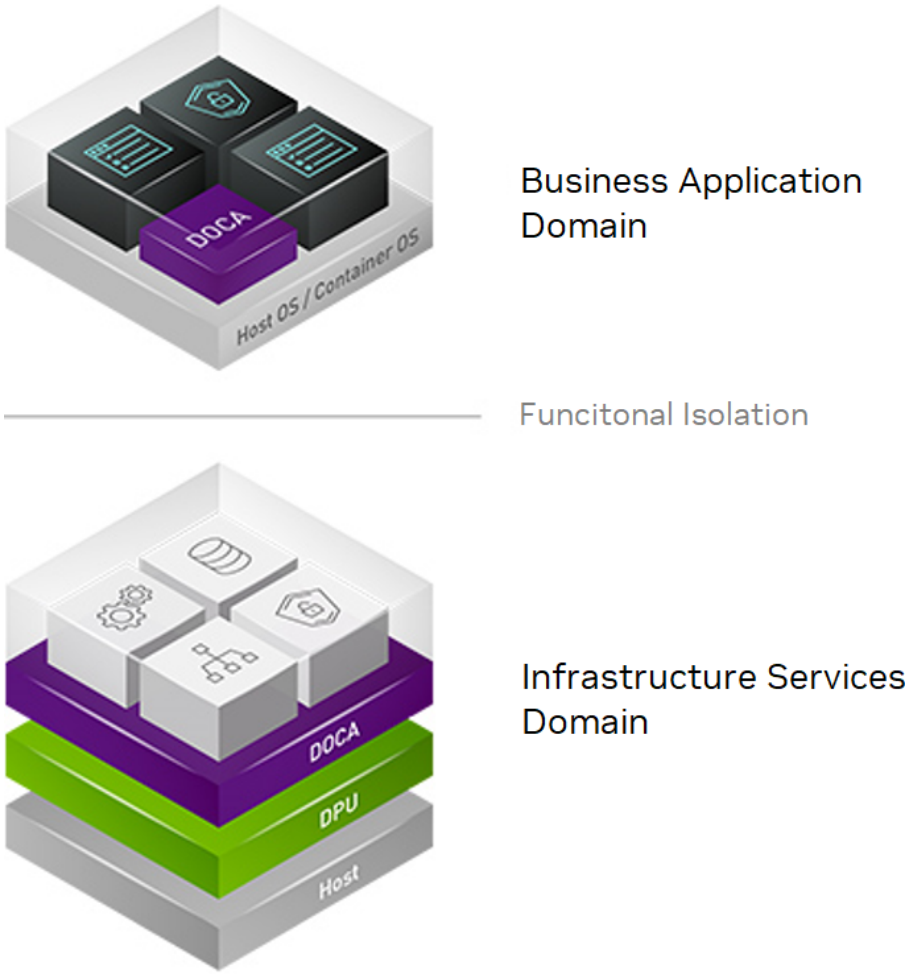
2.3.2 DOCA Components

DOCA software consists of a development and a runtime environment.

- DOCA-Devel provides industry-standard open APIs and frameworks, including Data Plane Development Kit (DPDK) and P4 for networking and security, and the Storage Performance Development Kit (SPDK) for storage. The frameworks simplify application offload with integrated NVIDIA acceleration packages. The Devel environment supports a range of operating systems and distributions and includes drivers, libraries, tools, documentation, and reference applications.



- **DOCA runtime** includes tools for provisioning, deploying, and orchestrating containerized services on BlueField Platforms in bulk across the data center.



2.3.3 BlueField Networking Platform User Types

2.3.3.1 BlueField Administrator

A BlueField administrator can be a system admin, an IT specialist, a security operations specialist, or anyone managing data center servers and their functionality. The admin would usually be interfacing with BlueField configuration and DOCA services and applications running on the BlueField Platform.

Common operations performed by the BlueField admin:

- Updating the BlueField image
- Running reference applications on the BlueField Platform
- Running DOCA services on the BlueField Platform

For more information, please visit BlueField Administrator Quick Start Guide.

2.3.3.2 DOCA Developer

A DOCA developer creates the services and applications that run on top of the BlueField Platform and usually interfaces with DOCA libraries and drivers to create the necessary workflow and functionality.

Common operations performed by the DOCA developer:

- Developing DOCA applications using DOCA libraries and drivers
- Compiling DOCA reference applications
- Using DOCA sample code to create a new workflow

For more information, please refer to the DOCA Developer Quick Start Guide.

2.4 DOCA EULA

2.4.1 End-User License Agreement

This NVIDIA DOCA License agreement (“Agreement) is a legal agreement between you and Mellanox Technologies, Ltd. ("NVIDIA") and governs the use of the NVIDIA DOCA software and related materials provided under this Agreement (“SOFTWARE”).

This Agreement can be accepted only by an adult of legal age of majority in the country in which the SOFTWARE is used. If you are entering this Agreement on behalf of a company or other legal entity, you represent that you have legal authority and “you” will mean the entity you represent.

By using the SOFTWARE, you affirm that you have reached the legal age of majority, you accept the terms of this Agreement, and you take legal and financial responsibility for the actions of your permitted users.

You agree to use the SOFTWARE only for purposes that are permitted by (a) this Agreement, and (b) any applicable law, regulation or generally accepted practices or guidelines in the relevant jurisdictions.

1. License. Subject to the terms of this Agreement, NVIDIA hereby grants you a non-exclusive, non-transferable license, without the right to sublicense (except as expressly provided in this Agreement) to:

1. Install and use the SOFTWARE,
2. Modify and create derivative works of sample or reference source code delivered in the SOFTWARE (“Derivatives”),
3. Use the provided SOFTWARE to develop your own implementation of the API, provided that such implementation does not modify NVIDIA’s APIs, and

4. Distribute the following portions of the SOFTWARE as incorporated in object code format into a software application, subject to the distribution requirements indicated in Section 2 of this Agreement: API headers, drivers, libraries and sample applications.

BlueField SNAP software and materials, if delivered to you under this Agreement, are licensed only for use in BlueField DPUs and SuperNICs ("Networking Platform"), Per Networking Platform. "Per Networking Platform" license means a license that allows concurrent authorized users to use the SOFTWARE in a single BlueField Networking Platform under the license, and in some cases the SKU or documentation will indicate the maximum number of concurrent authorized users or virtual machines per Networking Platform. Notwithstanding contrary terms in Section 1 above, you may not use or copy BlueField SNAP software without the necessary licenses.

2. Distribution Requirements. These are the distribution requirements for you to exercise the grants above:

1. An application must have material additional functionality, beyond the included portions of the SOFTWARE.
2. The distributable portions of the Software shall only be accessed by your application.
3. The following notice shall be included in distributed modifications and derivative works of source code: "This software contains source code provided by Mellanox Technologies Ltd."
4. Unless you have a separate agreement in writing with NVIDIA , any developer tools provided under this Agreement are delivered for your internal use only.
5. You agree to distribute the SOFTWARE subject to the terms at least as protective as the terms of this Agreement, including (without limitation) terms relating to the license grant, license restrictions and protection of NVIDIA's intellectual property rights. Additionally, you agree that you will protect the privacy, security and legal rights of your application users.
6. You agree to notify NVIDIA in writing of any known or suspected distribution or use of the SOFTWARE not in compliance with the requirements of this Agreement, and to enforce the terms of your agreements with respect to the distributed portions of the SOFTWARE.

3. Authorized Users. You may allow employees and contractors of your entity or of your subsidiary(ies) to access and use the SOFTWARE from your secure network to perform work on your behalf. If you are an academic institution you may allow users enrolled or employed by the academic institution to access and use the SOFTWARE from your secure network. You are responsible for the compliance with the terms of this Agreement by your authorized users. Any act or omission that if committed by you would constitute a breach of this Agreement will be deemed to constitute a breach of this Agreement if committed by your authorized users.

4. Limitations. Your license to use the Software and Derivatives is restricted as stated in this Section 4 ("License Restrictions"). You will cooperate with NVIDIA and, upon

NVIDIA's written request, you will confirm in writing and provide reasonably requested information to verify your compliance with the terms of this Agreement.

1. The SOFTWARE is licensed for you to develop applications only for their use in systems with NVIDIA DPUs, NVIDIA SuperNICs or NVIDIA adapter products or related NVIDIA adapter products. Except as provided in this Agreement, you may not modify, reverse engineer, decompile or disassemble, or remove copyright or other proprietary notices from any portion of the SOFTWARE or copies of the SOFTWARE.
2. You may not distribute or disclose to third parties the output of the SOFTWARE where the output reveals functionality or performance data pertinent to NVIDIA hardware or software products, the results of benchmarking, competitive analysis, regression or performance data relating to the SOFTWARE without the prior written permission from NVIDIA .
3. Except as expressly provided in this Agreement, you may not copy, sell, rent, sublicense, transfer, distribute or otherwise make available to others (except as stated in Section 3 ("Authorized Users"), modify, or create derivative works of any portion of the SOFTWARE or Derivates. For clarity, unless you have an agreement with NVIDIA for this purpose you may not distribute or sublicense the SOFTWARE as a stand-alone product.
4. Unless you have an agreement with NVIDIA for this purpose, you may not indicate that an application created with the SOFTWARE is sponsored or endorsed by NVIDIA.
5. You may not bypass, disable, or circumvent any technical limitation, encryption, security, digital rights management or authentication mechanism in the SOFTWARE.
6. You may not use the SOFTWARE or Derivatives in any manner that would cause them to become subject to an open source software license subject to the terms in the Section 8 below ("Components Under Other Licenses").
7. You may not replace any NVIDIA software components in the Software that are governed by this Agreement with other software that implements NVIDIA APIs.
8. You may not reverse engineer, decompile or disassemble any portion of the output generated using Software elements for the purpose of translating such output artifacts to target a non-NVIDIA platform.
9. You may not use the SOFTWARE in or with any system or application where the use or failure of such system or application developed or deployed with SOFTWARE could result in injury, death or catastrophic damage ("Mission Critical Applications"). NVIDIA will not be liable to you or any third party, in whole or in part, for any claims or damages arising from uses in Mission Critical Applications.
10. You agree to defend, indemnify and hold harmless NVIDIA and its affiliates, and their respective employees, contractors, agents, officers and directors, from and against any and all claims, damages, obligations, losses, liabilities, costs or debt, fines, restitutions and expenses (including but not limited to attorney's fees and costs incident to establishing the right of indemnification) arising out of or related

to your use of the SOFTWARE outside of the scope of this Agreement, or not in compliance with its terms.

5. Confidentiality. You agree that you will not use, nor authorize others to use, NVIDIA Confidential Information, except as necessary for the performance of this Agreement, and that you will not disclose NVIDIA Confidential Information to any third party, except to permitted users under this Agreement that have a need to know such Confidential Information for the purpose of this Agreement, provided that each such recipient is subject to a written agreement that includes confidentiality obligations consistent with these terms. You will protect the NVIDIA Confidential Information with at least the same degree of care that you use to protect your own similar confidential and proprietary information, but no less than a reasonable degree of care. “Confidential Information” means the Software including its features and functionality, output, and any results of benchmarking or other competitive analysis or regression or performance data relating to the Software.

6. Updates NVIDIA may, at its option, make available patches, workarounds or other updates to this SOFTWARE. Unless the updates are provided with their separate governing terms, they are deemed part of the SOFTWARE licensed to you as provided in this Agreement. You agree that the form and content of the SOFTWARE that NVIDIA provides may change without prior notice to you.

7. Pre-Release Versions. SOFTWARE versions identified as alpha, beta, preview, early access or otherwise as pre-release may not be fully functional, may contain errors or design flaws, and may have reduced or different security, privacy, availability, and reliability standards relative to commercial versions of NVIDIA software and materials. You may use a pre-release SOFTWARE version at your own risk, understanding that these versions are not intended for use in production or business-critical systems. NVIDIA may choose not to make available a commercial version of any pre-release SOFTWARE. NVIDIA may also choose to abandon development and terminate the availability of a pre-release SOFTWARE at any time without liability.

8. Components Under Other Licenses. The Software may include or be distributed with components provided with separate legal notices or terms that accompany the components, such as open source software licenses and other license. The components are subject to the applicable other licenses, including any proprietary notices, disclaimers, requirements and extended use rights; except that this Agreement will prevail regarding the use of third-party open source software, unless a third-party open source software license requires its license terms to prevail. Open source software license means any software, data or documentation subject to any license identified as an open source license by the Open Source Initiative (http://opensource.org), Free Software Foundation (http://www.fsf.org) or other similar open source organization or listed by the Software Package Data Exchange (SPDX) Workgroup under the Linux Foundation (http://www.spdx.org).

9. Ownership.

9.1 NVIDIA Ownership. The Software, including all intellectual property rights, is and will remain the sole and exclusive property of NVIDIA or its licensors. Except as expressly

granted in this Agreement, (i) NVIDIA reserves all rights, interests and remedies in connection with the Software and (ii) no other license or right is granted to you by implication, estoppel or otherwise.

9.2 Your Ownership. Subject to the rights of NVIDIA and its suppliers in the SOFTWARE, which continue to be licensed as stated in this Agreement, even when incorporated in your products or services and the extent permitted by applicable law, as between you and NVIDIA, you hold all rights, title and interest in and to your applications and your Derivatives you develop as permitted in this Agreement including their respective intellectual property rights.

10. Feedback. You may, but are not obligated to, provide suggestions, requests, fixes, modifications, enhancements or other feedback regarding or in connection with your use of the Software (collectively, "Feedback"). Feedback, even if designated as confidential by you, will not create any confidentiality obligation for NVIDIA or its affiliates. If you provide Feedback, you hereby grant NVIDIA , its affiliates and its designees a non-exclusive, perpetual, irrevocable, sublicensable, worldwide, royalty-free, fully paid-up and transferable license, under your intellectual property rights, to publicly perform, publicly display, reproduce, use, make, have made, sell, offer for sale, distribute (through multiple tiers of distribution), import, create derivative works of and otherwise commercialize and exploit the Feedback at NVIDIA's discretion. You will not give Feedback (i) that you have reason to believe is subject to any restriction that impairs the exercise of the grant stated in this section, such as third-party intellectual property rights or (ii) subject to license terms which seek to require any product incorporating or developed using such Feedback, or other intellectual property of NVIDIA or its affiliates, to be licensed to or otherwise shared with any third party.

11. DISCLAIMER OF WARRANTIES. THE SOFTWARE IS PROVIDED by NVIDIA AS-IS and with all faults. TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW NVIDIA AND ITS AFFILIATES EXPRESSLY DISCLAIM ALL WARRANTIES and Representations, WHETHER EXPRESS, IMPLIED OR STATUTORY, INCLUDING without limitation, WARRANTIES OF TITLE, MERCHANTABILITY, NON-INFRINGEMENT, OR FITNESS FOR A PARTICULAR PURPOSE. Without limiting the foregoing, NVIDIA DOES NOT WARRANT THAT THE SOFTWARE WILL MEET YOUR REQUIREMENTS; THAT ANY DEFECTS OR ERRORS WILL BE CORRECTED; THAT ANY CERTAIN CONTENT WILL BE AVAILABLE; OR THAT THE SOFTWARE IS FREE OF VIRUSES OR OTHER HARMFUL COMPONENTS. NO INFORMATION OR ADVICE GIVEN BY NVIDIA WILL IN ANY WAY INCREASE THE SCOPE OF ANY WARRANTY EXPRESSLY PROVIDED IN THIS AGREEMENT.

12. LIMITATIONS OF LIABILITY.

12.1 Disclaimers. TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, in no event will NVIDIA AND ITS AFFILIATES BE LIABLE FOR ANY (I) Indirect, SPECIAL, INCIDENTAL, PUNITIVE OR CONSEQUENTIAL DAMAGES, OR (II) Damages for the (A) COSTS OF PROCURING SUBSTITUTE PRODUCTS or (B) LOSS of PROFITS, Revenues, USE, DATA OR GOODWILL ARISING OUT OF OR related to This Agreement WHETHER BASED UPON BREACH OF CONTRACT, TORT (INCLUDING NEGLIGENCE), Strict LIABILITY OR otherwise AND EVEN IF NVIDIA HAS PREVIOUSLY BEEN ADVISED OF THE

POSSIBILITY OF SUCH DAMAGES and even if a Party's remedies fail their essential purpose.

12.2 Damages Cap. Additionally, to the maximum extent permitted by applicable law, NVIDIA'S AND ITS AFFILIATES TOTAL CUMULATIVE Aggregate LIABILITY for any and all liabilities, obligations or claims ARISING OUT OF THIS Agreement will not EXCEED US$10.00.

13. Your Privacy: Collection and Use of Information.

13.1 Privacy Policy. Please review the NVIDIA Privacy Policy, located at https://www.nvidia.com/en-us/about-nvidia/privacy-policy, which explains NVIDIA's policy for collecting and using data, as well as visit the NVIDIA Privacy Center, located at https://www.nvidia.com/en-us/privacy-center, to manage your consent and privacy preferences.

13.2 Collection Purposes. NVIDIA may collect certain personal information, such as your name and email address or those of your authorized users, and other information necessary to authenticate and enable you or your authorized users' access to the Software. Where appropriate you will disclose to, and obtain any necessary consent from, your authorized users to allow NVIDIA to collect such information.

13.3 Third Party Privacy Practices. The Software may contain links to third party websites and services. NVIDIA encourages you to review the privacy statements on those sites and services that you choose to visit to understand how they may collect, use and share your data. NVIDIA is not responsible for the privacy statements or practices of third-party sites or services.

14. Termination. This Agreement will terminate automatically without notice from NVIDIA if you fail to comply with any of the terms in this Agreement or if you commence or participate in any legal proceeding against NVIDIA with respect to the SOFTWARE. Additionally, NVIDIA may terminate this Agreement with prior written notice to you, if NVIDIA decides to no longer provide the SOFTWARE in a country or, in NVIDIA's sole discretion, the continued use of it is no longer commercially viable or creates liabilities for NVIDIA . Upon any termination of this Agreement, you must stop using and destroy all copies of the SOFTWARE. Upon written request, you will certify in writing that you have complied with your commitments under this section. Your prior distributions in accordance with this Agreement are not affected by the termination of this Agreement. All provisions of this Agreement will survive termination, except for the license granted to you.

15. Governing Law and Jurisdiction. This Agreement will be governed in all respects by the laws of the United States and of the State of Delaware, without regard to the conflicts of laws principles or the United Nations Convention on Contracts for the International Sale of Goods. The state or federal courts residing in Santa Clara County, California shall have exclusive jurisdiction over any dispute or claim arising out of this Agreement and the parties irrevocably consent to personal jurisdiction in those courts; except that, either party may apply for injunctive remedies or an equivalent type of urgent legal relief in any jurisdiction.

16. General.

16.1 No Assignment. This Agreement and your rights and obligations thereunder may not be assigned by you by any means or operation of law without NVIDIA's prior written consent and any attempt to do so is null and void. NVIDIA may assign, delegate, or transfer its rights and obligations under this Agreement by any means or operation of law.

16.2 Trade and Compliance. You agree to comply with all applicable export, import, trade and economic sanctions laws and regulations, including U.S. Export Administration Regulations and Office of Foreign Assets Control regulations. Any violation of such laws by you will void any warranty for the associated products and technologies. You confirm (a) your understanding that export or reexport of certain NVIDIA products or technologies may require a license or other approval from appropriate authorities and (b) that you will not export or reexport any products or technology, directly or indirectly, without first obtaining any required license or other approval from appropriate authorities, (i) to any countries that are subject to any U.S. or local export restrictions (currently including, but not necessarily limited to, Belarus, Cuba, Iran, North Korea, Russia, Syria, the Region of Crimea, Donetsk People's Republic Region and Luhansk People's Republic Region); (ii) to any end user who you know or have reason to know will utilize them in the design, development or production of nuclear, chemical or biological weapons, missiles, rocket systems, unmanned air vehicles capable of a maximum range of at least 300 kilometers, regardless of payload, or intended for military end-use, or any weapons of mass destruction; (iii) to any end-user who has been prohibited from participating in the U.S. or local export transactions by any governing authority; or (iv) to any known military or military-intelligence end-user or for any known military or military-intelligence end-use in accordance with U.S. trade compliance laws and regulations. Use of the Software under this Agreement must be consistent with NVIDIA's pdf (nvidia.com).

16.3. Government Rights. The SOFTWARE, documentation and technology ("Protected Items") are "Commercial products" as this term is defined at 48 C.F.R. 2.101, consisting of "commercial computer software" and "commercial computer software documentation" as such terms are used in, respectively, 48 C.F.R. 12.212 and 48 C.F.R. 227.7202 & 252.227-7014(a)(1). Before any Protected Items are supplied to the U.S. Government, you will (i) inform the U.S. Government in writing that the Protected Items are and must be treated as commercial computer software and commercial computer software documentation developed at private expense; (ii) inform the U.S. Government that the Protected Items are provided subject to the terms of the Agreement; and (iii) mark the Protected Items as commercial computer software and commercial computer software documentation developed at private expense. In no event will you permit the U.S. Government to acquire rights in Protected Items beyond those specified in 48 C.F.R. 52.227-19(b)(1)-(2) or 252.227-7013(c) except as expressly approved by NVIDIA in writing.

16.4. Notices. Please direct your legal notices or other correspondence to NVIDIA Corporation, 2788 San Tomas Expressway, Santa Clara, California 95051, United States of America, Attention: Legal Department with a copy emailed to legalnotices@nvidia.com. If NVIDIA needs to contact you about the Software, you

consent to receive the notices by email and agree that such notices will satisfy any legal communication requirements.

16.5 Force Majeure. Neither party will be liable during any period where an event or circumstance prevents or delays that party from performing its obligations under this Agreement and that event or circumstance: (i) is not within the reasonable control of that party and is not the result of that party's negligence, and (ii) cannot be overcome or avoided by that party using reasonably diligent efforts.

16.6 Severability and Amendment. If a court of competent jurisdiction rules that a provision of this Agreement is unenforceable, that provision will be deemed modified to the extent necessary to make it enforceable and the remainder of this Agreement will continue in full force and effect. Any amendment to this Agreement must be in writing and signed by authorized representatives of both parties.

16.7 Construction. The headings in the Agreement are included solely for convenience and are not intended to affect the meaning or interpretation of the Agreement. As required by the context of the Agreement, the singular of a term includes the plural and vice versa.

16.8. Entire Agreement. Regarding the subject matter of this Agreement, the parties agree that (i) this Agreement constitutes the entire and exclusive agreement between the parties and supersedes all prior or contemporaneous communications and (ii) and any additional or different terms or conditions contained in purchase orders, order acknowledgements, invoices or otherwise are null and void.

17. Licensing. If the distribution terms in this Agreement are not suitable for your organization, or for any questions regarding this Agreement, please contact NVIDIA at DOCA_License@nvidia.com .

3 Quick Start for BlueField Developers

This section contains the following pages:

- DOCA Developer Quick Start Guide

3.1 DOCA Developer Quick Start Guide

This guide details the basic steps to bring up the NVIDIA DOCA development environment and to build and run the DOCA reference applications provided along with the DOCA software framework package.

3.1.1 Introduction

NVIDIA DOCA brings together a wide range of powerful APIs, libraries, and frameworks for programming and accelerating modern data center infrastructures. Like NVIDIA® CUDA® for GPUs, DOCA is a consistent and essential resource across all existing and future generations of BlueField DPU and SuperNIC products.

This document is intended for those wishing to develop applications using the DOCA framework.

> ⚠ Not sure which installation type to use? To expand on different DOCA user types and the relevant installation for each, see BlueField and DOCA User Types.

3.1.2 Install BlueField Networking Platform

Install the BlueField networking platform into your host according to the installation instructions in the BlueField's hardware user guide. The steps include installing BlueField into the PCIe slot and properly securing it in the chassis. Make sure your host OS is listed under the "Supported Host OS and Features per DOCA-Host Installation Profile" section.

3.1.3 Install DOCA Software Package

A detailed step-by-step process for downloading and installing the required development software on both the host and BlueField can be found in the DOCA Installation Guide for Linux.

During installation, you must change the default password, `ubuntu`, to access the NVIDIA® BlueField® networking platform.

3.1.4 Access BlueField

After a successful installation, on the host, the RShim driver exposes a virtual Ethernet device called `tmfifo_net0`.

1. Configure the host side of the `tmfifo_net0` with a static IP to enable IPv4-based communication to the BlueField OS according to the instructions in section "Virtual Ethernet Interface" of the "Host-side Interface Configuration" page in the *NVIDIA BlueField DPU BSP* document.
2. Log into BlueField's Ubuntu-based OS by running the following command from the host:

   ```
   host# ssh ubuntu@192.168.100.2
   ```

   Use the BlueField networking platform password you defined during the installation process.

At this stage DOCA is installed on BlueField and the host server.

3.1.5 Run Reference DOCA Application

DOCA package assets (e.g., references, tools) are located on Bluefield and on the host under `/opt/mellanox/doca/`.

The DOCA package includes a set of reference applications to facilitate developer on-boarding. Please refer to the DOCA Reference Applications and DOCA Programming Guide for more information.

To run the DOCA Secure Channel reference application which demonstrates accelerated and secure message transmission between the host and BlueField over the Comm Channel interface:

1. Run the application as server on the BlueField networking platform using the following command (all parameters are available in the DOCA Secure Channel Application Guide):

```
# /opt/mellanox/doca/applications/secure_channel/bin/doca_secure_channel -s 256 -n 10 -p 03:00.0 -r 3b:00.0
```

2. Run the application as client on the host using the following command (all parameters are available in the DOCA Secure Channel Application Guide):

```
# /opt/mellanox/doca/applications/secure_channel/bin/doca_secure_channel -s 256 -n 10 -p 3b:00.0
```

3.1.6 More Information

To learn more about NVIDIA BlueField networking platforms, refer to the NVIDIA BlueField Hardware Manuals.

> For questions, comments, and feedback, please contact us at doca-feedback@nvidia.com.

4 Installation and Setup

This section contains the following page:

- DOCA Profiles
- BlueField Modes of Operation
- DOCA Installation Guide for Linux
- DOCA Developer Guide

4.1 DOCA Profiles

This document introduces and compares the different NVIDIA DOCA Host installation profiles, helping users select the most suitable configuration for their workloads and environments.

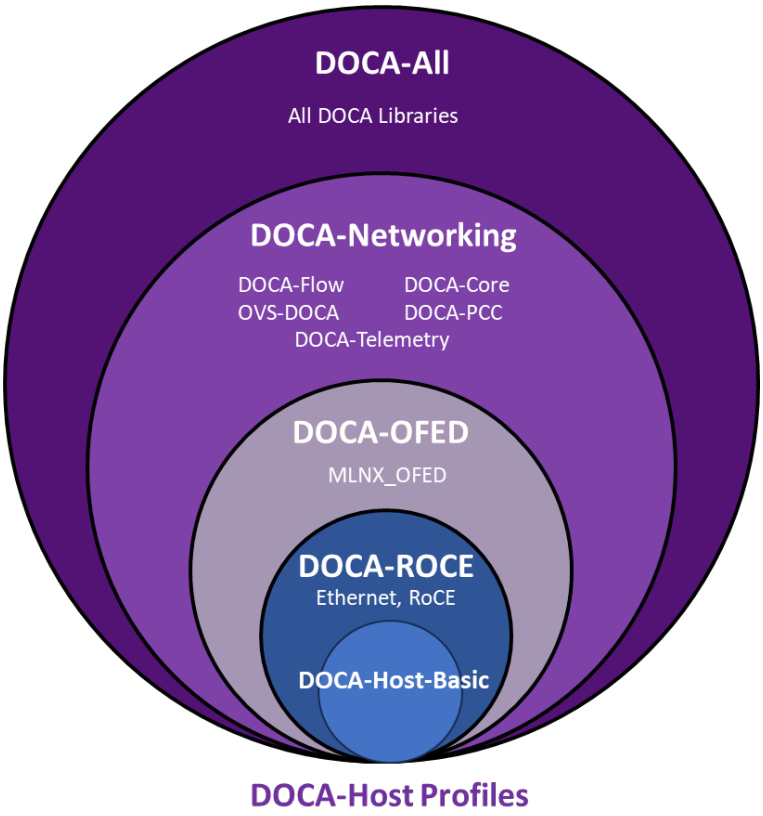
4.1.1 Introduction

NVIDIA DOCA can be installed on host machines to support a range of NVIDIA BlueField DPUs and ConnectX SmartNICs. To meet the needs of different deployment scenarios, DOCA offers installation profiles—validated packages that streamline setup based on the desired functionality.

The following are the available DOCA profiles:

- `doca-all`
- `doca-networking`
- `doca-ofed`
- `doca-roce`
- doca-host-basic

DOCA functionality is limited by the specific device capabilities.



4.1.2 Which Profile to Install?

The functionality of DOCA-Host is limited by the device capabilities (for example, ConnectX devices cannot utilize DOCA libraries such as DPA, even if `doca-all` is installed on the host).

For BlueField devices:

- NVIDIA recommends the `doca-all` profile
- If you require the smallest installation package for networking-only purposes, use `doca-networking`
- For MLNX_OFED-like installations, use `doca-ofed` (no additional DOCA functionality)
- For RoCE functionality only, install `doca-roce`
- doca-host-basic will provide the common basic networking functionality, similar to doca-roce but without MFT and FW-Updater

For ConnectX devices:

- NVIDIA recommends the `doca-networking` profile

- For deployments with both BlueField and ConnectX devices, use `doca-all`. This is also a good, scalable option for deployments that do not currently use either BlueField or ConnectX devices but eventually might.
- For MLNX_OFED-like installation use `doca-ofed` (no additional DOCA functionality)
- For RoCE functionality only, install `doca-roce`
- For common networking functionality without the added Tools, install doca-host-basic

4.1.3 Profile Details

4.1.3.1 doca-all

Purpose	Install the full DOCA suite, including all libraries, drivers, and tools
Includes	• All DOCA libraries and drivers • MLNX_OFED • DOCA Core • MLNX-DPDK • OVS-DOCA • DOCA Flow
Recommended for	• Full-featured BlueField deployments • Users needing access to all DOCA functionalities • Future-proof mixed BlueField/ConnectX environments

⚠ Some components may require additional manual installation after the default package is installed.

4.1.3.2 doca-networking

Purpose	Networking-specific installation without full DOCA library overhead
Includes	• MLNX_OFED • DOCA Core • DOCA-PCC • OVS-DOCA • DOCA Flow
Recommended for	• Users focused on accelerated networking • BlueField or ConnectX environments where only networking functionality is required

4.1.3.3 doca-ofed

Purpose	Driver-only installation equivalent to MLNX_OFED
Includes	• MLNX_OFED drivers and tools
Recommended for	• Minimalist setups with no DOCA user-space components • Compatibility-focused deployments

4.1.3.4 doca-roce

Purpose	Lightweight RDMA-over-Ethernet (RoCE) functionality
Includes	• rdma-core • ofed-scripts • mlnx-tools • mlnx-ofa_kernel • perftest
Recommended for	• RoCE-only applications • Low-footprint installations

4.1.3.5 doca-host-basic

Purpose	Lightweight Ethernet only functionality
Includes	• rdma-core • mlnx-tools • mlnx-ofa_kernel • perftest • mlnx-ethtool • mlnx-iproute2
Recommended for	• Low-footprint installations with basic Ethernet networking

4.1.4 Supported Devices

All profiles support the following NVIDIA hardware:

- BlueField-3
- BlueField-2
- ConnectX-8
- ConnectX-7
- ConnectX-6 DX / LX / standard
- ConnectX-5
- ConnectX-4 LX

⚠ DOCA functionality is limited by the specific device capabilities. For example, ConnectX devices cannot use certain DOCA libraries, such as DPA.

4.1.5 Profile Installation Notes

Each DOCA-Host profile is supported on a subset of operating systems. Refer to Supported Host OS per DOCA-Host Installation Profile for device-specific compatibility information. To install a profile, follow the installation steps in DOCA-Host Installation and Upgrade .

4.1.6 MLNX_OFED to DOCA-OFED Transition Guide

This guide covers what users must know about the DOCA-Host unified software stack for NVIDIA networking products.

4.1.6.1 Introduction

MLNX_OFED is a software stack that provides kernel drivers, user space libraries, and management tools for NVIDIA networking products, including ConnectX and BlueField adapters. MLNX_OFED has been the standard software stack for NVIDIA networking products for many years, providing high performance, scalability, and compatibility with various operating systems and applications.

With the introduction of NVIDIA BlueField Networking Platform and DOCA as the software framework to support it, there are 2 host-server software packages dedicated for different devices.

DOCA-Host is the unified software package for your host-server, supporting both BlueField and ConnectX. Customers may choose to use the Inbox drivers of the operating system vendor. The drivers with the latest features are included as part of NVIDIA software packages, and specifically DOCA-OFED.

4.1.6.2 What is DOCA-Host?

DOCA-Host can be installed on the host-server and used by customers with different workloads and requirements. The DOCA-Host package includes drivers, libraries, and tools to support the NVIDIA® BlueField® networking platform (DPU or SuperNIC) and NVIDIA® ConnectX® SmartNIC, Ethernet and InfiniBand, with both kernel and user-space components. Depending on their needs, customers may choose not to install the full DOCA-Host package on their host server but only the subset of components and tools relevant for their use case.

To support the different use cases, DOCA includes DOCA-Host Installation Profiles, which are a subset of the full DOCA installation.

> DOCA-Host profiles are validated and tested installation packages.

The following are the available DOCA profiles:

- doca-all – intended for users who wish to utilize the full extent of DOCA libraries and drivers
- doca-networking – intended for users who wish to benefit only from the networking functionality of DOCA
- doca-ofed – intended for users who wish to have the same user experience and content as MLNX_OFED. Doca-ofed installs the MLNX_OFED drivers and tools and does not include any other DOCA components.

4.1.6.3 What is DOCA-OFED?

DOCA-OFED is an equivalent package of MLNX_OFED, providing the same functionality as MLNX_OFED and including the same kernel drivers, user space libraries, and management tools for NVIDIA networking products. DOCA-OFED supports the same OSs and applications as MLNX_OFED.

4.1.6.4 Why Switch to DOCA-OFED and DOCA-Host?

DOCA-OFED is a 1-to-1 substitute for MLNX_OFED. All customers using MLNX_OFED on their host-server should install DOCA-OFED instead.

Following the last release of MLNX_OFED, no new features will be added to MLNX_OFED. All new features will only be included as part of DOCA-OFED.

4.1.6.5 Switching to DOCA-OFED and DOCA-Host

Switching to DOCA-Host with any of the installation profiles, and specifically DOCA-OFED, is a straightforward process. You just need to follow these steps:

1. Download the latest DOCA-Host package from the NVIDIA website or public repo.
2. Uninstall the existing MLNX_OFED package from your system.
3. Install the DOCA-OFED package on your host server using standard Linux package manager.
4. Reboot your system and verify that the DOCA-OFED components are working properly.

4.1.6.5.1 Installation Example of DOCA-OFED from Online Repo

```
# echo "[doca]
name=DOCA Online Repo
baseurl=https://linux.mellanox.com/public/repo/doca/2.7.0/rhel9.4/x86_64/
enabled=1
# gpgcheck=0" > /etc/yum.repos.d/doca.repo
# sudo dnf clean all
# sudo dnf -y install doca-ofed
```

4.1.6.5.2 Installation Example of DOCA-OFED Offline Repo

```
# wget https://www.mellanox.com/downloads/DOCA/DOCA_v2.7.0/host/doca-host-2.7.0-209000_24.04_rhel94.x86_64.rpm
# sudo rpm -i doca-host-2.7.0-209000_24.04_rhel94.x86_64.rpm
# sudo dnf clean all
# sudo dnf -y install doca-ofed
```

4.1.6.6 MLNX_EN Transition

With the transition from MLNX_OFED, the MLNX_EN lite weight software package will also no longer be supported. Customers who wish to get the smaller package of drivers available via MLNX_EN thus far, are advised to use Inbox drivers, providing the same components.

DOCA-Host will also support a new installation profile, DOCA-RoCE, which is a subset of DOCA_OFED and includes only Ethernet and RoCE drivers, without IB specific components. So, customers can also use this profile which includes more content than MLNX_EN.

4.1.6.7 Transition Timeline

The transition timeline from MLNX_OFED to DOCA-OFED gives users enough time to switch to the new software stack. The timeline for the transition is as follows:

- October 2024 – The last standalone release of MLNX_OFED. Following this release, MLNX_OFED will no longer receive support for new features or enhancements.

  > Customers are encouraged to switch to DOCA-OFED as soon as possible to stay up-to-date on new features and enhancements for NVIDIA networking products.

- October 2024-October 2027 – The last standalone MLNX_OFED release will receive critical bug fixes and security updates for MLNX_OFED users as part of its long-term support (LTS) plan
- October 2027 – MLNX_OFED will no longer receive support or updates by NVIDIA (MLNX_OFED end of life)

Users are strongly advised to switch to DOCA-OFED before this date, to avoid any compatibility or security issues.

This section is intended for customers who plan to use an Inbox-based solution and do not want to install DOCA-HOST.

For this use case, the Linux kernel must include the required patches to enable GPUDirect RDMA between NVIDIA Blackwell GPUs and ConnectX-8 (CX8) using Data Direct technology.

For reference, the NVIDIA-maintained kernel sources that include these patches (Linux-nvidia-64k-6.17) are available here:

- https://code.launchpad.net/~canonical-kernel/ubuntu/+source/linux-nvidia/+git/noble/+ref/nvidia-6.17-next

For the comprehensive list of patches, refer to:

- **https://docs.nvidia.com/grace/patches-config-guide/platform-software-patches-config.html**

Ensure the following prerequisite packages are installed on the target host

These packages will be consumed from the Linux distribution inbox repositories not from DOCA-OFED.

- Install the required inbox packages:
  - **Libibumad3**
  - **libibumad-dev**
  - librdmacm-dev

DEB-based	$ sudo apt install -y \ libibumad3 \ libibumad-dev \ librdmacm-dev
RPM-based	$ sudo yum install -y \ libibumad \ libibumad-devel \ librdmacm-devel

if any other rdma tools (e.g. ibstat via infiniband-diags package) are needed they need to be installed from upstream before installing doca-host package repo.

1. Install doca-host repository
2. Install MFT required packages:

- kernel-mft-dkms
- Mft

- mft-mlx5
- mft-nvredfish

DEB-based	$ sudo apt install -y \
	  kernel-mft-dkms \
	  mft \
	  mft-mlx5 \
	  mft-nvredfish

RPM-based	$ sudo yum install -y \
	  kernel-mft-dkms \
	  mft \
	  mft-mlx5 \
	  mft-nvredfish

- **doca-host repository installation**

Plug-in the doca-host bundle included in the release packages, from which users will install the necessary dependencies.

DEB-based	$ sudo dpkg -i <repo_file>
	
	$ sudo apt update

RPM-based	$ sudo rpm -Uvh <repo_file>
	
	$ sudo yum makecache

Example commands:

$ sudo dpkg -i doca-host_2.10.0-093442-25.01-ubuntu2204_amd64.deb

$ sudo apt update

4.1.6.8 Summary

DOCA-OFED is the new software stack for NVIDIA networking products, with the exact same user experience as MLNX_OFED. Users are encouraged to switch to DOCA-OFED as soon as possible to enjoy the full potential of NVIDIA Networking products. Users can download the latest DOCA-OFED package from the NVIDIA website or directly from DOCA public repo, and follow the simple installation steps.

The last standalone release of MLNX_OFED will be October 2024. Afterwards, MLNX_OFED enters the LTS period and will only receive critical bug fixes and security updates for 3 years.

In October 2027, MLNX_OFED will no longer be supported or updated by NVIDIA.

4.2 BlueField Modes of Operation

This page details the different operational modes for NVIDIA® BlueField® networking platforms (DPU, Zero-trust, and NIC modes) and provides instructions for configuring and switching between them.

4.2.1 Introduction

BlueField devices feature the following modes of operation:

Mode of Operation	External Host Trust Level	Description	Default on SKUs	Can be Configured to All Other Modes?
NIC Mode	Host-trusted	The Arm cores of BlueField are inactive, and the device functions as an NVIDIA® ConnectX® network adapter.	SuperNIC SKUs default mode	Yes [1]
DPU Mode	Host-trusted	The Arm cores of BlueField are active, and the embedded Arm system runs services that manage the NIC resources and data path.	DPU SKUs default mode	Yes
	Zero Trust (restricted)	The Arm cores of BlueField are active, and the embedded Arm system runs services to manage the NIC resources and data path while enforcing restrictions on the external host (host isolation).	-	Yes

1. BFx H20 converged accelerator is limited to NIC Mode only.

4.2.1.1 NIC Mode

In NIC Mode, BlueField operates as a ConnectX network adapter for the external host. For BlueField-3, the Arm cores are inactive, while for BlueField-2, the Arm cores are active but non-functional.

Operating in NIC Mode on BlueField-3 reduces power consumption, improves network performance, and minimizes the host memory footprint.

⚠ BlueField-3 SuperNIC SKUs are shipped in NIC Mode by default.

⚠ Multi-host is not supported when BlueField is operating in NIC Mode.

4.2.1.2 DPU Mode

In this operation mode, Arm cores active, known also as embedded CPU function ownership (ECPF) mode, is the default mode for the BlueField DPU family of SKUs.

In DPU Mode, the NIC resources and functionality are owned and controlled by the embedded Arm subsystem. All network communication to the host flows through a virtual switch control plane hosted on the Arm cores that manages all networking traffic coming and going from the host.

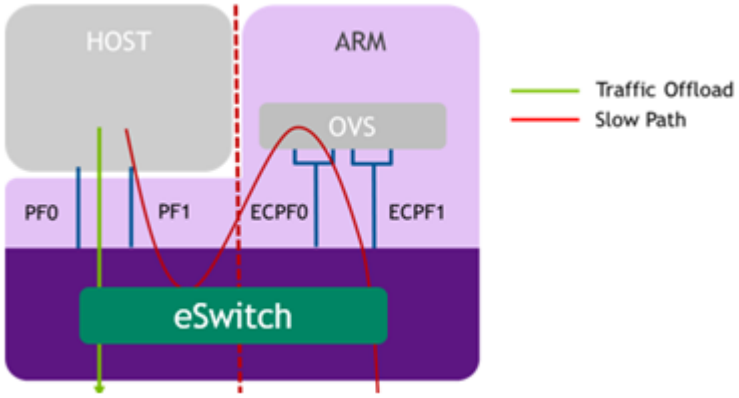
While working in this mode, the BlueField is the trusted function managed by the data center and host administrator for provisioning, management and orchestration (eg. load network drivers, reset an interface, bring an interface up and down, update the firmware, change the mode of operation on BlueField, etc).

⚠ BlueField-2 DPU and BlueField-3 DPU SKUs are shipped in DPU Mode by default.

⚠ Socket Direct is not supported when BlueField is operating in DPU Mode.

4.2.1.2.1 DPU Mode Architecture

In DPU Mode, the BlueField DPU provides the host system with access to network functions, while the host's capabilities are restricted and managed by the Arm processor within the BlueField.



4.2.1.2.1.1 Traffic Management and Paths

The Embedded Control and Processing Framework (ECPF) controls the NIC's embedded switch (eswitch). All network traffic between the host interface and the network initially passes through the BlueField's Arm processor via Representors. This path, where traffic is processed by the Arm processor, is referred to as the "slow path".

To improve performance, the Arm processor can define rules in the eswitch through the ECPF, allowing packets to bypass the Arm processor and be processed directly by the eswitch. This is known as the "fast path", which reduces latency and increases throughput by offloading traffic processing from the Arm to the eswitch.

A virtual switch running on the Arm processor may integrate both slow path and fast path functionalities by processing and classifying only the first packet of a new flow. For subsequent packets in the flow, the virtual switch defines eswitch rules, enabling fast path processing for the remainder of the traffic.

4.2.1.2.1.2 Initialization Process

At startup, network access to the host is initially blocked. This restriction remains until the virtual switch running on the Arm processor loads the default out-of-box rules to manage the ECPF on the BlueField. Once these rules are loaded, network traffic to the host is automatically enabled.

> ⚠ The driver on the host system can only be loaded after the driver on the BlueField has been loaded and has completed NIC configuration. Additionally, all Interface Configuration Memory (ICM) is allocated by the ECPF and resides in the BlueField's memory.

4.2.1.2.2 InfiniBand in DPU Mode

In DPU Mode, when operating with an InfiniBand network, OpenSM must be executed from the BlueField Arm side rather than the host side. Similarly, InfiniBand management tools such as `sminfo`, `ibdev2netdev`, and `ibnetdiscover` can only be used from the BlueField Arm side and are not accessible from the host side.

4.2.1.3 DPU Mode in Zero Trust

Zero Trust, also known as Restricted Mode, is a specialized variation of DPU Mode that enhances security by preventing the host system administrator from accessing BlueField from the host side. Once Zero Trust mode is enabled, the BlueField must be fully controlled by the data center administrator via the Arm cores or the BMC connection, rather than through the host.

This mode enforces security and isolation by restricting the host from performing operations that could compromise BlueField. The following operations can be restricted individually in Zero Trust mode:

- Port ownership – The host cannot assign itself as the port owner
- Hardware counters – The host is denied access to hardware counters
- Tracer functionality – The tracer functionality is blocked
- RShim interface – The RShim interface is disabled

- Firmware flash – firmware flashing from the host is restricted

Zero Trust mode ensures a robust security boundary between the host and BlueField, making it an ideal configuration for environments requiring strict control and isolation.

4.2.2 Moving Between Operation Modes

Transitioning between operation modes can be achieved through various configuration interfaces as presented in the following table.

> ⚠ Some configuration interfaces may be locked out when operating in Zero Trust (Restricted) Mode.

Interface	From	To	Configuration option available by default for this interface?	Configuration option can be locked-out [2] for this interface?
External Host command line	DPU Mode	NIC Mode	Yes	Yes
	NIC Mode	DPU Mode	Yes	Yes
	DPU Mode	DPU Mode with Zero Trust	No	Always blocked
	DPU Mode with Zero Trust	DPU Mode	No	Always blocked
	DPU Mode with Zero Trust	NIC Mode	Not supported	N/A
Host UEFI Menu	DPU Mode	NIC Mode	Yes	Yes
	NIC Mode	DPU Mode	Yes	Yes
	DPU Mode	DPU Mode with Zero Trust	No	Always blocked
	DPU Mode with Zero Trust	DPU Mode	No	Always blocked
	DPU Mode with Zero Trust	NIC Mode	Not supported	N/A
Arm OS command line	DPU Mode	NIC Mode	Yes	No
	NIC Mode	DPU Mode	N/A	N/A
	DPU Mode	DPU Mode with Zero Trust	Yes	No

Interface	From	To	Configuration option available by default for this interface?	Configuration option can be locked-out [2] for this interface?
	DPU Mode with Zero Trust	DPU Mode	Yes	No
	DPU Mode with Zero Trust	NIC Mode	Not supported	N/A
Arm UEFI Menu	DPU Mode	NIC Mode	Yes	No
	NIC Mode	DPU Mode	Yes	No
	DPU Mode	DPU Mode with Zero Trust	No [3]	No
	DPU Mode with Zero Trust	DPU Mode	No [3]	No
	DPU Mode with Zero Trust	NIC Mode	Not supported	N/A
DPU-BMC Redfish	DPU Mode	NIC Mode	Yes	No
	NIC Mode	DPU Mode	Yes	No
	DPU Mode	DPU Mode with Zero Trust	No [3]	No
	DPU Mode with Zero Trust	DPU Mode	No [3]	No
	DPU Mode with Zero Trust	NIC Mode	Not supported	N/A
Platform-BMC NC-SI OEM commands	DPU Mode	NIC Mode	Yes	No
	NIC Mode	DPU Mode	Yes	No
	DPU Mode	DPU Mode with Zero Trust	No [3]	No
	DPU Mode with Zero Trust	DPU Mode	No [3]	No
	DPU Mode with Zero Trust	NIC Mode	Not supported	N/A

2. Blocked or restricted
3. Roadmap

4.2.2.1 Identifying Which Mode BlueField is Currently Operating In

Interface	Command	Response
Using external host command line	`host> sudo mlxconfig -d /dev/mst/<device> q INTERNAL_CPU_OFFLOAD_ENGINE`	Output format: `RO INTERNAL_CPU_OFFLOAD_ENGINE ENABLED(0)` • `ENABLED(0)` means BlueField is running in DPU Mode • `DISABLED(1)` means BlueField is running in NIC Mode • `RO` is marked for read only, and indicates DPU Mode with Zero Trust
Using external host UEFI (HII) menu	Navigate to specific device and select `BlueField Internal Cpu Configuration`. 	`Internal Cpu Offload Engine` indicates the mode BlueField is currently operating in: • Disabled – BlueField is operating in NIC Mode • Enabled – BlueField is operating in DPU Mode Using Arm UEFI (GUI) menu	Access the Arm UEFI menu by pressing the Esc button twice on the console and navigate to `Device Manager` → `System Configuration` → `BlueField Modes`.	The `NIC Mode` menu indicates the mode BlueField is currently operating in: • `NicMode` – BlueField is operating in NIC Mode • `DpuMode` – BlueField is operating in DPU Mode 
<table>

4.2.2.2 Changing Mode

For the configuration to take effect, Arm and NIC components must undergo a reset. Power cycle is recommended.

4.2.2.2.1 Using External Host Command Line

From Mode	To Mode	Command

DPU Mode	NIC Mode	For BlueField-3:
		`host> sudo mlxconfig -d /dev/mst/<device> s INTERNAL_CPU_OFFLOAD_ENGINE=1`
		For BlueField-2:
		`host> sudo mlxconfig -d /dev/mst/<device> s INTERNAL_CPU_PAGE_SUPPLIER=1 INTERNAL_CPU_ESWITCH_MANAGER=1 INTERNAL_CPU_IB_VPORT0=1 INTERNAL_CPU_OFFLOAD_ENGINE=1`

NIC Mode	DPU Mode	For BlueField-3:
		`host> sudo mlxconfig -d /dev/mst/<device> s INTERNAL_CPU_OFFLOAD_ENGINE=0`
		For BlueField-2:
		`host> sudo mlxconfig -d /dev/mst/<device> s INTERNAL_CPU_PAGE_SUPPLIER=0 INTERNAL_CPU_ESWITCH_MANAGER=0 INTERNAL_CPU_IB_VPORT0=0 INTERNAL_CPU_OFFLOAD_ENGINE=0`

DPU Mode	DPU Mode with Zero Trust	N/A
DPU Mode with Zero Trust	DPU Mode	N/A
DPU Mode with Zero Trust	NIC Mode	Not supported. Move from DPU Mode with Zero Trust to DPU Mode first, and then from DPU Mode to NIC Mode. • Perform a system-level reset when moving from Zero Trust to DPU Mode before configuring NIC Mode. • Ensure to disable Zero Trust configuration before transitioning to NIC Mode. • Operating in NIC Mode with Zero Trust (Restricted) configuration is not supported and may lead to undefined behavior.

4.2.2.2.2 Using External Host UEFI Menu

From Mode	To Mode	Command
DPU Mode	NIC Mode	 Select `BlueField Internal Cpu Configuration`. To enable NIC Mode, set `Internal Cpu Offload Engine` to `Disabled`.

From Mode	To Mode	Command
NIC Mode	DPU Mode	 Select `BlueField Internal Cpu Configuration`. To enable DPU Mode, set `Internal Cpu Offload Engine` to `Enabled`.
DPU Mode	DPU Mode with Zero Trust	N/A
DPU Mode with Zero Trust	DPU Mode	N/A

From Mode	To Mode	Command
DPU Mode with Zero Trust	NIC Mode	Not supported. Move from DPU Mode with Zero Trust to DPU Mode first, and then from DPU Mode to NIC Mode. • Perform a system-level reset when moving from Zero Trust to DPU Mode before configuring NIC Mode. • Ensure to disable Zero Trust configuration before transitioning to NIC Mode. • Operating in NIC Mode with Zero Trust (Restricted) configuration is not supported and may lead to undefined behavior.

4.2.2.2.3 Using Arm OS Command Line

From Mode	To Mode	Command

DPU Mode	NIC Mode	For BlueField-3:
		`bf> sudo mlxconfig -d /dev/mst/<device> s INTERNAL_CPU_OFFLOAD_ENGINE=1`
		For BlueField-2:
		`bf> sudo mlxconfig -d /dev/mst/<device> s INTERNAL_CPU_PAGE_SUPPLIER=1 INTERNAL_CPU_ESWITCH_MANAGER=1 INTERNAL_CPU_IB_VPORT0=1 INTERNAL_CPU_OFFLOAD_ENGINE=1`

NIC Mode	DPU Mode	Not Applicable (Arm OS is not available)
DPU Mode	DPU Mode with Zero Trust	`bf> $ sudo mlxprivhost -d /dev/mst/<device> r --disable_rshim --disable_tracer --disable_counter_rd --disable_port_owner`
DPU Mode with Zero Trust	DPU Mode	`bf> $ sudo mlxprivhost -d /dev/mst/<device> p`
DPU Mode with Zero Trust	NIC Mode	Not supported. Move from DPU Mode with Zero Trust to DPU Mode first, and then from DPU Mode to NIC Mode. • Perform a system-level reset when moving from Zero Trust to DPU Mode before configuring NIC Mode. • Ensure to disable Zero Trust configuration before transitioning to NIC Mode. • Operating in NIC Mode with Zero Trust (Restricted) configuration is not supported and may lead to undefined behavior.

4.2.2.2.4 Using Arm UEFI Menu

From Mode	To Mode	Command
DPU Mode	NIC Mode	1. Access the Arm UEFI menu by pressing the Esc button twice on the console. 2. Select `Device Manager` → `System Configuration` → `BlueField Modes`. 3. Set the `NIC Mode` option to `NicMode` to enable NIC Mode. 4. Exit `BlueField Modes` and `System Configuration` and make sure to save the settings. 5. Exit the UEFI setup using the "reset" option. The configuration is not yet applied and BlueField is expected to boot in DPU Mode. 6. Issue power cycle to apply new configuration.
NIC Mode	DPU Mode	1. Access the Arm UEFI menu by pressing the Esc button twice on the console. 2. Select `Device Manager` → `System Configuration` → `BlueField Modes`. 3. Set the `NIC Mode` option to `DpuMode` to enable DPU Mode. 4. Exit `BlueField Modes` and `System Configuration` and make sure to save the settings. 5. Exit the UEFI setup using the "reset" option. The configuration is not yet applied and BlueField is expected to boot in NIC Mode. 6. Issue power cycle to apply new configuration.
DPU Mode	DPU Mode with Zero Trust	Roadmap
DPU Mode with Zero Trust	DPU Mode	Roadmap

From Mode	To Mode	Command
DPU Mode with Zero Trust	NIC Mode	Not supported. Move from DPU Mode with Zero Trust to DPU Mode first, and then from DPU Mode to NIC Mode. • Perform a system-level reset when moving from Zero Trust to DPU Mode before configuring NIC Mode. • Ensure to disable Zero Trust configuration before transitioning to NIC Mode. • Operating in NIC Mode with Zero Trust (Restricted) configuration is not supported and may lead to undefined behavior.

4.2.2.2.5 Using DPU-BMC Redfish

From Mode	To Mode	Command
DPU Mode	NIC Mode	`curl -k -u root:'password' -H 'content-type: application/json' -d '{"Mode": "NicMode"}' -X POST https://bmc_ip/redfish/v1/Systems/Bluefield/Oem/Nvidia/Actions/Mode.Set` To apply configuration, two consecutive Arm reboots are required.
NIC Mode	DPU Mode	`curl -k -u root:'password' -H 'content-type: application/json' -d '{"Mode": "DpuMode"}' -X POST https://bmc_ip/redfish/v1/Systems/Bluefield/Oem/Nvidia/Actions/Mode.Set` To apply configuration, two consecutive Arm reboots are required.
DPU Mode	DPU Mode with Zero Trust	Roadmap
DPU Mode with Zero Trust	DPU Mode	Roadmap
DPU Mode with Zero Trust	NIC Mode	Not supported. Separated Host Mode is obsolete for BlueField DPU/SuperNIC SKUs and should not be used, even if it remains visible in some configuration menus or options.

Separated Host Mode is available only for BlueField controller SKUs, where the BlueField Arm OS is the sole CPU/OS in the chassis.

4.3 DOCA Installation Guide for Linux

Follow the steps in this section to set up NVIDIA DOCA in your Linux environment.

4.3.1 Introduction

To deploy the BF-Bundle software on the BlueField networking platform (DPU or SuperNIC), you must:

1. Install or upgrade DOCA on the host side.
2. Install or upgrade BF-Bundle on the BlueField device.

4.3.2 Supported Networking Platforms

DOCA supports the following networking platforms:

- BlueField: refer to the BlueField hardware manuals for version-specific support information

- ConnectX: refer to the ConnectX hardware manuals for version-specific DOCA-Host support information

4.3.3 Hardware Prerequisites

For BlueField platform users, this guide assumes that a BlueField device has been installed in a server according to the instructions in your DPU's hardware user guide.

4.3.4 DOCA Packages

See information in the DOCA Release Notes.

4.3.5 Supported Host OS per DOCA-Host Installation Profile

Refer to Supported Host OS per DOCA-Host Installation Profile in the release notes to for OS-specific profile support information.

4.3.6 Setting Up Build Environment for Developers

For full instructions about setting up a development environment, refer to the DOCA Developer Guide.

4.3.7 Available BF-Bundle Installation and Upgrade Methods

Methods	Description	Purpose	Scope	Tool	Capability	Links
BFB image	BlueField bootstream (BFB) image for OS deployment on the BlueField DPUs	Production	All OSs	BFB installation (`install.sh`)	Installs OS, Kernel, and pre-built binaries	BF-Bundle Installation and Upgrade

Methods	Description	Purpose	Scope	Tool	Capability	Links
Standard Linux tools	Enables upgrading DOCA components using standard Linux tools (e.g., `apt update` and `yum update`). This process utilizes native package manager repositories to upgrade DPUs without the need for a full installation.	Day 2/ Production	All OSs	Based on Linux tools (apt/ yum)	Updates components that include changes only	
ISO	ISO image	Installation	Ubuntu 22.04	PXE	Installs OS, Kernel, and pre-built binaries	Deploying BlueField Software Using ISO with PXE
Bfb-build	Meant for BlueField users wishing to build their own BFB image for OS deployment on BlueField DPUs	To create custom BFB with special kernel and compile additional packages	All OSs	bfb-build	Installs OS, Kernel, and pre-built binaries	Bfb-build github
BF-FW bundle	A firmware-only BFB image which includes UEFI, NIC firmware, and BMC firmware	Upgrade only firmware components	Only firmware	BFB installation (`install.sh`)	Upgrade firmware components only	NVIDIA DOCA Downloads BF-FW Bundle

4.3.8 DOCA-Host Installation and Upgrade

The following options are available for installing or upgrading DOCA-Host:

Method	Option Name	Description
Installation	DOCA local repo package	This option installs DOCA components
Upgrade	DOCA online repo	This option upgrades DOCA components using online repo from the Internet

Find the relevant DOCA installation files for your host in the NVIDIA DOCA Downloads page.

This page provides basic instructions for setting up DOCA on a standard system. For device-specific setups, refer to the respective device documentation, as additional steps may be required.

4.3.8.1 Uninstalling Software from Host

> If DOCA-Host version 2.6.0 or greater is installed you can refer to "Upgrading Software on Host" section.

Full uninstallation is required before installing DOCA-Host:

Deb-based

```
host# for f in $( dpkg --list | grep -E 'doca|flexio|dpa-gdbserver|dpa-stats|dpa-resource-mgmt|
dpaeumgmt|dpdk-community' | awk '{print $2}' ); do echo $f ; sudo apt remove --purge $f -y ; done
host# sudo /usr/sbin/ofed_uninstall.sh --force
host# sudo apt-get autoremove
```

RPM-based

```
host# for f in $(rpm -qa | grep -i doca ) ; do sudo yum -y remove $f; done
host# sudo /usr/sbin/ofed_uninstall.sh --force
host# sudo yum autoremove
host# sudo yum makecache
```

Installation and upgrade requirements:

- Installed kernel headers that match the version of the currently running kernel.

  > If the `build` directory exists in under `/lib/modules/$(uname -r)/build`, then the kernel headers are installed.

- The same gcc version that the currently running kernel was built with.

4.3.8.2 Installing Software on Host

1. Install DOCA local repo package for host:
   - For deb-based distributions:
     i. Download the DOCA host repo from the NVIDIA DOCA Downloads page.
     ii. Install the deb repo:

     ```
     host# sudo dpkg -i <repo_file>.deb
     ```

     iii. Run the update command:

     ```
     host# apt-get update
     ```

iv. Install any of the profiles supported for your OS and architecture. Refer to "Supported Host OS per DOCA-Host Installation Profile" (e.g., `doca-all`) for more information.

```
host# sudo apt install -y doca-all
```

v. Update the firmware:

```
host# sudo apt install -y mlnx-fw-updater
```

- For RPM-based distributions:

> **Required**
>
> DKMS ≥ 3.2 must be installed on the system as a package.

i. Download the DOCA host repo from the NVIDIA DOCA Downloads page.

ii. Install the rpm repo:

```
host# sudo rpm -Uvh <repo_file>.rpm
```

iii. For non-SLES systems, run:

```
host# sudo yum makecache
```

iv. For SLES systems, run the following to verify the package signing:

```
host# zypper --gpg-auto-import-keys refresh
```

> Continue the procedure using `zypper` instead of `yum`.

v. Install any of the profiles supported for your OS and architecture (e.g., doca-all):

```
host# yum/zypper install -y doca-all
```

vi. Update the firmware:

```
host# yum/zypper install -y mlnx-fw-updater
```

> **Required**
>
> If you are running on a secure-boot-enabled OS, please refer to "Kernel Module Signing" before continuing.

2. Load the drivers:

```
host# sudo /etc/init.d/openibd restart
```

3. Initialize MST:

```
host# sudo mst restart
```

4.3.8.3 Upgrading Software on Host

To update existing DOCA host packages, follow these steps:

1. Install the newer version of the DOCA host repository as detailed in section "Installing Software on Host".
2. Upgrade the DOCA packages:
   - To upgrade from DOCA version 2.5.x, all DOCA and OFED related packages should be removed. For detailed instructions on how to uninstall these packages, please refer to the uninstall section "Uninstalling Software from Host".
   - To upgrade from DOCA 2.6.0 or later, use the following command:
     - For DEB-based distributions:

       ```
       host# apt install <doca-profile>
       ```

     - For RPM-based distributions:

       ```
       host# yum upgrade <doca-profile>
       ```

     - For SLES systems:

       ```
       host# zypper update <doca-profile>
       ```

   - Before upgrading `mlnx-fw-updater`, make sure to restart MST first:

     ```
     host# mst restart
     ```

4.3.8.4 Package and Kernel Module Signing

This section highlights the signing methods used to ensure the authenticity and integrity of the packages and kernel modules.

4.3.8.4.1 Package Signing

RPM packages are signed with a GPG key, enabling users to confirm that the packages come from a trusted NVIDIA source and have not been altered.

During installation, package managers automatically fetch and verify the signature while updating their metadata cache.

For more details, see Installing Software on Host.

4.3.8.4.2 Kernel Module Signing

With the integration of DKMS (Dynamic Kernel Module Support), DOCA-Host no longer includes pre-built, Nvidia-signed kernel drivers. Instead, the DOCA-Host installation process uses DKMS to automatically build and sign the kernel modules using a locally generated key pair.

To load these drivers on a secure-boot-enabled OS, the DKMS-generated public key must be enrolled in the system's key database. This enrollment is performed after the DOCA-Host installation is complete:

1. Import the public key to the Machine Owner Key (MOK) list using the `mokutil` utility:

   ```
   # mokutil --import /var/lib/dkms/mok.pub
   ```

2. You are prompted to create and confirm a password for this one-time enrollment request.
3. Reboot the system.
4. During the boot process, follow the on-screen prompts from the MOK utility to enroll the key. You will need the password created in step 2.

4.3.8.5 DOCA Extra Package and doca-kernel-support

`doca-kernel-support` is a script intended to rebuild kernel modules included with DOCA-host. It builds a single package (i.e., `rpm` or `deb`) that contains a repository of packages (i.e., `dnf` or `apt`).

Rebuilt kernel modules with `doca-kernel-support` are not signed by default. To sign them, follow the note in step 2 below.

DOCA-host provides binary builds of kernel modules for some specific kernels. This script rebuilds kernel modules included with DOCA-host for a custom kernel version and creates an RPM or DEB package that holds all of those rebuilt modules for easy install.

`doca-kernel-support` does not support customized or unofficial kernels.

`doca-kernel-support` is no longer required when using non-default kernels. DKMS rebuilds kernel modules automatically during the regular installation process.

To run `doca-kernel-support`:

1. Run:

```
host# apt/yum install -y doca-extra
```

2. Execute the `doca-kernel-support` script which rebuilds and installs the DOCA-host kernel modules with the running kernel:

```
host# /opt/mellanox/doca/tools/doca-kernel-support
```

To sign the kernel modules, run this command instead:

```
host# MODULE_SIGN_PUB_KEY=/path/to/pub_key.der MODULE_SIGN_PRIV_KEY=/path/to/priv_key.priv
WITH_MOD_SIGN=1 /opt/mellanox/doca/tools/doca-kernel-support
```

The output may end with `rpm` or `deb` with the following general format:

```
doca-kernel-support: Built single package: <doca-kernel-repo>
doca-kernel-support: Done
```

Output example:

```
doca-kernel-support: Built single package: /tmp/DOCA.EuUfkWfV7Z/doca-kernel-
repo-2.9.0-1.kver.5.14.0.356.el9.x86.64.x86_64.rpm
doca-kernel-support: Done
```

`doca-kernel-support` does not support customized or unofficial kernels.

3. Install the generated meta-package on the desired DOCA profile:

The examples provided install DOCA kernel repos (RPM/DEB) with `doca-ofed` profile, but other profiles may be installed if they are supported.

- For SLES:

```
host# rpm -Uvh <doca-kernel-repo>
host# zypper refresh
host# zypper install <doca-userspace-metapackage>
host# zypper modifyrepo --disable doca
host# zypper install doca-kernel-KERNEL_VERSION     # For all the meta-package, not just this
 single package
host# zypper modifyrepo --enable doca
```

Example:

```
host# rpm -Uvh <doca-kernel-repo>
host# zypper refresh
host# zypper install doca-ofed-userspace
host# zypper modifyrepo --disable doca
host# zypper install doca-kernel-5.14.21.150500.53.default     # For all the meta-package, not just
this single package
host# zypper modifyrepo --enable doca
```

- For RPM-based distributions:

```
host# rpm -Uvh <doca-kernel-repo>
host# dnf makecache
host# dnf install <doca-userspace-metapackage>
host# dnf install --disablerepo=doca doca-kernel-KERNEL_VERSION     # For all the meta-package, not
just this single package
```

Example:

```
host# rpm -Uvh /tmp/DOCA.EuUfkWfV7Z/doca-kernel-repo-2.9.0-1.kver.5.14.0.356.el9.x86.64.x86_64.rpm
host# dnf makecache
host# dnf install doca-ofed-userspace
host# dnf install --disablerepo=doca doca-kernel-5.14.0.356.el9.x86.64.x86_64.noarch
```

- For DEB-based distributions:

```
host# dpkg -i <doca-kernel-repo>
host# apt update
host# apt install <doca-profile>
```

Example:

```
host# dpkg -i /tmp/DOCA.J8JYxEmffD/doca-kernel-repo-2.9.0-6.4.0.mlnx_2.9.0_amd64.deb
host# apt update
host# apt install doca-ofed
```

4. (Optional) Retrieve installed packages and their versions as part of DOCA Host installation:

```
host# /opt/mellanox/doca/tools/doca-info

Versions:
- DOCA Base MLNX_OFED_LINUX-24.07-0.5.5.0
- MFT 4.29.0-127

UEFI\ATF versions:
- mst_device: mt41692_pciconf0
     UEFI Version: 4.7.0-42-g13081ae
     ATF Version: 4.7.0-25-g5569834

Firmware (Current):
- BlueField-3 32.41.1000

DOCA:
- doca-all 2.8.0-0.0.4
- doca-apsh-config 2.8.0079-1
- doca-bench 2.8.0079-1
…

DOCA Dependencies:
…
- flexio 24.07.2300
- mlnx-dpdk 22.11.0-2407.0.10

OFED:
…
- rdma-core 2407mlnx52-1.2407055
…
- ucx 1.17.0-1.2407055
…
```

⚠ If BlueField has a BF-Bundle version older than 2.7.0 installed on it, the UEFI/ATF versions would appear as N/A. If your version is 2.7.0 or higher and still see N/A, then perform driver restart on the host:

```
/etc/init.d/openibd restart
```

4.3.8.6 Storage Installation

1. Before installation, search for the required package using your system's package manager:

```
# apt/zypper/dnf/yum search mlnx-nvme
# apt/zypper/dnf/yum search mlnx-nfsrdma
```

2. Once the correct package name is identified, install it using:

```
# apt/zypper/dnf/yum install <full-package-name>
```

Installation examples:

- For SLES:

```
# zypper search mlnx-nvme
# zypper install mlnx-nvme-kmp-default
```

- For Debian-based systems:

```
# apt search mlnx-nvme
# apt search mlnx-nfsrdma
# apt install mlnx-nvme-dkms
# apt install mlnx-nfsrdma-dkms
```

4.3.8.6.1 VMA Installation

VMA is compatible with the latest DOCA-Host drivers, firmware, and libraries.

For users looking to install or upgrade VMA, DOCA provides `doca-libvma`, a meta-package that installs the driver stack, libvma, and all necessary dependencies.

To install `doca-libvma`, follow the instructions under section "Installing Software on Host" and substitute `doca-all` with `doca-libvma` in the following command:

```
# Original command
sudo <apt/yum/zypper> install -y doca-all
# Updated command
sudo <apt/yum/zypper> install -y doca-libvma
```

For the list of systems required to work with VMA, refer to the VMA documentation.

4.3.8.6.2 XLIO Installation

XLIO is compatible with the latest DOCA-Host drivers, firmware, and libraries.

For users looking to install or upgrade XLIO, DOCA `doca-libxlio`, a meta-package that installs the driver stack, libxlio, and all necessary dependencies.

To install `doca-libxlio`, follow the instructions under section "Installing Software on Host" while substituting `doca-all` with `doca-libxlio` in the following command:

```
# Original command
sudo <apt/yum/zypper> install -y doca-all
# Updated command
sudo <apt/yum/zypper> install -y doca-libxlio
```

For the list of systems required to work with XLIO, please see the XLIO documentation.

4.3.8.7 Installing Proprietary Packages

The installation procedure does not install proprietary packages. Those packages are installed upon request.

List of close-source proprietary packages:

- Clusterkit
- DPCP
- hcoll
- sharp
- ibutils2
- opensm

Currently, the only way to install these packages is by using an already-built RPM or DEB file from a similar primary OS.

The following table maps community OSs which are most similar to primary OSs:

Community OS	Most Similar Primary OS
Alma 8.5	RHEL 8.5
Anolis OS 8.4	RHEL 8.5
CentOS Stream 8	RHEL 8
CentOS Stream 9	RHEL 9
EulerOS-V2.0.SP10	EulerOS-V2.0.SP11
Fedora 35	RHEL 8.5
OpenEuler-20.03.SP1	OpenEuler20 SP3
OpenSUSE 15.3	SLES15 SP3
Photon OS 3.0	RHEL 7.9

Community OS	Most Similar Primary OS
UOS-V20-1040d	Debian 10.8

4.3.8.7.1 Download and Install MFT and Firmware

- Download MFT
- Download firmware

4.3.8.8 DOCA-Host Installation and DKMS Management Guide

4.3.8.8.1 Introduction

DOCA-Host is a host software stack that provides kernel drivers, user space libraries, and management tools for NVIDIA networking products, including ConnectX and BlueField adapters. It ensures high performance, scalability, and compatibility across various operating systems and applications.

The DOCA-Host stack utilizes DKMS (Dynamic Kernel Module Support) to build and install kernel modules directly from source on the host machine.

The changes in architecture include the following points:

- Source-based build – The DOCA repository no longer contains prebuilt kernel drivers; instead, modules are compiled during installation via DKMS.
- Repository structure – NVIDIA no longer publishes repositories for minor OS releases (e.g., RHEL 9.3). Users must now utilize repositories published per Major OS release (e.g., RHEL 9.x), allowing DKMS to handle kernel differences.
- Module signing – Because modules are built locally, they are not signed by NVIDIA.

4.3.8.8.2 Understanding DKMS

DKMS is a framework that enables the automatic rebuilding and reinstallation of Linux kernel modules whenever the host server's kernel version is updated.

DKMS offers the following benefits:

- DKMS creates a trigger that compiles drivers against new kernel headers immediately upon update installation.
- This eliminates the need for specific binaries for every minor OS kernel update or manual source recompilation after system updates.

4.3.8.8.3 Supported Platforms and Profiles

The following operating systems support the DOCA-Host DKMS implementation:

- RHEL (via `doca-all`)
- Ubuntu (via `doca-all`)
- Oracle (via `doca-all`)
- Debian (via `doca-all`)
- SLES (via `doca-ofed`)

This architecture applies to all DOCA-Host profiles that include kernel components:

- `doca-roce`
- `doca-ofed`
- `doca-networking`
- `doca-all`

⚠ User-space–only metapackages are not affected by these changes

4.3.8.8.4 Installation Procedure

Select the repository corresponding to the Major OS version. For example, installations on RHEL 9.4 or RHEL 9.6 must use the RHEL 9 repository.

The following steps outline the installation process using Rocky Linux 9.6 as an example target, utilizing the RHEL 9 repository:

1. If DOCA-Host or MLNX-OFED packages are currently installed, they must be removed prior to installation to prevent conflicts.

```
host# for f in $(rpm -qa | grep -i doca ) ; do sudo yum -y remove $f; done
host# sudo /usr/sbin/ofed_uninstall.sh --force
host# sudo yum autoremove
host# sudo yum makecache
```

2. You must install DKMS and the kernel headers matching your currently running kernel.
    a. Enable EPEL (if required for `dkms` availability):

```
sudo dnf install -y epel-release
```

    b. Install build tools and headers:

```
sudo dnf install -y dkms gcc make perl mokutil kernel-devel-$(uname -r) kernel-headers-$(uname -r)
```

3. Download and install the Major Version repository RPM (e.g., RHEL 9):

```
sudo rpm -Uvh <DOCA_HOST_REPO_RPM_FOR_RHEL9>
```

```
sudo dnf makecache
```

4. Install the desired stack (e.g., `doca-all`) and the firmware updater:

```
sudo dnf install -y doca-all mlnx-fw-updater
```

4.3.8.8.5 Secure Boot and Package Signing

Standard installation packages (RPM/DEB) are signed to verify they originate from NVIDIA.

Kernel modules built via DKMS are not NVIDIA-signed. For systems with Secure Boot enabled, DKMS utilizes a locally generated key pair to sign the built modules.

To ensure the modules load correctly on Secure Boot systems, the public key must be enrolled via the Machine Owner Key (MOK) utility:

1. Import the DKMS public key:

```
sudo mokutil --import /var/lib/dkms/mok.pub
```

2. Reboot the server:

```
sudo reboot
```

3. Complete the enrollment process via the MOK menu during the system boot sequence.

4.3.9 BF-Bundle Installation and Upgrade

> ⚠ You must update DOCA on the host side before installing the BF-bundle on the BlueField device.

Users have three options for installing or upgrading DOCA on BlueField DPU or SuperNIC:

Method	Option Name	Description
Installation	BF-bundle DOCA image	This option overwrites the entire boot partition with an Ubuntu 22.04 installation and updates BlueField and NIC firmware
Upgrade	Standard Linux Tools	This option upgrades DOCA components without overwriting the boot partition. Use this option to preserve configurations or files on BlueField itself
Installation	ISO DOCA image	This option overwrites the entire boot partition with an Ubuntu 22.04 installation

Find the DOCA installation files for BlueField on the NVIDIA DOCA Downloads page.

4.3.9.1 Installing DOCA-Host

Make sure to update DOCA on the host side before installing the BF-bundle on the BlueField.

4.3.9.2 Installing Software on BlueField Using BF-Bundle

The ATF will not boot 150W BlueField-3 platforms if the ATX +12V power supply is not connected. This requirement ensures the proper operation of the BlueField device. For detailed instructions on connecting the external power supply connector, refer to the NVIDIA BlueField-3 Networking Platform User Guide.

Users can install DOCA on BlueField DPU or SuperNIC by upgrading the full DOCA image on the BlueField device. This process overwrites the entire boot partition with an Ubuntu 22.04 installation and updates BlueField and NIC firmware. It also sets up the OVS bridge.

Upgrading DOCA components on BlueField networking platforms, such as DPUs or SuperNICs, using standard Linux tools will install the new `doca-eula` package at `/etc/NVIDIA/doca-license/DOCA-EULA.txt`. By installing this package, you accept the NVIDIA DOCA SDK end-user license agreement.

4.3.9.2.1 Option 1 – No Pre-defined Password

To change the default Ubuntu password during the BFB bundle installation, proceed to Option 2.

To install a BFB, use the following command:

```
host# sudo bfb-install --rshim rshim<N> --bfb <image_path.bfb>
```

Where:

- `<N>` – the appropriate RShim device identifier. If you have only one BlueField device, use `rshim0`.

- `<image_path.bfb>` – Replace this with the path to the BFB image file.

To list the RShim devices present on your system, run the following command:

```
host# ls -la /dev/ | grep rshim
```

> ⚠ By default, `bfb-install` will clear the RShim log in `/dev/rshim<N>/misc` and save it as `tmp/bfb-install-rshim[N].log` instead. To preserve the RShim log in `/dev/rshim<N>/misc`, provide the `--keep-log` argument to the `bfb-install` command line.

4.3.9.2.2 Option 2 – Set Pre-defined Password

Ubuntu users can set a unique password for the `ubuntu` user in the `bf.cfg` configuration file, which will be applied automatically at the end of the BlueField BFB bundle installation.

To do this, follow these steps:

1. Generate the hashed password:

   ```
   host# openssl passwd -1
   Password:
   Verifying - Password:
   $1$3B0RIrfX$TlHry93NFUJzg3Nya00rE1
   ```

2. Add the password hash to the `bf.cfg` configuration file:

   ```
   host# echo ubuntu_PASSWORD='$1$3B0RIrfX$TlHry93NFUJzg3Nya00rE1' > bf.cfg
   ```

3. Use the `--config` flag to specify the configuration file when running the installation command:

   ```
   host# sudo bfb-install --rshim rshim<N> --bfb <image_path.bfb> --config bf.cfg
   ```

   > ⚠ If `--config` is not used, then upon first login to the BlueField device, users will be prompted to update the default `ubuntu` password.

   > ⚠ Optionally, to upgrade the BlueField integrated BMC firmware using BFB bundle, please provide the current BMC root credentials in a `bf.cfg` file, as shown in the following:

   ```
   BMC_PASSWORD="<root password>"
   BMC_USER="root"
   ```

```
BMC_REBOOT="yes"
```

Unless previously changed, the default BMC root password is `0penBmc`.

The following is an example output of Ubuntu-22.04 BFB bundle installation:

```
host# sudo bfb-install --rshim rshim0 --bfb bf-bundle-2.7.0_24.04_ubuntu-22.04_prod.bfb --config bf.cfg
Pushing bfb 1.41GiB 0:02:02 [11.7MiB/s]
[           <=>                                 ]
Collecting BlueField booting status. Press Ctrl+C to stop
 INFO[PSC]: PSC BL1 START
 INFO[BL2]: start
 INFO[BL2]: boot mode (rshim)
 INFO[BL2]: VDDQ: 1120 mV
 INFO[BL2]: DDR POST passed
 INFO[BL2]: UEFI loaded
 INFO[BL31]: start
 INFO[BL31]: lifecycle GA Secured
 INFO[BL31]: VDD: 850 mV
 INFO[BL31]: runtime
 INFO[BL31]: MB ping success
 INFO[UEFI]: eMMC init
 INFO[UEFI]: eMMC probed
 INFO[UEFI]: UPVS valid
 INFO[UEFI]: PMI: updates started
 INFO[UEFI]: PMI: total updates: 1
 INFO[UEFI]: PMI: updates completed, status 0

 INFO[MISC]: Changing the default password for user ubuntu
 INFO[MISC]: Ubuntu installation completed
 INFO[MISC]: Updating NIC firmware...
 INFO[MISC]: NIC firmware update done
 INFO[MISC]: Installation finished
```

4. To verify that the BlueField device has completed booting, wait 90 seconds after the installation process finishes and run the following command:

```
host# sudo cat /dev/rshim<N>/misc
...
 INFO[MISC]: Linux up
 INFO[MISC]: DPU is ready
```

5. Retrieve installed packages and their versions as part of BF-Bundle installation:
    a. Log in to BlueField.
    b. Run the following command:

```
bf# sudo bf-info
```

Example output:

```
Firmware:
- ATF: v2.2(release):4.11.0-31-g3cc9f6506
- UEFI: 4.11.0-44-gb67dfb4a53
- BSP: 4.11.0.13582
- NIC Firmware: 32.45.0350
- BMC Firmware: 25.04-3
- CEC Firmware: 00.02.0195.0000

Drivers:
- mlnx-dpdk:  'MLNX_DPDK 22.11.2504.0.2'
- Kernel: 5.15.0-1064-bluefield

Tools:
- MFT: 4.32.0-94
- mstflint: 4.29.0-1

Storage:
- mlnx-libsnap 1.6.0-1
- spdk 23.01.5-24
- virtio-net-controller 24.10.15-1

DOCA:
- doca-apsh-config 2.9.0064-1
```

```
- libdoca-sdk-urom-dev 2.9.0064-1
...
FlexIO:
- flexio-samples 24.10.2447
- flexio-sdk 24.10.2447
...
SoC Platform:
- mlxbf-gige-modules 1.0-0.kver.6.1.0-11-arm64
- sdhci-of-dwcmshc-modules 1.0-0.kver.6.1.0-11-arm64
...
OFED:
rdma-core 2410mlnx54-1.2410051
ucx 1.18.0-1.2410051
...
```

6. Run the following command to configure the `tmfifo_net0` interface over IPv4 for SSH access to the BlueField Arm OS:

```
host# ifconfig tmfifo_net0 192.168.100.1/24
```

Establish an SSH connection to the BlueField Arm OS with 192.168.100.2 (preconfigured default) using the following command:

```
host# ssh ubuntu@192.168.100.2
```

4.3.9.3 Upgrading BlueField Using Standard Linux Tools

This procedure allows for upgrading DOCA components on BlueField networking platforms (DPUs or SuperNICs) using standard Linux tools (e.g., `apt update` and `yum update`). This method uses native package manager repositories to update components without requiring a full reinstallation.

Important!

Although this method allows you to update specific DOCA components, the combinations resulting from selective updates are not validated by NVIDIA. NVIDIA only validates the full installation of the BF-Bundle package.

Upgrading DOCA components on BlueField networking platforms using standard Linux tools will install the new `doca-eula` package located at `/etc/NVIDIA/doca-license/DOCA-EULA.txt`. By installing this package, you accept the NVIDIA DOCA SDK end-user license agreement.

This process has the following benefits:

- Only updates components that include modifications
- Includes upgrade of:
  - DOCA drivers and libraries
  - DOCA reference applications
  - BSP (UEFI/ATF) upgrade while maintaining the configuration

        - NIC firmware upgrade while maintaining the configuration
        - BMC components upgrade
    - Does not:
        - Impact user binaries
        - Upgrade non-Ubuntu OS kernels
    - After completion of BlueField upgrade:
        - If NIC firmware was not updated, perform BlueField Arm reset (software reset/reboot BlueField)
        - If NIC firmware was updated, perform firmware reset (`mlxfwreset`) or perform a graceful shutdown and power cycle

4.3.9.3.1 DEB-based

	Action	Instructions
1	Export the desired distribution	Export `DOCA_REPO` with the relevant URL: `<bf> $ export DOCA_REPO="<URL>"` • GA: https://linux.mellanox.com/public/repo/doca/latest/ubuntu22.04/dpu-arm64 • Latest-2.9-LTS: https://linux.mellanox.com/public/repo/doca/latest-2.9-LTS/ubuntu22.04/dpu-arm64 • Latest-2.5-LTS: https://linux.mellanox.com/public/repo/doca/latest-2.5-LTS/ubuntu22.04/dpu-arm64
2	Add GPG key to APT trusted keyring	`<bf> $ curl $DOCA_REPO/nvidia-doca-debian-gpg-public-key.asc | gpg --dearmor > /etc/apt/trusted.gpg.d/nvidia-doca-debian-gpg-public-key.gpg`
3	Add DOCA online repository	`<bf> $ echo "deb [signed-by=/etc/apt/trusted.gpg.d/nvidia-doca-debian-gpg-public-key.gpg] $DOCA_REPO ./" > /etc/apt/sources.list.d/doca.list`
4	Update index	`<bf> $ apt update`
5	Choose one of the two options for packages upgrade	**Option 1** Upgrade BlueField FW Bundle package (including ATF-UEFI, NIC firmware, and BMC firmware): `<bf> $ apt install bf-fwbundle`

	Action	Instructions

		Option 2
		• For non-Ubuntu, run:
		`<bf> $ apt install bf2-bmc-fw-signed bf3-bmc-fw-signed bf3-bmc-gi-signed bf3-bmc-nic-fw* bf2-cec-fw-signed bf3-cec-fw-signed`
		`<bf> $ apt upgrade`
		• For Ubuntu only, check the current kernel version:
		`uname -r`
		• If the kernel version matches the kernel version you are upgrading to, run:
		`<bf> $ apt install bf2-bmc-fw-signed bf3-bmc-fw-signed bf3-bmc-gi-signed bf3-bmc-nic-fw* bf2-cec-fw-signed bf3-cec-fw-signed`
		`<bf> $ apt upgrade`
		• If the kernel version does not match the kernel version you are upgrading to:
		i. Install new kernel:
		`<bf> $ apt install linux-image-<new> linux-modules-<new> linux-modules-extra-<new> linux-headers-<new>`
		ii. Reboot and verify new kernel installation with `uname -r`.
		iii. Remove old kernel:
		`<bf> $ apt purge linux-image-<old> linux-modules-<old> linux-modules-extra-<old> linux-headers-<old>`
		iv. Cleanup and refresh:
		`<bf> $ apt autoremove --purge && update-grub`
		v. Install the required DOCA/BMC/CEC packages:
		`<bf> apt install doca-runtime doca-devel`
		`<bf> apt install bf2-bmc-fw-signed bf3-bmc-fw-signed bf3-bmc-gi-signed bf3-bmc-nic-fw* bf2-cec-fw-signed bf3-cec-fw-signed`
		vi. Ensure `sshpass` is installed (required for the "Component activation" step below):
		`<bf> command -v sshpass >/dev/null 2>&1 || { apt-get update && apt-get install -y sshpass; }`
		vii. Perform system upgrade:
		`<bf> $ apt upgrade`

	Action	Instructions

6	Configure BMC parameters	Add the BMC user and password to config file `/etc/bf-upgrade.conf`. The format of `bf-upgrade.conf` should be identical to `bf.cfg`. Refer to "Customizing BlueField Software Deployment" for information.
		`<bf> $ cat > /etc/bf-upgrade.conf << EOF`
		`BMC_USER="<username>"`
		`BMC_PASSWORD="<password>"`
		`WITH_NIC_FW_UPDATE="yes"`
		`BMC_REBOOT="yes"`
		`EOF`
		⚠ `BMC_REBOOT="yes"` causes a warm boot to the BMC, losing connectivity.

7	Component activation	`<bf> $ dpu-bmc-upgrade` ℹ The upgrade process should take up to 20 minutes. ℹ The script performs fwreset if it is supported.
8	Apply the new changes, NIC firmware, and UEFI/ATF	For the upgrade to take effect, perform BlueField system reboot. ⚠ This step triggers immediate reboot of the BlueField Arm cores.

4.3.9.3.2 RPM-based

	Action	Instructions
1	Export the desired distribution	Export `DOCA_REPO` with the relevant URL: `<bf> $ export DOCA_REPO="<URL>"` • GA – https://linux.mellanox.com/public/repo/doca/latest/openeuler22.03sp3/dpu-arm64/ • Latest-2.9-LTS – https://linux.mellanox.com/public/repo/doca/latest-2.9-LTS/openeuler22.03sp3/dpu-arm64/ • Latest-2.5-LTS – https://linux.mellanox.com/public/repo/doca/latest-2.5-LTS/anolis8.6/dpu-arm64/

2	Add DOCA online repository	`echo "[doca]`
		`name=DOCA Online Repo`
		`baseurl=$DOCA_REPO`
		`enabled=1`
		`gpgcheck=0`
		`repo_gpgcheck=1`
		`gpgkey=$DOCA_REPO/nvidia-doca-rpm-gpg-public-key.asc`
		`priority=10`
		`cost=10" > /etc/yum.repos.d/doca.repo`
		A file is created under `/etc/yum.repos.d/doca.repo`.

	Action	Instructions
3	Update index	<bf> $ yum makecache
4	Package upgrade	**Option 1** Upgrade BlueField FW Bundle package (including ATF-UEFI, NIC firmware, and BMC firmware): <bf> $ dnf install bf-fwbundle

	Action	Instructions
		Option 2 1. Remove the deprecated `hcoll` package: ``` <bf> $ rpm -e --nodeps hcoll ``` 2. Manage the kernel version locks to ensure the system applies the kernel required by DOCA: • For non-Anolis OS, install `versionlock` and clear existing kernel locks: ``` <bf> $ dnf install -y 'dnf-command(versionlock)' <bf> $ dnf versionlock delete kernel* ``` • For Anolis OS, install `versionlock` and add specific kernel locks: ``` <bf> dnf install -y 'dnf-command(versionlock)' <bf> dnf versionlock add \ > kernel-5.10.134-13.1.an8.aarch64 \ > kernel-core-5.10.134-13.1.an8.aarch64 \ > kernel-rpm-macros-129-1.0.2.an8.noarch \ > kernel-headers-5.10.134-13.1.an8.aarch64 \ > kernel-modules-5.10.134-13.1.an8.aarch64 \ > kernel-modules-extra-5.10.134-13.1.an8.aarch64 \ > kernel-devel-5.10.134-13.1.an8.aarch64 \ > anolis-release-8.6-4.an8.aarch64 \ > anolis-repos-8.6-4.an8.aarch64 \ > anolis-gpg-keys-8.6-4.an8.noarch ``` 3. Install BMC/CEC firmware packages: ``` <bf> dnf install -y bf2-bmc-fw-signed bf3-bmc-fw-signed bf3-bmc-gi-signed bf3-bmc-nic-fw* bf2-cec-fw-signed bf3-cec-fw-signed ``` 4. Ensure `sshpass` is installed (required for "Components activation" phase) ``` <bf> command -v sshpass >/dev/null 2>&1 || { dnf install -y sshpass || yum install -y sshpass; } ``` 5. Upgrade the system packages: • For non-Anolis OS: ``` <bf> $ dnf upgrade --nobest ``` • For Anolis OS, remove deprecated gRPC package and exclude specific trace and daemon packages during upgrade: ``` <bf> $ dnf -y remove doca-grpc <bf> $ dnf --exclude='libtraceevent*,rasdaemon*' upgrade ``` 6. For non-Anolis OS lock the kernel packages to the current version: ``` <bf> $ dnf versionlock kernel* ``` 7. Update boot configuration: • For non-Anolis OS, update the GRUB configuration to ensure the correct default boot entry. Replace `<OS_NAME>` with your OS directory name (e.g., `rocky`, `openEuler`). ``` sed -i 's/^GRUB_DEFAULT=.*/GRUB_DEFAULT=0/' /etc/default/grub grub2-mkconfig -o /boot/efi/EFI/<OS_NAME>/grub.cfg ```

	Action	Instructions

		• For Anolis OS, the GRUB2 package update may trigger a post-installation script that duplicates boot entries, causing boot failures. Verify if an `.rpmsave` backup exists and rename it to restore the correct configuration:
		`# Check if the rpmsave file exists`
		`ls /boot/efi/EFI/anolis/grub.cfg.rpmsave`
		`# If the file exists, rename it to replace the current config`
		`mv /boot/efi/EFI/anolis/grub.cfg.rpmsave /boot/efi/EFI/anolis/grub.cfg`

5	Configure BMC parameters	Add the BMC user and password to config file `/etc/bf-upgrade.conf`. The format of `bf-upgrade.conf` should be identical to `bf.cfg`. Refer to "Customizing BlueField Software Deployment" for information.
		`<bf> $ cat > /etc/bf-upgrade.conf << EOF`
		`BMC_USER="<username>"`
		`BMC_PASSWORD="<password>"`
		`WITH_NIC_FW_UPDATE="yes"`
		`BMC_REBOOT="yes"`
		`EOF`
		⚠ `BMC_REBOOT="yes"` causes a warm boot to the BMC, losing connectivity.

6	Components activation	`<bf> $ dpu-bmc-upgrade` ℹ The upgrade process should take up to 20 minutes. ℹ The script performs fwreset if it is supported.
7	Apply the new changes, NIC firmware, and UEFI/ATF	For the upgrade to take effect, perform BlueField system reboot. ⚠ This step triggers immediate reboot of the BlueField Arm cores.

4.3.9.4 Installing Multiple BlueField Devices with DOCA Installer Tool

The DOCA Installer is a utility for installing or upgrading one or more BlueField DPUs in parallel. It supports both `bf-bundle` and `bf-fw-bundle` image types and is compatible with multiple BlueField operation modes, including NIC mode, DPU mode, or both on the same host. Customization is supported through INI or YAML configuration files.

4.3.9.4.1 Prerequisites

Make sure to update DOCA on the host side before installing `doca-installer`.

DEB-based	1. Download and install the DOCA host repo from the NVIDIA DOCA Downloads page. 2. Install doca-installer using the following command: `host# apt-get install doca-installer`
RPM-based	1. Download the DOCA host repo from the NVIDIA DOCA Downloads page. 2. Install doca-installer using the following command: `host# sudo yum install doca-installer`

4.3.9.4.2 DOCA Installer Operation Modes

The installer supports the following execution modes:

- Global run (applies to all devices):

```
host# doca-installer -b <image_path.bfb> -c <path-to-config>
```

- Per PSID group (targets devices sharing the same PSID):

```
host# doca-installer -b <image_path.bfb> --psid <PSID> -c <path-to-config>
```

> To exclude devices when using global or per-PSID runs, use `--exclude rshim<X>`.

- Per RShim device (targets a specific RShim interface):

```
host# doca-installer -b <image_path.bfb> --rshim rshim<N> -c <path-to-config>
```

Where:

- `-c` or `--config-file` – defines a configuration via INI or YAML files

> To upgrade BMC, CEC, or Golden Image firmware, include `BMC_USER` and `BMC_PASSWORD` in the `bf.cfg` or `bf.yaml` file.

- `<path-to-config>` – Path to the INI or YAML configuration file
- `<image_path.bfb>` – Path to the BFB image file
- `<PSID>` – Shared PSID value for the target group

> Devices that do not match the provided PSID will not be upgraded.

- `<N>` – RShim device index (e.g., `0` for a single-device setup)

The `doca-installer` script attempts to load the new NIC firmware automatically, but if that fails, it will print out the following message:

```
INFO: At least one device requires a host power cycle for new NIC Firmware to be loaded.
```

If the script discovers that one or more of the devices did not have `BMC_REBOOT` set to `'yes'` as part of the configuration file, it will print out the following message:

```
WARNING: BMC_REBOOT is not configured for all devices or is not set to 'yes'.
BMC firmware updates will only take effect after a BMC reboot.
```

4.3.9.4.3 Configuration File Options

4.3.9.4.3.1 YAML Configuration File

The YAML format supports global and per-device customization using structured keys:

- `global_configs` – Shared parameters for all devices (e.g., credentials)
- `rshim` – Device-specific configurations
  - Each key under `rshim` (e.g., `rshim1`, `rshim2`) defines variables and methods for that device
- `variables` – Parameters that control the installation process (e.g., `WITH_NIC_FW_UPDATE`, `BMC_REBOOT`)
- `methods` – Custom shell commands run during installation. You can use YAML anchors (`&`, `*`) to reuse methods across devices.

When a value is defined both globally and per-device, the per-device value takes precedence.

Per-Device Configuration Only Example

```
rshim:
  rshim1:
    variables:
      BMC_USER: 'root'
      BMC_PASSWORD: '<root password>'
    methods:
      bfb_modify_os:
        command: |
          sed -i -e "s@192.168.100.2@192.168.101.2@" /mnt/var/lib/cloud/seed/nocloud-net/network-config
          sed -i -e "s@192.168.100.1@192.168.101.1@" /mnt/var/lib/cloud/seed/nocloud-net/network-config
```

Global Configuration Only Example

```
global_configs:
  variables:
    BMC_USER: 'root'
    BMC_PASSWORD: '<root password>'
```

Global and Per-Device Configuration Example

```
global_configs:
  variables:
    BMC_USER: 'root'
    BMC_PASSWORD: '<root password>'

rshim:
  rshim1:
    variables:
      WITH_NIC_FW_UPDATE: 'no'
  rshim2:
    variables:
      BMC_PASSWORD: '<rshim2 password>'
```

Reusing Methods with Anchors Example

```
global_configs:
  variables:
    BMC_USER: 'root'
    BMC_PASSWORD: '<root password>'

rshim:
  rshim1:
    variables:
      BMC_REBOOT: 'yes'
    methods:
      bfb_post_install: &default_post_install
        command: |
          echo "Running post-install on rshim1"

  rshim2:
    methods:
      bfb_post_install: *default_post_install
```

4.3.9.4.3.2 INI Configuration File

Per-Device Configuration ini Copy Edit Example

```
RSHIM0_BMC_USER="root"
RSHIM0_BMC_PASSWORD="<password>"

RSHIM1_BMC_USER="root"
RSHIM1_BMC_PASSWORD="<password>"
```

Shared and Per-Device Parameters Example

```
# Shared across all devices
BMC_USER="root"
BMC_PASSWORD="<password>"
NEW_BMC_PASSWORD="<new password>"

# Device-specific (optional)
RSHIM0_NET_RSHIM_MAC=00:1a:ca:ff:ff:01
RSHIM1_NET_RSHIM_MAC=00:1a:ca:ff:ff:03
```

4.3.9.4.4 Logs and Debuggability

The DOCA Installer tool provides extended logging and improved debuggability compared to the legacy `bfb-install` tool.

For each execution of the `doca-installer`, a unique log directory is created under:

```
/var/log/doca_installer_logs/doca_installer_<timestamp>
```

Each device will have its own directory with logs related only to that device. These directories contain detailed diagnostic files, such as:

- `rshim` diagnostics
- `lspci`
- `bfb-install` output
- `rshim misc` installation record output
- `mlxconfig` output
- `mlxprivhost` output
- `mstdump` output (if applicable)
- `flint`
- Register reads

The main directory itself holds key summary logs, including:

- Full execution log of the `doca-installer` tool
- System services
- `bfb-install` output
- Run result file saved in YAML

DOCA Installer Standalone Flags4.3.9.4.5

The `doca-installer` tool introduces enhanced capabilities for comparing target image firmware versions with those currently running on devices. This allows for safer, more controlled upgrade decisions.

4.3.9.4.5.1 Fetch Firmware Versions from Image

Use the `--show-target-fw` flag to display firmware versions embedded in the provided BFB image:

```
host# doca-installer -b <image_path.bfb> --show-target-fw
```

Example output:

```
|======================|
| Tool version | 1.3.3 |
|======================|

Extracting firmware versions from /root/bf-bundle-3.2.0-87_25.10_ubuntu-24.04_prod.bfb
```

```
Target Firmware Versions of the provided image:
============================================================
| Component    | BlueField-2         | BlueField-3          |

============================================================
```

4.3.9.4.5.2 Fetch Firmware Versions from Running Devices

Use the `--show-running-fw` flag to display firmware versions currently installed on each detected BlueField device:

```
host# doca-installer --show-running-fw
```

Example output:

```
Current firmware versions:

4 BF DPUs:
=================================================================================================================================
=================================================================================================================
| PSID          | Part Num            | Serial Num    | PCI Addr     | RSHIM Dev | Mode | Privileged | Pre Upgrade

=================================================================================================================================
=============================================================================================================
```

4.3.9.4.5.3 Compare Image vs. Running Firmware Versions

Use the `--compare` option to compare current firmware versions on each device with those contained in the image:

```
host# doca-installer -b <image_path.bfb> --compare
```

Example output:

```
Firmware Version Comparison:
=============================================================================================================
Device: 0000:17:00.0 (PSID: MT_0000000884, Type: BF3)
=============================================================================
| Component    | Current Version (Running) | Image Version (Offline)      |
|==============|===========================|==============================|

================================================================================
```

4.3.9.4.5.4 Fetch DPU Information

Use the `--show-doca-info` option to fetch `bf-info` content from the running DPUs. This feature is supported for devices running in DPU mode only.

> ⚠ This feature requires DOCA 3.2.0 or newer.

```
host# doca-installer --show-doca-info
```

Example output:

```
Device 1: 0000:ca:00.0
-----------------------------------------------
PSID: MT_0000000884
Device Type: BF3
MST Address: /dev/mst/mt41692_pciconf2

4.3.9.4.6 BlueField-2 Limitation

BlueField-2 is supported with the following features only:

- Parallel installation (single, global, per-PSID, exclude)
- Show target firmware
- Debuggability (extensive logs collection)

Due to firmware limitation, `doca-installer` will not be able to present the versions of ATF, UEFI, BMC and CEC:

```
3 BF DPUs:
================================================================================================================================================
================================================================================
| PSID          | Part Num         | Serial Num    | PCI Addr      | RSHIM Dev | Mode | Privileged | Pre Upgrade ATF |

================================================================================================================================================
================================================================================
```

4.3.9.5 Building Custom BFB Installation Image

To build a customized BlueField OS image, use the BFB build environment. For more details, refer to the bfb-build project in in GitHub.

To boot a customized BlueField OS image on a UEFI secure-boot-enabled BlueField (the default secure boot setting), the following conditions must be met:

- The OS image must be signed with a key already present in the UEFI DB (e.g., the Microsoft key)
- If the above is not possible, UEFI secure boot must be disabled to allow booting of an unsigned or differently signed image

For detailed instructions on managing UEFI secure boot, refer to the "Secure Boot" page in the BlueField Platform SW Documentation.

4.3.10 Additional SDKs for DOCA

4.3.10.1 Installing CUDA on NVIDIA Converged Accelerator

NVIDIA® CUDA® is a parallel computing platform and programming model designed by NVIDIA for general-purpose GPU computing. The following steps detail how to set up CUDA on your environment.

> These instructions assume that a BFB image has already been installed on your system.

To install CUDA on your converged accelerator:

1. Download and install the latest NVIDIA Data Center GPU driver.
2. Download and install CUDA.

> The CUDA version tested to work with DOCA SDK is 11.8.0.

> Downloading CUDA includes the latest NVIDIA Data Center GPU driver and CUDA toolkit. For more information about CUDA and driver compatibility, refer to the NVIDIA CUDA Toolkit Release Notes.

4.3.10.1.1 Configuring Operation Mode

There are two modes that the NVIDIA Converged Accelerator may operate in:

- Standard mode (default) – the BlueField and the GPU operate separately
- BlueField-X mode – the GPU is exposed to BlueField and is no longer visible on the host

To verify which mode the system is operating in, run:

```
host# sudo mst start
host# sudo mlxconfig -d <device-id> q PCI_DOWNSTREAM_PORT_OWNER[4]
```

- Standard mode output:

```
Device #1:
[…]
Configurations:                                 Next Boot
         PCI_DOWNSTREAM_PORT_OWNER[4]           DEVICE_DEFAULT(0)
```

To configure standard mode, run:

```
host# mlxconfig -d <device-id> s PCI_DOWNSTREAM_PORT_OWNER[4]=0x0
```

- BlueField-X mode output:

```
Device #1:
[…]
Configurations:                                 Next Boot
         PCI_DOWNSTREAM_PORT_OWNER[4]           EMBEDDED_CPU(15)
```

To configure BlueField-X mode, run:

```
host# mlxconfig -d <device-id> s PCI_DOWNSTREAM_PORT_OWNER[4]=0xF
```

Power cycle is required for configuration to take effect. For power cycle the host run:

```
host# ipmitool power cycle
```

4.3.10.1.2 Downloading and Installing CUDA Toolkit and Driver

This section details the necessary steps to set up CUDA on your environment. It assumes that a BFB image has already been installed on your environment.

1. Install CUDA by visiting the CUDA Toolkit Downloads webpage.

   Select the Linux distribution and version relevant for your environment.

   This section shows the native compilation option either on x86 or aarch64 hosts.

2. Test that the driver installation completed successfully. Run:

```
dpu# nvidia-smi

Tue Apr  5 13:37:59 2022
+-----------------------------------------------------------------------------+

+-----------------------------------------------------------------------------+
```

3. Verify that the installation completed successfully.
    a. Download CUDA samples repo. Run:

```
dpu# git clone https://github.com/NVIDIA/cuda-samples.git
```

    b. Build and run vectorAdd CUDA sample. Run:

```
dpu# cd cuda-samples/Samples/0_Introduction/vectorAdd
dpu# make
dpu# ./vectorAdd
```

    If the `vectorAdd` sample works as expected, it should output "`Test Passed`".

    If it seems that the GPU is slow or stuck, stop execution and run:

```
dpu# sudo setpci -v -d ::0302 800.L=201 # CPL_VC0 = 32
```

4.3.10.1.3 GPUDirect RDMA

For information on GPUDirect RMDA and more, refer to DOCA GPUNetIO documentation.

4.3.10.2 Installing Rivermax on BlueField

NVIDIA Rivermax offers a unique IP-based solution for any media and data streaming use case.

This section provides the steps to install Rivermax assuming that a BFB image has already been installed on your environment.

4.3.10.2.1 Downloading Rivermax Driver

1. Navigate to the NVIDIA Rivermax SDK product page.
2. Register to be able to download the driver package using the JOIN button at the top of the page.
3. Download the appropriate driver package according to your BFB under the "Linux" subsection. For example, for Ubuntu 22.04 BFB, download `rivermax_ubuntu2204_<version>.tar.gz`.

4.3.10.2.2 Installing Rivermax Driver

1. Copy the `.tgz` file to BlueField:

```
host# sudo scp -r rivermax_ubuntu2204_<version>.tar.gz ubuntu@192.168.100.2:/tmp/
```

2. Extract the Rivermax file:

```
dpu# sudo tar xzf rivermax_ubuntu2204_<version>.tar.gz
```

3. Install the Rivermax driver package:

```
dpu# cd <rivermax-version>/Ubuntu.22.04/deb-dist/aarch64/
dpu# sudo dpkg -i rivermax_<version>.deb
```

4.3.10.2.3 Installing Rivermax Libraries from DOCA

Rivermax libraries are compatibles with DOCA components and can be found inside the `doca-dpu-repo`.

1. Unpack the doca-dpu-repo:

```
dpu# sudo dpkg -i doca-dpu-repo-ubuntu2204-local_<version>_arm64.deb
```

2. Run apt update:

```
dpu# sudo apt-get update
```

3. Install the Rivermax libraries:

```
dpu# sudo apt install doca-sdk-rmax
dpu# sudo apt install libdoca-sdk-rmax-dev
```

For additional details and guidelines, please visit the NVIDIA Rivermax SDK product page.

4.4 DOCA Developer Guide

This guide details the recommended steps to set up an NVIDIA DOCA development environment.

4.4.1 Introduction

This guide is intended for software developers aiming to modify existing NVIDIA DOCA applications or develop their own DOCA-based software.

Instructions for installing DOCA on the NVIDIA® BlueField® Networking Platform (i.e., DPU or SuperNIC) can be found in the DOCA Installation Guide for Linux.

This guide focuses on the recommended flow for developing DOCA-based software, and will address the following scenarios:

- BlueField is accessible and can be used during the development and testing process
- BlueField is inaccessible, and the development happens on the host or on a different server

It is recommended to follow the instructions for the first scenario, leveraging BlueField during the development and testing process.

This guide recommends using DOCA's development container during the development process on BlueField Platforms or on the host. Deploying development containers allows multiple developers to work simultaneously on the same device (host or BlueField Platform) in an isolated manner and even across multiple different DOCA SDK versions. This can allow multiple developers to work on the BlueField Platform itself, for example, without needing to have a dedicated BlueField per developer.

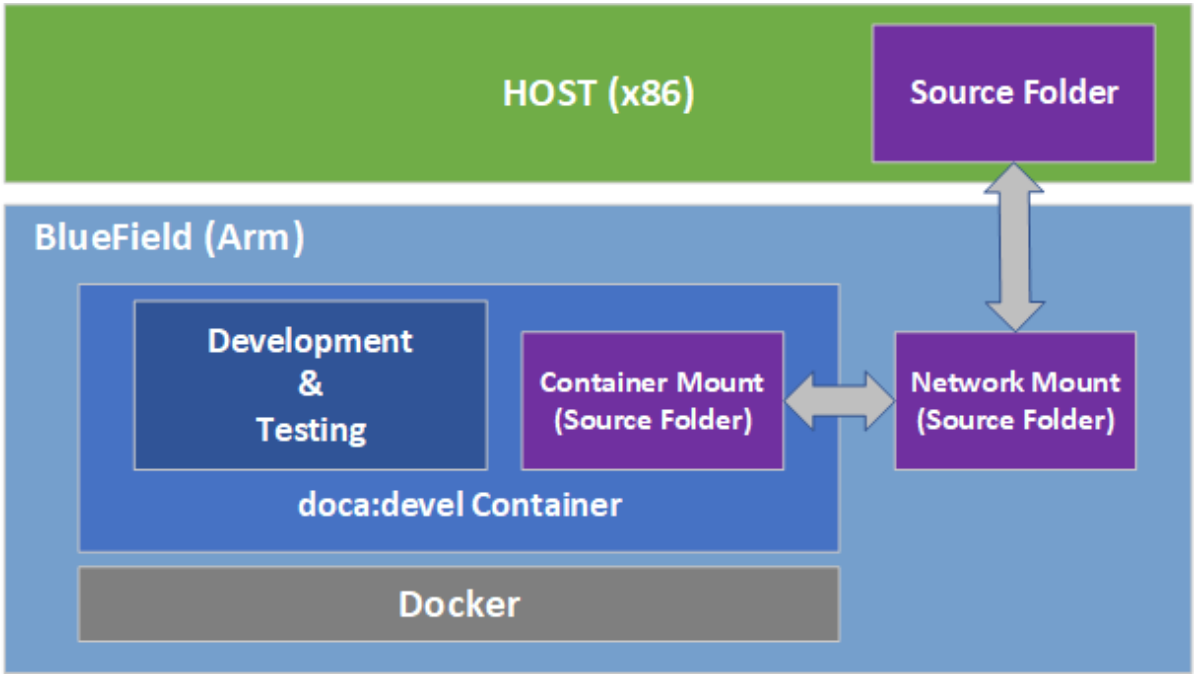
Another benefit of this container-based approach is that the development container allows developers to create and test their DOCA-based software in a user-friendly environment that comes pre-shipped with a set of handy development tools. The development container is focused on improving the development experience and is designed for that purpose, whereas the BlueField software is meant to be an efficient runtime environment for DOCA products.

For questions, comments, and feedback, please contact us at doca-feedback@nvidia.com.

4.4.2 Developing Using BlueField Networking Platform

4.4.2.1 Setup

DOCA's base image containers include a DOCA development container for the BlueField (`doca:devel`) which can be found on NGC. It is recommended to deploy this container on top of BlueField when preparing a development setup.



The recommended approach for working using DOCA's development container on top of the BlueField, is by using docker, which is already included in the supplied BFB image.

1. Make sure the docker service is started. Run:

```
sudo systemctl daemon-reload
sudo systemctl start docker
```

2. Pull the container image:
   a. Visit the NGC page of the DOCA base image.
   b. Under the "Tags" menu, select the desired development tag for BlueField.
   c. The container tag for the docker `pull` command is copied to your clipboard once selected. Example docker `pull` command using the selected tag:

```
sudo docker pull nvcr.io/nvidia/doca/doca:1.5.1-devel
```

3. Once loaded locally, you may find the image's ID using the following command:

```
sudo docker images
```

Example output:

```
REPOSITORY                  TAG           IMAGE ID       CREATED         SIZE
nvcr.io/nvidia/doca/doca    1.5.1-devel   931bd576eb49   10 months ago   1.49GB
```

4. Run the docker image:

```
sudo docker run -v <source-code-folder>:/doca_devel -v /dev/hugepages:/dev/hugepages --privileged --
net=host -it <image-name/ID>
```

For example, to map a source folder named `my_sources` into the same container tag from the example above, the command should look like this:

```
sudo docker run -v my_sources:/doca_devel -v /dev/hugepages:/dev/hugepages --privileged --net=host -it
nvcr.io/nvidia/doca/doca:1.5.1-devel
```

After running the command, you get a shell inside the container where you can build your project using the regular build commands:

- From the container's perspective, the mounted folder will be named `/doca_devel`

  > Make sure to map a folder with write privileges to `everyone`. Otherwise, the docker would not be able to write the output files to it.

- `--net=host` ensures the container has network access, including visibility to SFs and VFs as allocated on BlueField
- `-v /dev/hugepages:/dev/hugepages` ensures that allocated huge pages are accessible to the container

4.4.2.2 Development

It is recommended to do the development within the `doca:devel` container. That said, some developers prefer different integrated development environments (IDEs) or development tools, and sometimes prefer working using a graphical IDE until it is time to compile the code. As such, the recommendation is to mount a network share to BlueField (refer to DOCA DPU CLI for more information) and to the container.

> Having the same code folder accessible from the IDE and the container helps prevent edge cases where the compilation fails due to a typo in the code, but the typo is only fixed locally within the container and not propagated to the main source folder.

4.4.2.3 Testing

The container is marked as "privileged", hence it can directly access the hardware capabilities of the BlueField Platform. This means that once the tested program compiles successfully, it can be directly tested from within the container without the need to copy it to BlueField and running it there.

4.4.2.4 Publishing

Once the program passes the testing phase, it should be prepared for deployment. While some proof-of-concept (POC) programs are just copied "as-is" in their binary form, most deployments will probably be in the form of a package (`.deb` / `.rpm`) or a container.

Construction of the binary package can be done as-is inside the current `doca:devel` container, or as part of a CI pipeline that will leverage the same development container as part of it.

For the construction of a container to ship the developed software, it is recommended to use a multi-staged build that ships the software on top of the runtime-oriented DOCA base images:

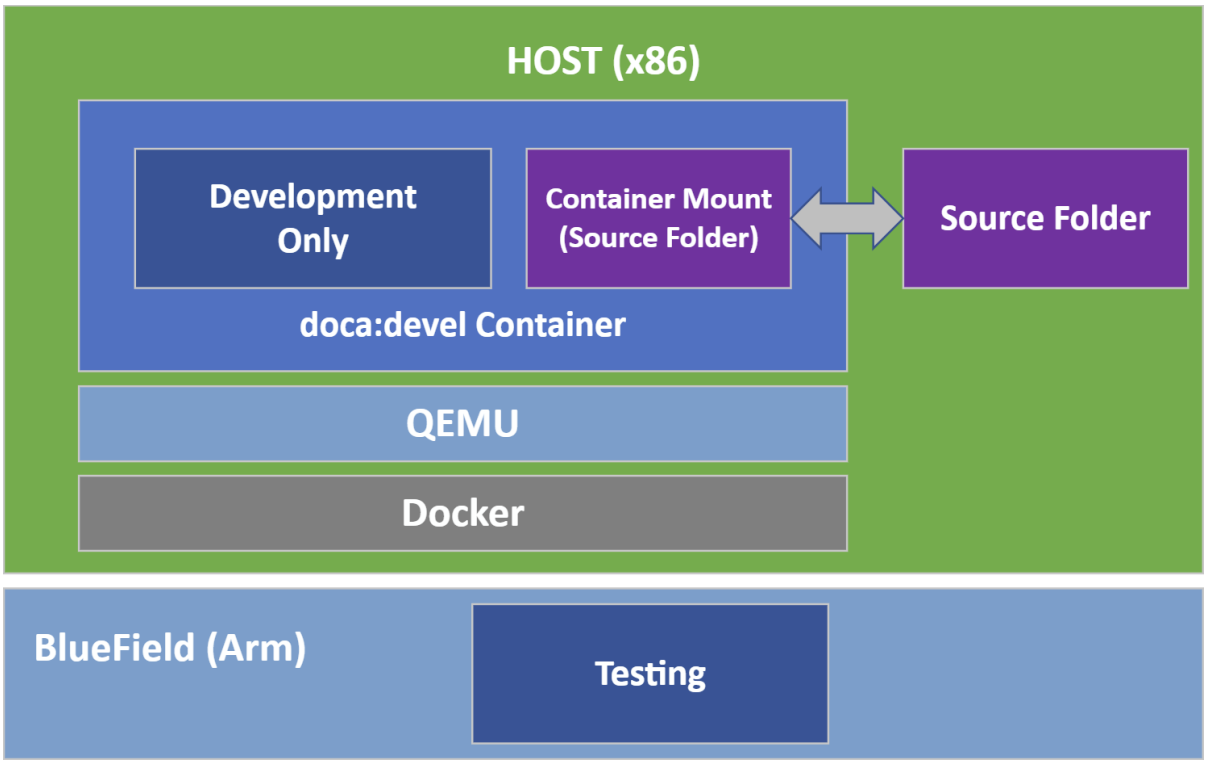
- `doca:base-rt` – slim DOCA runtime environment
- `doca:full-rt` – full DOCA runtime environment similar to the BlueField image

The runtime DOCA base images, alongside more details about their structure, can be found under the same NGC page that hosts the `doca:devel` image.

For a multi-staged build, it is recommended to compile the software inside the `doca:devel` container, and later copy it to one of the runtime container images. All relevant images must be pulled directly from NGC (using `docker pull`) to the container registry of BlueField.

4.4.3 Developing Without BlueField Networking Platform

If the development process needs to be done without access to a BlueField Platform, the recommendation is to use a QEMU-based deployment of a container on top of a regular x86 server. The development container for the host will be the same `doca:devel` image we mentioned previously.



4.4.3.1 Setup

1. Make sure Docker is installed on your host. Run:

   ```
   docker version
   ```

   If it is not installed, visit the official Install Docker Engine webpage for installation instructions.
2. Install QEMU on the host.

   > ⚠ This step is for x86 hosts only. If you are working on an aarch64 host, move to the next step.

Host OS	Command
Ubuntu	`sudo apt-get install qemu binfmt-support qemu-user-static` `sudo docker run --rm --privileged multiarch/qemu-user-static --reset -p yes`
CentOS/RHEL 7.x	`sudo yum install epel-release` `sudo yum install qemu-system-arm`
CentOS 8.0/8.2	`sudo yum install epel-release` `sudo yum install qemu-kvm`

Host OS	Command
Fedora	`sudo yum install qemu-system-aarch64`

3. If you are using CentOS or Fedora on the host, verify if `qemu-aarch64.conf` Run:

```
cat /etc/binfmt.d/qemu-aarch64.conf
```

   If it is missing, run:

```
echo ":qemu-aarch64:M::
\x7fELF\x02\x01\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\x02\x00\xb7:\xff\xff\xff\xff\xff\xff\xff\xfc\xff\xf
f\xff\xff\xff\xff\xff\xfe\xff\xff:/usr/bin/qemu-aarch64-static:" > /etc/binfmt.d/qemu-aarch64.conf
```

4. If you are using CentOS or Fedora on the host, restart system binfmt. Run:

```
$ sudo systemctl restart systemd-binfmt
```

5. To load and execute the development container, refer to the "Setup" section discussing the same docker-based deployment on the BlueField side.

> ⚠ The `doca:devel` container supports multiple architectures. Therefore, Docker by default attempts to pull the one matching that of the current machine (i.e., `amd64` for the host and `arm64` for BlueField). Pulling the `arm64` container from the x86 host can be done by adding the flag `--platform=linux/arm64`:
>
> ```
> sudo docker pull --platform=linux/arm64 nvcr.io/nvidia/doca/doca:1.5.1-devel
> ```

4.4.3.2 Development

Much like the development phase using BlueField, it is recommended to develop within the container running on top of QEMU.

4.4.3.3 Testing

While the compilation can be performed on top of the container, testing the compiled software must be done on top of a BlueField Platform. This is because the QEMU environment emulates an aarch64 architecture, but it does not emulate the hardware devices present on the BlueField Platform. Therefore, the tested program will not be able to access the devices needed for its successful execution, thus mandating that the testing is done on top of a physical BlueField.

Make sure that the DOCA version used for compilation is the same as the version installed on BlueField used for testing.

4.4.3.4 Publishing

The publishing process is identical to the publishing process when using BlueField.

5 DOCA Programming Guide

The DOCA Programming Guide is intended for developers wishing to utilize DOCA SDK to develop application on top of the NVIDIA® BlueField® DPUs and SuperNICs.

- DOCA Programming Overview is important to read for new DOCA developers to understand the architecture and main building blocks most applications will rely on.
- DOCA Development Best Practices outlines common development pitfalls and capabilities to speed up application development, qualification, and productization.
- DOCA Libraries describes in details how to use each DOCA library, its APIs, and different aspects related to that library. Users may choose to only read the pages concerning DOCA libraries required for their application.
- DOCA Utils includes modules that may be used by application developers to speed up their development process (e.g., DOCA Arg Parser which simplifies the creation of a command-line interface for your application).
- DOCA Drivers describes additional frameworks used within DOCA.

For questions, comments, and feedback, please contact us at doca-feedback@nvidia.com.

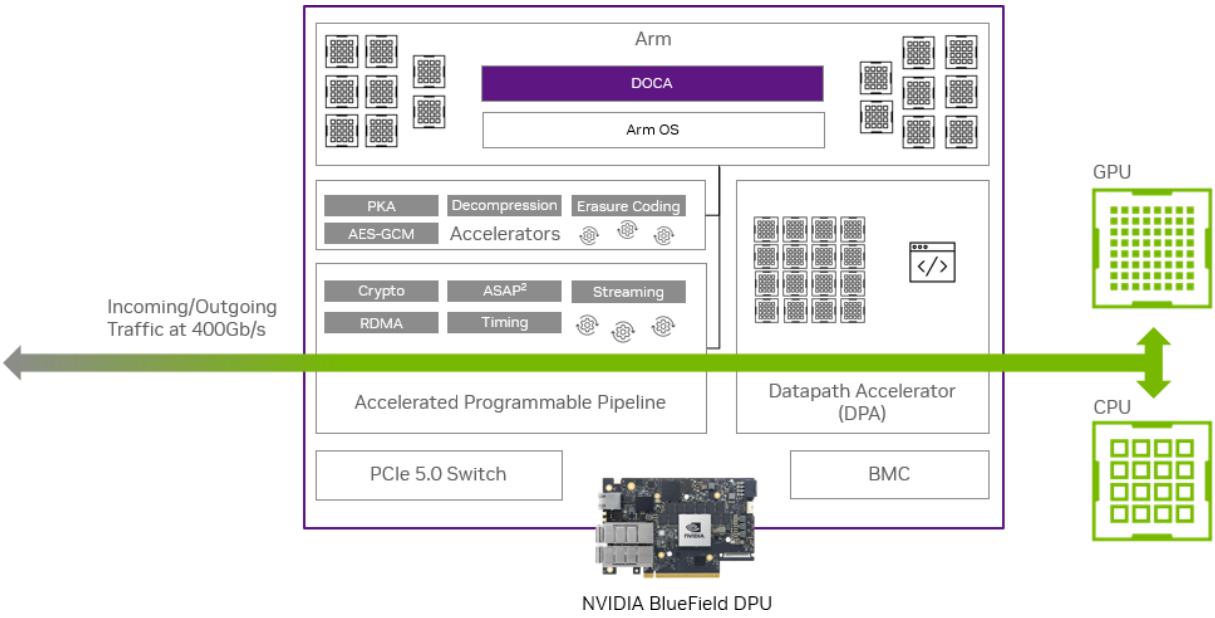
5.1 DOCA Programming Overview

This section contains the following pages:

- Hardware Architecture
- DOCA SDK Architecture

5.1.1 Hardware Architecture

BlueField's main hardware entities, which are optimized for different workloads.



5.1.1.1 Arm Cores

Optimized for control-path applications, general-purpose computing, and single-flow performance.

- 16 Arm Cortex-A78 cores for general-purpose processing
- Coherent Mesh architecture for efficient interconnectivity
- Last-Level Cache (LLC) for optimized memory performance
- DDR5 memory subsystem for high-speed data access
- Base OS and microservices for managing system resources

5.1.1.2 Accelerated Programmable Pipeline

Optimized for high-performance packet processing and advanced packet handling.

- Programmable 64-128 packet processor for flexible networking
- Multi-stage, highly parallelized architecture for throughput optimization
- Flow-based classification and action engine for efficient packet processing
- Support for RDMA, cryptographic acceleration, and time-based scheduling

5.1.1.3 Data-Path Accelerator

Designed for I/O-intensive applications, high insertion rate tasks, network flow processing, device emulation, and DMA operations.

- 16 hyper-threaded I/O and packet processing cores for handling intensive workloads

- Real-time OS for deterministic and low-latency operations

5.1.2 DOCA SDK Architecture

The DOCA SDK provides libraries for networking and data processing programmability, leveraging the NVIDIA® BlueField® networking platform (DPU or SuperNIC) and NVIDIA® ConnectX® NIC hardware accelerators.

The DOCA software framework is built on DOCA Core, which provides a unified software foundation for DOCA libraries. These libraries can be combined into processing pipelines or workflows that execute various offloaded tasks.

5.1.2.1 Device Subsystem

The DOCA SDK enables applications to offload resource-intensive tasks (e.g., encryption, compression) and network-related operations (e.g., packet acquisition, RDMA send) to specialized hardware.

5.1.2.1.1 Device Abstraction

The DOCA device subsystem provides an abstraction layer for the hardware processing units within BlueField and ConnectX devices. It allows applications to:

- Discover available hardware acceleration units provided by networking platforms
- Query capabilities and properties of these acceleration units
- Open and configure devices for libraries to allocate and share resources required for hardware acceleration

A system may have multiple available devices. Applications can select a device based on topology (e.g., PCIe address) or capabilities (e.g., encryption support).

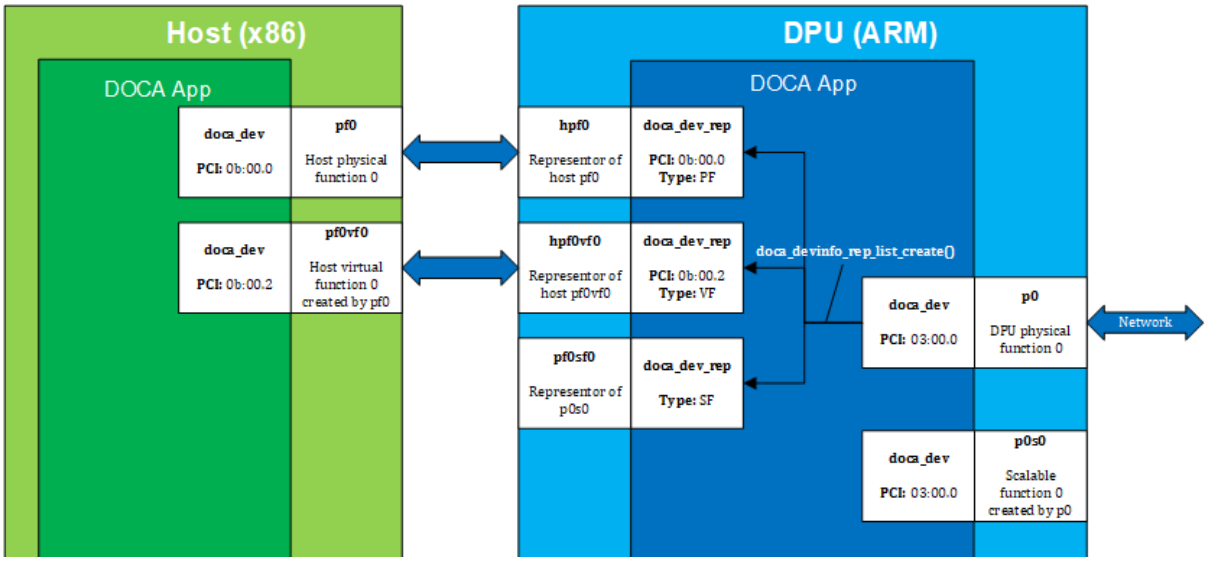
5.1.2.1.2 DOCA Device Types

DOCA Core defines two types of DOCA Devices:

- Local device – A physical or virtual device exposed on the local system (BlueField or host). This includes:
  - Physical function (PF)
  - Virtual function (VF)
  - Scalable function (SF)

- Representor device – A proxy device on the BlueField side that represents a host-side device. The host-side function (e.g., PF, VF, or SF) corresponds to a 1:1 mapped representor on BlueField.

The following figure provides an example of host local devices with representors on BlueField:



DPU Mode

The diagram shows typical topology when using BlueField in DPU mode as described in BlueField Modes of Operation.

The diagram shows BlueField (on the right side of the figure) connected to a host (on the left). The host has physical function PF0 with a child virtual function VF0.

The BlueField side has a representor-device per host function in a 1-to-1 ratio (e.g., `hpf0` is the representor device for the host's PF0 device, etc.) as well as a representor for each SF function, such that both the SF and its representor reside in BlueField.

For more details on the DOCA Device subsystem, see section "DOCA Device".

5.1.2.2 Memory Management Subsystem

Hardware-accelerated processing tasks require data buffers as inputs and outputs. The DOCA SDK employs zero-copy technology to maximize performance by avoiding unnecessary data movement.

To enable zero-copy, applications must pre-register memory before using it for data buffers. The memory management subsystem facilitates:

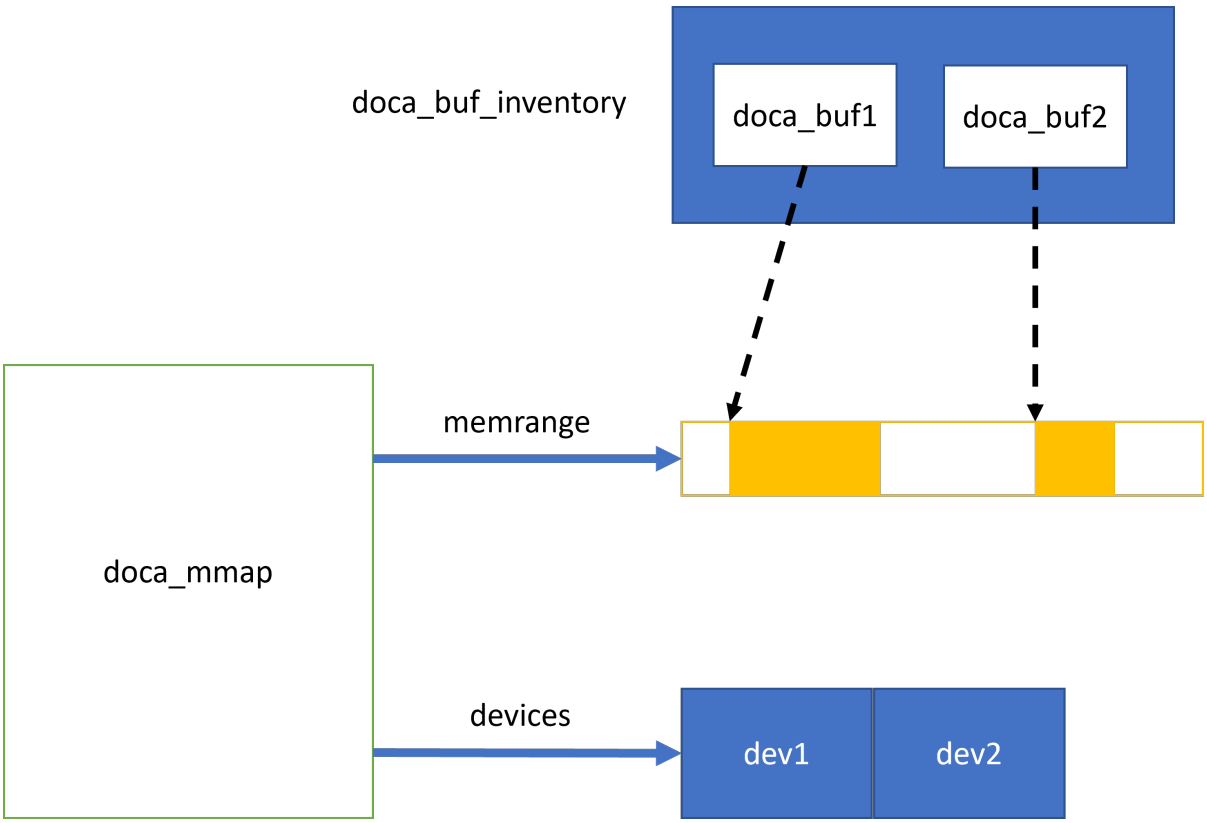
- Memory registration:

    - Defines an application memory range for storing data buffers
    - Allows one or more devices to access the registered memory
    - Sets access permissions (e.g., read-only, read-write)
- Data buffer allocation management:
    - Allocates data buffers within the registered memory range
    - Supports memory pooling over registered memory

DOCA memory has the following main components:

- `doca_buf` – Represents a data buffer used as input/output for DOCA library operations
- `doca_mmap` – Describes registered memory accessible to devices with defined permissions. Each `doca_buf` resides within a `doca_mmap` memory range.
- `doca_buf_inventory` – A pool of `doca_buf` objects with shared characteristics (see more in sections "DOCA Core Buffers" and "DOCA Core Inventories")

The following diagram shows the various modules within the DOCA memory subsystem:



The diagram shows a `doca_buf_inventory` containing 2 `doca_buf`s. Each `doca_buf` points to a portion of the memory buffer which is part of a `doca_mmap`. The mmap is populated with one continuous memory range and is registered with 2 DOCA Devices, `dev1` and `dev2`.

For more details about DOCA Memory management subsystem, see section "DOCA Memory Subsystem".

5.1.2.3 Execution Model

DOCA libraries abstract low-level hardware operations, allowing applications to focus on high-level processing tasks such as encryption, packet processing, and compression.

Each DOCA library defines dedicated APIs for performing these tasks. These libraries interact with hardware processing units via contexts.

5.1.2.3.1 Task and Event Model

DOCA APIs follow an asynchronous execution model, where applications interact with hardware through tasks and events:

- Task-based execution:
  a. The application prepares task arguments
  b. The application submits the task, requesting hardware processing
  c. The application receives a completion callback upon task completion
- Event-driven execution:
  a. The application registers for an event, instructing hardware to report when the event occurs
  b. The application receives a callback every time the event is triggered

5.1.2.3.2 Progress Engine – Managing Asynchronous Processing

Since hardware processing is asynchronous, DOCA provides a Progress Engine (PE) to manage task and event completion.

The PE supports:

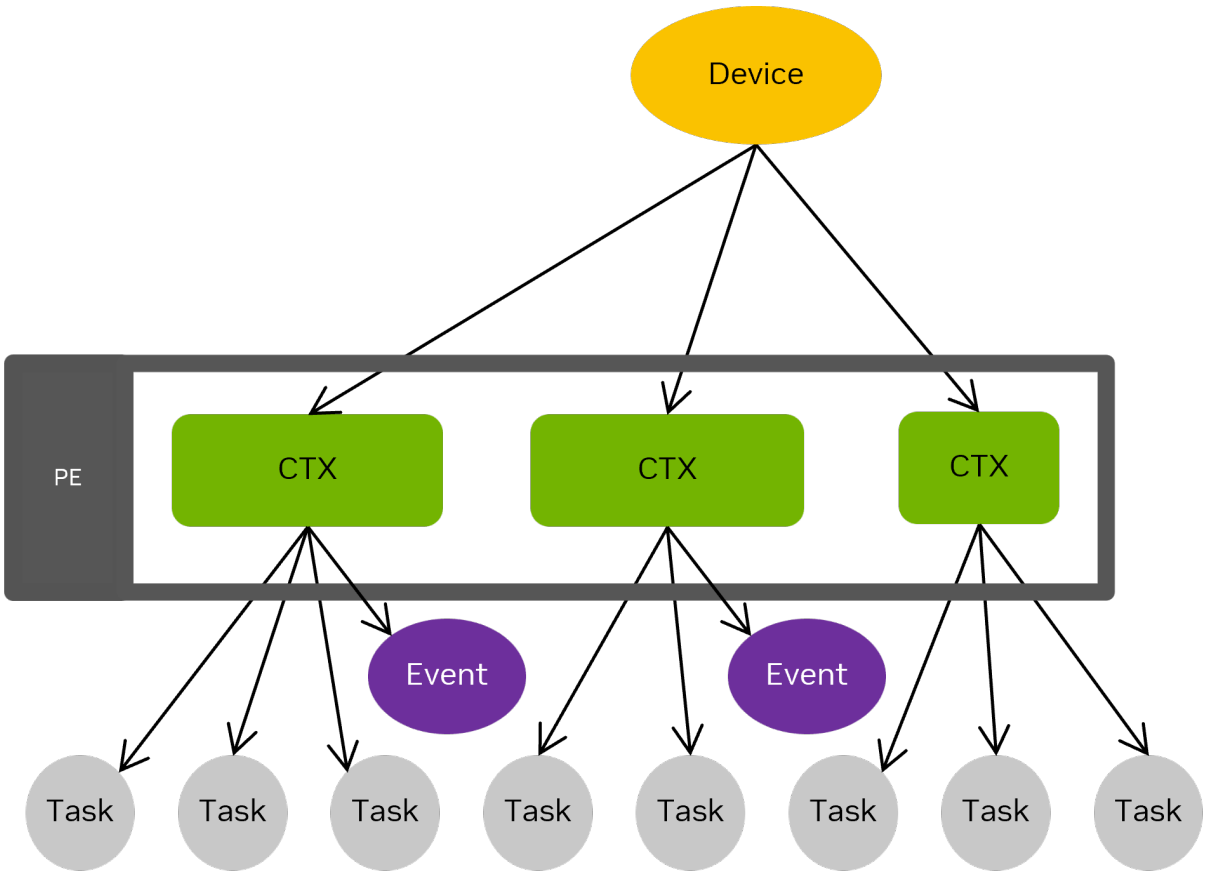
- Polling (or busy waiting) mode – The application repeatedly checks for completed tasks/events
- Notification mode – The application registers for OS-based notifications (e.g., Linux event FD) and is notified upon task/event completion

Once completion occurs, whether caused by a task or event, the relevant callback is invoked as part of the PE method.

A single PE instance allows waiting on multiple tasks/events from different contexts. As such, it is possible for an application to utilize a single PE per thread.

For more details about the DOCA Progress Engine, see section "DOCA Progress Engine".

The following diagram illustrates how a combination of various DOCA modules combine DOCA cross-library processing runtime.



The diagram shows 3 contexts utilizing the same device, each context has some tasks/events that have been submitted/registered by the application. All 3 contexts are connected to the same PE, where the application can use the same PE to wait on all completions at once.

For more details about DOCA Execution model see section "DOCA Execution Model".

5.2 DOCA Compatibility Policy

This page details the DOCA compatibility policy which governs how different components of the DOCA software stack—spanning the host, device, firmware, and hardware—and interact across different releases.

5.2.1 Introduction and Purpose

The DOCA compatibility policy provides customers with high velocity and flexibility during updates, enabling them to update specific layers of their system without requiring a full stack overhaul.

Key motivations:

- Decoupled updates – Supporting customers who have different teams managing separate parts of the software stack (e.g., firmware vs. user-space applications).
- Targeted upgrades – Allowing upgrades relevant to only a subset of devices on a server.
- Reduced maintenance – Minimizing downtime and complexity by only updating necessary components.
- Investment protection – Guaranteeing that customer applications will continue to operate successfully after updating to a newer DOCA software release.

This policy applies to all NVIDIA network device products and their associated software and firmware stacks.

5.2.2 Defining Compatibility

Compatibility is defined by the relationship between two layers when one is updated while the other remains unchanged. This relationship is defined using three key parameters: Layers, type, and direction.

5.2.2.1 Layers

Compatibility involves two interacting layers of the software/firmware stack running on either the host server or the network device.

5.2.2.2 Type of Compatibility

- Source compatibility (API persistence) – The ability to re-compile older source code without errors against newer platform libraries. This ensures that the published interfaces (APIs) remain consistent.
- Binary compatibility (symbols persistence) – The ability to run an older compiled program (binary) without errors against newer platform runtime libraries.
- Behavioral compatibility – Preserving the logical output and function of the code at runtime. Given the same input for the same interface, the same logical behavior is expected.

5.2.2.3 Direction of Compatibility

- Backward compatibility – The functionality continues to work when the lower layer (e.g., device firmware) is updated while the upper layer (e.g., host application) remains the same.
- Forward compatibility – The functionality continues to work when the upper layer is updated while the lower layer remains the same.

5.2.3 Software Release and Versioning Policy

DOCA product releases follow a structured cadence and versioning scheme to clearly communicate the scope of changes.

- Release cadence – The software platform package is released quarterly (e.g., Jan, Apr, July, Oct) as "General Availability (GA) releases," which include new features, performance enhancements, and bug fixes.
- Long-term support (LTS) – The October release of each year is designated as an LTS version.
- LTS versions are supported for three years.
- They receive updates that contain only bug fixes, no new features.
- An LTS version receives seven total updates ("LTS train") – three in the first year and two in each of the subsequent two years.
- Semantic versioning – NVIDIA follows the Semantic Versioning scheme (X.Y.Z), where:
- X – Major version – Incremented when incompatible API changes may be introduced.
- Y – Minor version – Incremented when new functionality is added in a backward compatible manner.
- Z – Patch version – Incremented for backward compatible bug fixes.

5.2.4 DOCA Compatibility Policy Types

DOCA defines specific compatibility policies based on the user role:

- DOCA Dependency Compatibility Policy – Designed for DOCA Administrators
- DOCA SDK Compatibility Policy – Designed for DOCA Developers

The following subpages describe these policies in more detail:

- DOCA Dependency Compatibility Policy

- DOCA SDK Compatibility Policy

5.2.5 DOCA Dependency Compatibility Policy

The DOCA Dependency Compatibility Policy ensures flexibility and efficiency during updates, enabling customers to upgrade specific layers of their system without requiring a full stack overhaul.

5.2.5.1 Key Objectives

- Decoupled updates: Supports environments where distinct teams manage separate parts of the software stack (e.g., firmware vs. user-space applications).
- Targeted upgrades: Enables upgrades targeted at specific subsets of devices within a server.
- Reduced maintenance overhead: Minimizes downtime and complexity by limiting updates to necessary components only.
- Operational continuity: Guarantees that customer applications continue to operate successfully after updating to a newer software platform release.

This policy applies to all NVIDIA network device products and their associated software and firmware stacks.

5.2.5.2 DOCA Dependency Policy Levels

DOCA defines two levels of dependency compatibility: Perpetual compatibility and Limited compatibility.

5.2.5.2.1 Level 1: Perpetual Dependency Compatibility

- Type: Perpetual forward and backward binary compatibility (e.g., a newer host component must work with an older firmware component, and vice versa).
- Condition: This is the highest level of support. Either the upper or lower layer may be upgraded independently, and all prior functionality is guaranteed to work seamlessly.
- Application: This policy applies to LTS (Long Term Support) update releases within a three-year support window.

5.2.5.2.2 Level 2: Limited Dependency Compatibility

- Type: Limited forward and backward binary compatibility.
- Condition: Breaking changes may be introduced annually, specifically with the October GA release.
- Limitation: Compatibility is guaranteed for all releases within a single annual cycle (October through July).

> The July release is fully compatible with the preceding April, January, and October releases of the same cycle. However, it may not be compatible with the next October release.

- Application: This policy applies to new GA feature releases.

> This does not apply to LTS update releases, which always follow Level 1 (Perpetual Dependency Compatibility).

5.2.5.3 Application of Policies

The following table summarizes how the compatibility policies apply to specific layers of the software stack:

#	Upper Layer	Lower Layer	Compatibility Level
1	DOCA-Host: DOCA-OFED profile	FW / BF-FW-Bundle	Level 1 – Perpetual
2	DOCA-Host: OTHER profiles (Networking, All)	FW / BF-FW-Bundle	Level 2 – Limited
3	DOCA-Host: DOCA-OFED profile	BF-Bundle	Level 1 – Perpetual
4	DOCA-Host: OTHER profiles (Networking, All)	BF-Bundle	Level 2 – Limited
5	DOCA-DPU	BF-FW-Bundle	Level 2 – Limited
6	DOCA Services (NGC and non-NGC)	BF-Bundle	Level 2 – Limited
7	DOCA Services (NGC and non-NGC)	FW / BF-FW-Bundle	Level 2 – Limited

5.2.5.4 Update Methodology

Compatibility support is a necessary precondition for supporting various customer update flows. While the exact flows are use-case dependent, this policy enables three primary update methodologies:

- Offline update: The system is taken offline during a maintenance window (usually involving a full system reboot) to apply changes. This is the simplest update method.

- Deferred update: New software is deployed without immediate service interruption. The system runs on the old version until a later system reset (determined by administrators) is performed for the changes to take effect.
- Hitless update: Updates are applied seamlessly without downtime or restart, maintaining continuous service availability. This typically applies to more granular components (e.g., a single service update).

> ⚠ Since the updated component must interact successfully with the rest of the system's un-updated components, it is advised to utilize containers to achieve this isolation.

5.2.6 DOCA SDK Compatibility Policy

The NVIDIA DOCA™ SDK enables developers to efficiently build applications and services on NVIDIA® BlueField® networking platforms.

DOCA follows a quarterly release cadence, delivering new features, performance enhancements, and critical bug fixes. The backward compatibility policy ensures that users can update to the latest DOCA software package—including libraries, drivers, and tools—without requiring modifications to their applications.

5.2.6.1 DOCA SDK Versioning

DOCA versions follow the Semantic Versioning scheme (i.e., X.Y.Z) where each component is updated based on the following criteria:

- Major version (X) – Introduces incompatible API changes
- Minor version (Y) – Adds functionality in a backward-compatible manner
- Patch version (Z) – Includes backward-compatible bug fixes

5.2.6.2 DOCA SDK API Backward Compatibility

A key characteristic of an enterprise-grade SDK is backward compatibility, which allows application developers to upgrade SDK versions without breaking existing functionality. This preserves their investment by ensuring applications remain operational across updates.

DOCA SDK APIs progress through the following lifecycle stages:

- Experimental – APIs marked as `DOCA_EXPERIMENTAL` are not guaranteed to be available in future releases.

- Stable – APIs marked as `DOCA_STABLE` are supported throughout the lifecycle of the current major version.
- Deprecated – APIs marked as `DOCA_DEPRECATED` will be removed in a future release. If previously marked as `DOCA_STABLE`, removal will occur in a major release.
- Removed – APIs that were available in an older major version but are no longer supported. If previously `DOCA_STABLE`, the binary representation remains intact to maintain binary backward compatibility.

The following sections describe the types of backward compatibility and how they align with semantic versioning.

5.2.6.2.1 Source Compatibility

Source compatibility ensures that a program written and compiled using libraries of a given DOCA SDK version continues to compile successfully with a newer DOCA SDK version.

As outlined in section "DOCA SDK Versioning", DOCA SDK maintains source compatibility across minor and patch versions. However, major version updates may introduce API changes, deprecations, or removals (refer to "DOCA SDK API Backward Compatibility" for details on API lifecycle stages). As a result, an application that compiles successfully with an older major version may require modifications to compile against a newer major version.

The above definition is aimed at DOCA SDK libraries & the symbols they expose. Compilation tools, on the other hand, may include better error or warning detection, resulting in failure to compile. This is a desired result, and is not considered "a source compatibility breakage".

5.2.6.2.2 Binary Compatibility

Binary compatibility ensures that a program dynamically linked to a given DOCA SDK library (`*.so`) can successfully link against a newer version of the same library.

Binary compatibility is only applicable for programs dynamically linked with DOCA SDK libraries.

DOCA SDK provides a versioned C-style application binary interface (ABI) that maintains binary compatibility across both minor and major versions. This guarantees that upgrading the installed DOCA SDK version does not break existing applications.

5.2.6.2.3 Behavioral Compatibility

Behavioral (or semantic) compatibility ensures that a function or component produces the same output given the same input. Applications developed, compiled, linked, and tested with a given DOCA SDK version will function correctly with newer DOCA SDK versions, as long as they rely on defined behaviors. Bug fixes are the only exceptions.

5.2.6.3 Backward Compatibility for Non-Opaque Structs Using CTSD

The compile-time struct dispatching (CTSD) mechanism enables backward compatibility for non-opaque structs in DOCA libraries.

CTSD allows developers to write applications using generic API and struct definitions, which the compiler replaces with version-specific implementations at compile time. This approach maintains type safety and runtime compatibility.

The mechanism employs a macro-based scheme to map version-agnostic names to version-specific implementations, ensuring type safety and compile-time verification.

For example, when a user writes code using `doca_flow_func()`, the compiler resolves it to the appropriate version-specific implementation (e.g., `internal_doca_flow_func_v2_4()`) based on the selected library version.

5.2.6.3.1 Library Version Management

Each DOCA library exposes non-opaque structs maintains its own version history, independent of the main DOCA SDK version. These versions are declared in the library's header file (e.g., `doca_flow.h`).

For instance, a library may define version constants such as:

```
#define LIB_FLOW_VERSION_2_4
#define LIB_FLOW_VERSION_2_5
```

5.2.6.3.2 User Responsibility

To use CTSD, users must specify the desired library version by setting a preprocessor definition. For example:

```
#define LIB_FLOW_VERSION LIB_FLOW_VERSION_2_4
```

By default, libraries use the latest available version.

For specific version changelogs and documentation, refer to the corresponding library's documentation.

5.2.6.4 DPA SDK Compatibility Considerations

DPA SDK present additional compatibility considerations that should be taken into consideration:

1. DPA applications consuming DPA SDK libraries are composed of two parts: Host process and Device process. The host process is dynamically linked with host SDK libraries, and the device side is statically linked with the Device SDK libraries. As a result, if DOCA is upgraded without recompiling the application, then in effect, new library code is loaded on the host, but old device library code is loaded on DPA. This presents a new compatibility limitation between device library and host library. This specific compatibility will follow the "**Limited dependency compatibility**" policy defined in DOCA Dependency Compatibility Policy, where the host library is newer than the device library (i.e. "forward compatibility" only).
2. DPA device libraries are statically linked with the application, thus the **binary compatibility** between the DPA device library and the DPA application is **not applicable**. New DPA device code can only be deployed by recompiling the DPA application.
3. DPACC compiler toolchain produces binary files using LLVM bitcode format. The underlying version of LLVM framework is updated in every October/Rel2B release. As a result, the compatibility between a binary DPA library generated by an older DPACC version and the DPACC used to build the application is also following the "**Limited dependency compatibility**" policy defined in DOCA Dependency Compatibility Policy.
4. DPACC (as any other compilation tool) may include better error or warning detection, resulting in failing to compile an application with a newer DPACC. This is a desired result and is not considered "a source compatibility breakage".

5.2.6.5 DOCA SDK Protocol Compatibility

Some DOCA SDK components facilitate communication between remote entities, such as:

- Host-to-BlueField
- BlueField-to-BlueField
- Host-to-host

Applications utilizing DOCA may be deployed in large clusters and upgraded at different times. To support seamless upgrades, DOCA SDK maintains protocol compatibility between different SDK versions, allowing for rolling upgrades without disrupting

operations. Nodes running different DOCA SDK versions can continue communicating throughout the transition.

5.2.6.6 DOCA SDK Dependencies Compatibility

DOCA is distributed as a meta-package, available in the following formats:

- `*.bfb` – For installation on the BlueField networking platform's Arm processor
- `*.rpm` / `*.deb` – For installation on the host server

Each package includes libraries, tools, executables, firmware, and sample applications.

DOCA SDK is tested as a complete package, ensuring that all components work together. There is no guarantee that upgrading individual components separately will maintain functionality. Therefore, updating to a newer DOCA version requires updating the entire meta-package.

5.3 DOCA Development Best Practices

The following sub-sections describe some best practices DOCA SDK users/developers should consider when using DOCA SDK.

- Capability Checking
- Debuggability

5.3.1 Capability Checking

Applications using a DOCA Device rely on a specific subset of features to function correctly. Therefore, it is recommended to verify whether the required features are available on the selected DOCA Device.

To facilitate this, the DOCA SDK provides capability APIs, a set of standardized APIs designed for querying feature support. These APIs should be used before initializing any resources to detect unsupported features early, allowing applications to implement fallback mechanisms instead of encountering unexpected errors during execution.

5.3.1.1 Device Capability

Applications using DOCA Core APIs may need to determine whether a specific DOCA Device supports required capabilities.

To achieve this, the `doca_devinfo` and `doca_devinfo_rep` APIs expose capabilities using the following prefixes:

- `doca_devinfo_cap_*`
- `doca_devinfo_rep_cap_*`

Examples:

```
doca_error_t doca_devinfo_cap_is_hotplug_manager_supported(const struct doca_devinfo *devinfo, uint8_t
*is_hotplug_manager);
doca_error_t doca_devinfo_rep_cap_is_filter_emulated_supported(const struct doca_devinfo *devinfo, uint8_t
*filter_emulated_supported);
```

5.3.1.2 Library Capability

Each DOCA library provides capability APIs for:

- Querying valid configuration property limits (e.g., maximum/minimum values)
- Verifying whether a specific library task is supported on a given DOCA Device

All library capability APIs follow the naming convention `doca_<library_name>_cap_*`.

Additionally:

- Configuration limitation capability APIs use the prefix `doca_<library_name>_cap_[task_<task_type>]_get_min/max_*`
- Task support capability APIs use the naming template `doca_<library_name>_cap_task_<task_type>_is_supported`

Examples from DOCA DMA:

```
doca_error_t doca_dma_cap_task_memcpy_is_supported(const struct doca_devinfo *devinfo);
doca_error_t doca_dma_cap_get_max_num_tasks(struct doca_dma *dma, uint32_t *max_num_tasks);
doca_error_t doca_dma_cap_task_memcpy_get_max_buf_size(const struct doca_devinfo *devinfo, uint64_t *buf_size);
```

5.3.1.3 Core Capability

Like other DOCA libraries, DOCA Core modules expose capability APIs to check feature availability.

Examples:

- A hotplugging application can verify if a DOCA Device supports hotplugging emulated PCIe functions using:

  ```
  doca_error_t doca_devinfo_cap_is_hotplug_manager_supported(const struct doca_devinfo *devinfo, uint8_t
  *is_hotplug_manager);
  ```

- An application using DOCA mmap for memory sharing between a host and BlueField must export the `doca_mmap` from the host and import it on BlueField.

Before proceeding, the application can verify if these operations are supported for a given a `doca_devinfo` using:

```
doca_error_t doca_mmap_cap_is_export_pci_supported(const struct doca_devinfo *devinfo, uint8_t
*mmap_export);
doca_error_t doca_mmap_cap_is_create_from_export_pci_supported(const struct doca_devinfo *devinfo, uint8_t
*from_export);
```

5.3.2 Debuggability

DOCA SDK provides structured error handling and logging mechanisms to help developers diagnose and resolve issues efficiently.

5.3.2.1 Return Values

All DOCA APIs return a status code of type doca_error_t.

It is essential to check the return value of every DOCA API call to ensure successful execution. In the event of an error, refer to the function's documentation for the meaning of the returned status code and appropriate troubleshooting steps.

5.3.2.2 SDK Logging

The DOCA SDK provides error messages and debug prints to aid in debugging and issue resolution.

To enable DOCA SDK log messages, an application must:

1. Create a logging backend.
2. Set the verbosity level (if needed).

For more details on configuring and using DOCA logging, refer to "Enabling DOCA SDK Libraries Logging".

5.4 DOCA Libraries

Each DOCA library provides APIs, documentation, and examples designed to accelerate the development of data-center and networking applications.

This section describes the available libraries, their support levels, and key usage guidelines.

The quality level of each library reflects the maturity and support status of its major functionality. Individual APIs within a library may have a different quality level (e.g., alpha

or beta). For detailed API-level quality information, refer to the respective library programming guide.

Library	Quality Level
DOCA Common	Beta
DOCA Flow	GA
Flex IO	GA
DOCA DPA	Beta
DOCA PCC	Beta
DOCA DMA	GA
DOCA Comch	GA
DOCA UROM	Alpha
DOCA RDMA	GA
DOCA Ethernet	Beta
DOCA GPUNetIO	Beta
DOCA App Shield	GA
DOCA Compress	GA
DOCA SHA	GA
DOCA STA	Alpha
DOCA Erasure Coding	GA
DOCA AES-GCM	GA
DOCA Rivermax	Beta
DOCA Telemetry Exporter	GA
DOCA Telemetry	GA
DOCA Device Emulation	GA
DOCA DevEmu PCI Generic	GA
DOCA DevEmu Virtio-FS	GA
DOCA Management	Beta

5.4.1 DOCA Common

DOCA Common consists of the following libraries:

- DOCA Core
- DOCA Log

5.4.1.1 DOCA Core

This document provides guidelines on using DOCA Core objects as part of DOCA SDK programming.

5.4.1.1.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

DOCA Core objects provide a unified and holistic interface for application developers to interact with various DOCA libraries. The DOCA Core API and objects bring a standardized flow and building blocks for applications to build upon while hiding the internal details of dealing with hardware and other software components. DOCA Core is designed to give the right level of abstraction while maintaining performance.

DOCA Core has the same API (header files) for both NVIDIA® BlueField® and CPU installations, but specific API calls may return `DOCA_ERROR_NOT_SUPPORTED` if the API is not implemented for that processor. However, this is not the case for Windows and Linux as DOCA Core does have API differences between Windows and Linux installations.

DOCA Core exposes C-language API to application writers and users must include the right header file to use according to the DOCA Core facilities needed for their application.

DOCA Core can be divided into the following software modules:

DOCA Core Module	Description
General	• DOCA Core enumerations and basic structures • Header files – `doca_error.h`, `doca_types.h`

DOCA Core Module	Description

Device handling	• Queries device information (host-side and BlueField) and device capabilities (e.g., device's PCIe BDF address)
	  • On BlueField
	  • Gets local BlueField devices
	  • Gets representors list (representing host local devices)
	  • On the host
	  • Gets local devices
	  • Gets representors list (representing local devices in the case of CX or DPU in NIC mode)
	  • Queries device capabilities and library capabilities
	• Opens and uses the selected device representor
	• Relevant entities – `doca_devinfo`, `doca_devinfo_rep`, `doca_dev`, `doca_dev_rep`
	• Header files – `doca_dev.h`
	There is a symmetry between representor entities and their corresponding "represented" devices. The use of the `rep` prefix in the API or object names indicates that the functionality or object is specific to a representor. This naming convention helps differentiate representor-specific components from others.

Memory management	• Handles optimized memory pools to be used by applications and enables sharing resources between DOCA libraries (while hiding hardware-related technicalities) • Data buffer services (e.g., linked list of buffers to support scatter-gather list) • Maps host memory to BlueField for direct access • Relevant entities – `doca_buf`, `doca_mmap`, `doca_buf_inventory`, `doca_buf_array`, `doca_bufpool` • Header files – `doca_buf.h`, `doca_buf_inventory.h`, `doca_mmap.h`, `doca_buf_array.h`, `doca_bufpool`
Progress engine and task execution	• Enables submitting tasks to DOCA libraries and track task progress (supports both polling mode and event-driven mode) • Relevant entities – `doca_ctx`, `doca_task`, `doca_event`, `doca_event_handle_t`, `doca_pe` • Header files – `doca_ctx.h`
Sync events	• Sync events are used to synchronize different processors (e.g., synchronize BlueField and host) • header files – `doca_dpa_sync_event.h`, `doca_sync_event.h`

The following sections describe DOCA Core's architecture and subsystems along with some basic flows that help users get started using DOCA Core.

5.4.1.1.2 Prerequisites

DOCA Core objects are supported on NVIDIA® BlueField® networking platforms (DPU or SuperNIC) and the host machine. Both must meet the following prerequisites:

- DOCA version 2.0.2 or greater
- NVIDIA® BlueField® software 4.0.2 or greater
- NVIDIA® BlueField®-3 firmware version 32.37.1000 and higher

- NVIDIA® BlueField®-2 firmware version 24.37.1000 and higher
- Please refer to the DOCA Compatibility Policy

5.4.1.1.3 Changes From Previous Releases

5.4.1.1.3.1 Changes in 2.10.0

Added

- `doca_error_t doca_devinfo_rep_get_iface_name(struct doca_devinfo_rep *devinfo_rep, char *iface_name, uint32_t size)`

Changed

- `doca_devinfo_rep_create_list(struct doca_dev *dev, int filter, struct doca_devinfo_rep ***dev_list_rep, uint32_t *nb_devs_rep)` ; now supports net representor discovery on host.

5.4.1.1.4 Architecture

The following sections describe the architecture for the various DOCA Core software modules. Please refer to the NVIDIA DOCA Library APIs for DOCA header documentation.

5.4.1.1.4.1 General

All core objects adhere to same flow that later helps in doing no allocations in the fast path.

The flow is as follows:

1. Create the object instance (e.g., `doca_mmap_create`).
2. Configure the instance (e.g., `doca_mmap_set_memory_range`).
3. Start the instance (e.g., `doca_mmap_start`).

After the instance is started, it adheres to zero allocations and can be used safely in the data path. After the instance is complete, it must be stopped and destroyed (`doca_mmap_stop` , `doca_mmap_destroy`).

There are core objects that can be reconfigured and restarted again (i.e., create → configure → start → stop → configure → start). Please read the header file to see if specific objects support this option.

doca_error_t

All DOCA APIs return the status in the form of `doca_error_t`.

```
typedef enum doca_error {
    DOCA_SUCCESS,
    DOCA_ERROR_UNKNOWN,
    DOCA_ERROR_NOT_PERMITTED,          /**< Operation not permitted */
    DOCA_ERROR_IN_USE,                 /**< Resource already in use */
    DOCA_ERROR_NOT_SUPPORTED,          /**< Operation not supported */
    DOCA_ERROR_AGAIN,                  /**< Resource temporarily unavailable, try again */
    DOCA_ERROR_INVALID_VALUE,          /**< Invalid input */
    DOCA_ERROR_NO_MEMORY,              /**< Memory allocation failure */
    DOCA_ERROR_INITIALIZATION,         /**< Resource initialization failure */
    DOCA_ERROR_TIME_OUT,               /**< Timer expired waiting for resource */
    DOCA_ERROR_SHUTDOWN,               /**< Shut down in process or completed */
    DOCA_ERROR_CONNECTION_RESET,       /**< Connection reset by peer */
    DOCA_ERROR_CONNECTION_ABORTED,     /**< Connection aborted */
    DOCA_ERROR_CONNECTION_INPROGRESS,  /**< Connection in progress */
    DOCA_ERROR_NOT_CONNECTED,          /**< Not Connected */
    DOCA_ERROR_NO_LOCK,                /**< Unable to acquire required lock */
    DOCA_ERROR_NOT_FOUND,              /**< Resource Not Found */
    DOCA_ERROR_IO_FAILED,              /**< Input/Output Operation Failed */
    DOCA_ERROR_BAD_STATE,              /**< Bad State */
    DOCA_ERROR_UNSUPPORTED_VERSION,    /**< Unsupported version */
    DOCA_ERROR_OPERATING_SYSTEM,       /**< Operating system call failure */
    DOCA_ERROR_DRIVER,                 /**< DOCA Driver call failure */
    DOCA_ERROR_UNEXPECTED,             /**< An unexpected scenario was detected */
    DOCA_ERROR_ALREADY_EXIST,          /**< Resource already exist */
    DOCA_ERROR_FULL,                   /**< No more space in resource */
    DOCA_ERROR_EMPTY,                  /**< No entry is available in resource */
    DOCA_ERROR_IN_PROGRESS,            /**< Operation is in progress */
    DOCA_ERROR_TOO_BIG,                /**< Requested operation too big to be contained */
 } doca_error_t;
```

See `doca_error.h` for more.

Generic Structures/Enum

The following types are common across all DOCA APIs.

```
union doca_data {
        void *ptr;
        uint64_t u64;
};

enum doca_access_flags {
    DOCA_ACCESS_LOCAL_READ_ONLY     = 0,
    DOCA_ACCESS_LOCAL_READ_WRITE    = (1 << 0),
    DOCA_ACCESS_RDMA_READ           = (1 << 1),
    DOCA_ACCESS_RDMA_WRITE          = (1 << 2),
    DOCA_ACCESS_RDMA_ATOMIC         = (1 << 3),
    DOCA_ACCESS_DPU_READ_ONLY       = (1 << 4),
    DOCA_ACCESS_DPU_READ_WRITE      = (1 << 5),
};

enum doca_pci_func_type {
        DOCA_PCI_FUNC_PF = 0, /* physical function */
        DOCA_PCI_FUNC_VF,     /* virtual function */
        DOCA_PCI_FUNC_SF,     /* sub function */
};
```

For more see `doca_types.h`.

5.4.1.1.4.2 DOCA Device

Local Device and Representor

There are 2 topologies for the representors model:

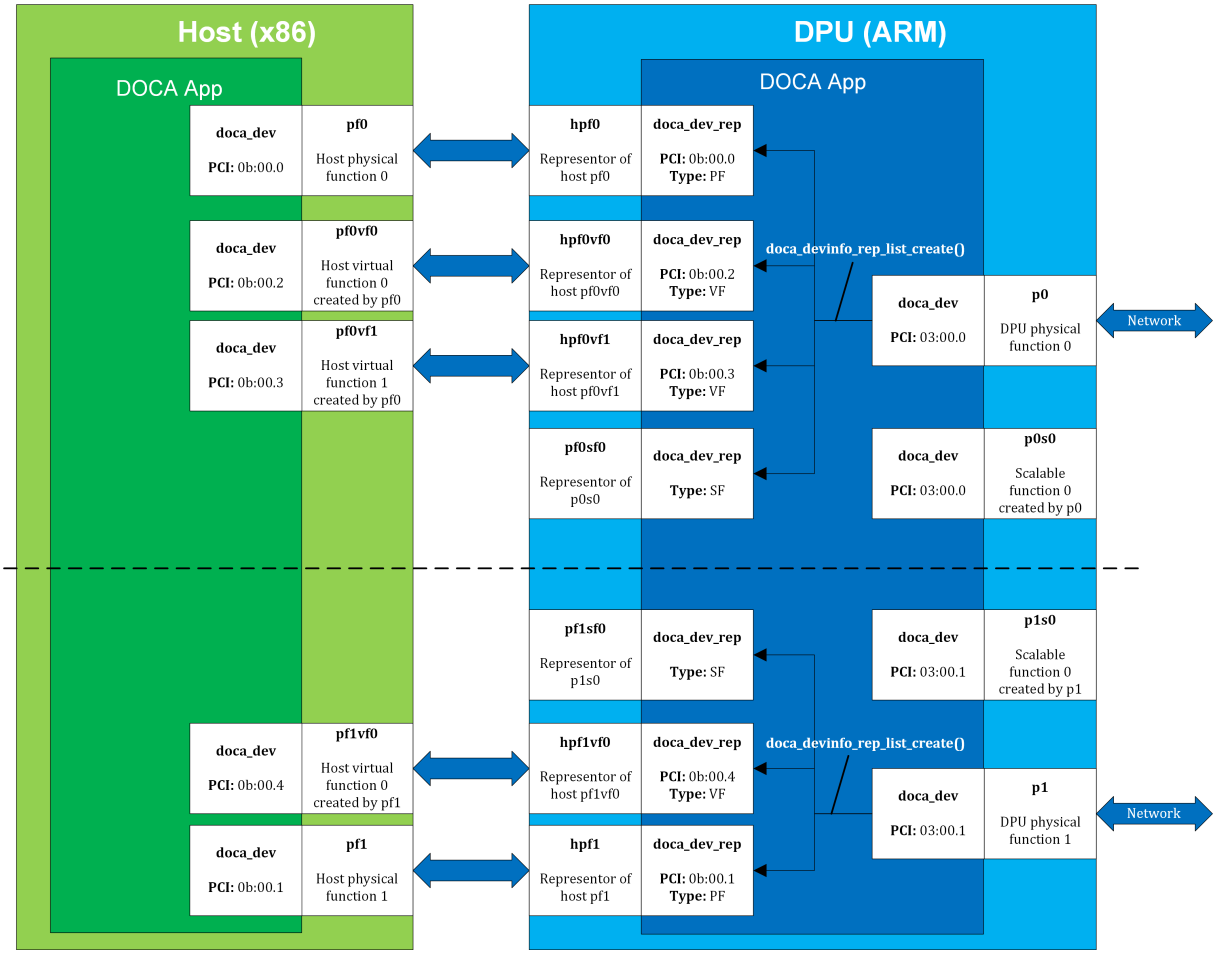
- DPU mode topology – BlueField must be operated in DPU mode (see explanation in section "DPU Topology").
- NIC mode topology – all devices and representors reside on the host. This is achieved using a BlueField operating in NIC mode or an NVIDIA® ConnectX® device. See explanation under DOCA Switching.

DPU Topology

A DOCA device represents an available processing unit, either hardware- or software-based. It exposes its properties to help applications select the most suitable device(s). DOCA Core supports two device types:

- Local device:
  - A physical device available on the local system (e.g., BlueField or host)
  - Capable of performing DOCA library processing tasks
- Representor device:
  - A proxy or representation of a local device
  - Typically used for host-side devices, with the representor located on the BlueField
  - Special Functions (SFs) reside entirely on the BlueField and also have their own representor devices

Topology Example



The following describes a typical topology, as shown in the diagram:

- Host topology:
  - The host system includes two physical functions (PFs): `PF0` and `PF1`.
  - `PF0` has two child virtual functions (VFs): `VF0` and `VF1`.

        - `PF1` has one associated VF: `VF0`.
        - Using the DOCA SDK API, users can query these five devices as local devices on the host.
    - BlueField side:
        - BlueField maintains a 1-to-1 relation with host functions through representor devices. For example, `hpf0` is the representor for the host's `PF0` device.
        - BlueField also includes representors for SF devices. Both the SFs and their representors reside on the BlueField.

Querying Devices on BlueField

When querying local devices on BlueField (not representors), the result includes:

- Two BlueField DPU PFs (`p0` and `p1` in this example). These are the parent devices for all other devices.
- Associated devices:
    - 7 representor devices:
        - 5 representors for host functions (`hpf*`, shown as arrows connecting the host to BlueField in the diagram).
        - 2 representors for SF devices (`pf0sf0` and `pf1sf0`).
    - 2 local SF devices: These are not representors but physical devices on the BlueField (`p0s0` and `p1s0`).

The topology is divided into two parts (separated by a dotted line in the diagram), each represented by a BlueField physical device (`p0` and `p1`). Each BlueField device acts as the parent of:

- Local devices (e.g., PFs, VFs, and SFs).
- Representor devices (host PFs, host VFs, and SFs).

The parent device has access to the representor devices of all associated functions through the `doca_devinfo_rep_list_create` API.

Local Device and Representor Matching

Based on the topology diagram, the mmap export APIs can be used as follows:

Device to Select on Host When Using doca_mmap_export_dpu()	BlueField Matching Representor	Device to Select on BlueField When Using doca_mmap_create_from_export()
`pf0` – `0b:00.0`	`hpf0` – `0b:00.0`	`p0` – `03:00.0`
`pf0vf0` – `0b:00.2`	`hpf0vf0` – `0b:00.2`	
`pf0vf1` – `0b:00.3`	`hpf0vf1` – `0b:00.3`	

Device to Select on Host When Using doca_mmap_export_dpu()	BlueField Matching Representor	Device to Select on BlueField When Using doca_mmap_create_from_export()
`pf1` – `0b:00.1`	`hpf1` – `0b:00.1`	`p1` – `03:00.1`
`pf1vf0` – `0b:00.4`	`hpf1vf0` – `0b:00.4`	

Expected Flow

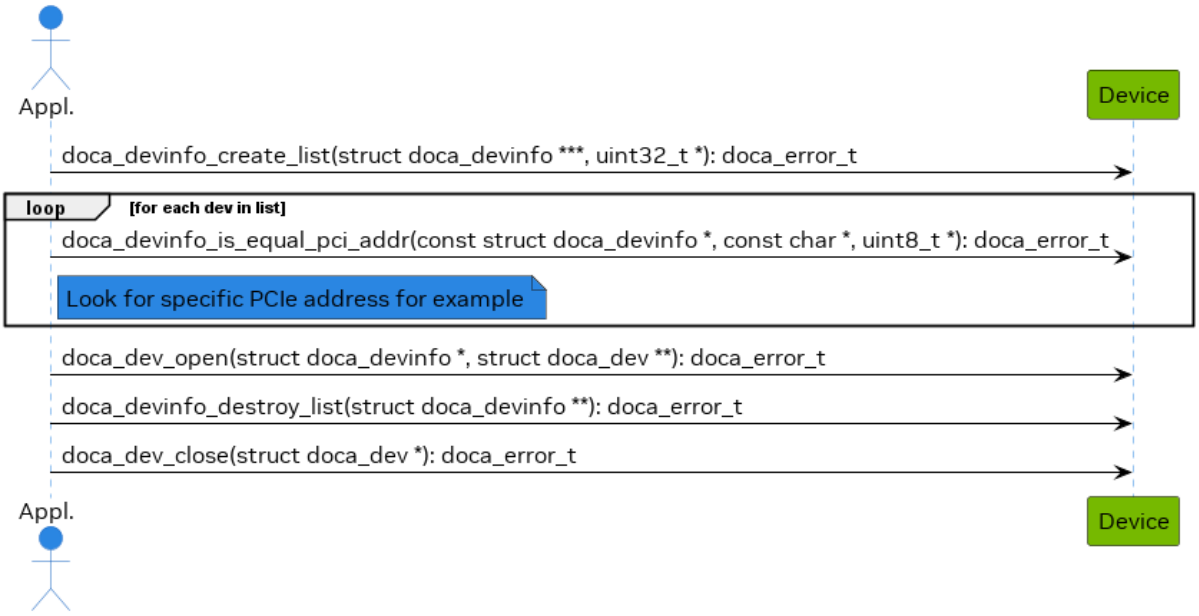
Device Discovery

To work with DOCA libraries or DOCA Core objects, an application must open and use a device available on the BlueField or the host.

Depending on the system setup, there are typically multiple devices available. For details on device topology and hierarchy, refer to the "DPU Topology" section.

An application can decide which device to select based on capabilities, the DOCA Core API, and every other library which provides a wide range of device capabilities. The flow is as follows:

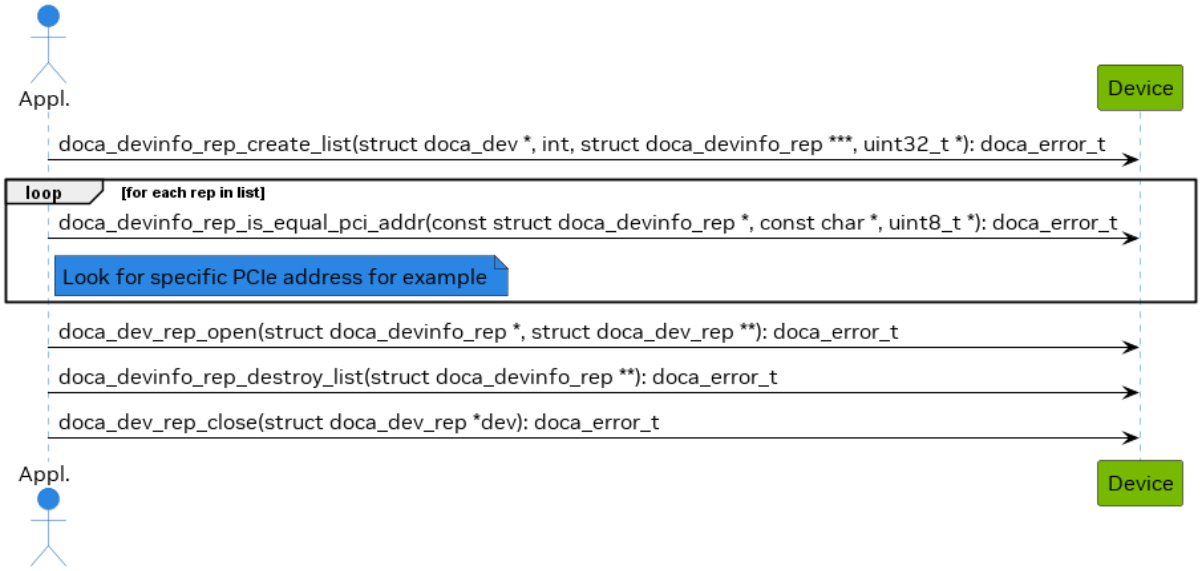
1. The application gets a list of available devices.
2. Select a specific `doca_devinfo` to work with according to one of its properties and capabilities. This example looks for a specific PCIe address.
3. Once a suitable `doca_devinfo` is identified, open the device using the DOCA Core API to obtain a `doca_dev` handle.
4. After opening the desired device, release the `doca_devinfo` list to free up resources.
5. Use the `doca_dev` handle to interact with DOCA libraries or perform desired operations.
6. When the application finishes using the device, ensure that the `doca_dev` is properly closed to release resources.



Representor Device Discovery

To work with DOCA libraries or DOCA Core objects, some applications must open and use a representor device. Before they can open the representor device and use it, applications need tools to allow them to select the appropriate representor device with the necessary capabilities. The DOCA Core API provides a wide range of device capabilities to help the application select the right device pair (device and its representor). The flow is as follows:

1. The application "knows" which device it wants to use (e.g., by its PCIe BDF address). It can be done using DOCA Core API or OS services.
2. The application gets a list of device representors for a specific device.
3. Select a specific `doca_devinfo_rep` to work with according to one of its properties. This example looks for a specific PCIe address.
4. Once a suitable `doca_devinfo_rep` is identified, open `doca_dev_rep`.
5. After the user opens the right device representor, they can close the `doca_devinfo_rep` list and continue working with `doca_dev_rep`. The application eventually must close `doca_dev_rep` too.



As mentioned previously, the DOCA Core API can identify devices and their representors that have a unique property (e.g., the BDF address, the same BDF for the device, and its representor).

> **Regarding representor device property caching, the function `doca_devinfo_rep_create_list` provides a snapshot of the DOCA representor device properties when it is called. If any representor's properties are changed dynamically (e.g., BDF address changes after bus reset), the device properties that the function returns would not reflect this change. One should create the list again to get the updated properties of the representors.**

DOCA Application Restart

Restarting a DOCA application can be done gracefully or non-gracefully. Each method has its own steps and considerations to ensure proper resource management and minimize downtime.

In a graceful restart, the application follows a structured process to ensure that all resources are properly managed and released before restarting. The application should first gracefully free all associated resources including those tied to the DOCA device (e.g., DOCA Flow switch ports and their components). After freeing the resources, the application calls `doca_dev_close` to close the DOCA device instance and then terminates. In a non-graceful restart, the application crashes unexpectedly without freeing the associated resources. The application is then started again.

The `doca_dev_accelerate_resource_reclaim` API can be useful in both scenarios to optimize the reclaim process for resources associated with the device. By retaining critical resources in the cache, this API ensures that they can be quickly reclaimed when needed, minimizing downtime and speeding up the recovery process, especially in non-graceful restart scenarios.

For a graceful restart, users should call the `doca_dev_accelerate_resource_reclaim` API before initiating the device resource cleanup. After calling the API, users can proceed with freeing all associated resources, closing the DOCA device instance with `doca_dev_close`, and terminating the application. This ensures that resources are properly managed and released before the application restarts.

For a non-graceful restart, where the application crashes unexpectedly, the `doca_dev_accelerate_resource_reclaim` API can be called periodically (e.g., every 5 seconds) to ensure readiness. This periodic invocation enables continuous retention of critical resources in the cache so that when the application restarts, these resources can be quickly reclaimed, minimizing downtime and speeding up the recovery process.

After restarting the application, whether gracefully or non-gracefully, the application should call `doca_dev_open` to create a new DOCA device instance.

> Immediately after the return of `doca_dev_open`, it is recommended to call the `doca_dev_accelerate_resource_reclaim` API to extend the retention period of the resources associated with the device in the cache.

Afterwards, the application should allocate the necessary resources associated with the DOCA device. This ensures that the application can resume its operations with the required resources in place, leveraging the retained resources in the cache for a faster and more efficient restart process.

> Using this API is not without cost, as it may lead to a lack or shortage of system resources, potentially causing overall system performance degradation. Only use the API for the specified use-cases above. If you are unsure about a specific application use-case, please contact NVIDIA Enterprise Support for questions.

5.4.1.1.4.3 DOCA Memory Subsystem

DOCA memory subsystem is designed to optimize performance while keeping a minimal memory footprint (to facilitate scalability) as main design goal.

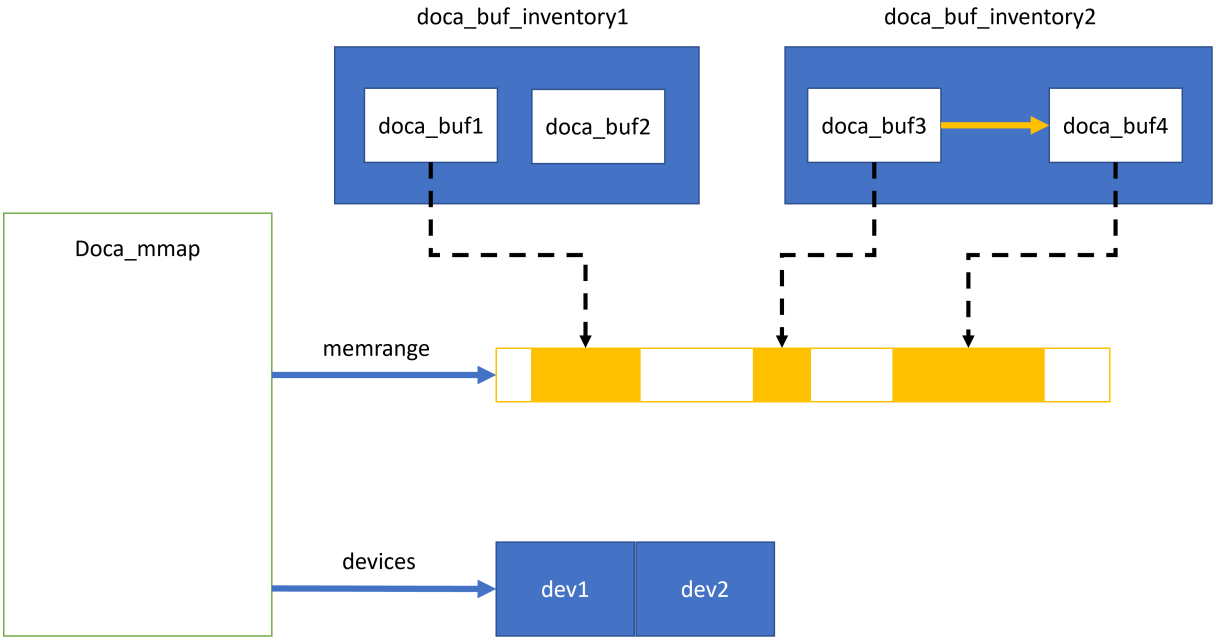
DOCA memory has the following main components:

- `doca_buf` – this is the data buffer descriptor. This is not the actual data buffer, rather, it is a descriptor that holds metadata on the "pointed" data buffer.
- `doca_mmap` – this is the data buffers pool which `doca_buf` points at. The application provides the memory as a single memory region, as well as permissions for certain devices to access it.

As the `doca_mmap` serves as the memory pool for data buffers, there is also an entity called `doca_buf_inventory` which serves as a pool of `doca_buf` with same

characteristics (see more in sections "DOCA Core Buffers" and "DOCA Core Inventories"). As all DOCA entities, memory subsystem objects are opaque and can be instantiated by DOCA SDK only.

The following diagram shows the various modules within the DOCA memory subsystem.



In the diagram, you may see two `doca_buf_inventory` s. Each `doca_buf` points to a portion of the memory buffer which is part of a `doca_mmap` . The mmap is populated with one continuous memory buffer `memrange` and is mapped to two devices, `dev1` and `dev2` .

Requirements and Considerations

- The DOCA memory subsystem mandates the usage of pools as opposed to dynamic allocation
  - Pool for `doca_buf` → `doca_buf_inventory`
  - Pool for data memory → `doca_mmap`
- The memory buffer in the mmap can be mapped to one device or more
- Devices in the mmap are restricted by access permissions defining how they can access the memory buffer
- `doca_buf` points to a specific memory buffer (or part of it) and holds the metadata for that buffer
- The internals of mapping and working with the device (e.g., memory registrations) is hidden from the application
- As best practice, the application should start the `doca_mmap` in the initialization phase as the start operation is time consuming. `doca_mmap` should not be started as part of the data path unless necessary.
- The host-mapped memory buffer can be accessed by BlueField

doca_mmap

`doca_mmap` is more than just a data buffer as it hides a lot of details (e.g., RDMA technicalities, device handling, etc.) from the application developer while giving the right level of abstraction to the software using it. `doca_mmap` is the best way to share memory between the host and BlueField so BlueField can have direct access to the host-side memory or vice versa.

DOCA SDK supports several types of mmap that help with different use cases: local mmap and mmap from export.

Local mmap

This is the basic type of mmap which maps local buffers to the local device(s).

1. The application creates the `doca_mmap`.
2. The application sets the memory range of the mmap using `doca_mmap_set_memrange`. The memory range is memory that the application allocates and manages (usually holding the pool of data sent to the device's processing units).
3. The application adds devices, granting the devices access to the memory region.
4. The application can set a custom access token for a device in the mmap, using `doca_mmap_set_export_access_token` so that mmap export operations use that token instead of an automatically generated random one.
5. The application can specify the access permission for the devices to that memory range using `doca_mmap_set_permissions`.
    - If the mmap is used only locally, then `DOCA_ACCESS_LOCAL_*` must be specified
    - If the mmap is created on the host but shared with BlueField (see step 6), then `DOCA_ACCESS_PCI_*` must be specified
    - If the mmap is created on BlueField but shared with the host (see step 6), then `DOCA_ACCESS_PCI_*` must be specified
    - If the mmap is shared with a remote RDMA target, then `DOCA_ACCESS_RDMA_*` must be specified
6. The application starts the mmap.

    From this point no more changes can be made to the mmap.

7. To share the mmap with BlueField/host or the RDMA remote target, call `doca_mmap_export_pci` or `doca_mmap_export_rdma` respectively. If appropriate access has not been provided, the export fails.

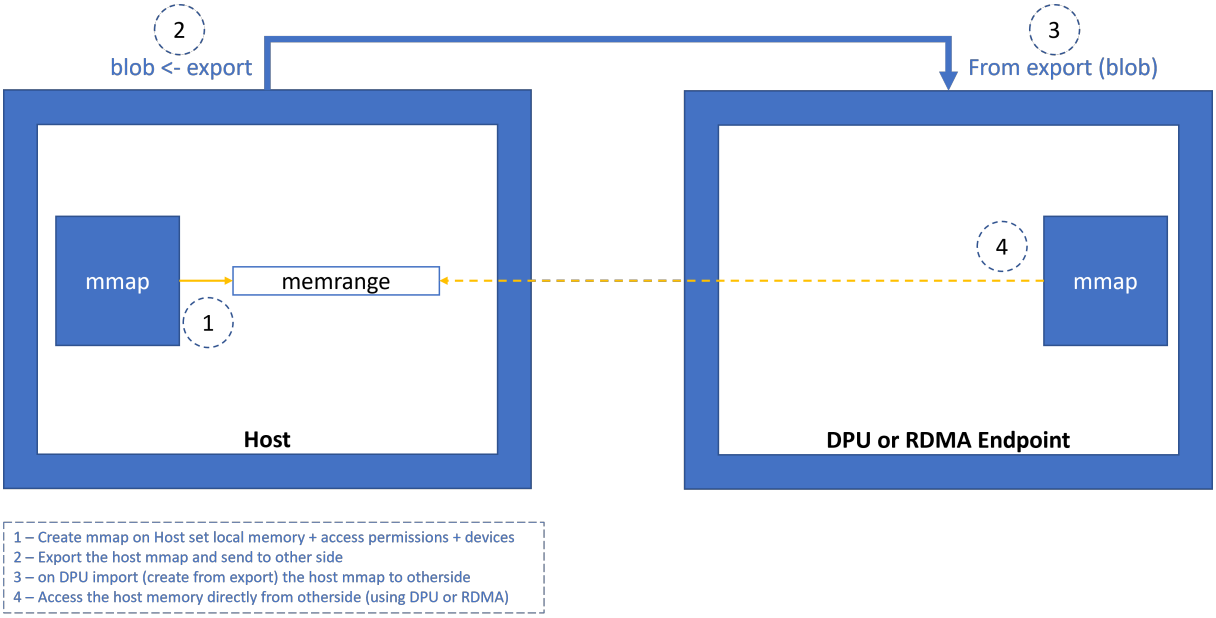
    The exported data contains sensitive information. Make sure to pass this data through a secure channel!

8. The generated blob from the previous step can be shared out of band using a socket. If shared with a BlueField, it is recommended to use the DOCA Comm Channel instead. See the DMA Copy Application Guide for the exact flow.

mmap from Export

This mmap is used to access the host memory (from BlueField) or the remote RDMA target's memory.

1. The application receives a blob from the other side. The blob contains data returned from step 6 in the former bullet.
2. The application calls `doca_mmap_create_from_export` and receives a new mmap that represents memory defined by the other side.



Now the application can create `doca_buf` to point to this imported mmap and have direct access to the other machine's memory.

BlueField can access memory exported to BlueField if the exporter is a host on the same machine. Or it can access memory exported through RDMA which can be on the same machine, a remote host, or on a remote BlueField.

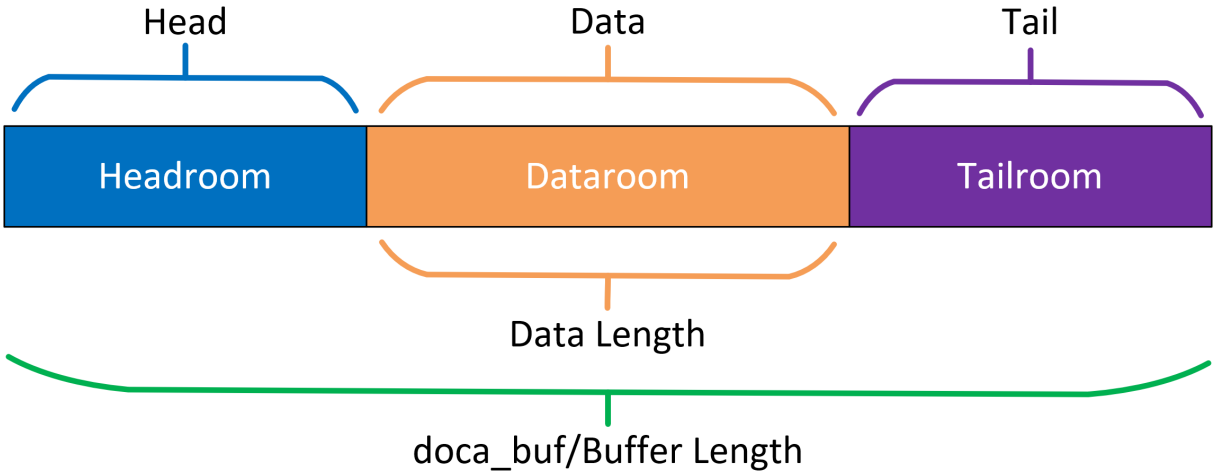
The host can only access memory exported through RDMA. This can be memory on a remote host, remote BlueField, or BlueField on same machine.

Buffers

The DOCA buffer object is used to reference memory that is accessible by BlueField hardware. The buffer can be utilized across different BlueField accelerators. The buffer may reference CPU, GPU, host, or even RDMA memory. However, this is abstracted so

once a buffer is created, it can be handled in a similar way regardless of how it got created. This section covers usage of the DOCA buffer after it is allocated.

The DOCA buffer has an address and length describing a memory region. Each buffer can also point to data within the region using the data address and data length. This distinguishes three sections of the buffer: The headroom, the dataroom, and the tailroom.



- Headroom – memory region starting from the buffer's address up to the buffer's data address
- Dataroom – memory region starting from the buffer's data address with a length indicated by the buffer's data length
- Tailroom – memory region starting from the end of the dataroom to the end of the buffer
- Buffer length – the total length of the headroom, the dataroom, and the tailroom

Buffer Considerations

- There are multiple ways to create the buffer but, once created, it behaves in the same way (see section "Inventories").
- The buffer may reference memory that is not accessible by the CPU (e.g., RDMA memory)
- The buffer is a thread-unsafe object
- The buffer can be used to represent non-continuous memory regions (scatter/gather list)
- The buffer does not own nor manage the data it references. Freeing a buffer does not affect the underlying memory.

Headroom

The headroom is considered user space. For example, this can be used by the user to hold relevant information regarding the buffer or data coupled with the data in the buffer's dataroom.

This section is ignored and remains untouched by DOCA libraries in all operations.

Dataroom

The dataroom is the content of the buffer, holding either data on which the user may want to perform different operations using DOCA libraries or the result of such operations.

Tailroom

The tailroom is considered as free writing space in the buffer by DOCA libraries (i.e., a memory region that may be written over in different operations where the buffer is used as output).

Buffer as Source

When using `doca_buf` as a source buffer, the source data is considered as the data section only (the dataroom).

Buffer as Destination

When using `doca_buf` as a destination buffer, data is written to the tailroom (i.e., appended after existing data, if any).

When DOCA libraries append data to the buffer, the data length is increased accordingly.

Scatter/Gather List

To execute operations on non-continuous memory regions, it is possible to create a buffer list. The list would be represented by a single `doca_buf` which represents the head of the list.

To create a list of buffers, the user must first allocate each buffer individually and then chain them. Once they are chained, they can be unchained as well:

- The chaining operation, `doca_buf_chain_list()`, receives two lists (heads) and appends the second list to the end of the first list
- The unchaining operation, `doca_buf_unchain_list()`, receives the list (head) and an element in the list, and separates them
- Once the list is created, it can be traversed using `doca_buf_get_next_in_list()`. `NULL` is returned once the last element is reached.
- The chaining operation, `doca_buf_chain_list_tail()`, appends a list head to a list tail. The application is responsible to maintain the list tail.

Passing the list to another library is same as passing a single buffer; the application sends the head of the list. DOCA libraries that support this feature can then treat the memory regions that comprise the list as one contiguous.

When using the buffer list as a source, the data of each buffer (in the dataroom) is gathered and used as continuous data for the given operation.

When using the buffer list as destination, data is scattered in the tailroom of the buffers in the list until it is all written (some buffers may not be written to).

Buffer Use Cases

The DOCA buffer is widely used by the DOCA acceleration libraries (e.g., DMA, compress, SHA). In these instances, the buffer can be provided as a source or as a destination.

Buffer use-case considerations:

- If the application wishes to use a linked list buffer and concatenate several `doca_buf`s to a scatter/gather list, the application is expected to ensure the library indeed supports a linked list buffer. For example, to check linked-list support for DMA memcpy task, the application may call `doca_dma_cap_task_memcpy_get_max_buf_list_len()`.
- Operations made on the buffer's data are not atomic unless stated otherwise
- Once a buffer has been passed to the library as part of the task, ownership of the buffer moves to the library until that task is complete

  > ⚠ When using `doca_buf` as an input to some processing library (e.g., `doca_dma`), `doca_buf` must remain valid and unmodified until processing is complete.

- Writing to an in-flight buffer may result in anomalous behavior. Similarly, there are no guarantees for data validity when reading from an in-flight buffer.

Inventories

The inventory is the object responsible for allocating DOCA buffers. The most basic inventory allows allocations to be done without having to allocate any system memory. Other inventories involve enforcing that buffer addresses do not overlap.

Inventory Considerations

- All inventories adhere to zero allocation after start.
- Allocation of a DOCA buffer requires a data source and an inventory.
  - The data source defines where the data resides, what can access it, and with what permissions.
  - The data source must be created by the application. For creation of mmaps, see `doca_mmap`.
- The inventory describes the allocation pattern of the buffers, such as, random access or pool, variable-size or fixed-size buffers, and continuous or non-continuous memory.
- Some inventories require providing the data source, `doca_mmap`, when allocating the buffers, others require it on creation of the inventory.
- All inventory types are thread-unsafe.

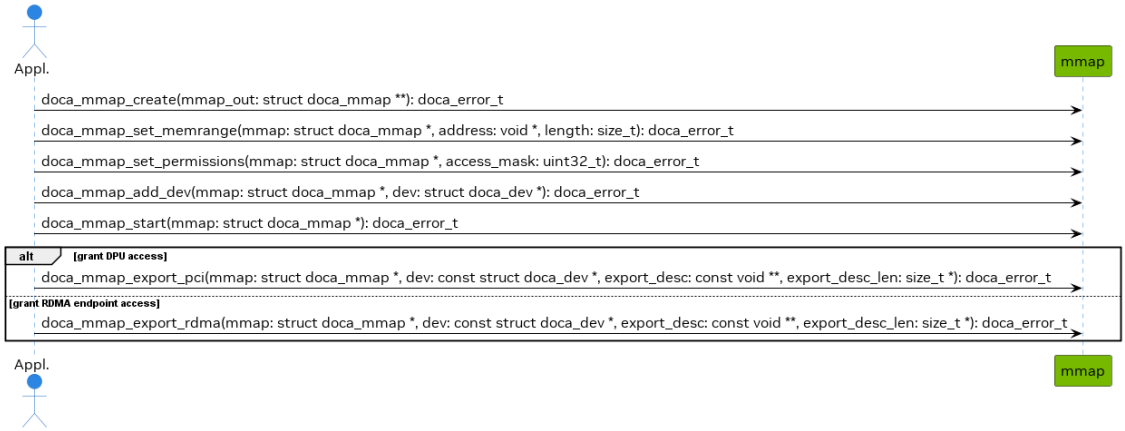
Inventory Types

Inventory Type	Characteristics	When to Use	Notes
`doca_buf_inventory`	Multiple mmaps, flexible address, flexible buffer size.	When multiple sizes or mmaps are used.	Most common use case.
`doca_buf_array`	Single mmap, fixed buffer size. User receives an array of pointers to DOCA buffers. In case of DPA, mmap and buffer size can be unconfigured and later can be set from the DPA.	Use for creating DOCA buffers on GPU or DPA.	`doca_buf_arr` can be configured on the CPU and created on the GPU or DPA
`doca_bufpool`	Single mmap, fixed buffer size, address not controlled by the user.	Use as a pool of buffers of the same characteristics when buffer address is not important.	Slightly faster than `doca_buf_inventory`.

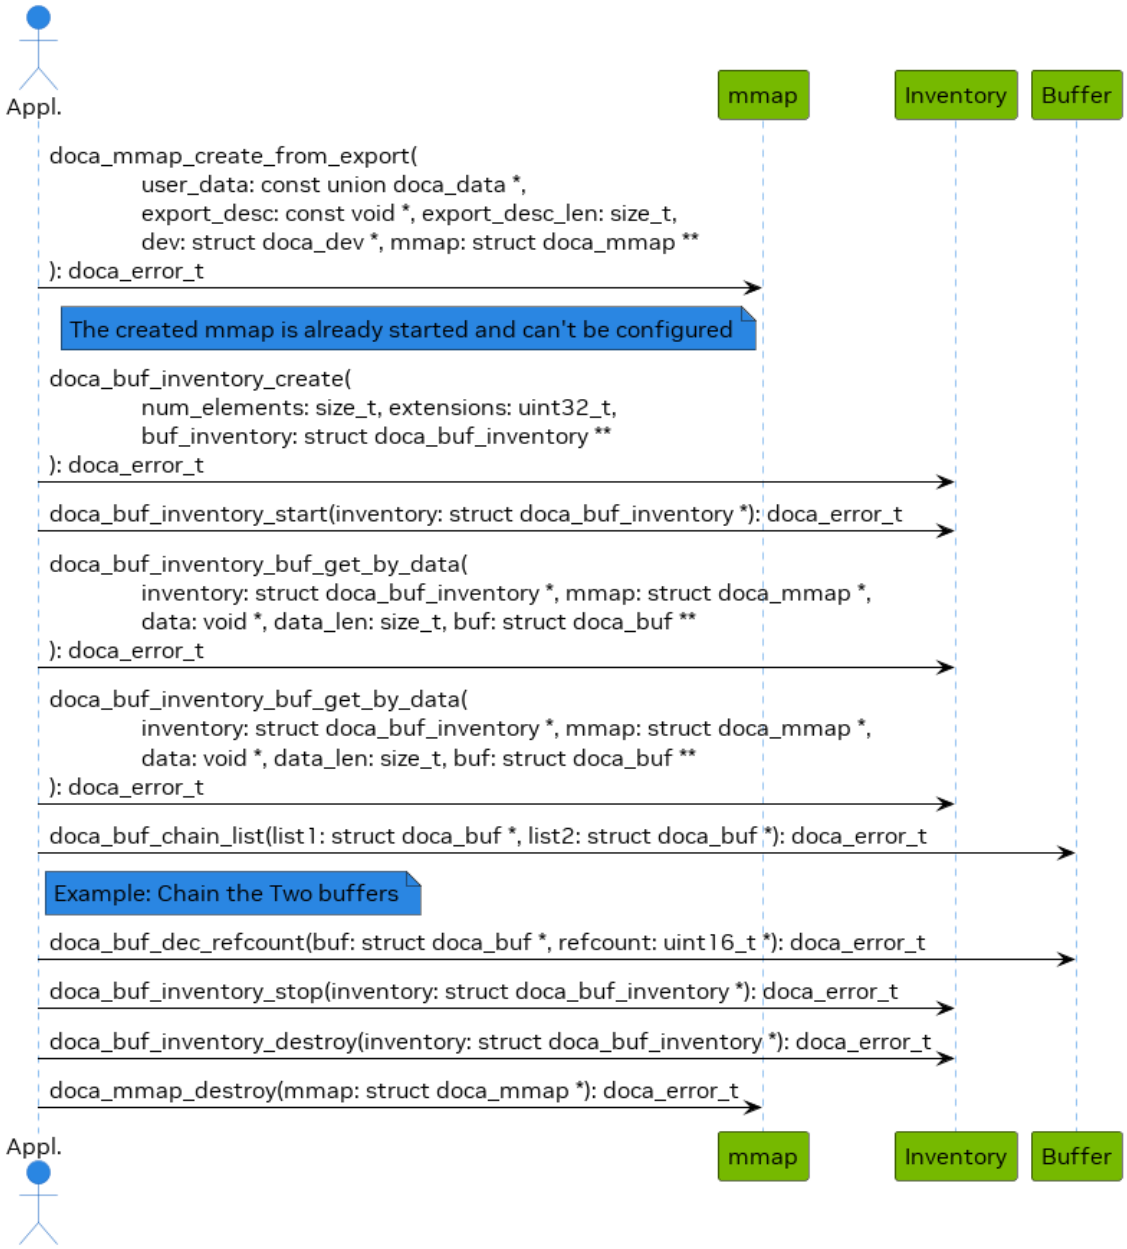
Example Flow

The following is a simplified example of the steps expected for exporting the host mmap to BlueField to be used by DOCA for direct access to the host memory (e.g., for DMA):

1. Create mmap on the host (see section "Expected Flow" for information on how to choose the `doca_dev` to add to mmap if exporting to BlueField). This example adds a single `doca_dev` to the mmap and exports it so the BlueField/RDMA endpoint can use it.



2. Import to the BlueField/RDMA endpoint (e.g., use the mmap descriptor output parameter as input to `doca_mmap_create_from_export`).



5.4.1.1.4.4 DOCA Execution Model

The execution model is based on hardware processing on data and application threads. DOCA does not create an internal thread for processing data.

The workload is made up of tasks and events. Some tasks transform source data to destination data. The basic transformation is a DMA operation on the data which simply copies data from one memory location to another. Other operations allow users to receive packets from the network or involve calculating the SHA value of the source data and writing it to the destination.

For instance, a transform workload can be broken into three steps:

1. Read source data (`doca_buf` see memory subsystem).
2. Apply an operation on the read data (handled by a dedicated hardware accelerator).
3. Write the result of the operation to the destination (`doca_buf` see memory subsystem).

Each such operation is referred to as a task (`doca_task`).

Tasks describe operations that an application would like to submit to DOCA (hardware or BlueField). To do so, the application requires a means of communicating with the hardware/BlueField. This is where the `doca_pe` comes into play. The progress engine (PE) is a per-thread object used to queue tasks to offload to DOCA and eventually receive their completion status.

`doca_pe` introduces three main operations:

1. Submission of tasks.
2. Checking progress/status of submitted tasks.
3. Receiving a notification on task completion (in the form of a callback).

A workload can be split into many different tasks that can be executed on different threads; each thread represented by a different PE. Each task must be associated to some context, where the context defines the type of task to be done.

A context can be obtained from some libraries within the DOCA SDK. For example, to submit DMA tasks, a DMA context can be acquired from `doca_dma.h` , whereas SHA context can be obtained using `doca_sha.h` . Each such context may allow submission of several task types.

A task is considered asynchronous in that once an application submits a task, the DOCA execution engine (hardware or BlueField) would start processing it, and the application can continue to do some other processing until the hardware finishes. To keep track of which task has finished, there are two modes of operation: polling mode and event-driven mode.

Requirements and Considerations

- The task submission/execution flow/API is optimized for performance (latency)
- DOCA does not manage internal (operating system) threads. Rather, progress is managed by application resources (calling DOCA API in polling mode or waiting on DOCA notification in event-driven mode).
- The basic object for executing the task is a `doca_task` . Each task is allocated from a specific DOCA library context.
- `doca_pe` represents a logical thread of execution for the application and tasks submitted to the progress engine (PE)

> ⚠ PE is not thread safe and it is expected that each PE is managed by a single application thread (to submit a task and manage the PE).

- Execution-related elements (e.g., `doca_pe`, `doca_ctx`, `doca_task`) are opaque and the application performs minimal initialization/configuration before using these elements
- A task submitted to PE can fail (even after the submission succeeds). In some cases, it is possible to recover from the error. In other cases, the only option is to reinitialize the relevant objects.
- PE does not guarantee order (i.e., tasks submitted in certain order might finish out-of-order). If the application requires order, it must impose it (e.g., submit a dependent task once the previous task is done).
- A PE can either work in polling mode or event-driven mode, but not in both at same time
- All DOCA contexts support polling mode (i.e., can be added to a PE that supports polling mode)

DOCA Context

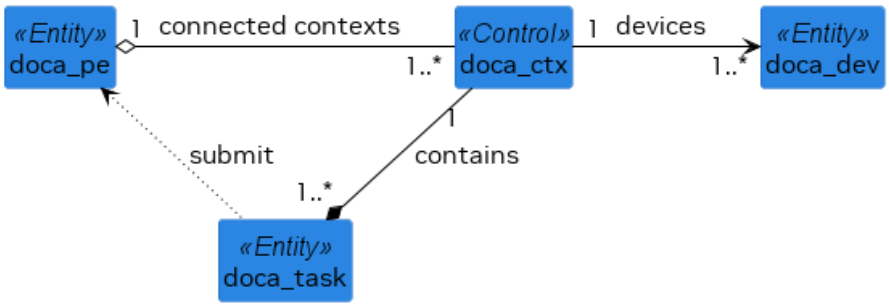
DOCA Context (`struct doca_ctx`) defines and provides (implements) task/event handling. A context is an instance of a specific DOCA library (i.e., when the library provides a DOCA Context, its functionality is defined by the list of tasks/events it can handle). When more than one type of task is supported by the context, it means that the supported task types have a certain degree of similarity to implement and utilize common functionality.

The following list defines the relationship between task contexts:

- Each context utilizes at least one DOCA Device functionality/accelerated processing capabilities
- For each task type there is one and only context type supporting it
- A context virtually contains an inventory per supported task type
- A context virtually defines all parameters of processing/execution per task type (e.g., size of inventory, device to accelerate processing)

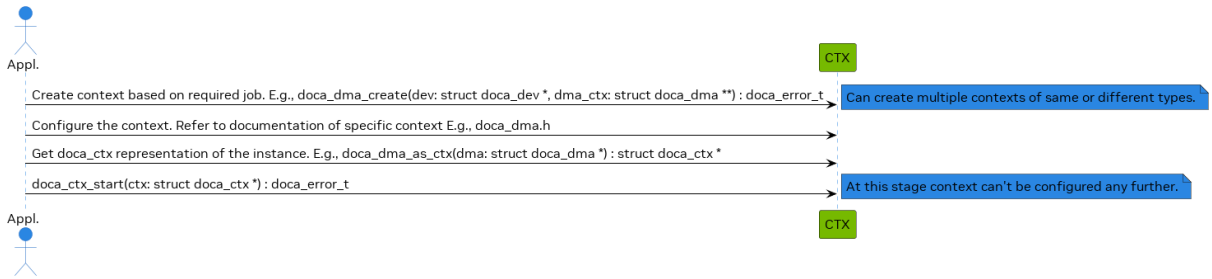
Each context needs an instance of progress engine (PE) as a runtime for its tasks (i.e., a context must be associated with a PE to execute tasks).

The following diagram shows the high-level (domain model) relations between various DOCA Core entities.



1. `doca_task` is associated to a relevant `doca_ctx` that executes the task (with the help of the relevant `doca_dev`).
2. `doca_task`, after it is initialized, is submitted to `doca_pe` for execution.
3. `doca_ctx`s are connected to the `doca_pe`. Once a `doca_task` is queued to `doca_pe`, it is executed by the `doca_ctx` that is associated with that task in this PE.

The following diagram describes the initialization sequence of a context:



After the context is started, it can be used to enable the submission of tasks to a PE based on the types of tasks that the context supports. See section "DOCA Progress Engine" for more information.

> ⚠ Context is a thread-unsafe object which can be connected to a single PE only.

Configuration Phase

A DOCA context must be configured before attempting to start it using `doca_ctx_start()`. Some configurations are mandatory (e.g., providing `doca_dev`) while others are not.

- Configurations can be useful to allow certain tasks/events, to enable features which are disabled by default, and to optimize performance depending on a specific workload.
- Configurations are provided using setter functions. Refer to context documentation for a list of mandatory and optional configurations and their corresponding APIs.
- Configurations are provided after creating the context and before starting it. Once the context is started, it can no longer be configured unless it is stopped again.

Examples of common configurations:

- Providing a device – usually done as part of the create API
- Enabling tasks or registering to events – all tasks are disabled by default

Execution Phase

Once context configuration is complete, the context can be used to execute tasks. The context executes the tasks by offloading the workload to hardware, while software polls the tasks (i.e., waits) until they are complete.

In this phase, an application uses the context to allocate and submit asynchronous tasks, and then polls tasks (waits) until completion.

The application must build an event loop to poll the tasks (wait), utilizing one of the following modes:

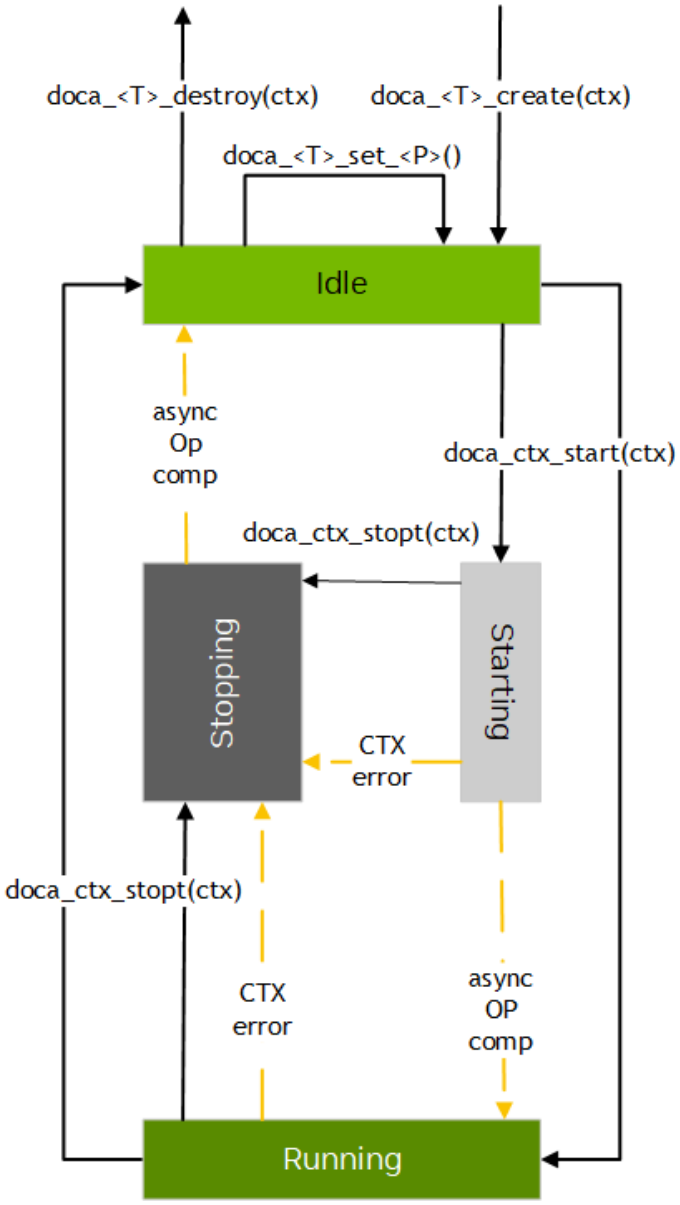
- Polling Mode
- Notification-driven Mode

In this phase, the context and all core objects perform zero allocations by utilizing memory pools. It is recommended that the application utilizes same approach for its own logic.

State Machine

State	Description
Idle	• 0 in-flight tasks • On init (right after `doca_<T>_create(ctx)`): All configuration APIs enabled • On reconf (on transition from stopping state): Some configuration APIs enabled
Starting	This state is mandatory for CTXs where transition to running state is conditioned by one or more async op completions/external events. For example, when a client connects to comm channel, it enters running state. Waiting for state change can be terminated by a voluntary (user) `doca_ctx_stop()` call or involuntary context state change due to internal error.
Running	• Task allocation/submission enabled (disabled in all other states) • All configuration APIs are disabled
Stopping	• Preparation before stopped state • Clean all in-flight tasks that may not complete in near future • Procedures relying on external entity actions should be terminated by CTX logic

The following diagram describes DOCA Context state transitions:



Internal Error

DOCA Context states can encounter internal errors at any time. If the state is starting or running, an internal error can cause an involuntary transition to stopping state.

For instance, an involuntary transition from running to stopping can happen when a task execution fails. This results in a completion with error for the failed task and all subsequent task completions.

After stopping, the state may become idle. However, `doca_ctx_start()` may fail if there is a configuration issue or if an error event prevented proper transition to starting or running state.

DOCA Task

A task is a unit of (functional/processing) workload offload-able to hardware. Most tasks utilize NVIDIA® BlueField® and NVIDIA® ConnectX® hardware to provide accelerated processing of the workload defined by the task. Tasks are asynchronous operations (e.g., tasks submitted for processing via non-blocking `doca_task_submit()` API).

Upon task completion, the preset completion callback is executed in context of `doca_pe_progress()` call. The completion callback is a basic/generic property of the task, similar to user data. Most tasks are IO operations executed/accelerated by NVIDIA device hardware.

Task Properties

Task properties share generic properties which are common to all task types and type-specific properties. Since task structure is opaque (i.e., its content not exposed to the user), the access to task properties provided by set/get APIs.

The following are generic task properties:

- Setting completion callback – it has separate callbacks for successful completion and completion with failure.
- Getting/setting user data – used in completion callback as some structure associated with specific task object.
- Getting task status – intended to retrieve error code on completion with failure.

For each task there is only one owner: a context object. The `doca_task_get_ctx()` API can be used to get the generic context object.

The following are generic task APIs:

- Allocating and freeing from CTX (internal/virtual) inventory
- Configuring via setters (or init API)
- Submit-able (i.e., implements `doca_task_submit(task)`)

Upon completion, there is a set of getters to access the results of the task execution.

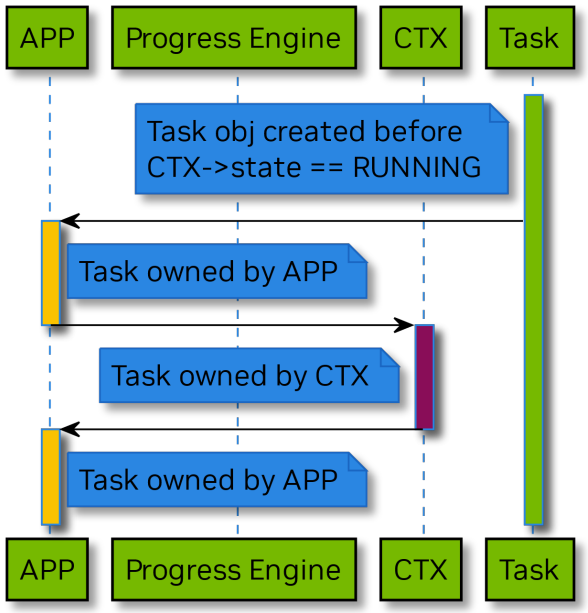
Task Lifecycle

This section describes the lifecycle of a DOCA Task, which is defined by a clear ownership model. From an application's perspective, a DOCA Context (CTX) provides a "virtual task inventory":

The entire task lifecycle is bound by the state of the DOCA Context:

- Begins: An application can only allocate a task when the owning CTX enters the `RUNNING` state.
- Ends: The application can no longer allocate tasks once the CTX leaves the `RUNNING` state (e.g., enters the `STOPPED` state).

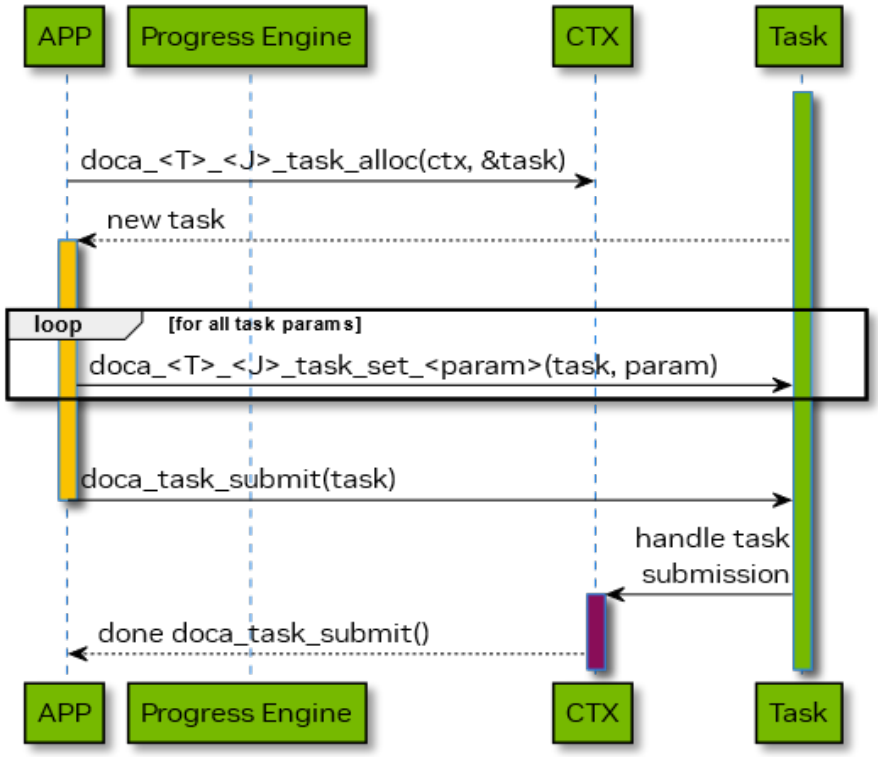
The core concept is that ownership of a task object is passed between the Application (APP) and the Context (CTX).



Phase 1: Task Allocation and Submission

This phase covers acquiring a task, setting its parameters, and submitting it for processing.

1. Allocation (APP Gains Ownership): The application requests a task from the context's inventory by calling a function like `doca_<T>_<J>_task_alloc(ctx, &task)`. Upon successful allocation, the task is owned by the application.
2. Configuration (APP Maintains Ownership): The application sets the task's parameters using functions templated as `doca_<T>_<J>_task_set_<param>(task, param)`. After each "set" call, the application retains ownership of the task object.
3. Submission (CTX Gains Ownership): Once all parameters are set, the application calls `doca_task_submit(task)`. This action passes ownership of the task object to the CTX for processing.

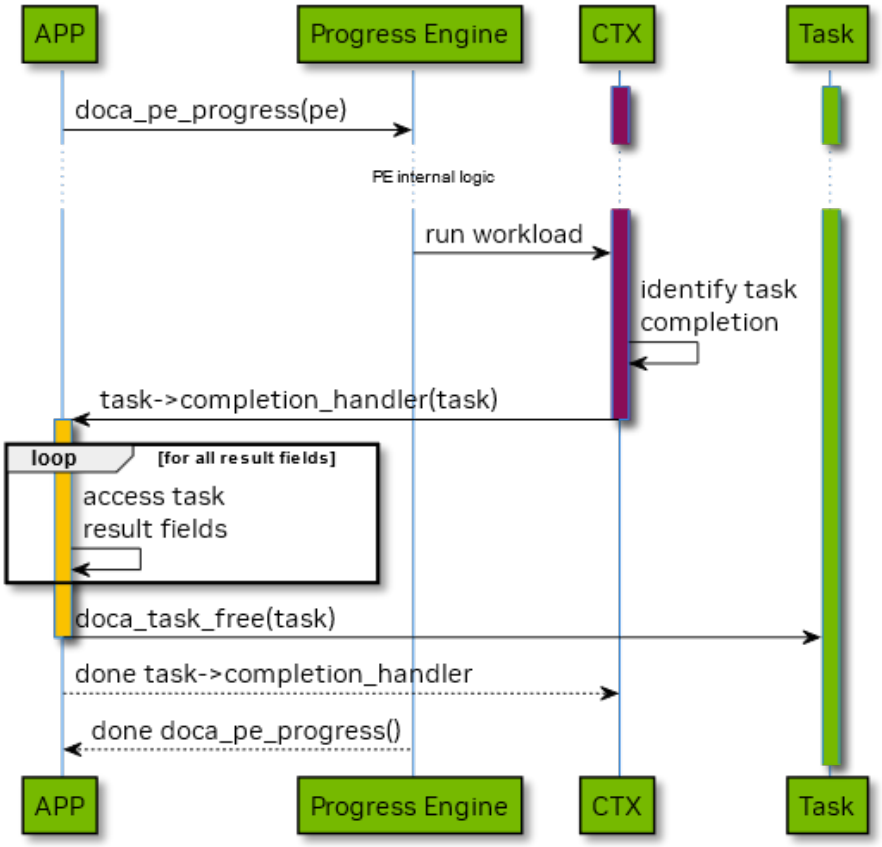


Phase 2: Task Processing and Completion

Once a task is submitted, the Progress Engine (PE) is responsible for its execution and completion.

1. Processing (Driven by APP): The task is processed by the hardware or software backend. The application must periodically call `doca_pe_progress(pe)` to drive this process. This function runs the PE's internal logic , executes the workload , and identifies completed tasks.
2. Completion (APP Regains Ownership): When the PE identifies a completed task, it invokes the application-provided completion handler (e.g., `task->completion_handler(task)`). As soon as this handler is called, ownership of the task is passed back to the application.

Inside the completion handler, the application can safely access the task's result fields.



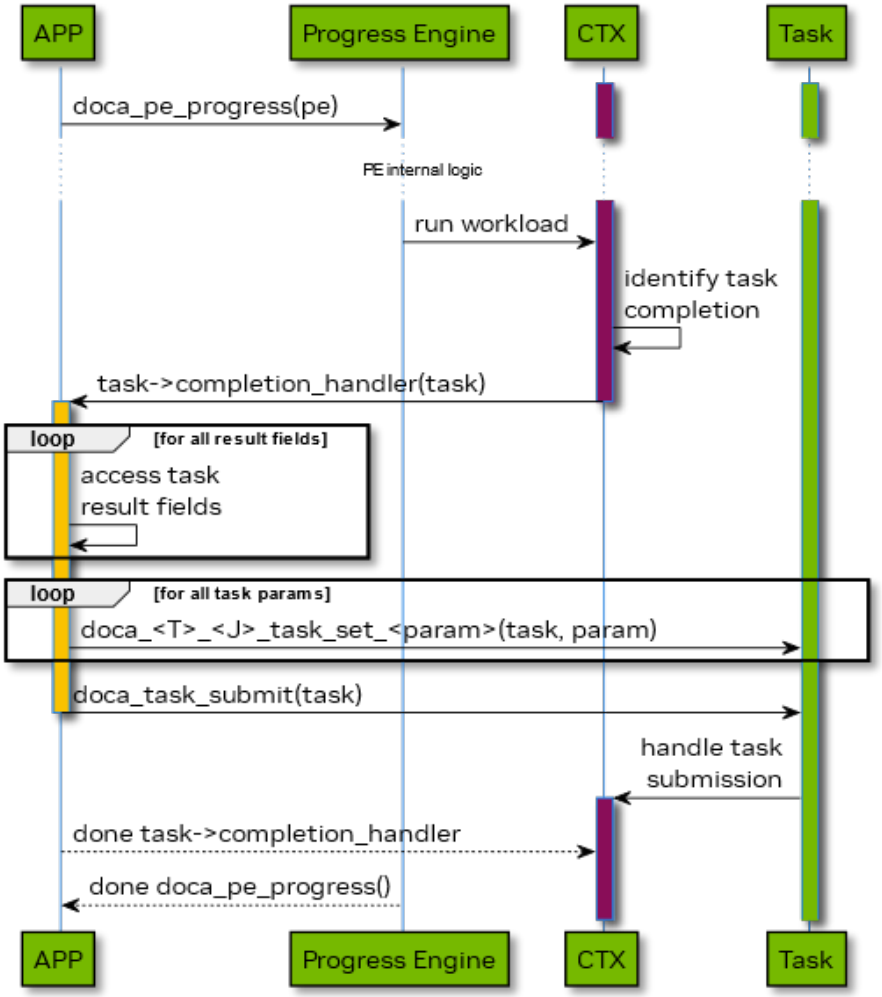
Phase 3: Post-Completion (Free or Re-submit)

After a task is completed and the application regains ownership, it has two choices inside the completion handler: free the task or re-submit it.

Option A: Freeing the Task

If the task is no longer needed, the application calls `doca_task_free(task)`. This action:

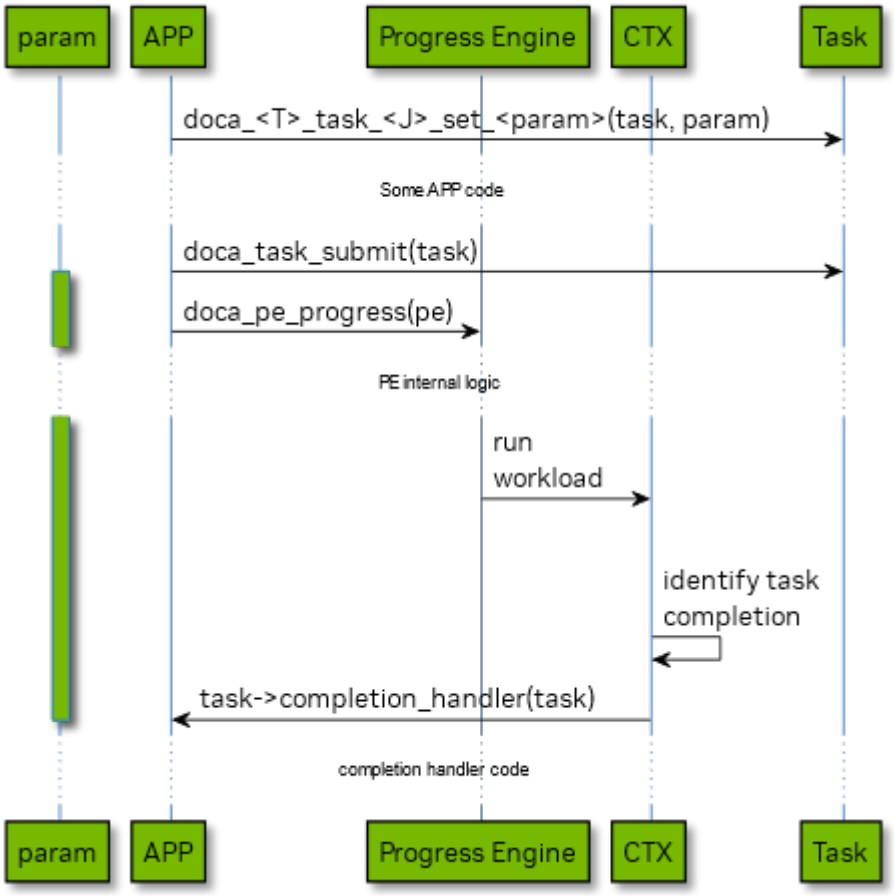
- Passes ownership of the task back to the CTX.
- Returns the task to the context's virtual inventory as an uninitialized, pre-allocated object, ready to be allocated again.



Option B: Re-submitting the Task (Task Chaining)

Instead of freeing the task, the application can immediately re-use it. This is a common pattern for high-performance "task chaining." From within the completion handler, the application can:

1. Access the task's results.
2. Set new parameters for the *next* operation (e.g., `doca_<T>_<J>_task_set_<param>(task, param)`).
3. Call `doca_task_submit(task)` again.



Note on Task Parameter Lifecycle

The lifecycle of a task's *parameters* (e.g., data buffers) is as critical as the task object itself.

- When the application calls `doca_task_submit(task)`, ownership of all task arguments (parameters) is passed to the DOCA Context.
- Ownership of these arguments is passed back to the application only when the task's `completion_handler` is invoked.

The application must not modify, destroy, or free any task-related arguments or objects while they are owned by the DOCA Context (i.e., after submission and before completion). Furthermore, task results are only valid within the scope of the completion callback. They should be considered invalidated after exiting the handler or after calling `doca_task_free()` or any `..._task_set_<param>()` function.

DOCA Progress Engine

The progress engine (PE) enables asynchronous processing and handling of multiple tasks and events of different types in a single-threaded execution environment. It is an

event loop for all context-based DOCA libraries, with I/O completion being the most common event type.

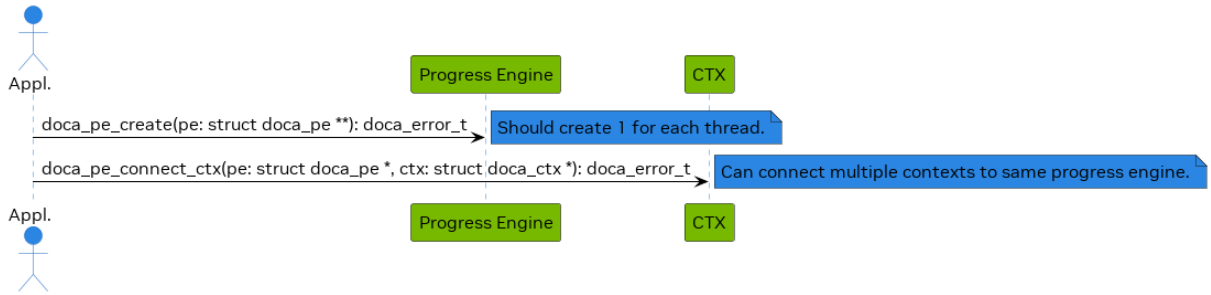
PE is designed to be thread unsafe (i.e., it can only be used in one thread at a time) but a single OS thread can use multiple PEs. The user can assign different priorities to different contexts by adding them to different PEs and adjusting the polling frequency for each PE accordingly. Another way to view the PE is as a queue of workload units that are scheduled for execution.

There are no explicit APIs to add and/or schedule a workload to/on a PE but a workload can be added by:

- Adding a DOCA context to PE
- Registering a DOCA event to probe (by the PE) and executing the associated handler if the probe is positive

PE is responsible for scheduling workloads (i.e., picking the next workload to execute). The order of workload execution is independent of task submission order, event registration order, or order of context associations with a given PE object. Multiple task completion callbacks may be executed in an order different from the order of related task submissions.

The following diagram describes the initialization flow of the PE:



After a PE is created and connected to contexts, it can start progressing tasks which are submitted to the contexts. Refer to context documentation to find details such as what tasks can be submitted using the context.

Note that the PE can be connected to multiple contexts. Such contexts can be of the same type or of different types. This allows submitting different task types to the same PE and waiting for any of them to finish from the same place/thread.

After initializing the PE, an application can define an event loop using one of these modes:

- Polling mode
- Blocking (notification-driven) mode

PE as Event Loop Mode of Operation

All completion handlers for both tasks and events are executed in the context of `doca_pe_progress()`. `doca_pe_progress()` loops for every workload (i.e., for each workload unit) scheduled for execution:

Run the selected workload unit. For the following cases:

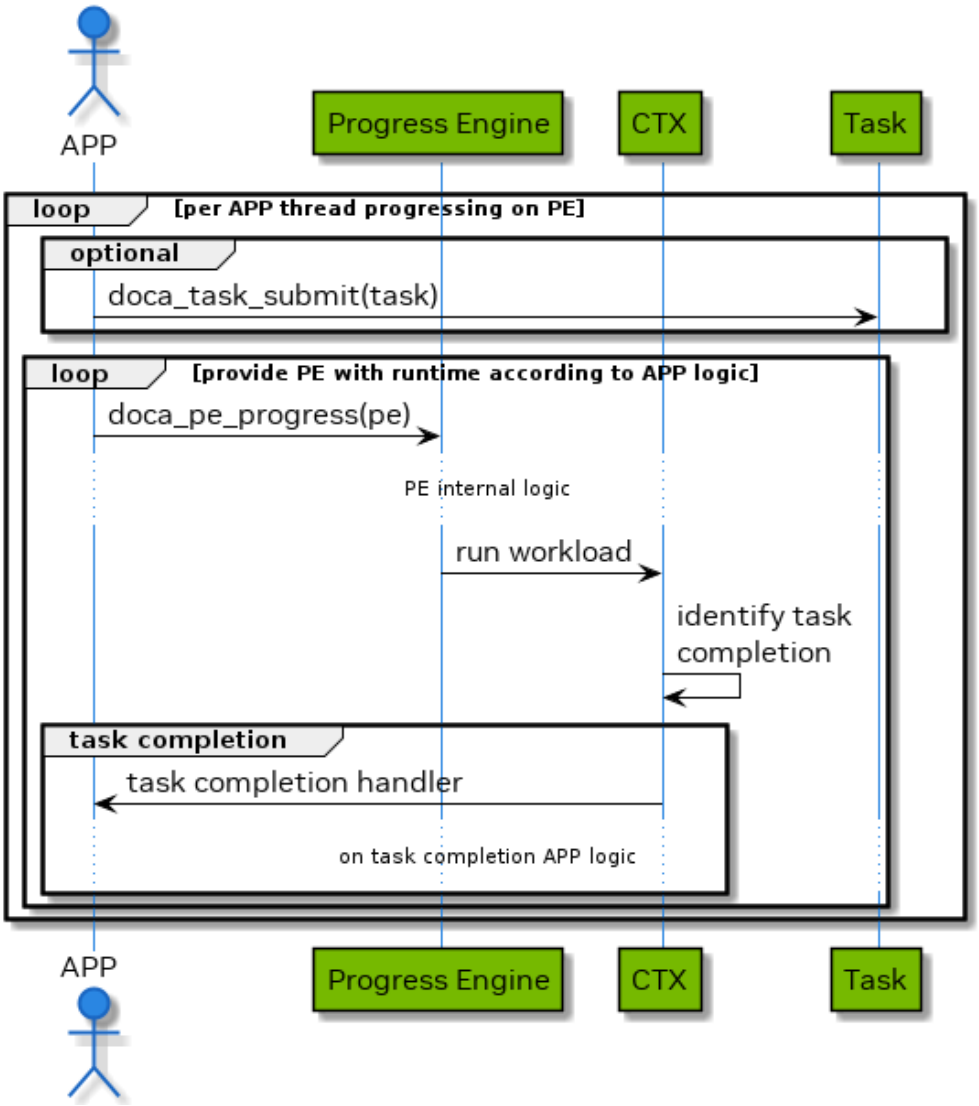
- Task completion, execute associated handler and break the loop and return status `made some progress`
- Positive probe of event, execute associated handler and break the loop and return status `made some progress`
- Considerable progress is made to contribute to future task completion or positive event probe, break the loop and return status `made some progress`

Otherwise, reach the end of the loop and return status `no progress`.

Polling Mode

In this mode, the application submits a task and then does busy-wait to find out when the task has completed.

The following diagram demonstrates this sequence:



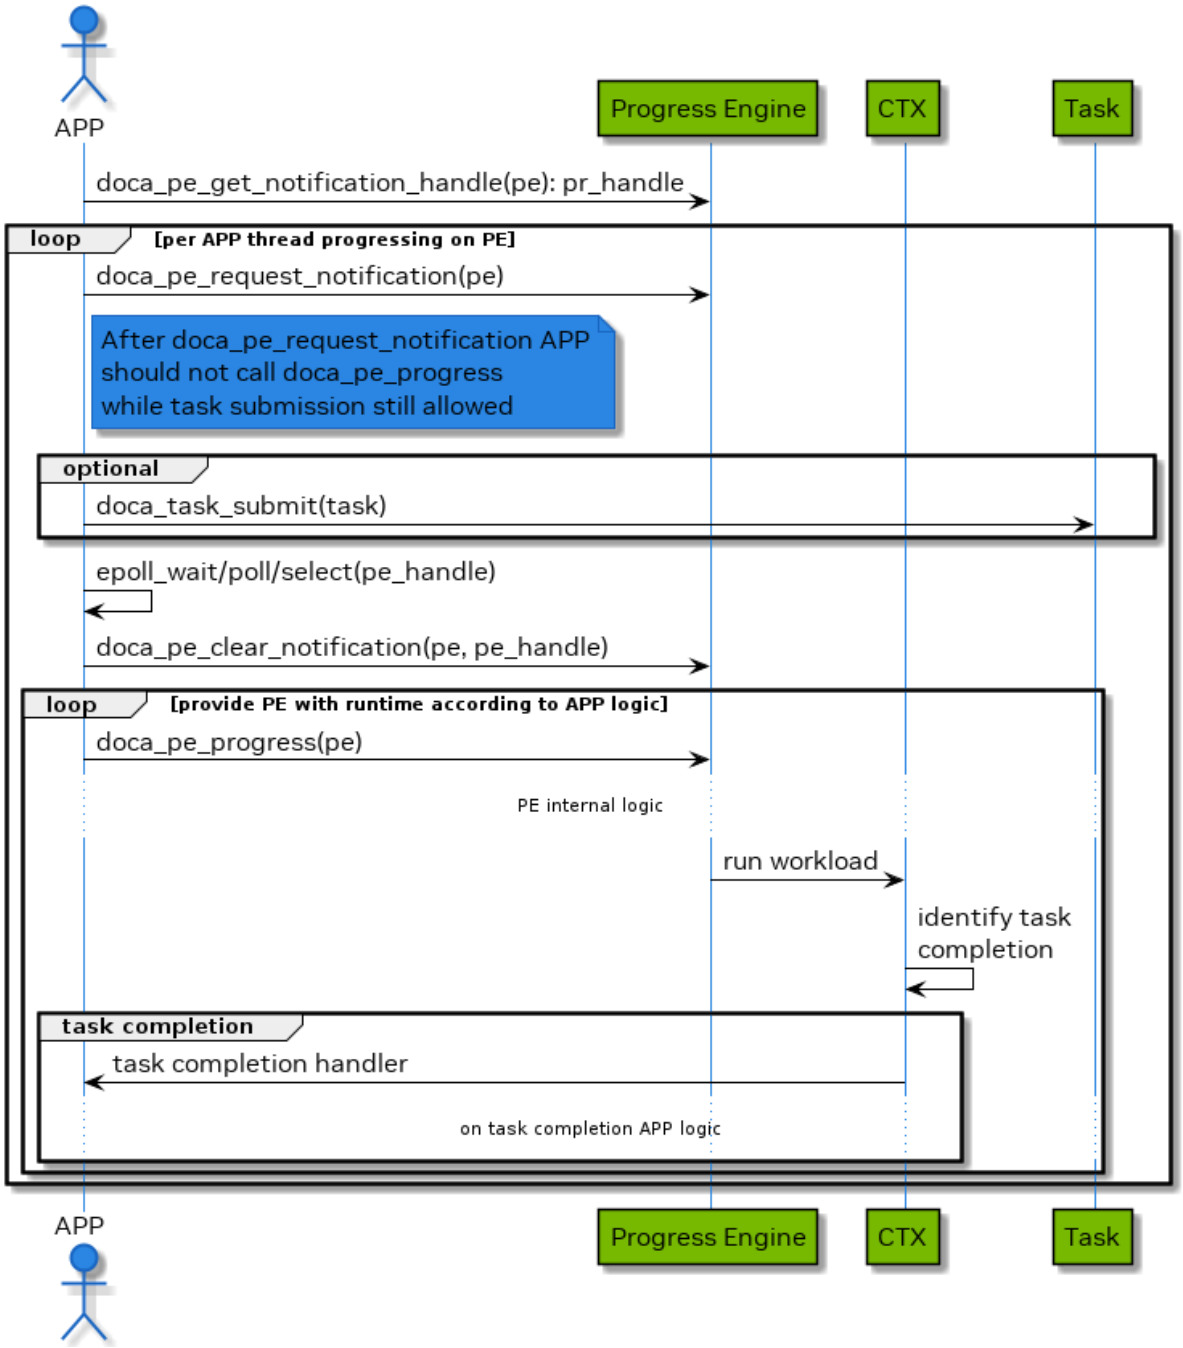
1. The application submits all tasks (one or more) and tracks the number of task completions to know if all tasks are done.
2. The application waits for a task to complete by consecutive polls on `doca_pe_progress()`.
    a. If `doca_pe_progress()` returns 1, it means progress is being made (i.e., some task completed or some event handled).
    b. Each time a task is completed or an event is handled, its preset completion or event handling callback is executed accordingly.
    c. If a task is completed with an error, preset task completion with error callback is executed (see section "Error Handling").
3. The application may add code to completion callbacks or event handlers for tracking the amount of completed and pending workloads.

⚠ In this mode, the application is always using the CPU even when it is doing nothing (busy-wait).

Blocking Mode - Notification Driven

In this mode, the application submits a task and then waits for a notification to be received before querying the status.

The following diagram demonstrates this sequence:



1. The application gets a notification handle from the `doca_pe` representing a Linux file descriptor which is used to signal the application that some work has finished.
2. The application then arms the PE with `doca_pe_request_notification()`.

> ⚠ This must be done every time an application is interested in receiving a notification from the PE.

> ⚠ After `doca_pe_request_notification()`, no calls to `doca_pe_progress()` are allowed. In other words, `doca_pe_request_notification()` should be followed by `doca_pe_clear_notification` before any calls to `doca_pe_progress()`.

3. The application submits a task.
4. The application waits (e.g., Linux epoll/select) for a signal to be received on the `pe-fd`.
5. The application clears the notifications received, notifying the PE that a signal has been received and allowing it to perform notification handling.
6. The application attempts to handle received notifications via (multiple) calls to `doca_pe_progress()`.

   > ⚠ There is no guarantee that the call to `doca_pe_progress()` would execute any task completion/event handler, but the PE can continue the operation.

7. The application handles its internal state changes caused by task completions and event handlers called in the previous step.
8. Repeat steps 2-7 until all tasks are completed and all expected events are handled.

Progress Engine versus Epoll

The epoll mechanism in Linux and the DOCA PE handles high concurrency in event-driven architectures. Epoll, like a post office, tracks "mailboxes" (file descriptors) and notifies the "postman" (the `epoll_wait` function) when a "letter" (event) arrives. DOCA PE, like a restaurant, uses a single "waiter" to handle "orders" (workload units) from "customers" (DOCA contexts). When an order is ready, it is placed on a "tray" (task completion handler/event handler execution) and delivered in the order received. Both systems efficiently manage resources while waiting for events or tasks to complete.

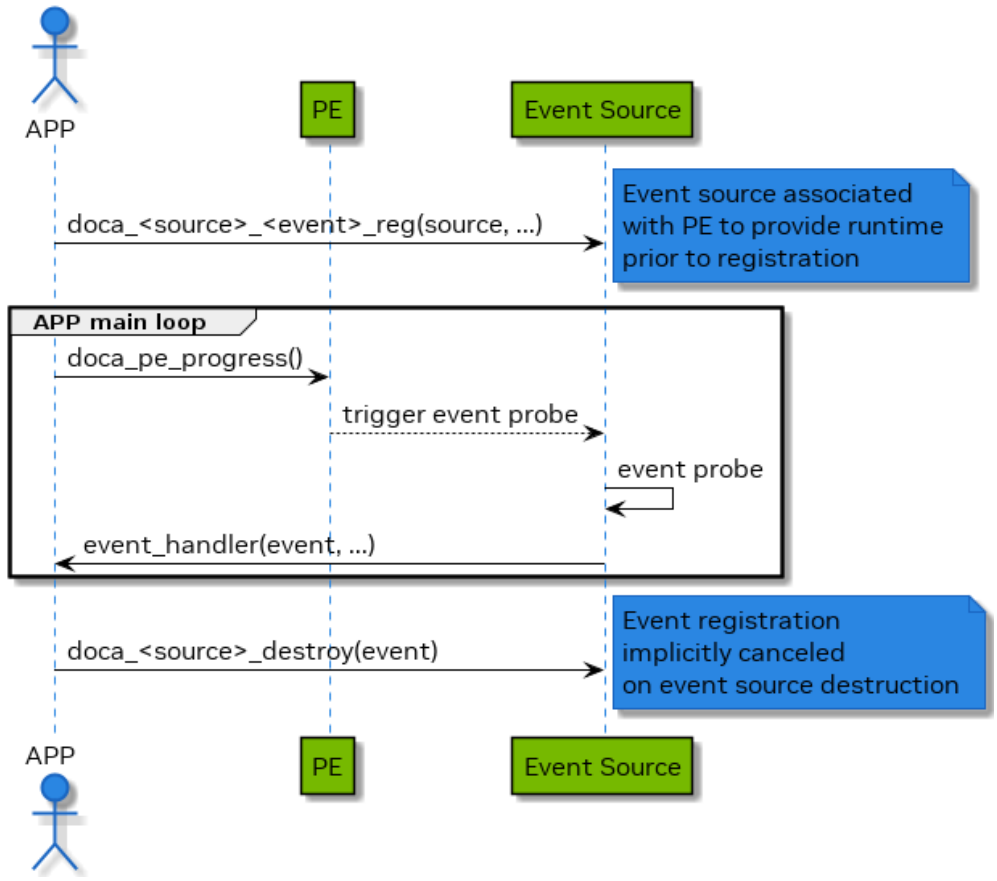
DOCA Event

An event is a type of occurrence that can be detected or verified by the DOCA software, which can then trigger a handler (a callback function) to perform an action. Events are associated with a specific source object, which is the entity whose state or attribute change defines the event's occurrence. For example, a context state change event is caused by the change of state of a context object.

To register an event, the user must call the `doca_<event_type>_reg(pe, ...)` function, passing a pointer to the user handler function and an opaque argument for

the handler. The user must also associate the event handler with a PE, which is responsible for running the workloads that involve event detection and handler execution.

Once an event is registered, it is periodically checked by the `doca_pe_progress()` function, which runs in the same execution context as the PE to which the event is bound. If the event condition is met, the handler function is invoked. Events are not thread-safe objects and should only be accessed by the PE to which they are bound.

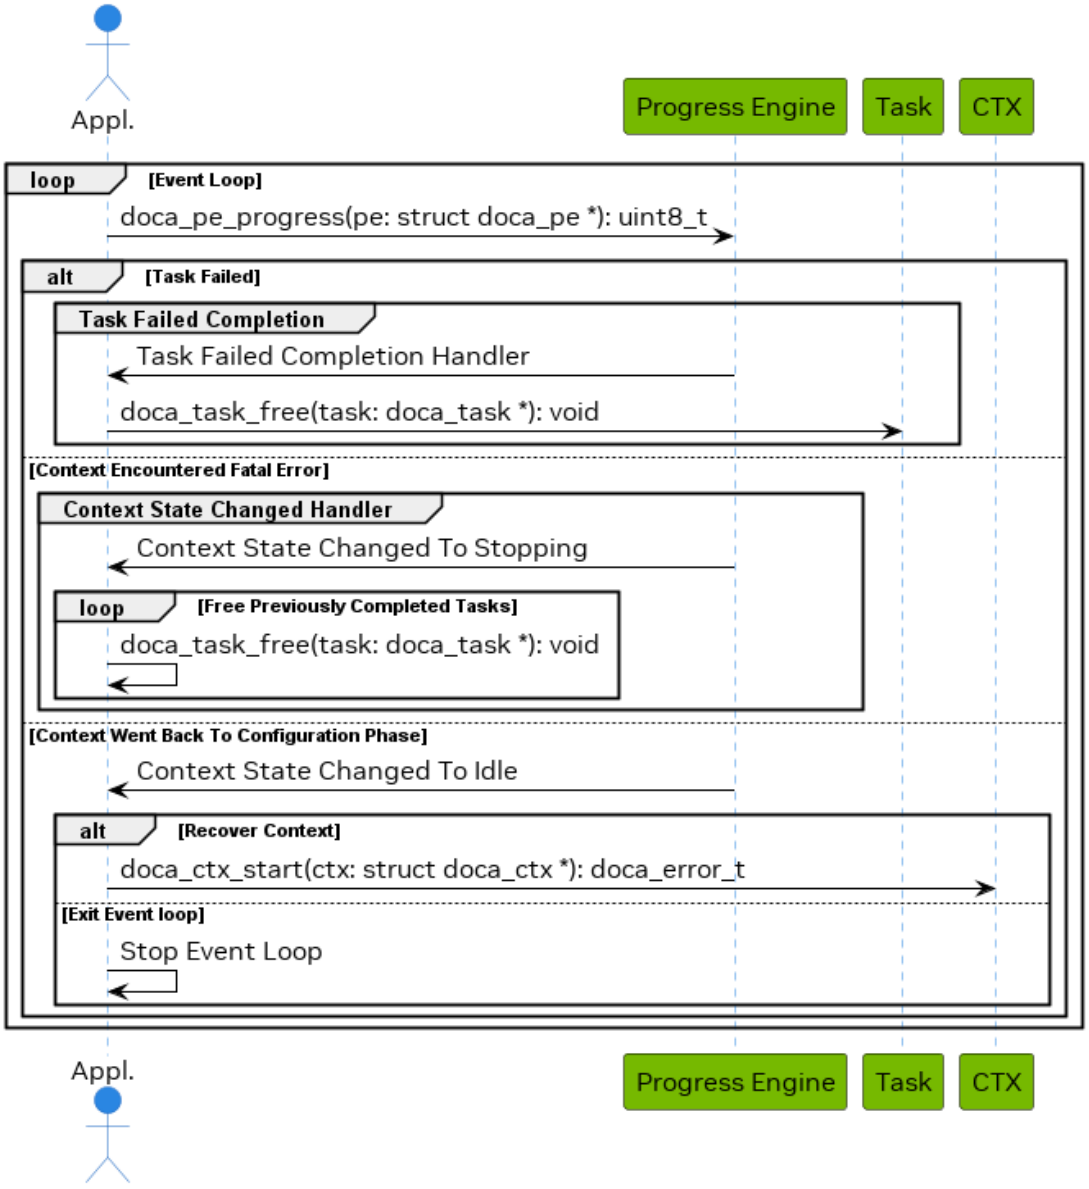


Error Handling

After a task is submitted successfully, consequent calls to `doca_pe_progress()` may fail (i.e., task failure completion callback is called).

Once a task fails, the context may transition to stopping state, in this state, the application has to progress all in-flight tasks until completion before destroying or restarting the context.

The following diagram shows how an application may handle an error from `doca_pe_progress()`:



1. Application runs event loop.
2. Any of the following may happen:
    - [Optional] Task fails, and the task failed completion handler is called
        - This may be caused by bad task parameters or another fatal error
        - Handler releases the task and all associated resources
    - [Optional] Context transitions to stopping state, and the context state changed handler is called
        - This may be caused by failure of a task or another fatal error
        - In this state, all in-flight tasks are guaranteed to fail
        - Handler releases tasks that are not in-flight if such tasks exist
    - [Optional] Context transitions to idle state, and the context state changed handler is called

- This may happen due to encountering an error and the context does not have any resources that must be freed by the application
- In this case, the application may decide to recover the context by calling start again or it may decide to destroy the context and possibly exit the application

Task and Event Batching

DOCA Batching is an approach for grouping multiple tasks or events of the same type and handling them as a single unit. DOCA offers two options of achieving this as described in the following subsections.

Batch Task/Event

In this batching option, a library (e.g., `doca_eth_txq`) offers a task that represents a batched operation (e.g., sending multiple packets), the task is considered a batch task and has a task type that is separate from the non-batched operation (e.g., sending a single packet).

To submit the batch task, the user is required to build the batch and then submit it at once, similar to submitting a regular task.

The completion of the batch is based on the completion of all items in the batch and is handled as the completion of a single unit. This allows for multiple DOCA Task initialization/submission and multiple DOCA Task/Event completion handling in a single API call (see DOCA Ethernet for example).

Iterative Batch

In this batching option, it is possible to utilize existing task types to build a batch operation, where each task within the batch is submitted individually and each task receives its own completion.

Furthermore, the batch is built iteratively, where the user is not required to have information for the entire batch ahead of time.

To utilize this option, the user can submit each task in the batch using an extended submit API `doca_task_submit_ex` while providing additional submit flags.

The extended submit API is similar to a regular submit API (`doca_task_submit`) but with the ability to receive submit flags. These flags are used as hints to the library that executes the tasks. They can have implications on the current task but may also have implications on previously submitted flags, as described in the following table:

Submit Flag [1]	Effect on Current Task		Effect on Previous Tasks [2]		Default Behavior of doca_task_submit	Comments
	Flag Provided	Flag not Provided	Flag Provided	Flag not Provided		
`DOCA_TASK_SUBMIT_FLAG_FLUSH`	Task is submitted for hardware execution immediately, and is considered "flushed".	Task may not be submitted for hardware execution, and is considered "unflushed".	All previous tasks which are considered unflushed become flushed.	None	Flag is provided	As long as the task is unflushed, it never completes. The flag allows batching such that multiple tasks are flushed at once, instead of individually.
`DOCA_TASK_SUBMIT_FLAG_OPTIMIZE_REPORTS`	The user does not receive task completion after hardware has completed execution of the task, and the completion is considered "unreported".	The user receives task completion after hardware has completed execution of the task, and the completion is considered "reported".	None	Once the hardware completes execution of this task, all previous [3] unreported completions become reported.	Flag is not provided	As long as the task is unreported, the user would never know that it has been completed. The completion of a task is reported through a completion callback using the progress engine. The library does not guarantee any order of execution/completion of tasks. The flag allows batching, such that multiple task completions are reported using a single hardware completion, instead of receiving a completion for every task.

1. Note that these flags are hints which may allow internal optimizations. However, on a task-by-task basis, the library may decide to ignore user flags and revert to default submit behavior.
2. "Previous tasks" only refers to tasks submitted to the same library instance (doca_ctx). The flags do not allow optimizations across different library instances.
3. "previous" refers to tasks that have been submitted before this one.

DOCA Graph facilitates running a set of actions (tasks, user callbacks, graphs) in a specific order and dependencies. DOCA Graph runs on a DOCA progress engine.

DOCA Graph creates graph instances that are submitted to the progress engine (`doca_graph_instance_submit`).

Nodes

DOCA Graph is comprised of context, user, and sub-graph nodes. Each of these types can be in any of the following positions in the network:

- Root nodes – a root node does not have a parent. The graph can have one or more root nodes. All roots begin running when the graph instance is submitted.
- Edge nodes – an edge node is a node that does not have child nodes connected to it. The graph instance is completed when all edge nodes are completed.
- Intermediate node – a node connected to parent and child nodes

Context Node

A context node runs a specific DOCA task and uses a specific DOCA context (`doca_ctx`). The context must be connected to the progress engine before the graph is started.

The task lifespan must be longer or equal to the life span of the graph instance.

User Node

A user node runs a user callback to facilitate performing actions during the run time of the graph instance (e.g., adjust next node task data, compare results).

Sub-graph Node

A sub-graph node runs an instance of another graph.

Using DOCA Graph

1. Create the graph using `doca_graph_create`.
2. Create the graph nodes (e.g., `doca_graph_node_create_from_ctx`).
3. Define dependencies using `doca_graph_add_dependency`.

   ⚠ DOCA graph does not support circle dependencies (e.g., A => B => A).
4. Start the graph using `doca_graph_start`.
5. Create the graph instance using `doca_graph_instance_create`.
6. Set the nodes data (e.g., `doca_graph_instance_set_ctx_node_data`).
7. Submit the graph instance to the PE using `doca_graph_instance_submit`.
8. Call `doca_pe_progress` until the graph callback is invoked.
   - Progress engine can run graph instances and standalone tasks simultaneously.

DOCA Graph Limitations

- DOCA Graph does not support circle dependencies
- DOCA Graph must contain at least one context node. A graph containing a sub-graph with at least one context node is a valid configuration.

DOCA Graph Sample

The graph sample is based on the DOCA DMA library. The sample copies 2 buffers using DMA.

The graph ends with a user callback node that compares source and destinations.

Running DOCA Graph Sample

1. Refer to the following documents:
   - NVIDIA DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - NVIDIA DOCA Troubleshooting Guide for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample:

   ```
   cd /opt/mellanox/doca/samples/doca_common/graph/
   meson build
   ninja -C build
   ```

3. Sample (e.g., `doca_graph`) usage:

   ```
   ./build/doca_graph
   ```

   No parameters required.

Alternative Data Path

DOCA Progress Engine utilizes the CPU to offload data path operations to hardware. However, some libraries support utilization of DPA and/or GPU.

Considerations:

- Not all contexts support alternative datapath
- Configuration phase is always done on CPU
- Datapath operations are always offloaded to hardware. The unit that offloads the operation itself can be either CPU/DPA/GPU.
- The default mode of operation is CPU
- Each mode of operation introduces a different set of APIs to be used in execution path. The used APIs are mutually exclusive for specific context instance.

DPA

Users must first refer to the programming guide of the relevant context (e.g., DOCA RDMA) to check if datapath on DPA is supported. Additionally, the guide provides what operations can be used.

To set the datapath mode to DPA, acquire a DOCA DPA instance, then use the `doca_ctx_set_datapath_on_dpa()` API.

After the context has been started with this mode, it becomes possible to get a DPA handle, using an API defined by the relevant context (e.g., `doca_rdma_get_dpa_handle()`). This handle can then be used to access DPA data path APIs within DPA code.

GPU

Users must first refer to the programming guide of the relevant context (E.g., DOCA Ethernet) to check if datapath on GPU is supported. Additionally, the guide provides what operations can be used.

To set the data path mode to GPU, acquire a DOCA GPU instance, then use the `doca_ctx_set_datapath_on_gpu()` API.

After the context has been started with this mode, it becomes possible to get a GPU handle, using an API defined by the relevant context (e.g., `doca_eth_rxq_get_gpu_handle()`). This handle can then be used to access GPU data path APIs within GPU code.

5.4.1.1.4.5 Object Life Cycle

Most DOCA Core objects share the same handling model in which:

1. The object is allocated by DOCA so it is opaque for the application (e.g., `doca_buf_inventory_create`, `doca_mmap_create`).
2. The application initializes the object and sets the desired properties (e.g., `doca_mmap_set_memrange`).
3. The object is started, and no configuration or attribute change is allowed (e.g., `doca_buf_inventory_start`, `doca_mmap_start`).
4. The object is used.
5. The object is stopped and deleted (e.g., `doca_buf_inventory_stop` → `doca_buf_inventory_destroy`, `doca_mmap_stop` → `doca_mmap_destroy`).

The following procedure describes the mmap export mechanism between two machines (remote machines or host-BlueField):

1. Memory is allocated on Machine1.
2. Mmap is created and is provided memory from step 1.
3. Mmap is exported to the Machine2 pinning the memory.
4. On the Machine2, an imported mmap is created and holds a reference to actual memory residing on Machine1.
5. Imported mmap can be used by Machine2 to allocate buffers.
6. Imported mmap is destroyed.
7. Exported mmap is destroyed.

8. Original memory is destroyed.

5.4.1.1.4.6 RDMA Bridge

The DOCA Core library provides building blocks for applications to use while abstracting many details relying on the RDMA driver. While this takes away complexity, it adds flexibility especially for applications already based on rdma-core. The RDMA bridge allows interoperability between DOCA SDK and rdma-core such that existing applications can convert DOCA-based objects to rdma-core-based objects.

Requirements and Considerations

- This library enables applications already using rdma-core to port their existing application or extend it using DOCA SDK.
- Bridge allows converting DOCA objects to equivalent rdma-core objects.

DOCA Core Objects to RDMA Core Objects Mapping

The RDMA bridge allows translating a DOCA Core object to a matching RDMA Core object. The following table shows how the one object maps to the other.

RDMA Core Object	DOCA Equivalent	RDMA Object to DOCA Object	DOCA Object to RDMA Object
`ibv_pd`	`doca_dev`	`doca_rdma_bridge_open_dev_from_pd`	`doca_rdma_bridge_get_dev_pd`
`ibv_mr`	`doca_buf`	`-`	`doca_rdma_bridge_get_buf_mkey`

5.4.1.1.4.7 DOCA Clock

The DOCA Clock library provides access to timestamps or cycle counters from clocks on both the calling host platform and an attached NVIDIA® BlueField® DPU or NVIDIA® ConnectX® adapter.

The API allows you to retrieve a value from a single clock or to perform a "cross-timestamp" between two different clocks (e.g., host and NIC) to get a correlated set of values.

Key API Functions

- `doca_clock_get_timestamp()` – Retrieves the current value from a single specified clock.
- `doca_clock_get_crosstimestamp()` – Simultaneously captures timestamps from two different clocks, providing a correlation between them.

Supported Clock Types

The library supports the clock types listed in the following table.

Clock Type	Description	Cap Function
NIC Free Running [4]	Internal device timer, typically running from boot time. (seconds/nanoseconds)	`doca_clock_cap_nic_free_running_is_supported()`
NIC Real Time [4]	Device's real-time clock. (seconds/nanoseconds)	`doca_clock_cap_nic_real_time_is_supported()`
NIC DPA Timer [4]	Device DPA clock. (seconds/nanoseconds, microsecond accuracy)	`doca_clock_cap_nic_dpa_timer_is_supported()`
Host Counter Cycles	Host CPU's internal counter. (cycles)	N/A
Host Real Time	Host CPU's real-time clock. (seconds/nanoseconds)	N/A
Host Monotonic	Host CPU's monotonic clock, typically running from boot time. (seconds/nanoseconds)	N/A
Host Monotonic Raw	Host CPU's monotonic clock without frequency adjustments. (seconds/nanoseconds)	N/A

4. NIC-based clocks are optional and their availability must be checked using the listed capability functions.

Considerations

Please note the following requirements and behaviors when using the DOCA Clock library:

- Real-Time Clock Configuration: To access or cross-timestamp the `NIC Real Time` clock, it must be enabled on the device.

```
sudo mlxconfig -d <device_id> set REAL_TIME_CLOCK_ENABLE=1
```

- Firmware Requirement: Firmware version 47.1000 or newer is required to access the `NIC DPA Timer`.
- Permissions: While most operations (querying single clocks, NIC-to-NIC cross-timestamps) can run without root permissions, some Host-to-NIC cross-timestamp operations may require root privileges.
- Precision and Support: The availability of specific cross-timestamp combinations depends on the host's Linux packages, kernel drivers, and NIC capabilities. The library automatically attempts to use the most precise method available for any given clock combination and returns an `accuracy` value (in nanoseconds) along with the timestamps.

5.4.1.1.5 DOCA Core Samples

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.1.1.5.1 Progress Engine Samples

All progress engine (PE) samples use DOCA DMA because of its simplicity. PE samples should be used to understand the PE not DOCA DMA.

pe_common

`pe_common.c` and `pe_common.h` contain code that is used in most or all PE samples.

Users can find core code (e.g., create MMAP) and common code that uses PE (e.g., `poll_for_completion`).

Struct `pe_sample_state_base` (defined in `pe_common.h`) is the base state for all PE samples, containing common members that are used by most or all PE samples.

pe_polling

The polling sample is the most basic sample for using PE. Start with this sample to learn how to use DOCA PE.

> You can diff between `pe_polling_sample.c` and any other `pe_x_sample.c` to see the unique features that the other sample demonstrates.

The sample demonstrates the following functions:

- How to create a PE
- How to connect a context to the PE
- How to allocate tasks
- How to submit tasks
- How to run the PE
- How to cleanup (e.g., destroy context, destroy PE)

  > Pay attention to the order of destruction (e.g., all contexts must be destroyed before the PE).

The sample performs the following:

1. Uses one DMA context.
2. Allocates and submits 16 DMA tasks.

> Task completion callback checks that the copied content is valid.

3. Polls until all tasks are completed.

pe_async_stop

A context can be stopped while it still processes tasks. This stop is asynchronous because the context must complete/abort all tasks.

The sample demonstrates the following functions:

- How to asynchronously stop a context
- How to implement a context state changed callback (with regards to context moving from stopping to idle)
- How to implement task error callback (check if this is a real error or if the task is flushed)

The sample performs the following:

1. Submits 16 tasks and stops the context after half of the tasks are completed.
2. Polls until all tasks are complete (half are completed successfully, half are flushed).

The difference between `pe_polling_sample.c` and `pe_async_stop_sample.c` is to learn how to use PE APIs for event-driven mode.

pe_event

Event-driven mode reduces CPU utilization (wait for event until a task is complete) but may increase latency or reduce performance.

The sample demonstrates the following functions:

- How to run the PE in event-driven mode

The sample performs the following:

1. Runs 16 DMA tasks.
2. Waits for event.

The difference between `pe_polling_sample.c` and `pe_event_sample.c` is to learn how to use PE APIs for event-driven mode.

pe_multi_context

A PE can host more than one instance of a specific context. This facilitates running a single PE with multiple BlueField devices.

The sample demonstrates the following functions:

- How to run a single PE with multiple instances of a specific context

The sample performs the following:

1. Connects 4 instances of DOCA DMA context to the PE.
2. Allocates and submits 4 tasks to every context instance.
3. Polls until all tasks are complete.

The difference between `pe_polling_sample.c` and `pe_multi_context_sample.c` is to learn how to use PE with multiple instances of a context.

pe_reactive

PE and contexts can be maintained in callbacks (task completion and state changed).

The sample demonstrates the following functions:

- How to maintain the context and PE in the callbacks instead of the program's main function

The user must make sure to:

- Review the task completion callback and the state changed callbacks
- Review the difference between `poll_to_completion` and the polling loop in main

The sample performs the following:

1. Runs 16 DMA tasks.
2. Stops the DMA context in the completion callback after all tasks are complete.

The difference between `pe_polling_sample.c` and `pe_reactive_sample.c` is to learn how to use PE in reactive model.

pe_single_task_cb

A DOCA task can invoke a success or error callback. Both callbacks share the same structure (same input parameters).

DOCA recommends using 2 callbacks:

- Success callback – does not need to check the task status, thereby improving performance
- Error callback – may need to run a different flow than success callback

The sample demonstrates the following functions:

- How to use a single callback instead of two callbacks

The sample performs the following:

1. Runs 16 DMA tasks.
2. Handles completion with a single callback.

The difference between `pe_polling_sample.c` and `pe_single_task_comp_cb_sample.c` is to learn how to use PE with a single completion callback.

pe_task_error

Task execution may fail causing the associated context (e.g., DMA) to move to stopping state due to this fatal error.

The sample demonstrates the following functions:

- How to mitigate a task error during runtime

The user must make sure to:

- Review the state changed callback and the error callback to see how the sample mitigates context error

The sample performs the following:

1. Submits 255 tasks.
2. Allocates the second task with invalid parameters that cause hardware to fail.
3. Mitigates the failure and polls until all submitted tasks are flushed.

The difference between `pe_polling_sample.c` and `pe_task_error_sample.c` is to learn how to mitigate context error.

pe_task_resubmit

A task can be freed or reused after it is completed:

- Task resubmit can improve performance because the program does not free and allocate the task.
- Task resubmit can reduce memory usage (using a smaller task pool).
- Task members (e.g., source or destination buffer) can be set, so resubmission can be used if the source or destination are changed every iteration.

The sample demonstrates the following functions:

- How to re-submit a task in the completion callback
- How to replace buffers in a DMA task (similar to other task types)

The sample performs the following:

1. Allocates a set of 4 tasks and 16 buffer pairs.
2. Uses the tasks to copy all sources to destinations by resubmitting the tasks.

The difference between `pe_polling_sample.c` and `pe_task_resubmit_sample.c` is to learn how to use task resubmission.

pe_task_try_submit

`doca_task_submit` does not validate task inputs (to increase performance). Developers can use `doca_task_try_submit` to validate the tasks during development.

Task validation impacts performance and should not be used in production.

The sample demonstrates the following functions:

- How to use `doca_task_try_submit` instead of `doca_task_submit`

The sample performs the following:

1. Allocates and tries to submit tasks using `doca_task_try_submit`.

The difference between `pe_polling_sample.c` and `pe_task_try_submit_sample.c` is to learn how to use `doca_task_try_submit`.

5.4.1.1.5.2 Graph Sample

The graph sample demonstrates how to use DOCA graph with PE. The sample can be used to learn how to build and use DOCA graph.

The sample uses two nodes of DOCA DMA and one user node.

The graph runs both DMA nodes (copying a source buffer to two destinations). Once both nodes are complete, the graph runs the user node that compares the buffers.

The sample runs 10 instances of the graph in parallel.

5.4.1.1.5.3 Clock Sample

The `doca_clock_cross_timestamp` sample demonstrates how to create and use a `doca_clock` context associated with a specific DOCA device.

The sample's behavior depends on the arguments provided:

- Single clock – If one clock is specified (using the `-c` flag), the program returns the current timestamp value for that single clock.
- Two clocks – If two clocks are specified (using both `-c` and `-n`), the program performs a cross-timestamp, returning the correlated values for both clocks and the achieved accuracy.

Sample usage:

```
Usage: doca_clock_cross_timestamp [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI device address
  -c, --primary-clock               'nic_fr', 'nic_rt', 'nic_dpa', 'host_cyles', 'host_rt', 'host_mon', or
'host_mon_raw'
  -n, --nic-clock                   'nic_fr', 'nic_rt', or 'nic_dpa'
```

5.4.1.1.6 Backward Compatibility of DOCA Core doca_buf

This section lists changes to the DOCA SDK which impacts backward compatibility.

5.4.1.1.6.1 DOCA Core doca_buf

Up to DOCA 2.0.2, the data length of the buffer is ignored when using the buffer as an output parameter, and the new data was written over the data that was there beforehand. From now on, new data is appended after existing data (if any) while updating the data length accordingly.

Because of this change, a destination buffer should be allocated without a data section (data length 0).

> ⚠ Allocating a destination buffer with data length = size will yield a buffer that can't be used as a destination buffer.

In cases where the data length is 0 in a destination buffer, this change would go unnoticed (as appending the data and writing to the data section has the same result).

Reusing buffers requires resetting the data length when wishing to write to the same data address (instead of appending the data), overwriting the existing data. A new function, `doca_buf_reset_data_len()`, has been added specifically for this need.

5.4.1.1.7 Sync Event

> ⚠ DOCA Sync Event API is considered thread-unsafe

> ⚠ DOCA Sync Event does not currently support GPU related features.

5.4.1.1.7.1 Introduction

DOCA Sync Event (SE) is a software synchronization mechanism for parallel execution across the CPU, DPU, DPA and remote nodes. The SE holds a 64-bit counter which can be updated, read, and waited upon from any of these units to achieve synchronization between executions on them.

To achieve the best performance, DOCA SE defines a subscriber and publisher locality, where:

- Publisher – the entity which updates (sets or increments) the event value
- Subscriber – the entity which gets and waits upon the SE

> Both publisher and subscriber can read (get) the actual counter's value.

Based on hints, DOCA selects memory locality of the SE counter, closer to the subscriber side. Each DOCA SE is configured with a single publisher location and a single subscriber location which can be the CPU or DPU.

The SE control path happens on the CPU (either host CPU or DPU CPU) through the DOCA SE CPU handle. It is possible to retrieve different execution-unit-specific handles (DPU/DPA/GPU/remote handles) by exporting the SE instance through the CPU handle. Each SE handle refers to the DOCA SE instance from which it is retrieved. By using the execution-unit-specific handle, the associated SE instance can be operated from that execution unit.

In a basic scenario, synchronization is achieved by updating the SE from one execution and waiting upon the SE from another execution unit.

5.4.1.1.7.2 Prerequisites

DOCA SE can be used as a context which follows the architecture of a DOCA Core Context, it is recommended to read the following sections of the DOCA Core page before proceeding:

- DOCA Execution Model
- DOCA Device
- DOCA Memory Subsystem

5.4.1.1.7.3 Environment

DOCA SE based applications can run either on the host machine or on the NVIDIA® BlueField® DPU target and can involve DPA, GPU and other remote nodes.

Using DOCA SE with DPU requires BlueField to be configured to work in DPU mode as described in BlueField Modes of Operation.

> Asynchronous wait on a DOCA SE requires NVIDIA® BlueField-3® or newer.

5.4.1.1.7.4 Architecture

DOCA SE can be converted to a DOCA Context as defined by DOCA Core. See DOCA Context for more information.

As a context, DOCA SE leverages DOCA Core architecture to expose asynchronous tasks/events offloaded to hardware.

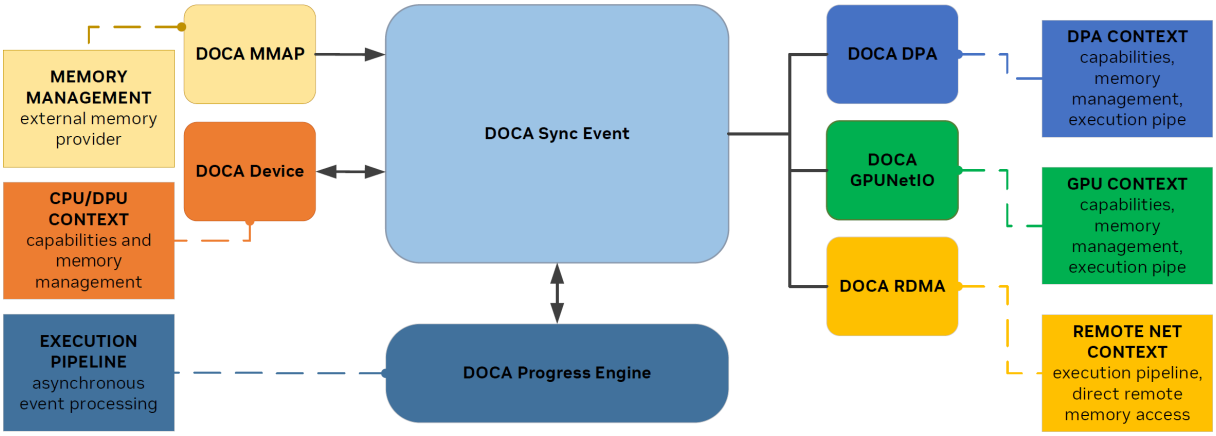
The figure that follows demonstrates components used by DOCA SE. DOCA Device provides information on the capabilities of the configured HW used by SE to control system resources.

DOCA DPA, GPUNetIO, and RDMA modules are required for cross-device synchronization (could be DPA, GPU, or remote peer respectively).

DOCA SE allows flexible memory management by its ability to specify an external buffer, where a DOCA mmap module handles memory registration for advanced synchronization scenarios.

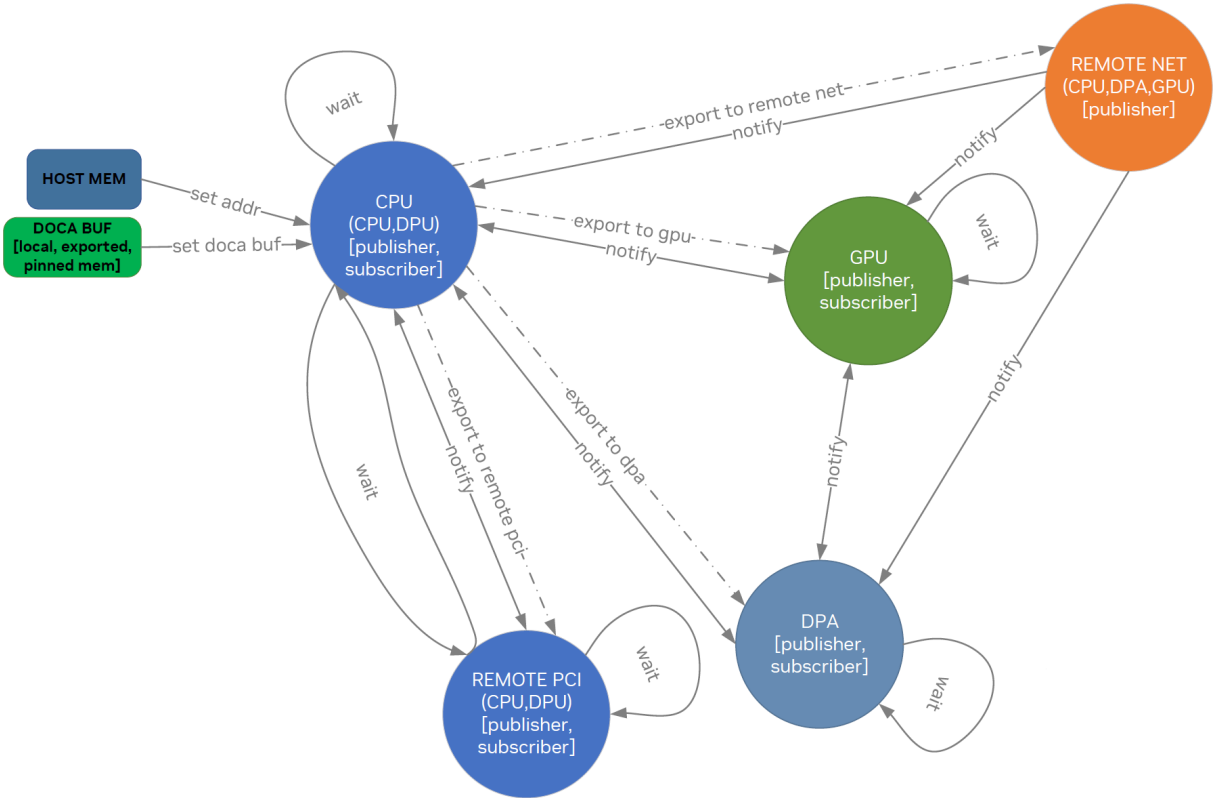
For asynchronous operation scheduling, SE uses the DOCA Progress Engine (PE) module.

DOCA Sync Event Components Diagram



The following diagram represents DOCA SE synchronization abilities on various devices.

DOCA Sync Event Interaction Diagram



DOCA Sync Event Objects

DOCA SE exposes different types of handles per execution unit as detailed in the following table.

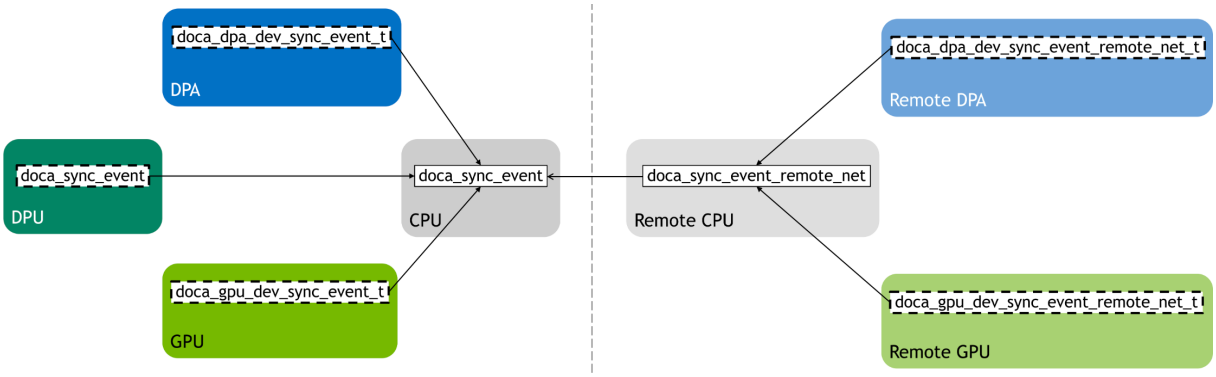
Execution Unit	Type	Description
CPU (host/DPU)	`struct doca_sync_event`	Handle for interacting with the SE from the CPU
DPU	`struct doca_sync_event`	Handle for interacting with the SE from the DPU
DPA	`doca_dpa_dev_sync_event_t`	Handle for interacting with the SE from the DPA
GPU	`doca_gpu_dev_sync_event_t`	Handle for interacting with the SE from the GPU
Remote net CPU	`doca_sync_event_remote_net`	Handle for interacting with the SE from a remote CPU
Remote net DPA	`doca_dpa_dev_sync_event_remote_net_t`	Handle for interacting with the SE from a remote DPA
Remote net GPU	`doca_gpu_dev_sync_event_remote_net_t`	Handle for interacting with the SE from a remote GPU

Each one of these handle types has its own dedicated API for creating the handle and interacting with it.

5.4.1.1.7.5 Configuration Phase

Any DOCA SE creation starts with creating CPU handle by calling `doca_sync_event_create` API.

After creation, the SE entity could be shared with local PCIe, remote CPU, DPA, and GPU by a dedicated handle creation via the DOCA SE export flow, as illustrated in the following diagram:



Operation Modes

DOCA SE exposes two different APIs for starting it depending on the desired operation mode, synchronous or asynchronous.

> ⚠ Once started, SE operation mode cannot be changed.

Synchronous Mode

Start the SE to operate in synchronous mode by calling `doca_sync_event_start`.

In synchronous operation mode, each data path operation (get, update, wait) blocks the calling thread from continuing until the operation is done.

> **⚠** An operation is considered done if the requested change fails and the exact error can be reported or if the requested change has taken effect.

Asynchronous Mode

To start the SE to operate in asynchronous mode, convert the SE instance to `doca_ctx` by calling `doca_sync_event_as_ctx`. Then use DOCA CTX API to start the SE and DOCA PE API to submit tasks on the SE (see section "DOCA Progress Engine" for more).

Configurations

Mandatory Configurations

These configurations must be set by the application before attempting to start the SE:

- DOCA SE CPU handle must be configured by providing the runtime hints on the publisher and subscriber locations. Both the subscriber and publisher locations must be configured using the following APIs:
  - `doca_sync_event_add_publisher_location_<cpu|dpa|gpu|remote_pci|remote_net>`
  - `doca_sync_event_add_subscriber_location_<cpu|dpa|gpu|remote_pci>`
- For the asynchronous use case, at least one task/event type must be configured. See configuration of tasks.

Optional Configurations

> **ℹ** If these configurations are not set, a default value is used.

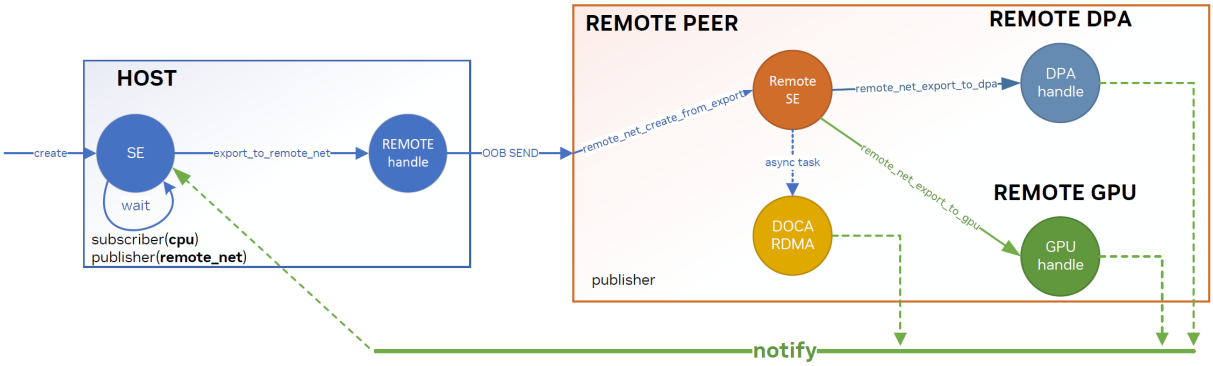
- These configurations provide an 8-byte buffer to be used as the backing memory of the SE. If set, it is user responsibility to handle the memory (i.e., preserve the memory allocated during DOCA SE lifecycle and free it after DOCA SE destruction). If not provided, the SE backing memory is allocated by the SE.
  - `doca_sync_event_set_addr`
  - `doca_sync_event_set_doca_buf`

Export DOCA Sync Event to Another Execution Unit

To use an SE from an execution unit other than the CPU, it must be exported to get a handle for the specific execution unit:

- DPA – `doca_sync_event_get_dpa_handle` returns a DOCA SE DPA handle (`doca_dpa_dev_sync_event_t`) which can be passed to the DPA SE data path APIs from the DPA kernel
- GPU – `doca_sync_event_get_gpu_handle` returns a DOCA SE GPU handle (`doca_gpu_dev_sync_event_t`) which can be passed to the GPU SE data path APIs for the CUDA kernel
- DPU – `doca_sync_event_export_to_remote_pci` returns a blob which can be used from the DPU CPU to instantiate a DOCA SE DPU handle (`struct doca_sync_event`) using the `doca_sync_event_create_from_export` function

DOCA SE allows notifications from remote peers (remote net) utilizing capabilities of the DOCA RDMA library. The following figure illustrates the remote net export flow:



- Remote net CPU – `doca_sync_event_export_to_remote_net` returns a blob which can be used from the remote net CPU to instantiate a DOCA SE remote net CPU handle (`struct doca_sync_event_remote_net`) using the `doca_sync_event_remote_net_create_from_export` function. The handle can be used directly for submitting asynchronous tasks through the `doca_rdma` library or exported to the remote DPA/GPU.
- Remote net DPA – `doca_sync_event_remote_net_get_dpa_handle` returns a DOCA SE remote net DPA handle (`doca_dpa_dev_sync_event_remote_net_t`) which can be passed to the DPA RDMA data path APIs from a DPA kernel
- Remote net GPU – `doca_sync_event_remote_net_get_gpu_handle` returns a DOCA SE remote net GPU handle (`doca_gpu_dev_sync_event_remote_net_t`) which can be passed to the GPU RDMA data path APIs from a CUDA kernel

The CPU handle (`struct doca_sync_event`) can be exported only to the location where the SE is configured.

Prior to calling any export function, users must first verify it is supported by calling the corresponding export capability getter: `doca_sync_event_cap_is_export_to_dpa_supported`, `doca_sync_event_cap_is_export_to_gpu_supported`, `doca_sync_event_cap_is_export_to_remote_pci_supported`, or `doca_sync_event_cap_is_export_to_remote_net_supported`.

Prior to calling any `*_create_from_export` function, users must first verify it is supported by calling the corresponding create from the export capability getter: `doca_sync_event_cap_is_create_from_export_supported` or `doca_sync_event_cap_remote_net_is_create_from_export_supported`.

Once created from an export, both the SE DPU handle `struct doca_sync_event` and the SE remote net CPU handle `struct doca_sync_event_remote_net` cannot be configured, but only the SE DPU handle must be started before it is used.

Data exported in `doca_sync_event_export_to_*` functions contains sensitive information. Make sure to pass this data through a secure channel!

Device Support

DOCA SE needs a device to operate. For instructions on selecting a device, see DOCA Core device discovery.

Both NVIDIA® BlueField®-2 and BlueField®-3 devices are supported as well as any `doca_dev` is supported.

Asynchronous wait (blocking/polling) is supported on NVIDIA® BlueField®-3 and NVIDIA® ConnectX®-7 and later.

As device capabilities may change in the future (see DOCA Capability Check), it is recommended to choose your device using any relevant capability method (starting with the prefix `doca_sync_event_cap_*`).

Capability APIs to query whether sync event can be constructed from export blob:

- `doca_sync_event_cap_is_create_from_export_supported`
- `doca_sync_event_cap_remote_net_is_create_from_export_supported`

Capability APIs to query whether sync event can be exported to other execution units:

- `doca_sync_event_cap_is_export_to_remote_pci_supported`
- `doca_sync_event_cap_is_export_to_dpa_supported`
- `doca_sync_event_cap_is_export_to_gpu_supported`
- `doca_sync_event_cap_is_export_to_remote_net_supported`
- `doca_sync_event_cap_remote_net_is_export_to_dpa_supported`
- `doca_sync_event_cap_remote_net_is_export_to_gpu_supported`

Capability APIs to query whether an asynchronous task is supported:

- `doca_sync_event_cap_task_get_is_supported`
- `doca_sync_event_cap_task_notify_set_is_supported`
- `doca_sync_event_cap_task_notify_add_is_supported`
- `doca_sync_event_cap_task_wait_eq_is_supported`
- `doca_sync_event_cap_task_wait_neq_is_supported`

5.4.1.1.7.6 Execution Phase

This section describes execution on CPU. For additional execution environments refer to section "Alternative Datapath Options".

DOCA Sync Event Data Path Operations

The DOCA SE synchronization mechanism is achieved using exposed datapath operations. The API exposes a function for "writing" to the SE and for "reading" the SE.

The synchronous API is a set of functions which can be called directly by the user, while the asynchronous API is exposed by defining a corresponding `doca_task` for each synchronous function to be submitted on a DOCA PE (see DOCA Progress Engine and DOCA Context for additional information).

> Remote net CPU handle (`struct doca_sync_event_remote_net`) can be used for submitting asynchronous tasks using the DOCA RDMA library.

> Prior to asynchronous task submission, users must check if the job is supported using `doca_error_t doca_sync_event_cap_task_<task_type>_is_supported` .

The following subsections describe the DOCA SE datapath operation with respect to synchronous and asynchronous operation modes.

Publishing on DOCA Sync Event

Setting DOCA Sync Event Value

Users can set DOCA SE to a 64-bit value:

- Synchronously by calling `doca_sync_event_update_set`
- Asynchronously by submitting a `doca_sync_event_task_notify_set` task

Adding to DOCA Sync Event Value

Users can atomically increment the value of a DOCA SE:

- Synchronously by calling `doca_sync_event_update_add`
- Asynchronously by submitting a `doca_sync_event_task_notify_add` task

Subscribe on DOCA Sync Event

Getting DOCA Sync Event Value

Users can get the value of a DOCA SE:

- Synchronously by calling `doca_sync_event_get`
- Asynchronously by submitting a `doca_sync_event_task_get` task

Waiting on DOCA Sync Event

Waiting for an event is the main operation for achieving synchronization between different execution units.

Users can wait until an SE reaches a specific value in a variety of ways.

Synchronously

`doca_sync_event_wait_gt` waits for the value of a DOCA SE to be greater than a specified value in a "polling busy wait" manner (100% processor utilization). This API enables users to wait for an SE in real time.

`doca_sync_event_wait_gt_yield` waits for the value of a DOCA SE to be greater than a specified value in a "periodically busy wait" manner. After each polling iteration, the calling thread relinquishes the CPU, so a new thread gets to run. This API allows a tradeoff between real-time polling to CPU starvation.

`doca_sync_event_wait_eq` waits for the value of a DOCA SE to be equal to a specified value in a "polling busy wait" manner (100% processor utilization). This API enables users to wait for an SE in real time.

`doca_sync_event_wait_eq_yield` waits for the value of a DOCA SE to be equal to a specified value in a "periodically busy wait" manner. After each polling iteration, the calling thread relinquishes the CPU so a new thread gets to run. This API allows a tradeoff between real-time polling to CPU starvation.

`doca_sync_event_wait_neq` waits for the value of a DOCA SE to not be equal to a specified value in a "polling busy wait" manner (100% processor utilization). This API enables users to wait for an SE in real time.

`doca_sync_event_wait_neq_yield` waits for the value of a DOCA SE to not be equal to a specified value in a "periodically busy wait" manner. After each polling iteration, the calling thread relinquishes the CPU so a new thread gets to run. This API allows a tradeoff between real-time polling to CPU starvation.

> ⚠ This wait method is supported only from the CPU.

Asynchronously

DOCA SE exposes an asynchronous wait method by defining a `doca_sync_event_task_wait_eq` and `doca_sync_event_task_wait_neq` tasks.

Users can wait for wait-job completion in the following methods:

- Blocking – get a `doca_event_handle_t` from the `doca_pe` to blocking-wait on
- Polling – poll the wait task by calling `doca_pe_progress`

> ℹ Asynchronous wait (blocking/polling) is supported on BlueField-3 and ConnectX-7 and later.

> ⚠ Users may leverage the `doca_sync_event_task_get` job to implement asynchronous wait by asynchronously submitting the task on a DOCA PE and comparing the result to some threshold.

Tasks

DOCA SE context exposes asynchronous tasks that leverage the DPU hardware according to the DOCA Core architecture. See DOCA Core Task.

Get Task

The get task retrieves the value of a DOCA SE.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_sync_event_task_get_set_conf`	`doca_sync_event_cap_task_get_is_supported`
Number of tasks	`doca_sync_event_task_get_set_conf`	-

Task Input

Common input described in DOCA Core Task.

Name	Description
Return value	8-bytes memory pointer to hold the DOCA SE value

Task Output

Common output described in DOCA Core Task.

Task Completion Success

After the task is completed successfully, the return value memory holds the DOCA SE value.

Task Completion Failure

If the task fails midway:

- The context may enter a stopping state if a fatal error occurs
- The return value memory may be modified

Task Limitations

All limitations are described in DOCA Core Task.

Notify Set Task

The notify set task allows setting the value of a DOCA SE.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_sync_event_task_notify_set_set_conf`	`doca_sync_event_cap_task_notify_set_is_supported`
Number of tasks	`doca_sync_event_task_notify_set_set_conf`	-

Task Input

Common input described in DOCA Core Task.

Name	Description
Set value	64-bit value to set the DOCA SE value to

Task Output

Common output described in DOCA Core Task.

Task Completion Success

After the task is completed successfully, the DOCA SE value is set to the given set value.

Task Completion Failure

If the task fails midway, the context may enter a stopping state if a fatal error occurs.

Task Limitations

This operation is not atomic. Other limitations are described in DOCA Core Task.

Notify Add Task

The notify add task allows atomically setting the value of a DOCA SE.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_sync_event_task_notify_add_set_conf`	`doca_sync_event_cap_task_notify_add_is_supported`
Number of tasks	`doca_sync_event_task_notify_add_set_conf`	-

Task Input

Common input described in DOCA Core Task.

Name	Description
Increment value	64-bit value to atomically increment the DOCA SE value by
Fetched value	8-bytes memory pointer to hold the DOCA SE value before the increment

Task Output

Common output described in DOCA Core Task.

Task Completion Success

After the task is completed successfully, the following occurs:

- The DOCA SE value is incremented according to the given increment value
- The fetched value memory holds the DOCA SE value before the increment

Task Completion Failure

If the task fails midway:

- The context may enter a stopping state if a fatal error occurs
- The fetched value memory may be modified.

Task Limitations

All limitations are described in DOCA Core Task.

Wait Equal-to Task

The wait-equal task allows atomically waiting for a DOCA SE value to be equal to some threshold.

Task Configuration

Description	API to set the configuration	API to query support
Enable the task	`doca_sync_event_task_wait_eq_set_conf`	`doca_sync_event_cap_task_wait_eq_is_supported`

Description	API to set the configuration	API to query support
Number of tasks	`doca_sync_event_task_wait_eq_set_conf`	-

Task Input

Common input described in DOCA Core Task.

Name	Description
Wait threshold	64-bit value to wait for the DOCA SE value to be equal to
Mask	64-bit mask to apply on the DOCA SE value before comparing with the wait threshold

Task Output

Common output described in DOCA Core Task.

Task Completion Success

After the task is completed successfully, the following occurs:

- The DOCA SE value is equal to the given wait threshold.

Task Completion Failure

If the task fails midway, the context may enter a stopping state if a fatal error occurs.

Task Limitations

Other limitations are described in DOCA Core Task.

Wait Not-equal-to Task

The wait-not-equal task allows atomically waiting for a DOCA SE value to not be equal to some threshold.

Task Configuration

Description	API to set the configuration	API to query support
Enable the task	`doca_sync_event_task_wait_neq_set_conf`	`doca_sync_event_cap_task_wait_neq_is_supported`
Number of tasks	`doca_sync_event_task_wait_neq_set_conf`	-

Task Input

Common input described in DOCA Core Task.

Name	Description
Wait threshold	64-bit value to wait for the DOCA SE value to be not equal to
Mask	64-bit mask to apply on the DOCA SE value before comparing with the wait threshold

Task Output

Common output described in DOCA Core Task.

Task Completion Success

After the task is completed successfully, the following occurs:

- The DOCA SE value is not equal to the given wait threshold.

Task Completion Failure

If the task fails midway, the context may enter a stopping state if a fatal error occurs.

Task Limitations

Limitations are described in DOCA Core Task.

Events

DOCA SE context exposes asynchronous events to notify about changes that happen unexpectedly, according to the DOCA Core architecture.

The only event DOCA SE context exposes is common events as described in DOCA Core Event.

5.4.1.1.7.7 State Machine

The DOCA SE context follows the Context state machine as described in DOCA Core Context State Machine.

The following subsection describe how to move to specific states and what is allowed in each state.

Idle

In this state, it is expected that the application will:

- Destroy the context; or
- Start the context

Allowed operations in this state:

- Configure the context according to section "Configurations"
- Start the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all tasks have been freed
Stopping	Call progress until all tasks are completed and then freed

Starting

This state cannot be reached.

Running

In this state, it is expected that the application will:

- Allocate and submit tasks
- Call progress to complete tasks and/or receive events

Allowed operations in this state:

- Allocate previously configured task
- Submit an allocated task
- Call stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

Stopping

In this state, it is expected that the application will:

- Call progress to complete all inflight tasks (tasks will complete with failure)
- Free any completed tasks

Allowed operations in this state:

- Call progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without freeing all tasks

5.4.1.1.7.8 DOCA Sync Event Tear Down

Multiple SE handles (for different execution units) associated with the same DOCA SE instance can live simultaneously, though the teardown flow is performed only from the CPU on the CPU handle.

Users must validate active handles associated with the CPU handle during the teardown flow because DOCA SE does not do that.

Stopping DOCA Sync Event

To stop a DOCA SE:

- Synchronous – call `doca_sync_event_stop` on the CPU handle

- Asynchronous – stop the DOCA context associated with the DOCA SE instance

> ⚠ Stopping a DOCA SE must be followed by destruction. Refer to section "Destroying DOCA Sync Event" for details.

Destroying DOCA Sync Event

Once stopped, a DOCA SE instance can be destroyed by calling `doca_sync_event_destroy` on the CPU handle.

Remote net CPU handle instance terminates and frees by calling `doca_sync_event_remote_net_destroy` on the remote net CPU handle.

Upon destruction, all the internal resources are released, allocated memory is freed, associated `doca_ctx` (if it exists) is destroyed, and any associated exported handles (other than CPU handles) and their resources are destroyed.

5.4.1.1.7.9 Alternative Datapath Options

DOCA SE supports datapath on CPU (see Execution Phase) and also on DPA and GPU.

GPU Datapath

DOCA SE does not currently support GPU related features.

DPA Datapath

> ℹ An SE with DPA-subscriber configuration currently supports synchronous APIs only.

Once a DOCA SE DPA handle (`doca_dpa_dev_sync_event_t`) has been retrieved it can be used within a DOCA DPA kernel as described in DOCA DPA Sync Event.

5.4.1.1.7.10 DOCA Sync Event Sample

This section provides DOCA SE sample implementation on top of the BlueField DPU.

The sample demonstrates how to share an SE between the host and the DPU while simultaneously interacting with the event from both the host and DPU sides using different handles.

Running DOCA Sync Event Sample

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.

2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_common/sync_event_<local|remote>_pci
meson /tmp/build
ninja -C /tmp/build
```

> ⚠ The binary `doca_sync_event_<local|remote>_pci` is created under `/tmp/build/`.

3. Sample usage:

```
Usage: doca_sync_event_remote_pci [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse all command flags from an input json file

Program Flags:
  -d, --pci-addr                    Device PCI address
  -r, --rep-pci-addr                DPU representor PCI address
  --async                           Start DOCA Sync Event in asynchronous mode (synchronous mode by
default)
  --async_num_tasks                 Async num tasks for asynchronous mode
  --atomic                          Update DOCA Sync Event using Add operation (Set operation by default)
```

> ⚠ The flag `--rep-pci-addr` is relevant only for the DPU.

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_sync_event_<local|remote>_pci -h
```

Samples

Sync Event Remote PCIe

> ⚠ This sample should be run (on the DPU or on the host) before Sync Event Local PCIe.

> ✓ These samples are also available on GitHub.

This sample demonstrates creating an SE from an export which is associated with an SE on a local PCIe (host or the DPU) and interacting with the SE to achieve synchronization between the host and DPU.

The sample logic includes:

1. Reading configuration files and saving their content into local buffers.
2. Locating and opening DOCA devices and DOCA representors (if running on the DPU) matching the given PCIe addresses.
3. Initializing DOCA Comm Channel.
4. Receiving SE blob through Comm Channel.
5. Creating SE from export.
6. Starting the above SE in the requested operation mode (synchronous or asynchronous).
7. Interacting with the SE:
    a. Waiting for signal from the host – synchronously or asynchronously (with busy wait polling) according to user input.
    b. Signaling the SE for the host – synchronously or asynchronously, using set or atomic add, according to user input.
8. Cleaning all resources.

Reference:

- `/opt/mellanox/doca/samples/doca_common/sync_event_remote_pci/sync_event_remote_pci_sample.c`
- `/opt/mellanox/doca/samples/doca_common/sync_event_remote_pci/sync_event_remote_pci_main.c`
- `/opt/mellanox/doca/samples/doca_common/sync_event_remote_pci/meson.build`

Sync Event Local PCIe

This sample should run (on the DPU or on the Host) only after Sync Event Remote PCIe has been started.

These samples are also available on GitHub.

This sample demonstrates how to initialize a SE to be shared with a remote PCIe (host or the DPU) how to export it to a remote PCIe, and how to interact with the SE to achieve synchronization between the host and DPU.

The sample logic includes:

1. Reading configuration files and saving their content into local buffers.
2. Locating and opening DOCA devices and DOCA representors (if running on the DPU) matching the given PCIe addresses.
3. Creating and configuring the SE to be shared with a remote PCIe.
4. Starting the above SE in the requested operation mode (synchronous or asynchronous).

5. Initializing DOCA Comm Channel.
6. Exporting the SE and sending it through the Comm Channel.
7. Interacting with the SE :
    a. Signaling the SE for the remote PCIe – synchronously or asynchronously, using set or atomic add, according to user input.
    b. Waiting for a signal – synchronously or asynchronously, with busy wait polling, according to user input.
8. Cleaning all resources.

Reference:

- `/opt/mellanox/doca/samples/doca_common/sync_event_local_pci/sync_event_local_pci_sample.c`
- `/opt/mellanox/doca/samples/doca_common/sync_event_local_pci/sync_event_local_pci_main.c`
- `/opt/mellanox/doca/samples/doca_common/sync_event_local_pci/meson.build`

5.4.1.1.8 Mmap Advise

5.4.1.1.8.1 Introduction

DOCA Mmap Advise is used to give advanced memory-related instructions to NVIDIA® BlueField® DPUs in order to improve system or application performance.

> ⚠ To use DOCA Mmap Advise with BlueField, the device must be configured to work in DPU mode as described in BlueField Modes of Operation.

The operations in the instructions are meant to influence the performance of the application, but not its semantics. The operations allow an application to inform the NIC how it expects it to use some mapped memory areas, so the BlueField's hardware can choose appropriate optimization techniques.

5.4.1.1.8.2 Prerequisites

DOCA Mmap Advise is a context and follows the architecture of a DOCA Core Context, it is recommended to read the following sections of the DOCA Core page before proceeding:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

5.4.1.1.8.3 Architecture

DOCA Mmap Advise is a DOCA Context as defined by DOCA Core. See DOCA Core Context for more information.

DOCA Mmap Advise currently supports the following list of advised operations:

- Cache Invalidate Operation

Cache Invalidate Operation

When data is processed by BlueField's cores it may be temporarily stored in the cores' system-level cache (i.e., L3 cache). When a cache line is occupied and new data must be written to it, the cache management sub-system evicts the existing data, usually based on LRU policy, by performing a write-back operation to store this data in the main (DDR) memory. When this data is not required to be stored in the BlueField's memory (e.g., it is host data and is no longer needed after it is copied to the host's memory), the cache's write-back operation wastes memory bandwidth that reduces overall system performance, which is undesirable. The simplest way to avoid this write-back operation is to mark the appropriate cache lines as "invalid". This enables their immediate reuse, without additional operations.

The cache invalidate operation facilitates invalidating a set of cache lines.

5.4.1.1.8.4 Environment

Applications based on DOCA Mmap Advise can run on the BlueField target.

Objects

Device and Device Representor

The MMAP Advise context requires a DOCA Device to operate. The device is used to access memory and perform the copy operation. See DOCA Core Device Discovery.

> For the same DPU, it does not matter which device is used (i.e., PF, VF, SF) as all these devices utilize the same hardware components.

> The device must stay valid for as long as the MMAP Advise instance is not destroyed.

Memory Buffers

The cache invalidate task requires one DOCA Buffer containing the address space to invalidate depending on the allocation pattern of the buffers (refer to the table in section "Inventory Types"). To find what kind of memory is supported, refer to the table in section "Buffer Support".

Buffers must not be modified or read during the cache invalidate operation.

5.4.1.1.8.5 Configuration Phase

To start using the context, users must go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context, to allow execution of tasks and retrieval of events.

Configurations

The context can be configured to match the application's use case.

To find if a configuration is supported, or what the min/max value for it is, refer to section "Device Support".

Mandatory Configurations

These configurations are mandatory and must be set by the application before attempting to start the context:

- At least one task/event type must be configured. See configuration of tasks and/or events in sections "Tasks" and "Events" respectively for information.
- A device with appropriate support must be provided upon creation

Device Support

DOCA Mmap Advise requires a device to operate. To pick a device, refer to DOCA Core Device Discovery.

As device capabilities may change (see DOCA Core Device Support), it is recommended to select your device using the following method:

- `doca_mmap_advise_cap_task_cache_invalidate_is_supported`

Some devices expose different capabilities as follows:

- Maximum cache invalidate buffer size may differ.

Buffer Support

Tasks support buffers with the following features:

Buffer Type	Buffer
Local mmap buffer	Yes
MMAP from PCIe export buffer	No
MMAP from RDMA export buffer	No
Linked list buffer	No

5.4.1.1.8.6 Execution Phase

This section describes execution on the CPU using DOCA Core Progress Engine.

Tasks

DOCA Mmap Advise exposes asynchronous tasks that leverage DPU hardware according to the DOCA Core architecture. See DOCA Core Task for information.

Cache Invalidate Task

The cache invalidate task facilitates invalidating a set of cache lines, preventing them from being written back to the RAM (thus increasing performance).

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_mmap_advise_task_invalidate_cache_set_conf`	`doca_mmap_advise_cap_task_cache_invalidate_is_supported`
Number of tasks	`doca_mmap_advise_task_invalidate_cache_set_conf`	–
Maximal buffer size	–	`doca_mmap_advise_task_cache_invalidate_get_max_buf_size`
Maximal buffer list size	–	–

Task Input

Common input as described in DOCA Core Task.

Name	Description
buffer	Buffer that points to the memory to be invalidated

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task is completed successfully:

- The cache is invalidated

Task Completion Failure

If the task fails midway:

- The context may enter stopping state, if a fatal error occurs
- The cache is not invalidated

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the buffer should not be read/written to
- Other limitations are described in DOCA Core Task

Events

DOCA Mmap Advise exposes asynchronous events to notify on changes that happen unexpectedly, according to DOCA Core architecture.

The only events DOCA Mmap Advise exposes are common events as described in DOCA Core Event.

5.4.1.1.8.7 State Machine

DOCA Mmap Advise context follows the context state machine as described in DOCA Core Context State Machine.

The following section describes how to move states and what is allowed in each state.

Idle

In this state it is expected that the application:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to section "Configurations"
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all tasks have been freed
Stopping	Call progress until all tasks are completed and freed

Starting

This state cannot be reached.

Running

In this state, it is expected that the application:

- Allocates and submits tasks
- Calls progress to complete tasks and/or receive events

Allowed operations:

- Allocating a previously configured task
- Submitting a task
- Calling stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

Stopping

In this state it is expected that the application:

- Calls progress to complete all in-flight tasks (tasks complete with failure)
- Frees any completed tasks

Allowed operations:

- Call progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without freeing all tasks

5.4.1.1.8.8 Alternative Datapath Options

DOCA Mmap Advise only supports datapath on the CPU. See section "Execution Phase".

5.4.1.1.8.9 Samples

Cache Invalidate Sample

The sample illustrates how to invalidate the cache for a memory range after copying it using DOCA DMA.

The sample logic includes:

1. Locating DOCA device.
2. Initializing needed DOCA core structures.
3. Populating DOCA memory map with two relevant buffers.
4. Allocating element in DOCA buffer inventory for each buffer.
5. Initializing DOCA DMA memory copy task object.
6. Initializing DOCA Mmap Advise cache invalidate task object
7. Submitting DMA task.
8. Polling for completion:
    a. Handling DMA task completion – submitting the cache invalidate task in the DMA task completion callback body.
    b. Handling cache invalidate task completion.
9. Polling for completion.
10. Destroying DMA, DOCA MMAP Advise, and DOCA Core objects.

5.4.1.2 DOCA Log

The DOCA logging infrastructure provides a mechanism for printing error messages, debug logs, and application-specific messages within the DOCA SDK.

To use DOCA logging, applications must include the `doca_log.h` header file in their source code.

5.4.1.2.1 Log Verbosity Level Enumerations

DOCA logging supports multiple verbosity levels, allowing applications to filter logs based on severity:

```
enum doca_log_level {
    DOCA_LOG_LEVEL_DISABLE = 10,    /**< Disable log messages */
    DOCA_LOG_LEVEL_CRIT = 20,       /**< Critical log level */
    DOCA_LOG_LEVEL_ERROR = 30,      /**< Error log level */
    DOCA_LOG_LEVEL_WARNING = 40,    /**< Warning log level */
    DOCA_LOG_LEVEL_INFO = 50,       /**< Info log level */
    DOCA_LOG_LEVEL_DEBUG = 60,      /**< Debug log level */
    DOCA_LOG_LEVEL_TRACE = 70,      /**< Trace log level */
};
```

The `DOCA_LOG_LEVEL_TRACE` verbosity level is available only if the macro `DOCA_LOGGING_ALLOW_TRACE` is defined before compilation.

Refer to `doca_log.h` for more information.

5.4.1.2.2 Logging Backends

A logging backend is the destination where log messages are directed. DOCA supports multiple backend types:

- FILE* – Any open file, including `stdout` or `stderr`
- File descriptor – Any valid file descriptor (e.g., raw files, sockets, pipes)
- Buffer (`buf`) – A memory buffer that stores log messages and triggers a callback for each message
- Syslog – Standard system logging mechanism

Each logging backend is initialized with the following default verbosity levels:

- Lower level – `DOCA_LOG_LEVEL_INFO`
- Upper level – `DOCA_LOG_LEVEL_CRIT`

DOCA SDK logs and application logs have different configurations and can be controlled independently through the DOCA logging API.

> All messages are sent to all backends that meet the configured verbosity level.

5.4.1.2.3 Enabling DOCA SDK Libraries Logging

DOCA SDK libraries automatically print debug and error messages to the configured logging backends.

The maximum number of logging backends can be queried using `doca_log_get_max_num_backends_sdk()`.

To create a logging backend for SDK logs, use:

```
doca_log_backend_create_with_file_sdk()
doca_log_backend_create_with_fd_sdk()
doca_log_backend_create_with_buf_sdk()
doca_log_backend_create_with_syslog_sdk()
```

> When creating a new SDK logging backend, the first message printed is the DOCA version, which is printed in verbosity level INFO.

The following functions control SDK logging levels:

- `doca_log_level_set_global_sdk_limit()` sets global verbosity level

  > This function applies to all SDK backends.

  > A newly created SDK backend's verbosity level is set to the SDK global verbosity level value by default.

- `doca_log_backend_set_sdk_level()` sets verbosity level for a specific SDK backend
- `doca_log_level_get_global_sdk_limit()` gets the global SDK verbosity level

> Log messages may change across DOCA versions. Do not rely on specific message formatting or content permanence.

5.4.1.2.4 Enabling DOCA Application Logging

Applications that use the DOCA SDK can utilize DOCA logging for structured logging

The maximum number of logging backends can be queried using `doca_log_get_max_num_backends()`.

The total number of application logging backends that can be created can be queried using the following function:

```
doca_log_get_max_num_backends()
```

To create an application logging backend, use:

```
doca_log_backend_create_with_file()
doca_log_backend_create_with_fd()
doca_log_backend_create_with_buf()
doca_log_backend_create_with_syslog()
```

The following functions configure logging limits:

- `doca_log_backend_set_level_{lower|upper}_limit()` sets lower and/or upper verbosity levels for a backend

  > The lower and upper verbosity levels of a newly created backend are set to the default values.

- `doca_log_backend_create_standard()` creates a standard, non-configurable logging setup. It creates two backends:
  - `stdout` – Logs messages up to `DOCA_LOG_LEVEL_INFO`
  - `stderr` – Logs messages from `DOCA_LOG_LEVEL_WARNING` to `DOCA_LOG_LEVEL_CRIT`
- `doca_log_backend_set_level_{lower|upper}_limit_strict()` sets strict limits for a backend (prevent future changes)
- `doca_log_level_set_global_{lower|upper}_limit()` sets global logging limits (affects all non-strict backends)

5.4.1.2.5 Logging DOCA Application Messages

To enable DOCA logging in an application, use the DOCA log registration macro at the beginning of each source file:

```
DOCA_LOG_REGISTER(source);
```

This registers a logger for that file and automatically manages teardown.

The length of the source provided to `DOCA_LOG_REGISTER()` cannot be greater than `DOCA_LOGGER_NAME_SIZE`.

Log messages are printed using the following macros (similar to `printf()` syntax):

```
DOCA_LOG_CRIT(format, ...);   // Critical error messages
DOCA_LOG_ERR(format, ...);    // Standard error messages
DOCA_LOG_WARN(format, ...);   // Warnings
DOCA_LOG_INFO(format, ...);   // Informational messages
DOCA_LOG_DBG(format, ...);    // Debug messages
DOCA_LOG_TRC(format, ...);    // Trace-level messages
```

Messages are printed to all application logging backends that fall within the configured verbosity range.

5.4.1.2.6 Controlling Verbosity Level of Loggers

Every logger, whether created by an SDK library or an application, operates independently. You can control the output of each logger by adjusting its individual verbosity level.

Use the following functions to create or destroy a list of active loggers:

- `doca_logger_create_list()` – Generates a list of all current loggers.
- `doca_logger_destroy_list()` – Frees the list memory.

Configuration changes (such as verbosity levels) are persistent and remain in effect even after the list is destroyed.

Once you have the list, you can manage individual loggers using:

- `doca_logger_set_level()` – Sets the verbosity level for a specific logger.
- `doca_logger_get_level()` – Retrieves the current verbosity level.
- `doca_logger_get_name()` – Retrieves the name of a logger.

To locate a specific logger within the list:

- `doca_logger_find_by_name()` – Returns a pointer to the logger matching the specified name.

5.4.2 DOCA Flow

This guide describes how to deploy the DOCA Flow library, the philosophy of the DOCA Flow API, and how to use it. The guide is intended for developers writing network

function applications that focus on packet processing (such as gateways). It assumes familiarity with the network stack and DPDK.

5.4.2.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

DOCA Flow is the most fundamental API for building generic packet processing pipes in hardware. The DOCA Flow library provides an API for building a set of pipes, where each pipe consists of match criteria, monitoring, and a set of actions. Pipes can be chained so that after a pipe-defined action is executed, the packet may proceed to another pipe.

Using DOCA Flow API, it is easy to develop hardware-accelerated applications that have a match on up to two layers of packets (tunneled).

- MAC/VLAN/ETHERTYPE
- IPv4/IPv6
- TCP/UDP/ICMP
- GRE/VXLAN/GTP-U/ESP/PSP
- Metadata

The execution pipe can include packet modification actions such as the following:

- Modify MAC address
- Modify IP address
- Modify L4 (ports)
- Strip tunnel
- Add tunnel
- Set metadata
- Encrypt/Decrypt

The execution pipe can also have monitoring actions such as the following:

- Count
- Policers

The pipe also has a forwarding target which can be any of the following:

- Software (RSS to subset of queues)
- Port
- Another pipe
- Drop packets

5.4.2.2 Prerequisites

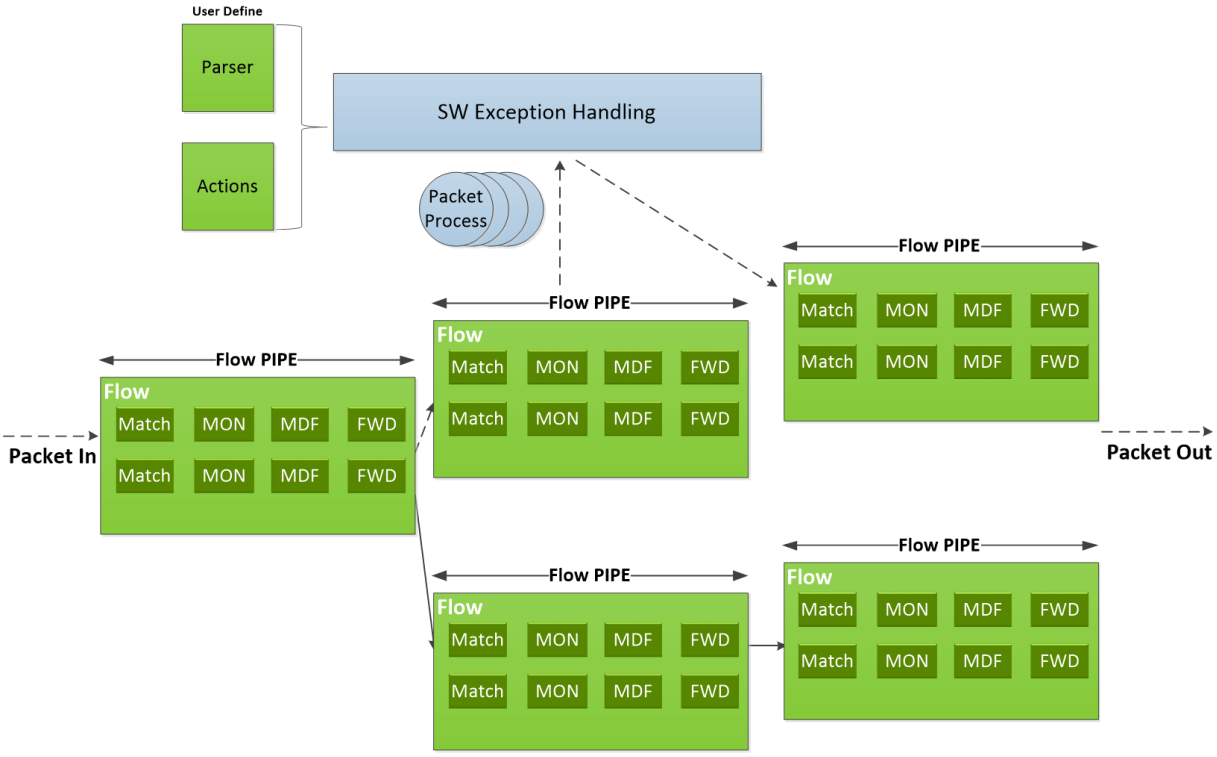
A DOCA Flow-based application can run on either the host machine or an NVIDIA® BlueField® DPU target.

These applications require the allocation of huge pages, which must be configured prior to execution. Use the following commands to allocate and mount 2MB huge pages:

```
$ echo '1024' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

5.4.2.3 Architecture

The following diagram shows how the DOCA Flow library defines a pipe template, receives a packet for processing, creates the pipe entry, and offloads the flow rule in NIC hardware.



Features of DOCA Flow:

- User-defined set of matches parser and actions
- DOCA Flow pipes can be created or destroyed dynamically
- Packet processing is fully accelerated by hardware with a specific entry in a flow pipe
- Packets that do not match any of the pipe entries in hardware can be sent to Arm cores for exception handling and then reinjected back to hardware

The DOCA Flow pipe consists of the following components:

- Monitor (MON in the diagram) - counts, meters
- Modify (MDF in the diagram) - modifies a field
- Forward (FWD in the diagram) - forwards to the next stage in packet processing

5.4.2.4 Steering Domains

DOCA Flow organizes pipes into high-level containers named domains to address the specific needs of the underlying architecture.

A key element in defining a domain is the packet direction and a set of allowed actions.

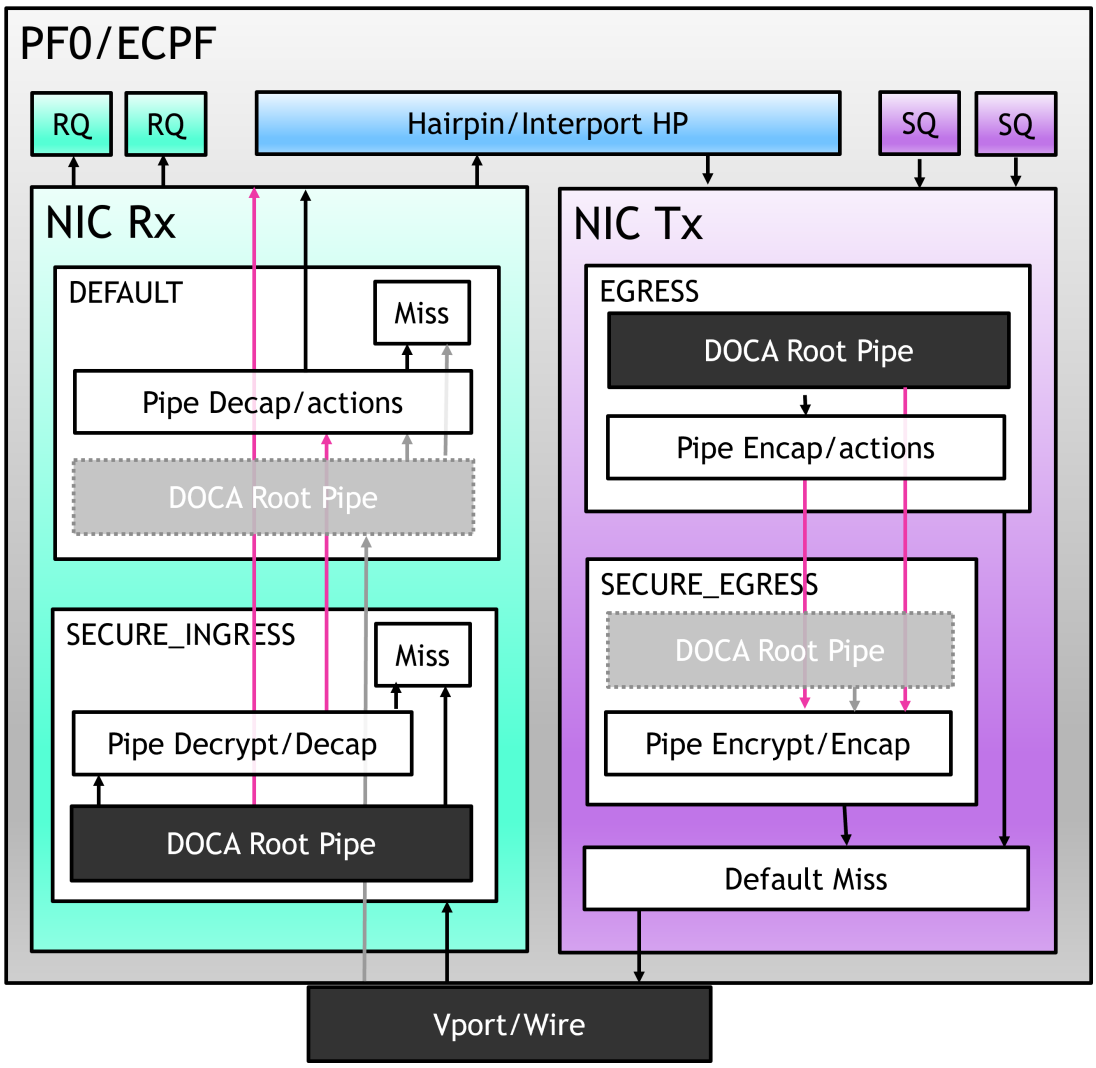
- A domain is a pipe attribute (also relates to shared objects)
- A domain restricts the set of allowed actions
- Transition between domains is well-defined (packets cannot cross domains arbitrarily)
- A domain may restrict the sharing of objects between packet directions
- Packet direction can restrict the move between domains

5.4.2.4.1 List of Steering Domains

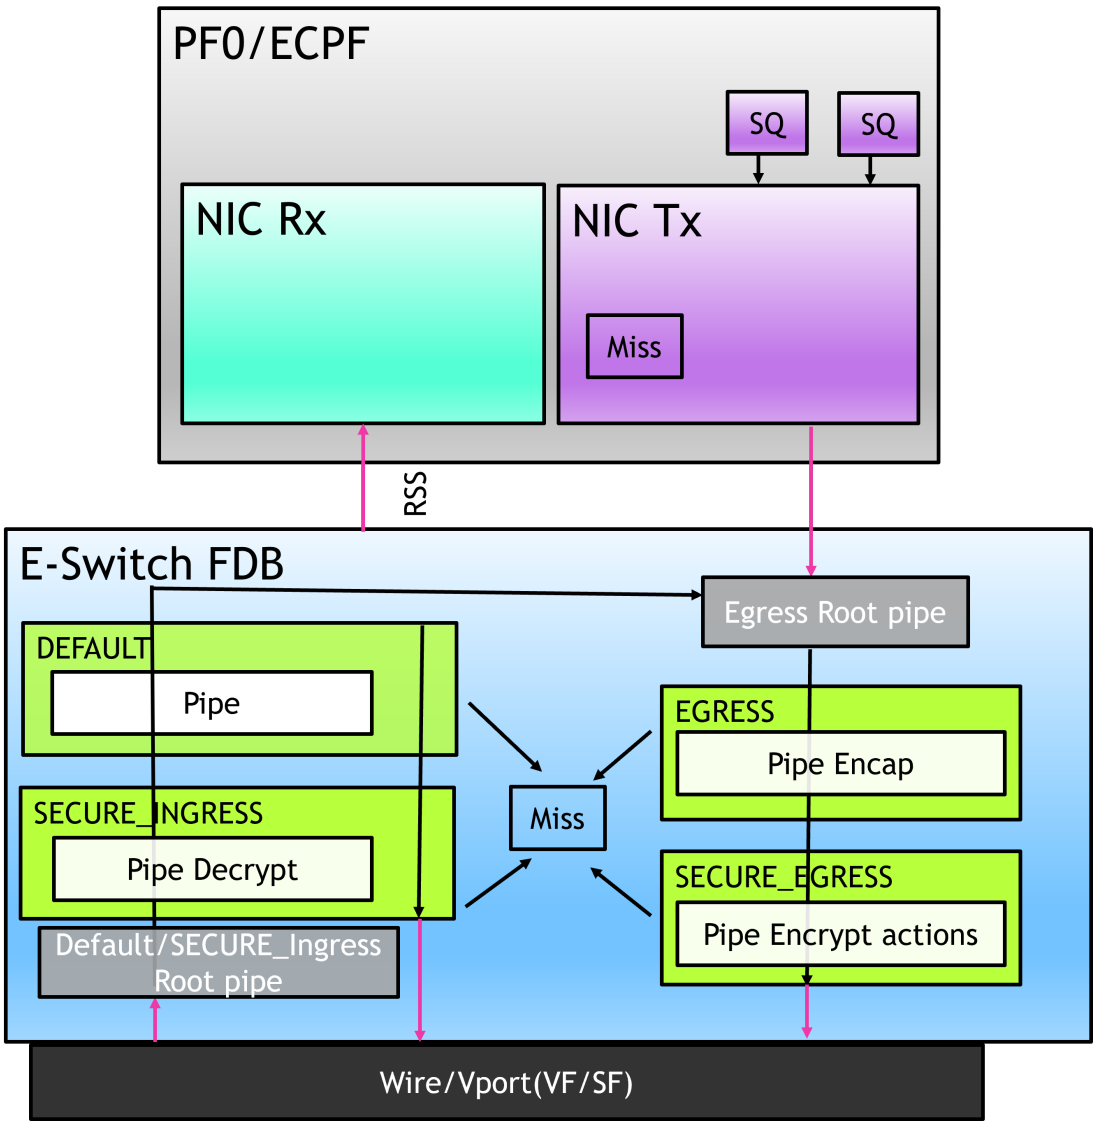
DOCA Flow provides the following set of predefined steering domains:

Domain	Description
`DOCA_FLOW_PIPE_DOMAIN_DEFAULT`	• Default domain for actions on ingress traffic • Secure actions are not allowed here • The next milestone is queue or pipe in the EGRESS domain • Miss action is: Drop
`DOCA_FLOW_PIPE_DOMAIN_SECURE_INGRESS`	• For secure actions on ingress traffic • Encapsulation and encrypting actions not allowed here • The only allowed domain for decrypting secure actions • The next milestone is queue or pipe in the DEFAULT or EGRESS domain • Only meta register is preserved • Miss action is: Drop
`DOCA_FLOW_PIPE_DOMAIN_EGRESS`	• Domain for actions on egress traffic • Secure actions are not allowed here • The next milestone is wire/representor or pipe in SECURE_EGRESS domain • Miss action is: Send to wire/representor
`DOCA_FLOW_PIPE_DOMAIN_SECURE_EGRESS`	• Domain for secure actions on egress traffic • Decapsulation actions are not allowed here • The only allowed domain for encrypting secure action • The next milestone is wire/representor • Miss action is: Send to wire/representor

5.4.2.4.2 Domains in VNF Mode



5.4.2.4.3 Domains in Switch Mode



In switch mode, forwarding from a pipe with the default domain to the egress domain root pipe is allowed, while forwarding from the egress domain to the default domain is not allowed.

Traffic from software Tx forwards to the egress root pipe.

A pipe with RSS forward follows the above rules.

Encap is suggested to be done from egress.

5.4.2.5 API

DOCA API is available through the DOCA API Reference.

> The pkg-config (`*.pc` file) for the DOCA Flow library is `doca-flow`.

5.4.2.6 Flow Life Cycle

5.4.2.6.1 Initialization Flow

Before using any DOCA Flow function, it is mandatory to call `doca_flow_init()`. This function initializes all resources required by the DOCA Flow library.

5.4.2.6.1.1 Pipe Mode

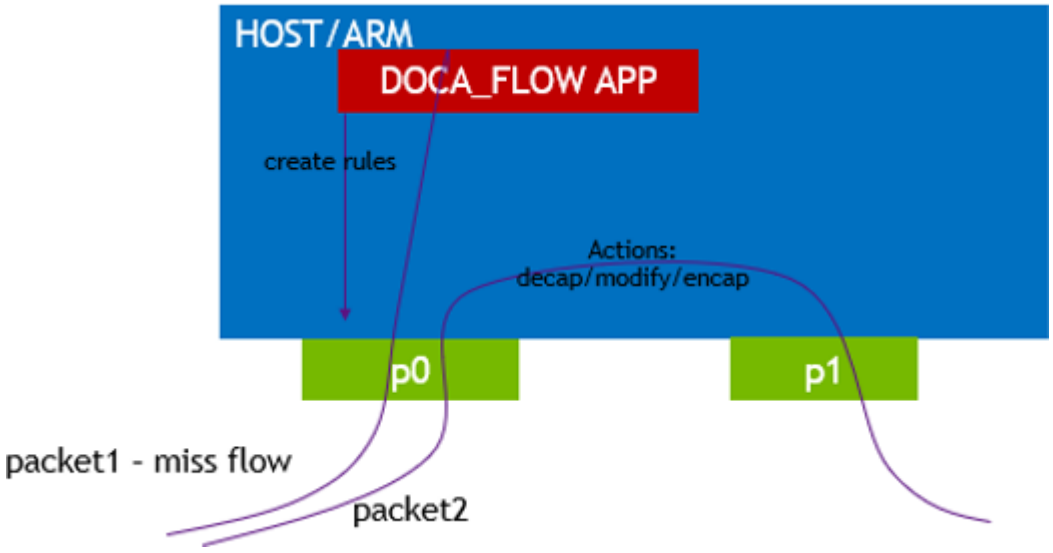
The pipe mode (set via `mode_args`) defines the fundamental traffic topology and default "miss" behavior for a DOCA port. When a port is initialized, this mode creates the initial miss rules.

DOCA supports the following modes:

VNF Mode

This mode is designed for Virtual Network Function (VNF) use cases. A packet arriving from one of the device's ports is processed and can be sent to another port. By default, any packet that does not match a user-defined pipe entry (a "miss") is forwarded to the host's RSS (Receive Side Scaling) queues.

Example scenario:



- Packet1 arrives at P0, does not match any existing entry, and is forwarded to the host's RSS queues.
- The application running on the host captures this packet, processes it, and creates a new pipe entry to handle this flow.
- Packet2 (part of the same flow) arrives, hits the new pipe entry, and has an action applied (e.g., VXLAN decap, modify, encap) before being sent out from P1.

To forward packets between ports, you must use `doca_flow_port_pair` to establish a port pair. Port pairing is unidirectional.

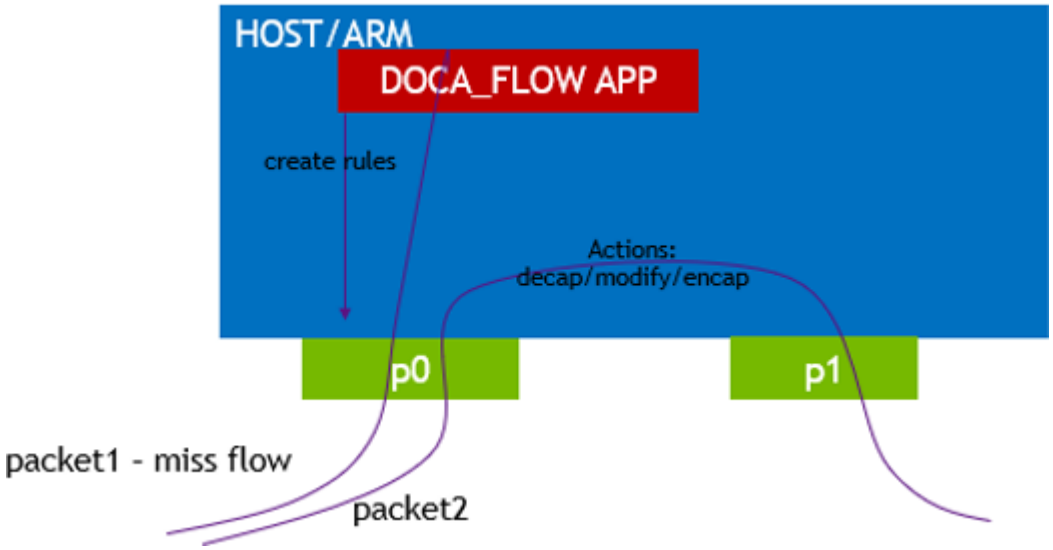
- Pairing Port X with Port Y allows forwarding from X to Y, but *not* from Y to X.
- To enable bidirectional forwarding, you must call `doca_flow_port_pair` a second time to pair Y with X.

After pairing, packets can be forwarded to either the paired port directly or the paired port's egress root pipe.

> ⚠ Forwarding from an ingress pipe to an egress pipe is only allowed to the `egress_root` pipe.

Switch Mode

This mode is used for internal switching and only allows representor ports (e.g., uplink representors and SF/VF representors). A packet is forwarded from one port to another. If a packet arrives from an uplink and does not match a user-defined pipe entry, it is received on all RSS queues of that uplink's representor.

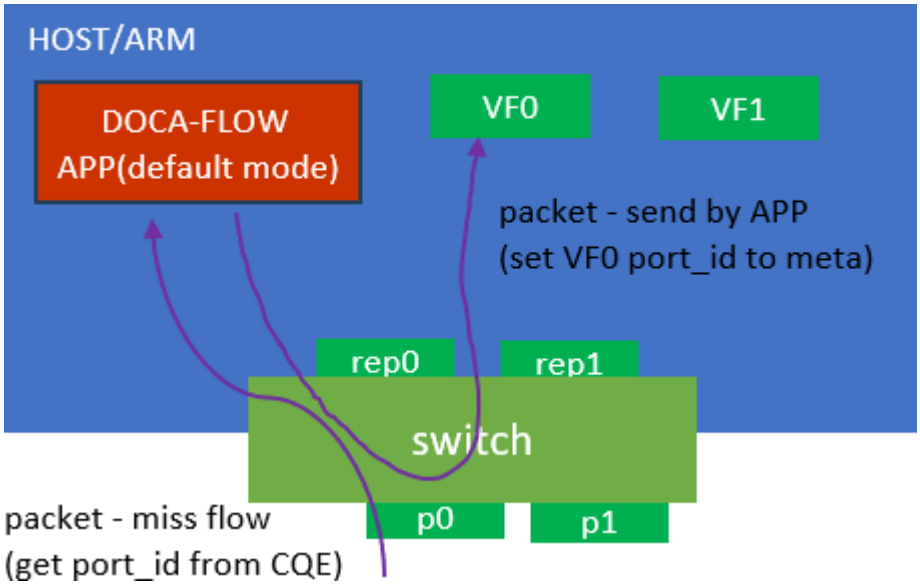


- The `doca_dev` field must be set in the `doca_flow_port_cfg` (using `doca_flow_port_cfg_set_dev()`).

> ⛔ **DPDK Port Initialization**

The application must not initialize VF/SF representor ports using the DPDK API. Functions such as `rte_eth_dev_configure()`, `rte_eth_rx_queue_setup()`, and `rte_eth_dev_start()` must not be called for these ports.

- Switch manager port: In switch mode, DOCA Flow unifies all ports under a single "switch manager port" for traffic management. This means all traffic is handled by this manager port. Applications only need to create an RSS pipe on the switch manager port to receive missed traffic and should manage all pipes on this port.
- `expert` Argument (`mode_args`): Switch mode can be configured with or without the `expert` argument. This setting changes how the source `port_id` of missed traffic is identified:
  - Without `expert` (default): Missed traffic sent to the software is tagged with the source `port_id` in the `mbuf` CQE field. This allows the application to identify the packet's origin. To send a packet, the application can set the destination `port_id` in the `mbuf` meta, and the packet will be sent directly to that port.
  - With `expert`: The `port_id` is not added to the packet. This gives the user full control to configure pipes freely and implement a custom solution for port identification.



Due to a firmware limitation, `port_id` information is missing for traffic that is cloned from a VF to an RSS pipe.

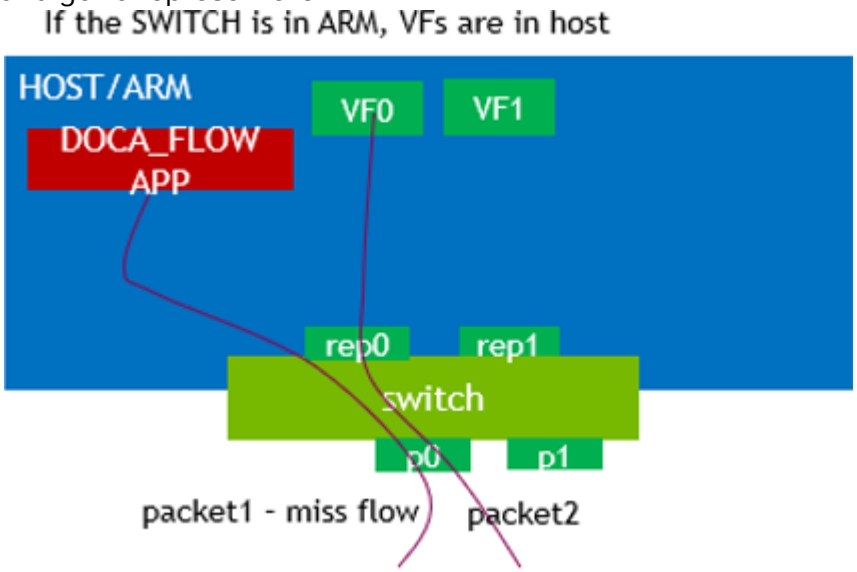
This mode (`mode_args`) defines the basic traffic in DOCA. It creates some miss rules when a DOCA port initializes. Currently, DOCA supports 3 modes:

- `vnf`
  A packet arriving from one of the device's ports is processed, and can be sent to another port. By default, missed packets go to RSS.
  The following diagram shows the basic traffic flow in `vnf` mode. Packet1 firstly misses and is forwarded to host RSS. The app captures this packet and decides how to process it and then creates a pipe entry. Packet2 will hit this pipe entry and do the action, for example, for VXLAN, will do decap, modify, and encap, then is sent out from P1.

  To forward packets between ports, use `doca_flow_port_pair` to establish a port pair. Port pairing is unidirectional, meaning that pairing port X with port Y allows forwarding from X to Y, but not the reverse. To enable forwarding from Y to X, you must pair Y with X using `doca_flow_port_pair` again. After pairing ports, packets can be forwarded to either the paired port directly or the paired port's egress root pipe, which sends packets through the egress routine.

  > ⚠ Forwarding from an ingress pipe to an egress pipe is only allowed to the `egress_root` pipe.

- `switch`
  Used for internal switching, only representor ports are allowed, for example, uplink representors and SF/VF representors. Packet is forwarded from one port to another. If a packet arrives from an uplink and does not hit the rules defined by the user's pipe, then the packet is received on all RSS queues of the representor of the uplink.
  The following diagram shows the basic flow of traffic in `switch` mode. Packet1 firstly misses to host RSS queues. The app captures this packet and decides to which representor the packet goes, and then sets the rule. Packets hit this rule and go to representor0.



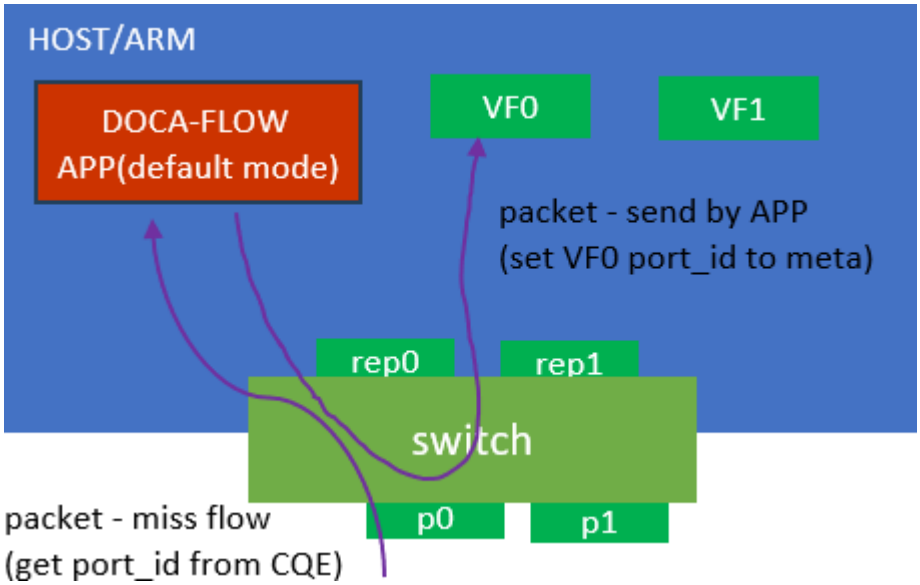
`doca_dev` field is mandatory in `doca_flow_port_cfg` (using `doca_flow_port_cfg_set_dev()`).

> ⚠ The application must avoid initialization of the VF/SF representor ports in DPDK API (i.e., the following functions `rte_eth_dev_configure()`, `rte_eth_rx_queue_setup()`, `rte_eth_dev_start()` must not be called for VF/SF representor ports).

DOCA Flow switch mode unifies all the ports to the switch manager port for traffic management. This means that all the traffic is handled by switch manager port. Users only must create an RSS pipe on the switch manager port to get the missed traffic, and they should only manage the pipes on the switch manager port. Switch mode can work with two different `mode_args` configurations: With or without `expert`. The way to retrieve the miss traffic source's `port_id` depends on this configuration:

- If `expert` is not set, the traffic misses to software would be tagged with `port_id` information in the mbuf CQE field to allow users to deduce the source `port_id`. Meanwhile, users can set the destination `port_id` to

mbuf meta and the packet is sent out directly to the destination port based on the meta information.



- If `expert` is set, the `port_id` is not added to the packet. Users can configure the pipes freely to implement their own solution.

  ⚠ Traffic cloned from the VF to the RSS pipe misses its `port_id` information due to firmware limitation.

5.4.2.6.2 Start Point

DOCA Flow API serves as an abstraction layer API for network acceleration. The packet processing in-network function is described from ingress to egress and, therefore, a pipe must be attached to the origin port. Once a packet arrives to the ingress port, it starts the hardware execution as defined by the DOCA API.

5.4.2.6.2.1 Port identifiers

`doca_flow_port` is an opaque object, as the DOCA Flow API is designed to be independent of any specific packet I/O framework (e.g., DPDK).
To begin using a DOCA Flow port, the user must call `doca_flow_port_start()`. This function associates the application's underlying port with a DOCA Flow port.

During this setup, the user must assign a **logical port ID** using the `doca_flow_port_cfg_set_port_id()` API.
This `port_id` is later referenced in:

- `doca_flow_parser_meta.port_id` - when matching packets received on a specific port
- `doca_flow_fwd.port_id` - when forwarding packets to a specific port

For DPDK-based applications, the DPDK `port_id` can be used directly as the logical port identifier.

5.4.2.6.2.2 DOCA Device

A DOCA device must be specified during `doca_flow_port_start()` to provide the necessary hardware context for the port.

- For **physical**, **virtual**, or **subfunction** devices (PF, VF, or SF), use the `doca_flow_port_cfg_set_dev()` API to associate a `doca_dev` object with the port.
- For **representor** ports, use the `doca_flow_port_cfg_set_dev_rep()` API to associate a `doca_dev_rep` object instead.

Providing a `doca_dev_rep` is what explicitly indicates that the port is a representor.

5.4.2.6.2.3 Actions Memory

The use of DOCA Flow actions mandates that sufficient memory will be allocated for them, in advance, per port. This is done using the `doca_flow_port_cfg_set_actions_mem_size()` API function. The recommended way of getting precise information about the expected actions memory consumption is the following:

1. During development, allocate a fixed high amount of actions memory, regardless of your actual pipeline.
2. Once the steering pipeline is ready, examine the program's actual consumption using the DOCA Flow Tune tool.
3. Using DOCA Flow Tune for calibration, update the parameter passed to the setter function.

Please note that in the hot upgrade use case, the total **actions memory** size set for all instances should not exceed the maximum resource limit of this hardware port.

5.4.2.6.3 Port Operation State

DOCA Flow ports can be initialized multiple times from different instances. Each instance prepares its pipeline, but only one actively receives port traffic at a time. The instance actively handling the port traffic depends on the operation state set by the `doca_flow_port_cfg_set_operation_state()` function:

- `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE` – The instance actively handles incoming and outgoing traffic
- `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE_READY_TO_SWAP` – The instance handles traffic actively when no other active instance is available
- `DOCA_FLOW_PORT_OPERATION_STATE_STANDBY` – The instance handles traffic only when no active or `active_ready_to_swap` instance is available
- `DOCA_FLOW_PORT_OPERATION_STATE_UNCONNECTED` – The instance does not handle traffic, regardless of the state of other instances

If the `doca_flow_port_cfg_set_operation_state()` function is not called, the default state `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE` is applied.

When a port is configured with a state that expects to handle traffic, it takes effect only after root pipes are created for this port.

When the active port is closed, either gracefully or due to a crash, the standby instance automatically becomes active without any action required.

The port operation state can be modified after the port is started using the `doca_flow_port_operation_state_modify()` function.

5.4.2.6.3.1 Use Case Examples

Hot Upgrade

This operation state mechanism allows upgrading the DOCA Flow program without losing any traffic.

To upgrade an existing DOCA Flow program with ports started in `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE` state (Instance A):

1. Open a new Instance B and start its ports in `DOCA_FLOW_PORT_OPERATION_STATE_STANDBY` state.
2. Modify Instance A's ports from `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE` to `DOCA_FLOW_PORT_OPERATION_STATE_UNCONNECTED` state. At this point, Instance B starts receiving traffic.
3. Close Instance A.
4. Open a new Instance C with `DOCA_FLOW_PORT_OPERATION_STATE_UNCONNECTED` state. Instance C is the upgraded version of Instance A.
5. Create the entire pipeline for Instance C.
6. Change Instance C's state from `DOCA_FLOW_PORT_OPERATION_STATE_UNCONNECTED` to `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE`. At this point, Instance B stops receiving traffic and Instance C starts.
7. Instance B can either be closed or kept as a backup should Instance C crash.

This mechanism also facilitates swapping two different DOCA Flow programs without losing any traffic.

To swap between two existing DOCA Flow programs with ports started in `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE` and `DOCA_FLOW_PORT_OPERATION_STATE_STANDBY` states (Instance A and Instance B, respectively):

1. Modify Instance A's ports from `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE` to `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE_READY_TO_SWAP`.
2. Modify Instance B's ports from `DOCA_FLOW_PORT_OPERATION_STATE_STANDBY` to `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE`. At this point, Instance B starts receiving traffic.
3. Modify Instance A's ports from `DOCA_FLOW_PORT_OPERATION_STATE_ACTIVE_READY_TO_SWAP` to `DOCA_FLOW_PORT_OPERATION_STATE_STANDBY`.

5.4.2.6.3.2 Limitations

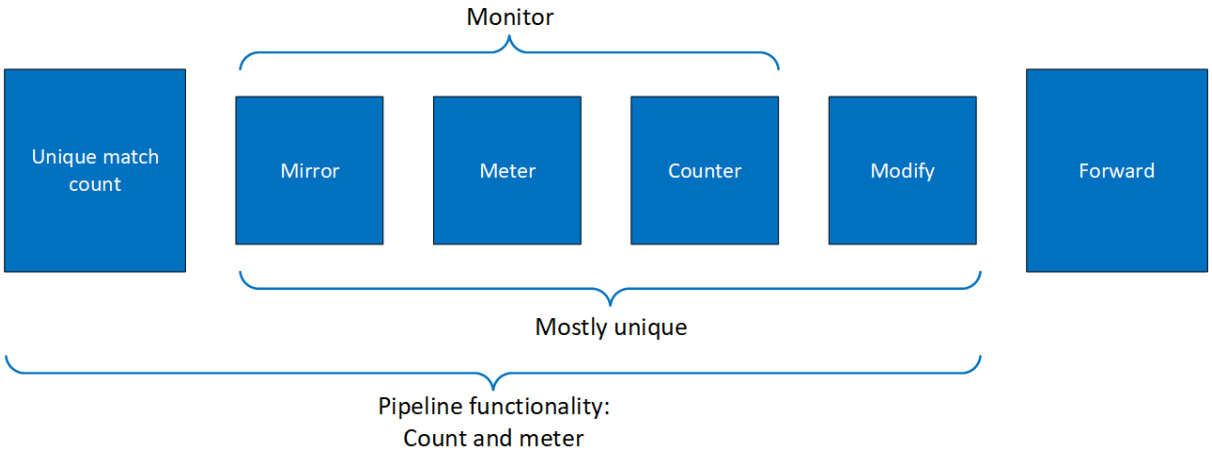
- Supported only in switch mode – the `mode_args` string must include `"switch"`.
- Only the switch port supports states; its representors are affected by its state. Starting a representor port or calling the modify function with a non-active operation state should fail.
- Two instances cannot be in the same operation state simultaneously, except for `DOCA_FLOW_PORT_OPERATION_STATE_UNCONNECTED`. If a new instance initializes a port while another instance with the same operation state exists, a `DOCA_ERROR_ALREADY_EXIST` error is returned either during port startup or root pipe creation.
- Due to an underlying driver limitation, each ASO object type (e.g., `METER`, `COUNTER`) is restricted to a maximum of 64 million (64M) objects per port.

5.4.2.6.4 Create Pipe and Pipe Entry

Pipe is a template that defines packet processing without adding any specific hardware rule. A pipe consists of a template that includes the following elements:

- Match
- Monitor
- Actions
- Forward

The following diagram illustrates a pipe structure.



The creation phase allows the hardware to efficiently build the execution pipe. After the pipe is created, specific entries can be added. A subset of the pipe may be used (e.g., skipping the monitor completely, just using the counter, etc).

5.4.2.6.4.1 Pipe Matching or Action Applying

DOCA Flow allows defining criteria for matching on a packet or for taking actions on a matched packet by modifying it. The information defining these criteria is provided through the following pointers:

- Match or action pointer – given at pipe or entry creation
- Mask pointer – optionally given at pipe creation

Defining criteria for matching or actions on a packet can be done at the pipe level, where it applies to all packets of a pipe, or specified on a per entry basis, where each entry defines the operation on either the match, actions, or both.

In DOCA Flow terminology, when a field is identified as CHANGEABLE at pipe creation, this means that the actual criterion of the field is deferred to entry creation. Different entries can provide different criteria for a CHANGEABLE field.

A match or action field can be categorized, during pipe creation, as one of the following:

- IGNORED – Ignored in either the match or action taking process
- CHANGEABLE – When the actual behavior is deferred to the entry creation stage
- SPECIFIC – Value is used as is in either match or action process

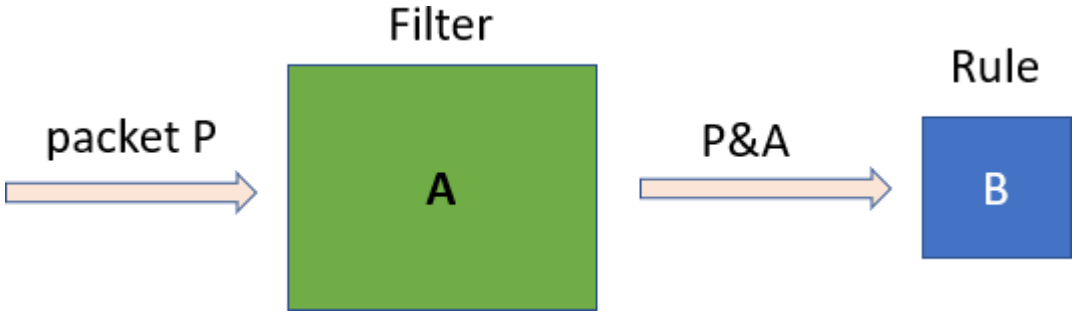
A mask field can either be provided, in which case it is called explicit matching, or action applying. If the mask pointer is NULL, we call it implicit matching or action applying. The following subsections provide the logic governing matching and action applying.

When a field value is specified as `0xffff` it means that all the field's bits are set (e.g., for TTL it means `0xff` and for IPv4 address it means `0xffffffff`).

⚠ Creating multiple entries with the same match criteria is not supported. Instead, use the update entry API to modify the existing entry.

Matching

Matching is the process of selecting packets based on their fields' values and steering them for further processing. Processing can either be further matching or actions applying.



The packet enters the green filter which modifies it by masking it with the value A. The output value, P&A, is then compared to the value B, and if they are equal, then that is a match.

The values of A and B are evaluated according to the values of the pipe configuration and entry configuration fields, according to the tables in sections "Implicit Matching" and "Explicit Matching".

Implicit Matching

Match Type	Pipe Match Value (V)	Pipe Match Mask (M)	Entry Match Value (E)	Filter (A)	Rule (B)
Ignore	0	NULL	N/A	0	0
Constant	0<V<0xffff	NULL	N/A	0xffff	V
Changeable (per entry)	0xffff	NULL	0≤E≤0xffff	0xffff	E

Explicit Matching

Match Type	Pipe Match Value (V)	Pipe Match Mask (M)	Entry Match Value (E)	Filter (A)	Rule (B)
Constant	V!=0xffff	0<M≤0xffff	0≤E≤0xffff	M	M&V
Changeable	V==0xffff	0<M≤0xffff	0≤E≤0xffff	M	M&E
Ignored	0≤V<0xffff	M==0	0≤E≤0xffff	0	0

Action Applying

Implicit Action Applying

Action Type	Pipe Action Value (V)	Pipe Action Mask (M)	Entry Action Value (E)	Action on the Field
Ignore	0	NULL	N/A	None
Constant	0 < V < 0xffff	NULL	N/A	Set to V
Changeable	0xffff	NULL	E	Set to E

Implicit action applying example:

- Destination IPv4 address is 255.255.255.255
- No mask provided
- Entry value is 192.168.0.1
- Result – The action field is changeable. Therefore, the value is provided by the entry. If a match on the packet occurs, the packet destination IPv4 address is changed to 192.168.0.1.

Meta only supports changeable action.

Explicit Action Applying

Assume P is packet's field value.

Action Type	Pipe Action Value (V)	Pipe Action Mask (M)	Entry Action Value (E)	Action on the Field
constant	V!=0xffff	0≤M≤0xffff	0≤E≤0xffff	set to (~M & P) | (M & V) In words: modify only bits that are set on the mask to the values in V
Changeable	V==0xffff	0<M≤0xffff	0≤E≤0xffff	set to (~M & P) | (M & E)
Ignored	0≤V<0xffff	M==0	0≤E≤0xffff	none

Explicit action applying example:

- Destination IPv4 address is 192.168.10.1
- Mask is provided and equals 255.255.0.0
- Entry value is ignored
- Result – If a match on the packet occurs, the packet destination IPv4 value changes to 192.168.0.0

5.4.2.6.4.2 Setting Pipe Match or Action

Match is a mandatory parameter when creating a pipe. Using the `doca_flow_match` struct, users must define the packet fields to be matched by the pipe.

For each `doca_flow_match` field, users select whether the field type is:

- Ignore (match any) – the value of the field is ignored in a packet. In other words, match on any value of the field.
- Constant (specific) – all entries in the pipe have the same value for this field. Users should not put a value for each entry.
- Changeable – the value of the field is defined per entry. Users must provide it upon adding an entry.

> ⚠ L4 type, L3 type, and tunnel type cannot be changeable.

> ⚠ `gtp_next_ext_hdr_type` supports only `psc` type (0x85).

The match field type can be defined either implicitly or explicitly using the `doca_flow_pipe_cfg_set_match(struct doca_flow_pipe_cfg *cfg, const doca_flow_match *match, const doca_flow_match *match_mask)` function. If `match_mask == NULL`, then it is done implicitly. Otherwise, it is explicit.

In the tables in the following subsections, an example is used of a 16-bit field (such as layer-4 destination port) where:

> ⚠ The same concept would apply to any other field (such as an IP address occupying 32 bits).

- P stands for the packet field value
- V stands for the pipe match field value
- M stands for the pipe mask field value
- E stands for the match entry field value

Implicit Match

Match Type	Pipe Match Value (V)	Pipe Match Mask (M)	Entry Match Value (E)	Filter (A)	Rule (B)
Ignore	0	NULL	N/A	0	0
Constant	0<V<0xffff	NULL	N/A	0xffff	V
Changeable (per entry)	0xffff	NULL	0≤E≤0xffff	0xffff	E

To match implicitly, the following considerations should be taken into account.

- Ignored fields:
  - Field is zeroed
  - Pipeline has no comparison on the field
- Constant fields – These are fields that have a constant value among all entries. For example, as shown in the following, the tunnel type is VXLAN:

```
match.tun.type = DOCA_FLOW_TUN_VXLAN;
```

These fields must only be configured once at pipe build stage, not once per new pipeline entry.

- Changeable fields – These are fields whose value may change per entry. For example, the following shows match on a destination IPv4 address of variable per-entry value (outer 5-tuple):

```
match.outer.ip4.dst_ip = 0xffffffff;
```

- The following is an example of a match, where:
  - Outer 5-tuple
    - L3 type is IPv4 – constant among entries by design
    - L4 type is UDP – constant among entries by design
    - Tunnel type is `DOCA_FLOW_TUN_VXLAN` – constant among entries by design
    - IPv4 destination address varies per entry
    - UDP destination port is always `DOCA_VXLAN_DEFAULT_PORT`
    - VXLAN tunnel ID varies per entry
    - The rest of the packet fields are ignored
  - Inner 5-tuple
    - L3 type is IPv4 – constant among entries by design
    - L4 type is TCP – constant among entries by design
    - IPv4 source and destination addresses vary per entry
    - TCP source and destination ports vary per entry
    - The rest of the packet fields are ignored

```
// filter creation
static void build_underlay_overlay_match(struct doca_flow_match *match)
{
    //outer
    match->outer.l3_type = DOCA_FLOW_L3_TYPE_IP4;
    match->outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP;
    match->tun.type = DOCA_FLOW_TUN_VXLAN;
    match->outer.ip4.dst_ip = 0xffffffff;
    match->outer.udp.l4_port.dst_port = DOCA_VXLAN_DEFAULT_PORT;
    match->tun.vxlan_tun_id = 0xffffffff;

    //inner
    match->inner.l3_type = DOCA_FLOW_L3_TYPE_IP4;
    match->inner.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_TCP;
    match->inner.ip4.dst_ip = 0xffffffff;
    match->inner.ip4.src_ip = 0xffffffff;
    match->inner.tcp.l4_port.src_port = 0xffff;
    match->inner.tcp.l4_port.dst_port = 0xffff;
}

// create entry specifying specific values to match upon
doca_error_t add_entry(struct doca_flow_pipe *pipe, struct doca_flow_port *port,
                       struct doca_flow_pipe_entry **entry)
{
    struct doca_flow_match match = {};
    struct entries_status status = {};
    doca_error_t result;

    match.outer.ip4.dst_ip = BE_IPV4_ADDR(7, 7, 7, 1);
    match.tun.vxlan_tun_id = RTE_BE32(9876);
    match.inner.ip4.src_ip = BE_IPV4_ADDR(8, 8, 8, 1);
    match.inner.ip4.dst_ip = BE_IPV4_ADDR(9, 9, 9, 1);
    match.inner.tcp.l4_port.src_port = rte_cpu_to_be_16(5678);
    match.inner.tcp.l4_port.dst_port = rte_cpu_to_be_16(1234);
    result = doca_flow_pipe_add_entry(0, pipe, &match, &actions, NULL, NULL, 0, &status, entry);
}
```

The fields of the `doca_flow_meta` struct inside the match are not subject to implicit match rules and must be paired with explicit mask values.

Explicit Match

Match Type	Pipe Match Value (V)	Pipe Match Mask (M)	Entry Match Value (E)	Filter (A)	Rule (B)
Constant	V!=0xffff	0<M≤0xffff	0≤E≤0xffff	M	M&V
Changeable	V==0xffff	0<M≤0xffff	0≤E≤0xffff	M	M&E
Ignored	0≤V<0xffff	M==0	0≤E≤0xffff	0	0

In this case, there are two `doca_flow_match` items, the following considerations should be considered:

- Ignored fields
  - M equals zero. This can be seen from the table where the rule equals 0. Since mask is also 0, the resulting packet after the filter is0. Thus, the comparison always succeeds.

```
match_mask.inner.ip4.dst_ip = 0;
```

- Constant fields
  These are fields that have a constant value. For example, as shown in the following, the inner 5-tuple match on IPv4 destination addresses belonging to the `0.0.0.0/24` subnet, and this match is constant among all entries:

```
// BE_IPV4_ADDR converts 4 numbers A,B,C,D to a big endian representation of IP address A.B.C.D
match.inner.ip4.dst_ip = 0;
match_mask.inner.ip4.dst_ip = BE_IPV4_ADDR(255, 255, 255, 0);
```

  For example, as shown in the following, the inner 5-tuple match on IPv4 destination addresses belonging to the `1.2.0.0/16` subnet, and this match is constant among all entries. The last two octets of the `match.inner.ip4.dst_ip` are ignored because the `match_mask` of `255.255.0.0` is applied:

```
// BE_IPV4_ADDR converts 4 numbers A,B,C,D to a big endian representation of IP address A.B.C.D
match.inner.ip4.dst_ip = BE_IPV4_ADDR(1, 2, 3, 4);
match_mask.inner.ip4.dst_ip = BE_IPV4_ADDR(255, 255, 0, 0);
```

  Once a field is defined as constant, the field's value cannot be changed per entry.

  Users should set constant fields to zero when adding entries for better code readability.

  A more complex example of constant matches may be achieved as follows:

```
match_mask.outer.tcp.l4_port.dst_port = rte_cpu_to_be_16(0xf0f0);
```

```
match.outer.tcp.l4_port.dst_port = rte_cpu_to_be_16(0x5020)
```

The following ports would be matched:

- 0x5020 - 0x502f
- 0x5120 - 0x512f
- ...
- 0x5f20 - 0x5f2f

Changeable fields

The following example matches on either FTP or TELNET well known port numbers and forwards packets to a server after modifying the destination IP address and destination port numbers. In the example, either FTP or TELNET are forwarded to the same server. FTP is forwarded to port 8000 and TELNET is forwarded to port 9000.

```
// at Pipe creation
doca_flow_pipe_cfg_set_name(pipe_cfg, "PORT_MAPPER");
doca_flow_pipe_cfg_set_type(pipe_cfg, DOCA_FLOW_PIPE_BASIC);
match.outer.tcp.l4_port.dst_port = rte_cpu_to_be_16(0xffff); // v
match_mask.outer.tcp.l4_port.dst_port = rte_cpu_to_be_16(0xffff); // M
doca_flow_pipe_cfg_set_match(pipe_cfg, &match, &match_mask);
actions_arr[0] = &actions;
doca_flow_pipe_cfg_set_actions(pipe_cfg, action_arr, NULL, NULL, 1);
doca_flow_pipe_cfg_set_is_root(pipe_cfg, true);

// Adding entries
// FTP
match.outer.tcp.l4_port.dst_port = rte_cpu_to_be_16(20); // E
actions.outer.ip4.src_ip = server_addr;
actions.outer.tcp.l4_port.dst_port = rte_cpu_to_be_16(8000);
result = doca_flow_pipe_add_entry(0, pipe, &match, &actions, NULL, NULL, 0, &status, entry);

// TELNET
match.outer.tcp.l4_port.dst_port = rte_cpu_to_be_16(23); // E
actions.outer.ip4.src_ip = server_addr;
actions.outer.tcp.l4_port.dst_port = rte_cpu_to_be_16(9000);
result = doca_flow_pipe_add_entry(0, pipe, &match, &actions, NULL, NULL, 0, &status, entry);
```

5.4.2.6.4.3 Relaxed Match

Relaxed matching mode grants users full control on matching fields and guarantees that no fields are implicitly added by DOCA Flow.

Relaxed Matching and Pipeline Design Considerations

Relaxed matching mode provides full control to the DOCA application developer over the match design, without adding implicit match logic by the DOCA Flow library. This approach increases user responsibility to prevent unintended side effects caused by packet layout similarities (e.g., between UDP and TCP source/destination ports) or by skipping header type validation before matching on header fields. For instance, matching solely on a UDP destination port does not verify the presence of an L4 header or confirm that the L4 header is of UDP type.

To ensure effective design, early-stage pipes should classify packet types to filter out undesired packets. As the pipeline progresses, later stages can focus on more specific packet types based on prior matches. Examples include:

- Match on VXLAN VNI:
  - For Early-stage pipes, ensure the packet contains a VXLAN header (this can be achieved in a single pipe):

        - The first pipe verifies the packet has a UDP header by matching the L4 packet type to UDP or the L3 `next_proto` field to UDP
        - The second pipe matches the UDP destination port to the commonly used VXLAN value (4789)
      - For later-stage pipes, match on the VXLAN VNI field
  - Match on UDP destination port:
      - For early-stage pipes, verify the packet contains a UDP header by matching the L4 packet type to UDP or the L3 `next_proto` field to UDP
      - For later-stage pipes, match on the UDP destination port field

Relaxed Matching Memory Footprint and Performance Impact

Consider the following strict matching mode example. There are three pipes:

- Basic pipe `A` with `match.outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_TCP` and `match.outer.tcp.flags = 1`
- Basic pipe `B` with `match.outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP` and `match.outer.udp.l4_port.src_port = 8080`
- Control pipe `C` with two entries to direct TCP traffic to pipe `A` and UDP traffic to pipe `B`. The first entry has `match.outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_TCP` while the second has `match.outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP`.

As a result, the hardware matches on the L4 header type twice:

- When the packet enters the filter in control pipe `C` to decide the next pipe
- When the packet enters the filter of pipe `A` or `B` to match on the L4 header fields

With particularly large pipelines, such double matches decrease performance and increase the memory footprint in hardware. Relaxed matching mode gives the user greater control of the match logic to eliminate the implicitly added matches, consequently reducing hardware memory footprint and improving performance as well.

Parser Meta Usage with Relaxed Match

Parser meta matching is particularly useful when it comes to matching on a specific packet type. In relaxed mode, type selectors in the `outer`, `inner`, and `tun` parts of the `doca_flow_match` structs are used only for the type cast of the underlying unions. Header-type (packet type) matches are available using the `parser_meta` API.

For example, the scenario from the previous section may be overwritten by changing the match of control pipe `C` (with the same `A` and `B` pipes):

- Basic pipe `A` with `match.outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_TCP` and `match.outer.tcp.flags = 1`

- Basic pipe `B` with `match.outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP` and `match.outer.udp.l4_port.src_port = 8080`
- Control pipe `C` with two entries to direct TCP traffic to pipe `A` and UDP traffic to pipe `B`. The first entry has `match.parser_meta.outer_l4_type = DOCA_FLOW_L4_META_TCP` while the second has `match.parser_meta.outer_l4_type = DOCA_FLOW_L4_META_UDP`.

As a result, the hardware performs the L4 header-type match only once, when the packet enters the filter of control pipe. Basic pipes' `match.outer.l4_type_ext` are used only for the selection of the `match.outer.tcp` or `match.outer.udp` structures during the inspection of match struct.

Examples

The following code snippets are used to demonstrate the redesign of a pipeline with relaxed matching for non-tunnel match cases.

The following is the code before the redesign:

```
static void pipe_match_build(struct doca_flow_match *match)
{
    match->outer.l3_type = DOCA_FLOW_L3_TYPE_IP4;
    match->outer.ip4.dst_ip = 0xffffffff;
    match->outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP;
    match->outer.udp.l4_port.src_port = 22;
}
```

Without relaxed matching, the following hardware matches were performed for the code snippet above:

- L3 header type is IPv4 – constant among entries by design
- L4 header type is UDP – constant among entries by design
- IPv4 destination address varies per entry
- UDP source port is constant among entries
- The rest of the packet fields are ignored

With relaxed matching the following pipeline stages, where `pipe1` forwards packets to `pipe2`, should be considered to achieve a similar match as above:

```
static void pipe1_match_build(struct doca_flow_match *match)
{
    // Classifier logic. Only IPv4, UDP packets are to be forwarded to pipe2
    match.parser_meta.outer_l3_type = DOCA_FLOW_L3_META_IPV4;
    match.parser_meta.outer_l4_type = DOCA_FLOW_L4_META_UDP;
}

static void pipe2_match_build(struct doca_flow_match *match)
{
    // Main logic. Match on the specific packet fields
    match->outer.l3_type = DOCA_FLOW_L3_TYPE_IP4;
    match->outer.ip4.dst_ip = 0xffffffff;
    match->outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP;
    match->outer.udp.l4_port.src_port = 22;
}
```

The following code snippet demonstrates the redesign of a pipeline with relaxed matching for tunnel match cases:

```
static void pipe1_match_build(struct doca_flow_match *match)
{
    match->outer.l3_type = DOCA_FLOW_L3_TYPE_IP4;
    match->outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP;
    match->tun.type = DOCA_FLOW_TUN_VXLAN;
    match->outer.ip4.dst_ip = 0xffffffff;
    match->outer.udp.l4_port.src_port = 0x22;
    match->tun.vxlan_tun_id = 0xffffffff;
}
```

Without relaxed matching, the following hardware matches were performed for the code snippet above:

- L3 type is IPv4 – constant among entries by design
- L4 type is UDP – constant among entries by design
- Tunnel type is `DOCA_FLOW_TUN_VXLAN` – constant among entries by design
- IPv4 destination address varies per entry
- UDP source port is always 22
- VXLAN tunnel ID varies per entry
- The rest of the packet fields are ignored

With relaxed matching, the following pipeline stages, where `pipe1` forwards packets to `pipe2`, should be considered to achieve a similar match as above:

```
static void pipe1_match_build(struct doca_flow_match *match)
{
    // Classifier logic. Only IPv4, UDP packets are to be forwarded to pipe2
    match.parser_meta.outer_l3_type = DOCA_FLOW_L3_META_IPV4;
    match.parser_meta.outer_l4_type = DOCA_FLOW_L4_META_UDP;
}

static void pipe2_match_build(struct doca_flow_match *match)
{
    // Main logic. Match on the specific packet fields
    match->outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP;
    match->outer.udp.l4_port.src_port = 22;
    match->outer.udp.l4_port.dst_port = DOCA_VXLAN_DEFAULT_PORT;
    match->outer.l3_type = DOCA_FLOW_L3_TYPE_IP4;
    match->outer.ip4.dst_ip = 0xffffffff;
    match->tun.type = DOCA_FLOW_TUN_VXLAN;
    match->tun.vxlan_tun_id = 0xffffffff;
}
```

Relaxed Matching Considerations

With relaxed matching, header type fields within `outer`, `inner`, or `tun` structs no longer indicate a match on the specific protocol. They are used solely as a selector for the relevant header fields. For example, to match on `outer.ip4.dst_ip`, users must set `outer.l3_type = DOCA_FLOW_L3_TYPE_IP4`. With this match, the L3 header is checked for the IPv4 destination address, however there is no check that the L3 header is of IPv4 type. It is user responsibility to make sure that packets arriving to such a filter indeed have an L3 header of type IPv4.

To match on a specific protocol/tunnel type, consider the following:

- To match on an inner/outer L3/L4 protocol type, users can use relevant `doca_flow_parser_meta` fields as explained above. For example, for outer protocols, `parser_meta.outer_l[3,4]_type` fields can be used.
- To match on a specific tunnel type, users should match on a tunnel according to its specification. For example, for a VXLAN tunnel, a match on UDP destination

port 4789 can be used. Another option is to use the L3 next protocol field. For example, for IPv4 with next header GRE, one can match on the IPv4 headers' next protocol field value to match GRE IP protocol number 47.

More relaxed matching design best practices can be found in the samples Flow Drop, Flow VXLAN Encap, and LPM with Exact Match Logic.

⚠ With relaxed matching, to achieve a match-all functionality, either one of the following methods can be used during pipe creation:

- Set the `match_mask` structure to NULL and set the match structure to all zeroes
- Set the `match_mask` structure to all zeroes while the match structure have any setting

⚠ With relaxed matching, if any of the selectors is used without setting a relevant field, the pipe/entry creation would fail with the following error message:

```
failed building active opcode - active opcode <opcode number> is protocol only
```

5.4.2.6.4.4 Setting Pipe Actions

Pipe Actions Execution Order

When setting actions, they are executed in the following order:

1. Crypto (decryption)
2. Decapsulation
3. Pop
4. Meta
5. Outer
6. Tun
7. Push
8. Encapsulation
9. Crypto (encryption)

The `desc_array` field in `struct doca_flow_actions_descs` is executed by order of the array after the above action execution.

Auto-modification

Similarly to setting pipe match, actions also have a template definition.

Similarly to `doca_flow_match` in the creation phase, only the subset of actions that should be executed per packet are defined. This is done in a similar way to match, namely by classifying a field of `doca_flow_actions` to one of the following:

- Ignored field – field is zeroed, modify is not used.
- Constant fields – when a field must be modified per packet, but the value is the same for all packets, a one-time value on action definitions can be used
- Changeable fields – fields that may have more than one possible value, and the exact values are set by the user per entry

```
actions.outer.ip4.dst_ip = 0xffffffff
```

> ⚠ The `action_mask` should be set as `0xffffffff` and action as 0 if the user wants to configure 0 to this field.

> ⚠ Changeable shared encap/decap actions must use shared resources that have been configured in advance.

> ⚠ A single pipe cannot be created with both a changeable shared encap/decap action and a changeable FWD action at the same time. This configuration is not supported and will fail.

> ⚠ To use both a changeable shared encap/decap action and a changeable FWD action, implement them in sequential pipes. Use one pipe for the encap/decap action, and then use a subsequent pipe for the FWD action.

Explicit Modification Type

It is possible to force constant modification or per-entry modification with action mask. For example:

```
static void
create_constant_modify_actions(struct doca_flow_actions *actions,
                               struct doca_flow_actions *actions_mask,
                               struct doca_flow_action_descs *descs)
{
        actions->outer.l4_type_ext = DOCA_FLOW_L4_TYPE_EXT_UDP;
        actions->outer.udp.src_port = 0x1234;
        actions_mask->outer.udp.src_port = 0xffff;
}
```

Copy Field

The action descriptor can be used to copy between the packet field and metadata. For example:

```
#define META_U32_BIT_OFFSET(idx) (offsetof(struct doca_flow_meta, u32[(idx)]) << 3)

static void
create_copy_packet_to_meta_actions(struct doca_flow_match *match,
                                   struct doca_flow_action_desc *desc)
{
        desc->type = DOCA_FLOW_ACTION_COPY;
        desc->field_op.src.field_string = "outer.ipv4.src_ip";
        desc->field_op.src.bit_offset = 0;
        desc->field_op.dst.field_string = "meta.data";
        desc->field_op.dst.bit_offset = META_U32_BIT_OFFSET(1); /* Bit offset of meta.u32[1] */;
```

```
}
```

Multiple Actions List

Creating a pipe is possible using a list of multiple actions. For example:

```
static void
create_multi_actions_for_pipe_cfg()
{
    struct doca_flow_actions *actions_arr[2];
    struct doca_flow_actions actions_0 = {0}, actions_1 = {0};
    struct doca_flow_pipe_cfg *pipe_cfg;

    /* input configurations for actions_0 and actions_1 */

    actions_arr[0] = &actions_0;
    actions_arr[1] = &actions_1;
    doca_flow_pipe_cfg_set_actions(pipe_cfg, actions_arr, NULL, NULL, 2);
}
```

Summary of Action Types

Pipe Creation				Entry Creation	Behavior
action_desc		Pipe Actions	Pipe Actions Mask	Entry Actions	
doca_flow_action_type	Configuration				
`DOCA_FLOW_ACTION_AUTO/` `action_desc = NULL`	No specific config	`0`	`0`	N/A	Field ignored, no modification
		`0`	`mask` != 0	N/A	Apply `0` and `mask` to all entries
		`val` != 0 && `val` != 0xFF	`mask` != 0	N/A	Apply `val` and `mask` to all entries
		`val` = 0xFF	`mask` = 0	N/A	Apply `0xFF` to all entries
		`val` = 0xFF	`mask` != 0	Define `val` per entry	Apply entry's `val` and `mask`
`DOCA_FLOW_ACTION_ADD` Add field value or from `src`	Define only the `dst` field and width	`val` != 0	N/A	N/A	Add to dst this `val` to all entries
		`val` == 0	N/A	Define `val` per entry	Add to dst entry's `val`
	Define the `src` and `dst` fields and width	Define the source and destination fields. • Meta field → header field • Header field → meta field • Meta field → meta field	N/A	N/A	Add data from `src` fields to `dst` for all entries

Pipe Creation				Entry Creation	Behavior
action_desc		Pipe Actions	Pipe Actions Mask	Entry Actions	
doca_flow_action_type	Configuration				
`DOCA_FLOW_ACTION_COPY` Copy field to another field	N/A	Define the source and destination fields. • Meta field → header field • Header field → meta field • Meta field → meta field	N/A	N/A	Copy data between fields for all entries

Queue Balancing for Non-shared Actions

For non-shared actions, each action resource handle is implicitly bound to a specific entry. To enable faster, lock-free access during entry creation, these action resource handles are cached on a per-queue basis, mirroring how entries are added.

Therefore, applications should distribute entry additions evenly across all available queues. This practice prevents cache fragmentation and ensures efficient use of action resources.

If entries are distributed unevenly, it can lead to a worst-case scenario where the number of successfully attached action handles is slightly lower than the total number of defined resources, even if those resources are technically available system-wide.

5.4.2.6.4.5 Setting Pipe Monitoring

If a meter policer should be used, then it is possible to have the same configuration for all policers on the pipe or to have a specific configuration per entry. The meter policer is determined by the FWD action. If an entry has NULL FWD action, the policer FWD action is taken from the pipe.

The monitor also includes the aging configuration, if the aging time is set, this entry ages out if timeout passes without any matching on the entry.

For example:

```
static void build_entry_monitor(struct doca_flow_monitor *monitor, void *user_ctx)
{
    monitor->aging_sec = 10;
}
```

Refer to Pipe Entry Aged Query for more information.

5.4.2.6.4.6 Setting Pipe Forwarding

The FWD (forwarding) action is the last action in a pipe, and it directs where the packet goes next. Users may configure one of the following destinations:

- Send to software (representor)
- Send to wire
- Jump to next pipe
- Drop packets

The FORWARDING action may be set for pipe create, but it can also be unique per entry.

Pipe forwarding can be set either at creation time or be deferred to entry addition:

- If the `fwd.type` type is not `DOCA_FLOW_FWD_CHANGEABLE`, any match on the pipe, on any entry, is forwarded to the specified target
- If the `fwd.type` type is `DOCA_FLOW_FWD_CHANGEABLE`, the target would match on whatever is defined in the `fwd.type` field of the specific entry

Putting this logic in a table look like this:

Pipe Fwd.type	Entry Fwd.type	Actual Forward	Comment
Equals `DOCA_FLOW_FWD_CHANGEABLE`	X	X	X must not equal `DOCA_FLOW_FWD_CHANGEABLE`
X != `DOCA_FLOW_FWD_CHANGEABLE`	Does not care	X	

When a pipe includes meter monitor `<cir, cbs>`, it must have `fwd` defined as well as the policer.

The following is an RSS forwarding example:

```
fwd.type = DOCA_FLOW_FWD_RSS;
fwd.rss_type = DOCA_FLOW_RESOURCE_TYPE_NON_SHARED;
fwd.rss.queues_array = queues;
fwd.rss.outer_flags = DOCA_FLOW_RSS_IPV4 | DOCA_FLOW_RSS_UDP;
fwd.rss.nr_queues = 4;
```

Queues point to the `uint16_t` array that contains the queue numbers. When a port is started, the number of queues is defined, starting from zero up to the number of queues minus 1. RSS queue numbers may contain any subset of those predefined queue numbers. For a specific match, a packet may be directed to a single queue by having RSS forwarding with a single queue.

Changeable RSS forwarding is supported. When creating the pipe, the `num_of_queues` must be set to `0xffffffff`, then different forwarding RSS information can be set when adding each entry.

```
fwd->num_of_queues = 0xffffffff;
```

The packet is directed to the port. In many instances the complete pipe is executed in the hardware, including the forwarding of the packet back to the wire. The packet never arrives to the software.

Example code for forwarding to port:

```
struct doca_flow_fwd *fwd = malloc(sizeof(struct doca_flow_fwd));
memset(fwd, 0, sizeof(struct doca_flow_fwd));
fwd->type = DOCA_FLOW_FWD_PORT;
fwd->port_id = port_id; // this should the same port_id that was set in doca_flow_port_cfg_set_port_id()
```

The type of forwarding is `DOCA_FLOW_FWD_PORT` and the only data required is the `port_id` as defined in `DOCA_FLOW_PORT`.

⚠ The destination port for any FWD action (identified by `fwd->port_id`) must be started in advance by calling `doca_flow_port_start()`.

⚠ A single pipe cannot be created with both a changeable shared encap/decap action and a changeable FWD action simultaneously. This configuration is not supported.

Changeable port forwarding is also supported. When creating the pipe, the `port_id` must be set to `0xffff`, then different forwarding `port_id` values can be set when adding each entry.

```
fwd->port_id = 0xffff;
```

5.4.2.6.4.7 Shared Resources

DOCA Flow supports several types of resources that can be shared. The supported types of resources can be:

- Meters
- Counters
- RSS queues
- PSPs
- Encap
- Decap
- IPsec SA

Shared resources can be used by several pipes and can save device and memory resources while promoting better performance.

To create and configure shared resource, the user should go through the steps detailed in the following subsections.

Creating Shared Resource Configuration Object

Call `doca_flow_cfg_create(&flow_cfg)`, passing a pointer to `struct doca_flow_cfg` to be used to fill the required parameters for the shared resource.

> ⚠ The `struct doca_flow_cfg` object is used for configuring other resources besides the aforementioned shared resources, but this section only refers to the configuration of shared resources.

Setting Number of Shared Resources per Shared Resource Type

This can be done by calling `doca_flow_cfg_set_nr_shared_resource()`. Refer to the API documentation for details on the configuration process.

Conclude the configuration by calling `doca_flow_init()`.

Configuring Shared Resource

When shared resources are allocated, they are assigned identifiers ranging from 0 and increasing incrementally. For example, if the user configures two shared counters, they would bear the identifiers 0 and 1.

> ⚠ Note that each resource has its own identifier space. So, if users have two shared counters and three meters, they would bear identifiers 0..1 and 0..2 respectively.

Configuring the shared resources requires the user to call `doca_flow_shared_resource_set_cfg()`.

Binding Shared Resource

A shared resource must be bound by calling `doca_flow_shared_resources_bind()` which binds the resource to a pointer. The object to which the resource is bound is usually a `struct doca_flow_port` pointer.

Using Shared Resources

After a resource has been configured, it can be used by referring to its ID.

In the case of meters, counters, they are referenced through `struct doca_flow_monitor` during pipe creation or entry addition.

Querying Shared Resource

Querying shared resources can be done by calling `doca_flow_shared_resources_query()`. The function accepts the resource type and an array of resource numbers and returns an array of `struct doca_flow_shared_resource_result` with the results.

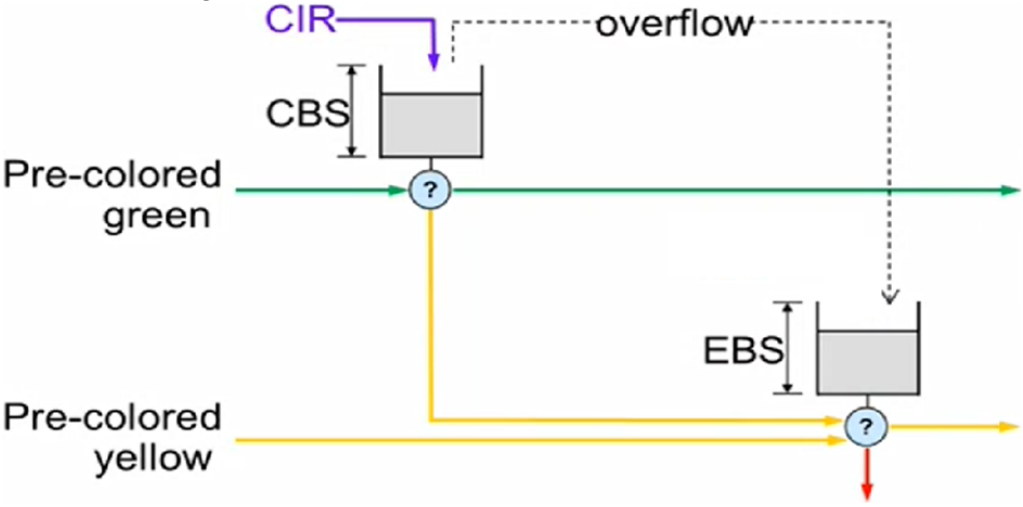
Shared Meter Resource

A shared meter can be used in multiple pipe entries (hardware steering mode support only).

The shared meter action marks a packet with one of three colors: Green, Yellow, and Red. The packet color can then be matched in the next pipe, and an appropriate action may be taken. For example, packets marked in red are usually dropped. So, the next pipe to meter action may have an entry which matches on red and has fwd type `DOCA_FLOW_FWD_DROP`.

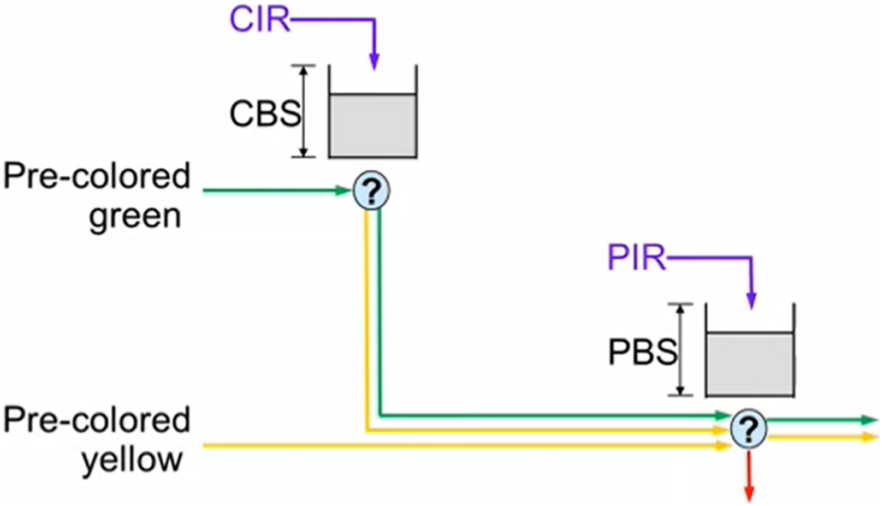
DOCA Flow supports three marking algorithms based on RFCs: 2697, 2698, and 4115.

RFC 2697 – Single-rate Three Color Marker (srTCM)



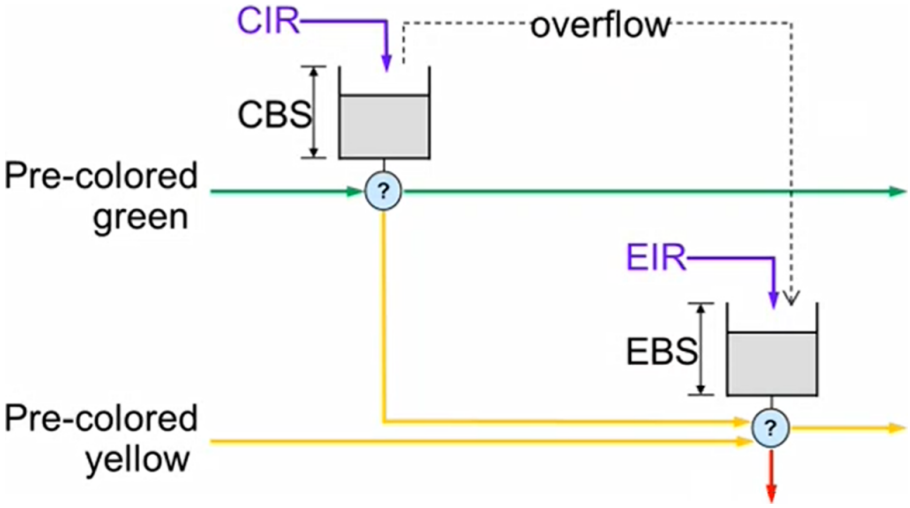
CBS (committed burst size) is the bucket size which is granted credentials at a CIR (committed information rate). If CBS overflow occurs, credentials are passed to the EBS (excess burst size) bucket. Packets passing through the meter consume credentials. A packet is marked green if it does not exceed the CBS, yellow if it exceeds the CBS but not the EBS, and red otherwise. A packet can have an initial color upon entering the meter. A pre-colored yellow packet will start consuming credentials from the EBS.

RFC 2698 – Two-rate Three Color Marker (trTCM)



CBS and CIR are defined as in RFC 2697. PBS (peak burst size) is a second bucket which is granted credentials at a PIR (peak information rate). There is no overflow of credentials from the CBS bucket to the PBS bucket. The PIR must be equal to or greater than the CIR. Packets consuming CBS credentials consume PBS credentials as well. A packet is marked red if it exceeds the PIR. Otherwise, it is marked either yellow or green depending on whether it exceeds the CIR or not. A packet can have an initial color upon entering the meter. A pre-colored yellow packet starts consuming credentials from the PBS.

RFC 4115 – trTCM without Peak-rate Dependency



EBS is a second bucket which is granted credentials at a EIR (excess information rate) and gets overflowed credentials from the CBS. For the packet marking algorithm, refer to RFC 4115.

All information rates (i.e., CIR, PIR, EIR) are measured in one of two units:

- Per bytes (`DOCA_FLOW_METER_LIMIT_TYPE_BYTES`); or
- Per packets (`DOCA_FLOW_METER_LIMIT_TYPE_PACKETS`)

The following sections present the steps for configuring and using shared meters to mark packets.

Bandwidth Measurement

When testing a DOCA Flow meter, it is important to understand that the rate-limiting parameters (CIR, PIR, EIR) apply to the information rate, not the full L2 Ethernet frame. The information rate typically refers to the inner IP layer of the packet.

Because of this, to accurately measure the metered bandwidth and verify that it matches your settings, you must perform a mathematical adaptation to exclude the non-IP layer overhead from your byte count.

Measurement Method

The recommended method is to take two measurements, 1 second apart, after the traffic stream has been stable for at least 5 seconds.

Terminology:

- `pckts1` and `bytes1`: The total number of packets and bytes measured at time `X` (where `X` ≥ 5 seconds).
- `pckts2` and `bytes2`: The total number of packets and bytes measured at time `X+1` second.

The true metered bandwidth (in bytes per second) is the adapted byte count, which is calculated by subtracting the total overhead from the total bytes measured during that one-second interval:

```
Adapted Byte Count = (bytes2 - bytes1) - (overhead_bytes * (pckts2 - pckts1))
```

Here, `overhead_bytes` is the size of all non-IP-layer headers for your specific packet type.

Overhead Examples

The `overhead_bytes` value depends on the packet's structure. Common examples include:

- Simple IP packets: `18 bytes`
  - (14-byte MAC header + 4-byte FCS)
- VLAN packets: `22 bytes`
  - (14-byte MAC header + 4-byte VLAN tag + 4-byte FCS)
- MPLS tunnel packets: `50 bytes`
  - (14-byte MAC header + 4-byte MPLS + 20-byte Tunnel IP + 8-byte Tunnel UDP + 4-byte FCS)

Verifying the Rate

You can then compare the calculated bandwidth against your meter's settings:

- For byte-based limits (`DOCA_FLOW_METER_LIMIT_TYPE_BYTES`): The expected bandwidth is the Adapted Byte Count calculated above.
- For packet-based limits (`DOCA_FLOW_METER_LIMIT_TYPE_PACKETS`): The expected bandwidth is the packet delta: `(pckts2 - pckts1)`.

Shared IPsec SA Resource

The Shared IPsec Security Association (SA) resource is used to manage the IPsec ESP protocol for both encryption and decryption. This resource is referenced from the `doca_flow_actions` struct via the `doca_flow_crypto_actions` field.

Default Hardware Offload Behavior

By default, the resource manages the sequence number (SN) state in hardware (i.e., `sn_offload` is enabled). This includes:

- Encryption: Automatically incrementing the sequence number (SN) for each packet.
- Decryption: Performing anti-replay protection. The anti-replay status (syndrome) is stored in `meta.u32[0]`.

Manual Software SN Control

To manage the sequence number in software, the `sn_offload` feature must be disabled in the port configuration passed to `doca_flow_port_start` (see the DOCA API References for details).

> ⚠ When `sn_offload` is disabled, the following hardware offload fields in the resource configuration are ignored:
>
> - `sn_offload_type`
> - `win_size`
> - `sn_initial`
> - `lifetime_threshold`

Querying the Resource

When `sn_offload` is enabled, you can query the shared IPsec SA resource to retrieve its current state:

- For an encryption resource: The query returns the current sequence number (SN).
- For a decryption resource: The query returns the lower bound of the anti-replay window.

> ⚠ Querying the resource is not supported when `sn_offload` is disabled.

State Maintenance

To ensure a valid resource state during operation, the `doca_flow_crypto_ipsec_resource_handle` function should be called periodically.

Shared Encap Resource

The shared encap resource defines a specific, reusable encapsulation configuration. Each unique configuration, primarily defined by its reformat type (`is_l2`) and size, is represented by a shared encap ID.

This ID allows the same encapsulation to be applied across multiple pipes and entries.

Key characteristics:

- This feature is supported only in hardware steering mode.
- Once a shared encap resource is configured and assigned an ID, its settings (like type and size) cannot be modified.
- The "shared encap action" in a pipe uses this resource ID to encapsulate a packet with the pre-configured tunnel information.

Shared Decap Resource

The shared decap resource defines a specific, reusable decapsulation configuration. Each unique configuration, primarily defined by its reformat type (`is_l2`) and size, is represented by a **shared decap ID**.

This ID allows the same decapsulation to be applied across multiple pipes and entries.

Key characteristics:

- This feature is supported only in hardware steering mode.
- Once a shared decap resource is configured and assigned an ID, its settings (like type and size) cannot be modified.
- If the `is_l2` flag is set to false (indicating a non-L2 decap), Ethernet information must be provided in the configuration.
- The "shared decap action" in a pipe uses this resource ID to decapsulate the packet according to the pre-configured rules.

Shared PSP Resource

The PSP shared resource is used for PSP encryption. The resource should be pointed to from the `doca_flow_crypto_actions` struct in `doca_flow_actions` .

The resource should be configured with a key to encrypt the packets. See DOCA API References for PSP key generation for a reference about key handling on decrypt side.

5.4.2.6.4.8 Creating a Pipe

Once all pipe parameters are defined, call `doca_flow_pipe_create` to create the pipe.

> Refer to the DOCA API documentation to see which fields are optional and may be skipped. It is typically recommended to set optional fields to 0 when not in use. See Miss Pipe and Control Pipe for more information.

On success, this function returns a handle to the pipe, which is required when adding new entries. If creation fails, the function returns `NULL` . An error struct, if provided by the user, will be populated with the error details.

A pipe acts as a container for its entries. When a pipe is destroyed, all entries bound to it are automatically removed. For more details, see the Pipe Entry section.

Implementing Priority

DOCA Flow does not have an explicit priority field for pipes or entries. Priority is managed through the order of operation and rule insertion.

- Chaining (Recommended) – The most explicit way to implement priority is to create a chain. Create a "miss" rule in a high-priority pipe that forwards traffic to the next, lower-priority pipe (e.g., match `PIPE1`, and on miss, jump to `PIPE2`).
- Insertion Order (Overlapping Entries) – Priority can also be determined by the order in which entries are added to pipes.
    - If two pipes have overlapping match criteria, the pipe whose entries were added last has the higher priority.
    - For example, to make `PIPE1` (high-priority) take precedence over `PIPE2` (low-priority), you must add all entries for `PIPE2` first, *followed* by the overlapping entries for `PIPE1`.

Pipe Sizing and Caching

When you define the number of entries for a pipe, this number must account for both active entries and entries held in internal caches.

This means the actual number of entries your application can add will be less than the total defined size. The total number of cached entries is limited to (1K * number of queues), and this cache size cannot exceed 2% of the total pipe size.

5.4.2.6.4.9 Pipe Entry (doca_flow_pipe_add_entry)

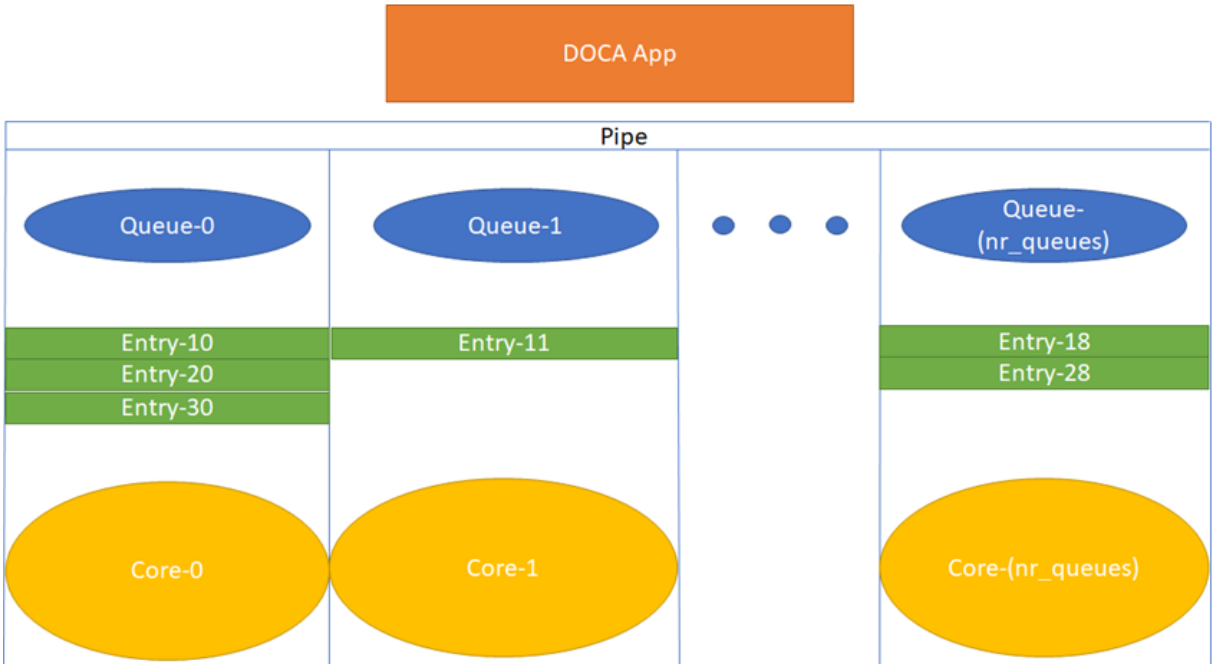
An entry is a specific instance inside of a pipe. When defining a pipe, users define match criteria (subset of fields to be matched), the type of actions to be done on matched packets, monitor, and, optionally, the FWD action.

When a user calls `doca_flow_pipe_add_entry()` to add an entry, they must define the values for the match criteria and action parameters. If a Forward (FWD) action was not defined as constant for the entire pipe, it is mandatory to specify the FWD action for each entry.

Concurrency and Queue Affinity

DOCA Flow is designed to support millions of new entries per second. To achieve this, its architecture requires that entry-addition operations be parallelized.

This is managed by assigning a dedicated `pipe_queue` ID to each CPU core that will be adding entries. Having a unique queue ID per core prevents the need for data-structure locking and enables efficient, parallel interaction with the hardware.



Each core must use its own dedicated `pipe_queue` ID when calling `doca_flow_pipe_add_entry`. Using the same `pipe_queue` ID from different cores simultaneously will cause a race condition and lead to undefined behavior.

Usage Notes

- Applications must not add, remove, or update pipe entries from within a `doca_flow_entry_process_cb` callback.
- Applications should distribute entry additions evenly across all queues. This prevents cache fragmentation and ensures efficient resource use. In a worst-case scenario where entries are not balanced, the number of successfully inserted entries may be slightly lower than the total number defined during pipe creation.

Failure Path

Entry insertion can fail in two places, `add_entry` and `add_entry_cb`.

- When `add_entry` fails, no cleanup is required.
- When `add_entry` succeeds, a handle is returned to the user. If the subsequent `add_entry_cb` fails, the user is responsible for releasing the handle through a `rm_entry` call. This `rm_entry` call is expected to return `DOCA_SUCCESS` and is expected to invoke `doca_rm_entry_cb` with a successful return code.

Pipe Entry Counting

By default, no counter is added. If defined in monitor, a unique counter is added per entry.

> ⚠ Having a counter per entry affects performance and should be avoided if it is not required by the application.

The retrieved statistics are stored in struct `doca_flow_query`.

> ⚠ Counters have a granularity of 1 second.

Pipe Entry Aged Query

When a user calls `doca_flow_aging_handle()`, this query is used to get the aged-out entries by the time quota in microseconds. The user callback is invoked by this API with the aged entries.

Since the number of flows can be very large, the query of aged flows is limited by a quota in microseconds. This means that it may return without all flows and requires the user to call it again. When the query has gone over all flows, a full cycle is done.

5.4.2.6.4.10 Pipe Entry (doca_flow_pipe_update_entry)

Updating an entry requires available space in the pipe. If the pipe is full, the function returns `DOCA_ERROR_AGAIN`. To proceed with the update, you may need to release an existing entry to free up space.

5.4.2.6.4.11 Pipes with Multiple Actions

DOCA Flow allows you to define a pipe with an array of multiple, distinct actions. This feature is useful for creating multiple flow entries that share the same match criteria but require different actions.

When adding or updating an entry (e.g., with `doca_flow_pipe_add_entry`), you select which action to execute by providing its index in the `action_idx` argument.

> ⚠ Even if a pipe has multiple actions defined, only one action will be executed for any given packet that matches an entry.

Consider a case where two flows are needed with identical match criteria but different actions:

1. Pipe creation: A pipe is created with two actions defined in its `actions` array:
    - Index 0: An action to `modify_mac`.
    - Index 1: An action to `modify_ip`.
2. Entry addition:
    - Entry A is added (e.g., `match L4_PORT=80`) with its `action_idx` set to `0`. Packets matching this entry will have their MAC modified.

- Entry B is added (e.g., `match L4_PORT=80`) with its `action_idx` set to `1`. Packets matching this entry will have their IP modified.

5.4.2.6.4.12 Pipe Chaining, Priority, and Miss Handling

This section describes how to chain pipes together to implement priority, how to use Control Pipes to resolve complex matching conflicts, and how the Port Default Miss handler works.

Implementing Priority with `fwd_miss` (Miss-Pipe Chaining)

DOCA Flow implements priority by chaining pipes. A pipe's `fwd_miss` handler defines what to do with a packet if it does not match any entry within that pipe. This allows you to create a "miss-pipe" chain:

1. A packet is looked up in `Pipe 1` (the highest priority table).
2. If it matches an entry, the action is taken.
3. If it does not match, the `fwd_miss` handler forwards the packet to `Pipe 2`.
4. The lookup process repeats in `Pipe 2`.

This `fwd_miss` behavior is configured in the `struct doca_flow_fwd` of a pipe. When creating a pipe, the `fwd_miss` struct's `next_pipe` field specifies where to send non-matching packets.

The `fwd_miss` handler only supports two forwarding types:

- `DOCA_FLOW_FWD_PIPE`: Forwards the packet to another pipe for further processing.
- `DOCA_FLOW_FWD_DROP`: Drops the packet.

> ⚠ Other forwarding types, such as forwarding to a port or an RSS queue, are not supported in a `fwd_miss` handler.

Root Pipes vs. Chained Pipes

A pipe's role is defined by the `is_root` flag in its `struct doca_flow_pipe_cfg`:

- `is_root = true`: This is a root pipe. It is executed immediately on packet arrival. Only one root pipe is allowed. If you need multiple root-level "pipes", you must create a single root control pipe that forwards packets to different non-root pipes.
- `is_root = false`: This is a non-root pipe (a "next pipe"). It is not executed on packet arrival and can only be reached by being the target of a `DOCA_FLOW_FWD_PIPE` action (e.g., from another pipe's entry or `fwd_miss` handler).

Control Pipes and Prioritized Entries

Internally, DOCA Flow implements the `fwd_miss` handler as a flow entry with the lowest possible priority. This can create conflicts.

For example, consider a pipe that:

1. Matches specific VXLAN flows and sends them to RSS.
2. Has a `fwd_miss` handler to hairpin all other (non-matching) packets.

If a new VXLAN packet arrives for an IP that does not have a specific flow entry, it will not match (1) and will incorrectly fall through to (2), where it is hairpinned instead of being sent to RSS.

The solution is to use a Control Pipe. A Control Pipe allows you to add entries with *explicit* priorities, giving you fine-grained control to resolve these conflicts.

- You add prioritized entries to a Control Pipe by calling `doca_flow_control_pipe_add_entry()`.
- This function includes a `priority` field (where 0 is the highest and 7 is the lowest), which overrides the default insertion-order priority.

Example for Resolving Conflicts with Control Entries

Using the scenario above, you can fix the conflict with a Control Pipe:

1. Configure `fwd_miss`: Set the pipe's `fwd_miss` handler to hairpin packets. This creates an internal "hairpin" rule at the lowest priority (e.g., priority 7).
2. Add a control entry: Call `doca_flow_control_pipe_add_entry()` to add a new, higher-priority rule:
    - Priority: `6` (higher than the `fwd_miss` rule's priority of 7).
    - Match: Match *all* VXLAN packets (not just specific IPs).
    - Forward: Forward to the RSS pipe.

As a result, the new VXLAN packet no longer matches a specific IP, but it *will* match the new "all VXLAN" control entry at priority 6. It is correctly forwarded to RSS and never falls through to the lowest-priority (7) `fwd_miss` rule.

Port Default Miss

This is the final fallback action for the port, used when a pipe's `fwd_miss` is not set (i.e., `NULL`).

By default, this forwards all non-matched traffic to the kernel and is active as soon as the port is started. The target of this default miss can be controlled using the following API:

```
enum doca_flow_port_default_miss_type {
    DOCA_FLOW_PORT_DEFAULT_MISS_KERNEL = 0,
    DOCA_FLOW_PORT_DEFAULT_MISS_RSS,
    DOCA_FLOW_PORT_DEFAULT_MISS_DROP,
};

doca_error_t doca_flow_port_update_default_miss(
    struct doca_flow_port *port,
    enum doca_flow_port_default_miss_type default_miss,
```

```
    bool counter_en
);

doca_error_t doca_flow_port_query_default_miss(
    struct doca_flow_port *port,
    struct doca_flow_resource_query *data
);
```

- The target of the default miss (`KERNEL` , `RSS` , or `DROP`) can be updated at any time.
- The counter (`counter_en`) can only be enabled *before* the first use of or update to the default miss, and it cannot be disabled once set.
- The `DOCA_FLOW_PORT_DEFAULT_MISS_RSS` option distributes packets over all existing RSS queues, hashing each packet using its L3/L4 information. Packets without a hashable L3/L4 header will receive a constant hash value.

5.4.2.6.4.13 doca_flow_pipe_lpm

The `doca_flow_pipe_lpm` pipe performs Longest Prefix Match (LPM) matching.

LPM Logic

LPM matching is performed on a single field specified at pipe creation, such as the outer destination IP. Each entry consists of a value and a mask (e.g., `10.0.0.0/8` , `10.10.0.0/16`). The LPM match is defined as the entry with the maximum number of matching bits.

For example, given two entries, `10.0.0.0/8` and `10.7.0.0/16` :

- An incoming IP of `10.1.9.2` matches `10.0.0.0/8` .
- An incoming IP of `10.7.9.2` matches `10.7.0.0/16` , as its 16-bit prefix is the longest match.

Exact Match (EM) Logic

In addition to LPM, the pipe can simultaneously apply Exact Match (EM) logic. The EM result is combined with the LPM result using a logical AND. If a packet matches the LPM logic but *fails* the EM logic, it is considered a pipe miss.

EM logic is supported on a combination of the following fields:

- `meta.u32[1]`
- `inner.eth.dst_mac`
- `tun.vxlan_tun_id`

A field (e.g., inner destination MAC) cannot be used for both LPM and EM at the same time.

The primary benefit of EM logic is to allow multiple entries to share the same LPM but have different EM values. For example, an application can have multiple entries for the same IP prefix `1.1.1.1/32` that match different meta values, such as `42` , `555` , and `1020` .

Support for `meta.u32[1]` allows for EM on any field, as its value can be copied to `meta.u32[1]` in a preceding pipe.

Enabling EM Logic

Enabling EM logic is a two-step process:

1. At pipe creation:
    - Specify the LPM field using the `match` parameter.
    - Enable the EM fields by fully masking them in the `match_mask` parameter (e.g., set `match_mask.meta.u32[1]` to all `0xFF` s, and/or `inner.eth.dst_mac`, and/or `tun.vxlan_tun_id`).
    - If using `tun.vxlan_tun_id`, `match_mask.tun.type` must be set to `DOCA_FLOW_TUN_VXLAN`.
2. At entry addition:
    - Provide the LPM value and its corresponding prefix mask (e.g., `1.1.1.1` and `/32`) in the `match` and `match_mask` structures, respectively.
    - Provide the EM values (e.g., `meta.u32[1] = 42`) in the `match` structure. The `match_mask` is *only* for the LPM field's prefix mask.

General Behavior and Limitations

- Actions and forwarding: The `actions` and `fwd` configurations for an LPM pipe work the same as for a basic DOCA Flow pipe.
- Root pipe: A `doca_flow_pipe_lpm` cannot be a root pipe. A root pipe must be created to forward packets to the LPM pipe.
- LPM field support: LPM matching can only be performed on inner/outer IP addresses and inner/outer MAC addresses.
- Monitoring: The monitor (`doca_flow_monitor`) for an LPM pipe only supports non-shared counters. Other monitoring capabilities are not supported.
- Insertion latency: Entry insertion for an LPM pipe can, in some cases, take milliseconds.
    - Best practice: Entries should be added from a control path rather than a fast data path.
    - Performance: To get the best insertion performance, add entries in large batches.

5.4.2.6.4.14 doca_flow_pipe_acl

`doca_flow_pipe_acl` uses access-control list (ACL) matching. ACL matching is five tuple of the `doca_flow_match`. Each entry consists of a value and a mask (e.g.,

10.0.0.0/8, 10.10.0.0/16, etc.) for IP address fields, port range, or specific port in the port fields, protocol, and priority of the entry.

ACL entry port configuration:

- Mask port is 0 ==> Any port
- Mask port is equal to match port ==> Exact port. Port with mask 0xffff.
- Mask port > match port ==> Match port is used as port from and mask port is used as port to

Monitor actions are not supported in ACL. FWD of the DOCA Flow ACL pipe works the same as the basic DOCA Flow pipe.

ACL supports the following types of FWD:

- `DOCA_FLOW_FWD_PORT`
- `DOCA_FLOW_FWD_PIPE`
- `DOCA_FLOW_FWD_DROP`

`doca_flow_pipe_acl` insertion max latency can be measured in milliseconds in some cases and, therefore, it is better to insert it from the control path. To get the best insertion performance, entries should be added in large batches.

⚠ An ACL pipe is not currently supported for IPv6.

⚠ An ACL pipe can be a root pipe.

⚠ An ACL pipe can be in ingress and egress domain.

⚠ The monitor (`doca_flow_monitor`) for an ACL pipe only supports non-shared counters. Other monitoring capabilities are not supported.

5.4.2.6.4.15 doca_flow_pipe_ordered_list

`doca_flow_pipe_ordered_list` allows the user to define a specific order of actions and multiply the same type of actions (i.e., specific ordering between counter/meter and encap/decap).

An ordered list pipe is defined by an array of actions (i.e., sequences of actions). Each entry can be an instance of one of these sequences. An ordered list pipe may consist of up to an array of 8 different actions. The maximum size of each action array is 4 elements. Resource allocation may be optimized when combining multiple action arrays in one ordered list pipe.

5.4.2.6.4.16 doca_flow_pipe_hash

The `doca_flow_pipe_hash` API allows for creating a pipe where entries are matched by an index, which is typically the result of a hash calculation on the packet.

Key characteristics of a hash pipe:

- A `doca_flow_match` structure is provided only at pipe creation.
- This `doca_flow_match` mask defines which packet fields are included in the hash calculation.
- Other features (e.g., `monitor`, `actions`, `fwd`) behave identically to a basic DOCA Flow pipe.
- The `nb_flows` (number of entries) defined in `doca_flow_pipe_attr` must be set to a power of 2.

Hash Map Algorithms

The hash pipe's behavior is defined by its map algorithm, which can be set using `doca_flow_pipe_cfg_set_hash_map_algorithm()`.

> If no algorithm is specified, the default `DOCA_FLOW_PIPE_HASH_MAP_ALGORITHM_HASH` is used.

The available algorithms are:

- `DOCA_FLOW_PIPE_HASH_MAP_ALGORITHM_HASH` – The default algorithm. Uses a standard hash function on the masked fields to calculate the index.
- `DOCA_FLOW_PIPE_HASH_MAP_ALGORITHM_RANDOM` – Directs packets to entries randomly. No match mask is required.
- `DOCA_FLOW_PIPE_HASH_MAP_ALGORITHM_IDENTITY` – Uses an identity function for mapping. This creates a one-to-one relationship between the hash value and the index.
- `DOCA_FLOW_PIPE_HASH_MAP_ALGORITHM_FLOODING` – Duplicates the packet to match the number of entries, causing the packet to hit all entries in the pipe.
  - Best practices for this design are shown in the "Flow Hash Flooding Pipe" sample.
  - The pipe is limited to a maximum of 254 entries.
  - This algorithm is not supported in the VNF egress direction.
  - Packet order is only guaranteed for the destination of the first entry.
  - `SECURE_EGRESS` limitation (pre-ConnectX-8) – If a hash pipe is in the `SECURE_EGRESS` domain, its flooding destination pipe cannot be a `SECURE_EGRESS` or `SECURE_INGRESS` pipe.

- `DOCA_FLOW_PIPE_HASH_MAP_ALGORITHM_SELECT_ENABLED` – Consistently directs packets to the same, single index within the pipe.

Dynamic Algorithm Selection

It is possible to specify the hash algorithm dynamically when forwarding a packet from another pipe.

When `DOCA_FLOW_FWD_HASH_PIPE` is used as a forwarding action, the application can specify which algorithm to apply. This allows a single hash pipe to be used in multiple ways, processing packets with different logic as needed.

5.4.2.6.4.17 Hardware Steering Mode

Users can enable hardware steering mode by setting devarg `dv_flow_en` to `2`.

The following is an example of running DOCA with hardware steering mode:

```
.... -a 03:00.0, dv_flow_en=2 -a 03:00.1, dv_flow_en=2....
```

The following is an example of running DOCA with software steering mode:

```
.... -a 03:00.0 -a 03:00.1 ....
```

The `dv_flow_en=2` means that hardware steering mode is enabled.

In the struct `doca_flow_cfg`, setting `mode_args` using (`doca_flow_cfg_set_mode_args()`) represents DOCA applications. If it is set with `hws` (e.g., `"vnf,hws"`, `"switch,hws"`, `"remmote_vnf,hws"`) then hardware steering mode is enabled.

In switch mode, `fdb_def_rule_en=0,vport_match=1,repr_matching_en=0,dv_xmeta_en=4` should be added to DPDK PMD devargs, which makes DOCA Flow switch module take over all the traffic.

To create an entry by calling `doca_flow_pipe_add_entry`, the parameter flags can be set as `DOCA_FLOW_WAIT_FOR_BATCH` or `DOCA_FLOW_NO_WAIT`:

- `DOCA_FLOW_WAIT_FOR_BATCH` means that this flow entry waits to be pushed to hardware. Batch flows then can be pushed only at once. This reduces the push times and enhances the insertion rate.
- `DOCA_FLOW_NO_WAIT` means that the flow entry is pushed to hardware immediately.

The parameter `usr_ctx` is handled in the callback set in struct `doca_flow_cfg`.

`doca_flow_entries_process` processes all the flows in this queue. After the flow is handled and the status is returned, the callback is executed with the status and `usr_ctx`.

If the user does not set the callback in `doca_flow_cfg`, the user can get the status using `doca_flow_entry_get_status` to check if the flow has completed offloading or not.

5.4.2.6.4.18 Pipe Resize

The move to HWS improves performance because rule insertion is implemented in hardware rather than software. However, this move imposes additional limitations, such as the need to commit in advance on the size of the pipes (the number of rule entries). For applications that require pipe sizes to grow over time, a static size can be challenging: Committing to a pipe size too small can cause the application to fail once the number of rule entries exceeds the committed number, and pre-committing to an excessively high number of rules can result in memory over-allocation.

This is where pipe resizing comes in handy. This feature allows the pipe size to increase during runtime with support for all entries in a new resized pipe.

> Pipe resizing is supported in a basic pipe and a control pipe.

Increasing Pipe Size

It is possible to set a congestion level by percentage (`CONGESTION_PERCENTAGE`). Once the number of entries in the pipe exceeds this value, a callback is invoked. For example, for a pipe with 1000 entries and a `CONGESTION_PERCENTAGE` of 80%, the `CONGESTION_REACHED` callback is invoked after the 800th entry is added.

Following the `CONGESTION_REACHED` callback, the application should call the pipe resize API (`resize()`). The following are optional callbacks during the resize callback:

- A callback on the new number of entries allocated to the pipe
- A callback on each entry that existed in the smaller pipe and is now allocated to the resized pipe

> The pipe pointer remains the same for the application to use even after being resized.

Upon completion of the internal transfer of all entries from the small pipe to the resized pipe, a `RESIZED` callback is invoked.

A `CONGESTION_REACHED` callback is received exactly once before the `RESIZED` callback. Receiving another `CONGESTION_REACHED` only happens after calling `resize()` and receiving its completion with a `RESIZED` callback.

List of Callbacks

- `CONGESTION_REACHED` – on the updated number of entries in the pipe (if pipe is resizable)

  > Receiving a `CONGESTION_REACHED` callback can occur after adding a small number of entries and for moving entries from a small to resized pipe. The application must always call pipe resize after receiving the `CONGESTION_REACHED` callback to handle such cases.

- `RESIZED` – upon completion of the resize operation

  > Calling pipe resize returns immediately. It starts an internal process that ends later with the `RESIZED` callback.

- `NR_ENTRIES_CHANGED` (optional) – on the new max number of entries in the pipe
- `ENTRY_RELOCATE` (optional) – on each entry moved from the small pipe to the resized pipe

Order of Operations for Pipe Resizing

1. Set a process callback on flow configuration:

```
struct doca_flow_cfg *flow_cfg;
doca_flow_cfg_create(&flow_cfg);
doca_flow_cfg_set_cb_pipe_process(flow_cfg, <pipe-process-callback>);
```

> This informs on `OP_CONGESTION_REACHED` and `OP_RESIZED` operations when applicable.

2. Set the following pipe attribute configurations:

```
struct doca_flow_pipe_cfg *pipe_cfg;
doca_flow_pipe_cfg_create(&pipe_cfg, port);
doca_flow_pipe_cfg_set_nr_entries(pipe_cfg, <initial-number-of-entries>);
doca_flow_pipe_cfg_set_is_resizable(pipe_cfg, true);
doca_flow_pipe_cfg_set_congestion_level_threshold(pipe_cfg, <CONGESTION_PERCENTAGE>);
doca_flow_pipe_cfg_set_user_ctx(pipe_cfg, <pipe-user-context>);

# Optional for each pipe queue number to be excluded from entries process:
doca_flow_pipe_cfg_set_excluded_queue(pipe_cfg, pipe_queue);
```

3. Start adding entries:

```
/* Basic pipe */
doca_flow_pipe_add_entry()
/* Control pipe */
doca_flow_pipe_control_add_entry()
```

4. Once the number of entries in the pipe crosses the congestion threshold, an `OP_CONGESTION_REACHED` operation callback is received.
5. Mark the pipe's congestion threshold event and, upon return, call `doca_flow_pipe_resize()`. For this call, add the following parameters:

- The new threshold percentage for calculating the new size.
- A callback on the new pipe size (optional):

```
doca_flow_pipe_resize_nr_entries_changed_cb nr_entries_changed_cb
```

- A callback on the entries to be transferred to the resized pipe:

```
doca_flow_pipe_resize_entry_relocate_cb entry_relocation_cb
```

6. Call `doca_flow_entries_process()` per queue in a loop to trigger the transfer of entries (per queue). It is relevant for both a basic pipe and a control pipe.
7. At this phase, adding new entries to the pipe is permitted. The entries are added directly to the resized pipe and therefore do not need to be transferred.
8. Once all entries are transferred on all queues, an `OP_RESIZED` operation callback is received (in the context of the last thread calling entries process. Also, at this point a new `OP_CONGESTION_REACHED` operation callback can be received again.

At this point calling `doca_flow_entries_process()` can be stopped for a control pipe. For a basic pipe an additional call is required to complete the call to `doca_flow_pipe_add_entry()`.

`doca_flow_entries_process()` has the following roles:

- Triggering entry transfer from the smaller to the bigger pipe (until an `OP_RESIZED` callback is received)
- Follow up API on previous `add_entries` API (basic pipe relevance only)
- If a specific queue is excluded on the resized pipe - calling entries process on that queue is not a must in order to receive the `OP_RESIZED` operation callback.
- The `OP_RESIZED` callback can only be received on a pipe non-excluded queue.

5.4.2.6.4.19 Excluded Queues

There are cases where an application uses a subset of queues for rules operations such as add/remove/update. On the other hand, resizing a pipe requires calling doca_flow_entries_process() on all queues to get an `OP_RESIZED` operation callback. This is where the excluded queues feature becomes handy: it enables excluding the pipe's queues where rule operations do not take part of.

- When calling pipe resize it is sufficient to process entries only on the non-excluded queues to get an `OP_RESIZED` operation callback for that pipe. Still - it is allowed to process entries of any queue (for any other pipe with this queue included).

- Before and during pipe destroy it is allowed to process entries (in parallel) on all pipe's excluded queues.

However, there are limitations when configuring a pipe's excluded queues:

- It is not allowed to add/remove/update entries on a pipe's excluded queues. There is no validity check or enforcement on this and it is up to the application to maintain this restriction. It is allowed to process entries of all queues at all times since `doca_flow_entreis_process()` API is not per pipe.

Excluded queue syntax

```
struct doca_flow_pipe_cfg *pipe_cfg;

doca_flow_pipe_cfg_create(&pipe_cfg, port);
...
/* The next configuration should be repeated for each excluded queue number individually */
doca_error_t doca_flow_pipe_cfg_set_excluded_queue(struct doca_flow_pipe_cfg *pipe_cfg, uint16_t pipe_queue);

# pipe_cfg - pointer to DOCA Flow pipe configuration struct.
# pipe_queue - the pipe queue number to exclude.
# Return code:
# - DOCA_SUCCESS - in case of success.
# - DOCA_ERROR_INVALID_VALUE - in case of invalid input.
```

- An excluded queue number must be between 0 to (max queues - 1).
- It is not allowed to exclude all queues of a pipe. At least one of the pipe's queues must remain non-excluded.

5.4.2.6.4.20 Hairpin Configuration

In switch mode, if `dev` is set in struct `doca_flow_port_cfg` (using `doca_flow_port_cfg_set_dev()`), then an internal hairpin is created for direct wire-to-wire fwd. Users may specify the hairpin configuration using `mode_args`. The supported options as follows:

- `hairpinq_num=[n]` – the hairpin queue number
- `use_huge_mem` – determines whether the Tx buffer uses hugepage memory
- `lock_rx_mem` – locks Rx queue memory

5.4.2.6.5 Teardown

5.4.2.6.5.1 Pipe Entry Teardown

When an entry is terminated by the user application or ages-out, the user should call the entry destroy function, `doca_flow_pipe_rm_entry()`. This frees the pipe entry and cancels hardware offload.

5.4.2.6.5.2 Pipe Teardown

When a pipe is terminated by the user application, the user should call the pipe destroy function, `doca_flow_pipe_destroy()`. This destroys the pipe and the pipe entries that match it.

When all pipes of a port are terminated by the user application, the user should call the pipe flush function, `doca_flow_port_pipes_flush()`. This destroys all pipes and all pipe entries belonging to this port.

During `doca_flow_pipe_destroy()` execution, the application must avoid adding/removing entries or checking for aged entries of any other pipes.

5.4.2.6.5.3 Port Teardown

When the port is not used anymore, the user should call the port stop function, `doca_flow_port_stop()`. This stops the DOCA port, disables the traffic, destroys the port and frees all resources of the port.

5.4.2.6.5.4 Flow Teardown

When the DOCA Flow is not used anymore, the user should call the flow destroy function, `doca_flow_destroy()`. This releases all the resources used by DOCA Flow.

5.4.2.7 Metadata

In DOCA Flow, a scratch area of size up to `DOCA_FLOW_META_MAX` bytes is available throughout the pipeline. This area functions like transient memory, allowing applications to store, modify, and match metadata values across multiple pipes.

You can set metadata values manually or copy them from packet fields. These values can then be matched in later pipes, with support for bit masking in both matching and modification operations.

5.4.2.7.1 Metadata Actions

Metadata can be modified using the following action types depending on their masks or descriptors:

- `SET` – Sets a metadata value from a pipe action or a specific entry action. The width of the value is defined by the action descriptor.

- `COPY` – Copies a value from a packet field, which can include other metadata fields. The width is also specified by the descriptor.

Refer to DOCA API References for details on `struct doca_flow_meta`.

5.4.2.7.2 Behavior and Usage Considerations

Metadata fields behave similarly to variables in programming languages but have specific characteristics within DOCA Flow:

- Some fields may be internally used by DOCA Flow actions and can be overwritten with opaque values
- Most fields do not retain their values when the packet crosses between NIC and FDB domains (i.e., if there is a transfer between two pipes belonging to the NIC and FDB domains the field data might be lost)
- Some fields support software datapath integration, allowing promotion to or from the software Rx/Tx paths.

5.4.2.7.3 Metadata Field Breakdown

Field	Description
`pkt_meta`	Intended exclusively for application use. Preserves its content across NIC/FDB domain boundaries. Available in the software Rx datapath. Values set in Tx can be observed in Rx.
`u32[0-3]`	Always available for application use. Content may not be preserved across NIC/FDB domain boundaries. May be used internally by DOCA Flow for certain pipe types or actions.
`u32[4]`	Always available for application use
`u32[5-max]`	Optionally available, depending on the hardware model, firmware configuration, and DOCA Flow operation mode

5.4.2.7.4 Pipe Design Consideration

Some pipe types or actions use specific bytes in the scratch area for internal operations. So, if:

1. PIPE-1 sets metadata
2. PIPE-A (intermediate) modifies the same bytes internally
3. PIPE-2 reads those bytes

Then the values may be overwritten by PIPE-A, leading to incorrect results in PIPE-2.

When designing a pipe tree, ensure metadata fields used across multiple pipes are not also internally consumed by intermediate pipes.

Some DOCA pipe types (or actions) use several bytes in the scratch area for internal usage. So, if the user has set these bytes in PIPE-1 and read them in PIPE-2, and between PIPE-1 and PIPE-2 there is PIPE-A which also uses these bytes for internal purposes, then these bytes are overwritten by the PIPE-A. This must be considered when designing the pipe tree.

5.4.2.7.5 Scratch Area Usage by Pipe Type

The following table shows which scratch area bytes (metadata fields) are used internally by different DOCA Flow pipe types.

If the application writes to any of these fields before or after they are used internally by a pipe, the values may be overwritten.

Pipe Type/Action	Elements Used in Scratch
Hash Pipe	`u32[3]` bits [31:16]
LPM Pipe	`u32[0]`
LPM Exact Match Pipe	`u32[0]`, `u32[1]`
ACL	`u32[0]` – `u32[3]`
IPsec Anti-Replay	`u32[0]` bits [7:0], `u32[1]`
METER COLOR	`u32[1]` bits [7:0]
NAT64	`u32[0]` – `u32[2]`

When designing the pipeline, avoid reading or writing to metadata fields that are used internally by intermediate pipes.

5.4.2.7.6 Supported Metadata Fields per Hardware and Mode

The number of available user metadata fields (starting from `u32[5]`) depends on the hardware generation and operating mode. The following table details which fields are available for application use.

Attempting to use an unavailable metadata field during pipe creation will cause the operation to fail.

Hardware Type and Mode	Available Fields
Before ConnectX-7, VNF mode, over PF (switchdev mode)	`u32[5]`
Before ConnectX-7, VNF mode, over VF / PF (non-switchdev)	`u32[5]` – `u32[6]`
Before ConnectX-7, SWITCH mode	None
ConnectX-7 and above, VNF mode, over PF (switchdev mode)	`u32[5]` – `u32[8]`
ConnectX-7 and above, VNF mode, over VF / PF (non-switchdev)	`u32[5]` – `u32[9]`
ConnectX-7 and above, SWITCH mode	`u32[5]` – `u32[7]`

The number of available fields listed above is the maximum. This number can be reduced by specific host configurations, firmware settings, or other enabled features.

Always verify hardware capabilities and operating mode when designing pipelines that rely on these extended metadata fields. An API to query these capabilities will be provided in a future release.

5.4.2.8 Custom Header

Network protocols evolve rapidly, often outpacing hardware support. To address the need for flexible packet processing, DOCA Flow provides support for custom headers. This allows applications to define and parse proprietary or new network protocols (such as GENEVE or eCPRI) directly in hardware without waiting for native firmware support.

5.4.2.8.1 Network Header Properties

A network header can vary in format, field composition, and length. The Custom Header feature categorizes these properties into the following groups:

- Header length: Indicates the size of the header. It can be a fixed value or dynamic (determined by a specific field within the header). For example, the IPv4 header uses a 4-bit IHL field to indicate its length.
- Next protocol: Defines how the parser identifies the subsequent header. This can be a fixed protocol type or determined dynamically by a dedicated field. For instance, the `Protocol` field in an IPv4 header dictates whether the next header is TCP, UDP, etc.
- Data fields: Specific segments of the header exposed for application logic. Applications can match on or modify these fields.
- TLV options: Describes variable-length options (Type-Length-Value), including overall option length, starting offset, option type, and individual length fields.

- Preceding protocols: Specifies valid preceding headers. For example, a GENEVE header typically follows a UDP header; an eCPRI header may follow either UDP or L2 headers.
- Following protocols: Specifies valid subsequent headers. For example, a tunnel header might be followed by an inner L2 or L3 header.
- Special attributes: Defines protocol characteristics, such as whether the protocol acts as a tunnel (a split point between outer and inner layers).

5.4.2.8.2 IPv4 Header Definition Example

The following table illustrates the structure of an IPv4 header. This layout serves as a reference for defining similar protocols using the Custom Header API.

Byte	0								1								2								3							
Offset	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
IPv4	Version				Header Length				TOS								Total length MSB								Total length LSB							
Offset	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
IPv4	Identification																-	DF	MF	Offset												
Offset	64	65	66	67	68	69	70	71	72	73	74	75	76	77	78	79	80	91	82	83	84	85	86	87	88	89	90	91	92	93	94	95
IPv4	Time to live								Next Protocol								Header checksum															
Offset	96	97-126																														127
IPv4	Source IP address																															
Offset	128	129-258																														159
IPv4	Destination IP address																															

- Header Length: This is a dynamic length determined by the 4-bit `IHL` field (bits 4-7). The value in this field is multiplied by 32 to calculate the total length in bits.

- Next Protocol: This is determined by the 8-bit `Protocol` field (bits 72-79). This value tells the parser which protocol header follows IPv4 (e.g., TCP, UDP).
- Data Fields: The application may define fields of interest for matching or modification, such as `Source IP` (32 bits at offset 96) and `Destination IP` (32 bits at offset 128).

5.4.2.8.3 GENEVE Header Definition Example

The following table illustrates the structure of a GENEVE header, emphasizing variable-length options.

Byte	0								1								2								3							
Offset	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
Geneve	Version			Options length					O	C	Reserved						Next protocol															
Offset	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
Geneve	Virtual Network Identifier (VNI)																								Reserved							

- Option Length: The 6-bit `Opt Len` field (bits 2-7) specifies the length of the options following the base header. The total length is calculated as `(Opt Len * 32) + 64` bits.
- Type: Hardware can match on the `Type` field (bits 72-79) to identify specific options, which is necessary because GENEVE options do not have a fixed order.
- Sample Fields**:** Applications can match or modify specific option data, such as `Option Class` and `Option Value`.

5.4.2.8.4 GENEVE Option Definition Example

The following list describes the properties of a GENEVE header, specifically focusing on how the hardware handles variable-length options.

Byte	0								1								2								3							
Offset	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Option	Option Class																Type								Rsvd			Length				
Offset	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
Option	Option value																															

- Option Length: This is a 5-bit field located at an offset of 27 bits. It specifies the length of the subsequent option data in 32-bit words. The hardware calculates the total header length by multiplying this value by 32 and adding the fixed header size (64 bits).
- Type: Located at an offset of 16 bits with a length of 8 bits. The hardware uses this value to identify specific options and capture the correct data into the configured sampler. This identification is essential because the order of GENEVE options is not fixed by the protocol; the hardware must match the type to locate the data.
- Sample Fields (`Option Class` , `Option Value`): These are the specific data fields the application intends to match or modify. For example, an application might define a sampler for the `Option Value` , located at an offset of 32 bits with a length of 32 bits.

5.4.2.8.5 UDP Header Definition Example

The following table illustrates the structure of a UDP header.

Byte	0								1								2								3							
Offset	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
UDP	Source Port																Destination Port															
Offset	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
UDP	Header + Payload length																Checksum															

- Source/Destination Port: 16-bit fields typically used for matching or modification.
- Header Length: Fixed at 64 bits (8 bytes).
- Next Protocol: The UDP header does not contain an explicit "Next Protocol" field. The payload is treated as generic data unless a specific context (like a tunneling destination port, e.g., VXLAN on port 4789) implicitly defines the next layer.

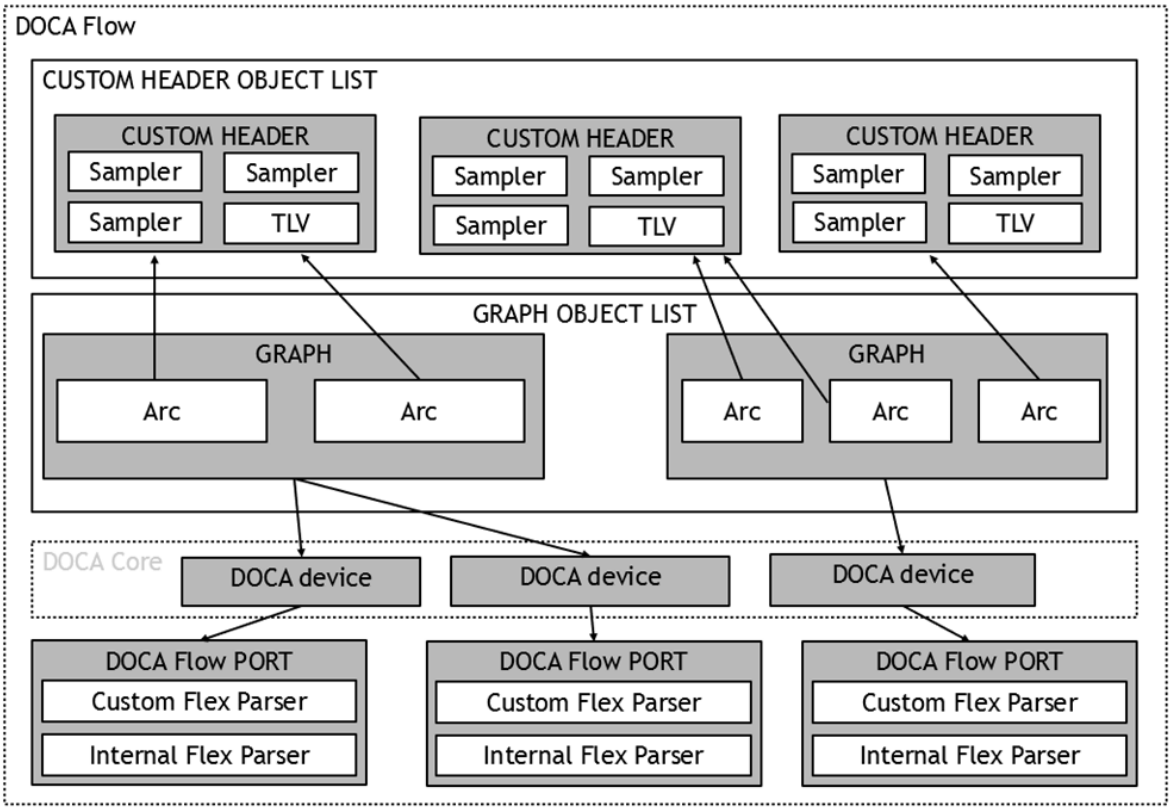
5.4.2.8.6 Custom Header Lifecycle

The following workflow describes the standard operation for custom headers:

1. **Define Structure:** The application defines the header layout (fields and lengths) based on the protocol specification.
2. **Create Parser Object:** The application creates a `doca_flow_parser` object. This object represents the new protocol header and is available for use across the DOCA instance. One object is created per protocol.
3. **Create Samplers:** The application creates "samplers" within the parser object. These identify specific data fields to be exposed for matching or modification.
4. **Set Attributes:** The application configures attributes such as header length calculation logic, next protocol identification, and tunnel behavior.
5. **Create Parse Graph:** The application creates one or more parse graphs. These graphs define the sequence of headers the hardware should expect.
6. **Define Arcs:** The application creates "arcs" to link native and custom headers within the graph, establishing valid transitions between protocols.
7. **Configure Match/Actions:** The application uses the `definition` structure to map new header fields to DOCA match and action APIs.
8. **Initialize:** The application initializes DOCA devices and binds the required parse graphs. Graphs can be bound to multiple devices; all ports on a device (VFs, SFs, representors) share the bound graphs.
9. **Teardown:** Upon exit, the application must destroy all custom header objects, parse graphs, and devices as part of the standard cleanup procedure.

1. application defines the header structures according to the protocol specification, or just the structure defining the necessary fields only
2. application creates the `custom header` object, which is DOCA global visible and represents the new protocol header applications wish to support. Application can support multiple new protocols and create multiple custom header objects, one per protocol
3. on top of the custom header object application creates the `samplers` - the local objects representing the data field to match on or modify with actions. Sampler can be configured to handle TLV option with a matched type value

4. application sets the custom header object attributes specifying how the header length should be calculated, whether there is a next protocol field, and whether the header is a tunnel header
5. application creates one or multiple `parse graph` objects, that is DOCA global visible object and represents the set of custom headers configured on one or more DOCA devices in hardware
6. on top of parge graph application creates an `arc`, the local object to link the native or custom headers in the header parsing chain. It tells the relations between headers and the following order
7. application configures *definitions* to represent the new header fields in DOCA match and actions structures. The required by `definitions` strings are provided from the created samplers
8. application initializes the `DOCA devices` and binds the required parse graphs. The parse graph can be bound to multiple devices, and multiple graphs can be bound to the same device. All network ports spawned on the top of the same device (VFs, SFs, representors) share the bound parse graphs
9. On the DOCA Flow, the library implicitly configures the hardware according to the configuration of the bound parse graphs, some firmware/hardware imposed errors might occur on this stage
10. application uses the match and action structure extensions provided by definitions to build the pipes matching on and modifying the fields in the custom headers
11. on exit application stops the DOCA Flow, destroys the devices, parse graphs, and custom headers – the usual cleanup procedure



5.4.2.8.7 Match and Actions Fields

Custom header fields are presented to DOCA match and action APIs as byte arrays via the `definition` structure. If a field width is not byte-aligned, it is right-aligned within the array, occupying the lower bits.

The `valid_bit` field in the metadata indicates whether the custom header was successfully identified and parsed in the current packet. This ensures matches are only applied when the header is present.

5.4.2.8.8 Known Limitations

There are some known limitations:

- Field alignment: Both the `next protocol` and dynamic `header length` fields must reside entirely within a single 32-bit word, aligned to the start of the header. They cannot cross a dword boundary due to hardware constraints.
- Header length field width: The supported width for a dynamic header length field is limited to 6 or 9 bits, depending on the hardware generation.
- Sampling limit: The total amount of data sampled for matching and modification cannot exceed eight 32-bit words (32 bytes) per header.

- Dummy fields: To maintain the correct header structure in software without exceeding the sampling limit, fields that are not required for matching can be defined as dummy fields in the configuration.
- Multiplier restrictions: The hardware calculates header length in 32-bit words. Therefore, multipliers of 1 (bytes) or 2 (16-bit words) are not fully supported due to hardware alignment behaviors.
- Parse graph vs. flow match: The input and output arcs defined in the parse graph configuration only instruct the hardware on *when* and *how* to capture sample fields from a recognized header. They do not enforce a match in the flow rules. It is the application's responsibility to ensure the flow rules explicitly match the required packet pattern (e.g., ensuring a specific header sequence exists) if strict adherence to the graph structure is required.

5.4.2.8.9 NIC Configuration for Custom Header Support

The Flex Parser is a specialized hardware feature on BlueField DPUs that enables programmable parsing of protocol headers. While the NIC contains fixed, built-in parsers for standard protocols defined at the time of hardware development, the Flex Parser allows DOCA to define and handle new or modified protocols and options.

BlueField-2 and BlueField-3 models support a maximum of 8 concurrent Flex Parser units. However, the actual number available to the application may be lower if the firmware reserves specific units for internal use (e.g., to support newer network protocols).

Two non-volatile parameters control the Flex Parser configuration, which can be modified using the `mlxconfig` utility

- `PROG_PARSE_GRAPH` – Setting this value to `True` makes the Flex Parser feature available for host software usage.
- `FLEX_PARSER_PROFILE_ENABLE` – This setting configures how the firmware allocates internal Flex Parser units for specific protocols.

Configuration steps:

1. Check the current device settings:

```
mlxconfig -d /dev/mst/mt41686_pciconf0 query
```

2. Enable the Flex Parser feature for the host:

```
mlxconfig -d /dev/mst/mt41686_pciconf0 set PROG_PARSE_GRAPH=1
```

3. Set the profile enable bit (e.g., to 4) to allocate resources for the custom header feature.

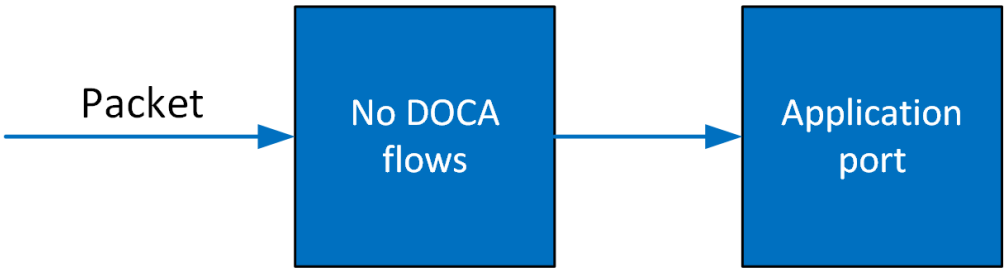
```
mlxconfig -d /dev/mst/mt41686_pciconf0 set FLEX_PARSER_PROFILE_ENABLE=4
```

4. A cold reboot of the NIC is required for these non-volatile configuration changes to take effect.

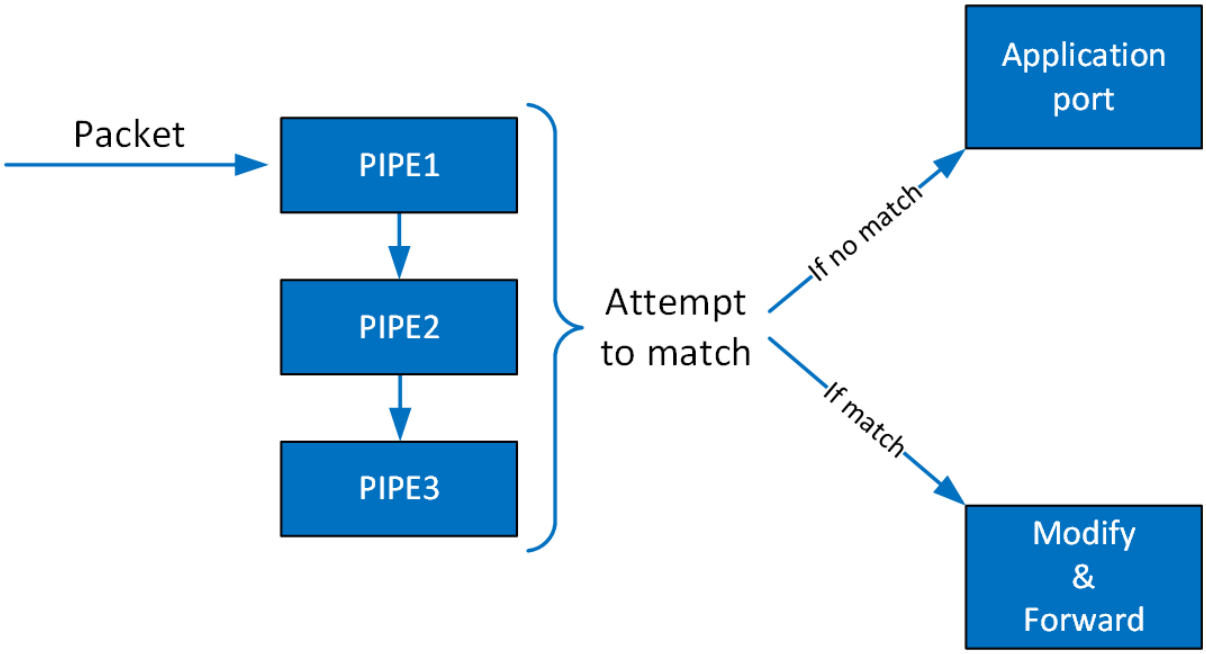
```
mlxfwreset -d /dev/mst/mt41686_pciconf0 -yes r
```

5.4.2.9 Packet Processing

In situations where there is a port without a pipe defined, or with a pipe defined but without any entry, the default behavior is that all packets arrive to a port in the software.



Once entries are added to the pipe, if a packet has no match then it continues to the port in the software. If it is matched, then the rules defined in the pipe are executed.



If the packet is forwarded in RSS, the packet is forwarded to software according to the RSS definition. If the packet is forwarded to a port, the packet is redirected back to the wire. If the packet is forwarded to the next pipe, then the software attempts to match it with the next pipe.

Note that the number of pipes impacts performance. The longer the number of matches and actions that the packet goes through, the longer it takes the hardware to process it. When there is a very large number of entries, the hardware must access the main memory to retrieve the entry context which increases latency.

5.4.2.10 Debug and Trace Features

DOCA Flow supports trace and debugging of DOCA Flow applications which enable collecting predefined internal key performance indicators (KPIs) and pipeline visualization.

5.4.2.10.1 Installation

The set of DOCA's SDK development packages include also a developer-oriented package that includes additional trace and debug features which are not included in the production libraries:

- `.deb` based systems – `libdoca-sdk-flow-trace`
- `.rpm` based systems – `doca-sdk-flow-trace`

These packages install the trace-version of the libraries under the following directories:

- `.deb` based systems – `/opt/mellanox/doca/lib/<arch>/trace`
- `.rpm` based systems – `/opt/mellanox/doca/lib64/trace`

5.4.2.10.2 Using Trace Libraries

5.4.2.10.2.1 Runtime Linking

The trace libraries are designed to allow a user to link their existing (production) program to the trace library without needing to recompile the program. To do so, one should simply update the matching environment variable so that the OS will prioritize loading libraries from the above trace directory.

The following is an example for such an update for the Ubuntu 22.04 BlueField image:

```
LD_LIBRARY_PATH=/opt/mellanox/doca/lib/aarch64-linux-gnu/trace:${LD_LIBRARY_PATH} doca_ipsec_security_gw <program parameters>
```

5.4.2.10.2.2 Compilation

The trace-level development packages in the previous section provide additional compilation definitions (`doca-flow-trace.pc`) to be used in addition to the regular

compilation definitions for the DOCA Flow SDK library (`doca-flow.pc`). It is recommended to use these compilation definitions for the following scenarios:

- Static linking of the trace-level DOCA Flow library into your program
- Regular (dynamic) linking of the trace-level DOCA Flow library into your program during development and testing

Although the latter could also be determined at runtime as explained in the previous section, many developers find it handy to compile directly against the trace version during initial development phases.

5.4.2.10.3 Trace Features

5.4.2.10.3.1 DOCA Log - Trace Level

DOCA's trace logging level (`DOCA_LOG_LEVEL_TRACE`) is compiled as part of this trace version of the library. That is, any program compiled against the library can activate this additional logging level through DOCA's API or even through DOCA's built-in argument parsing (ARGP) library:

```
LD_LIBRARY_PATH=/opt/mellanox/doca/lib/aarch64-linux-gnu/trace:${LD_LIBRARY_PATH} doca_ipsec_security_gw <program parameters> --sdk-log-level 70
```

5.4.2.10.3.2 DOCA Flow - Additional Sanity Checks

When using the trace version of the library, additional input sanitation checks are added, at the cost of introducing minor performance implications. These checks are meant to assist developers in their early steps of using the library, as they provide early detection and improved logging for common coding mistakes.

5.4.2.11 DOCA Flow Samples

This section provides DOCA Flow sample implementation on top of the BlueField.

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.2.11.1 Sample Prerequisites

A DOCA Flow-based program can either run on the host machine or on the BlueField.

Flow-based programs require an allocation of huge pages, hence the following commands are required:

```
$ echo '1024' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

5.4.2.11.2 Running the Sample

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

   ```
   cd /opt/mellanox/doca/samples/doca_flow/<sample_name>
   meson /tmp/build
   ninja -C /tmp/build
   ```

   The binary `doca_<sample_name>` will be created under `/tmp/build/`.
3. Sample (e.g., `flow_aging`) usage:

   ```
   Usage: doca_flow_aging [DPDK Flags] -- [DOCA Flags]

   DOCA Flags:
     -h, --help                            Print a help synopsis
     -v, --version                         Print program version information
     -l, --log-level                       Set the (numeric) log level for the program <10=DISABLE,
   20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
     --sdk-log-level                       Set the SDK (numeric) log level for the program <10=DISABLE,
   20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
     -j, --json <path>                     Parse command line flags from an input json file
   ```
4. For additional information per sample, use the `-h` option after the `--` separator:

   ```
   /tmp/build/doca_<sample_name> -- -h
   ```
5. The following is an example from an execution on the DPU:
   - CLI example for running the samples with "vnf" mode:

     ```
     /tmp/build/doca_<sample_name> -- -a aux/2 -a aux/3 -l 60
     ```
   - CLI example for running the VNF samples with `vnf,hws` mode:

     ```
     /tmp/build/doca_<sample_name> -- -a aux/2,dv_flow_en=2 -a aux/3,dv_flow_en=2 -l 60
     ```
   - CLI example for running the switch samples with `switch,hws` mode:

     ```
     /tmp/build/doca_<sample_name> -- -r pci/03:00.0,pf0sf[2-3] -l 60
     ```

When running on the BlueField with `switch,hws` mode, it is not necessary to configure the OVS.

DOCA switch sample hides the extra `fdb_def_rule_en=0,vport_match=1,repr_matching_en=0,dv_xmeta_en=4` DPDK devargs with a simple `-r` to specify the PCIe ID and representor information.

When running on the DPU using the command above, sub-functions must be enabled according to the BlueField Scalable Function User Guide.

When running on the host, virtual functions must be used according to the instructions in the DOCA Virtual Functions User Guide.

For additional information regarding the command line syntax of the device and device representor identifiers, please referr to the matching section in the DOCA Arg Parser Guide.

5.4.2.12 Field String Mapping

5.4.2.12.1 Field String Supported Actions

The following is a list of all the API fields available for matching criteria and action execution.

String Field	Path in The Structure		Set	Add		Copy		Condition	
	Match	Actions		Dst	Src	Dst	Src	A	B
`meta.data` (bit_offset < 32)	`meta.pkt_meta`	`meta.pkt_meta`	✔	✔	✔	✔	✔	✔	✔
`meta.data` (bit_offset ≥ 32)	`meta.u32[i]`	`meta.u32[i]`	✔	✔	✔	✔	✔	✔	✔
`parser_meta.hash.result`	None. See section "Copy Hash Result" for details.		N/A	N/A	✔	N/A	✔	✘	✘

String Field	Path in The Structure		Set	Add		Copy		Condition	
	Match	Actions		Dst	Src	Dst	Src	A	B
parser_meta.port.id	parser_meta.port_id		N/A	N/A	✘	N/A	✘	✘	✘
parser_meta.ipsec.syndrome	parser_meta.ipsec_syndrome		N/A	N/A	✘	N/A	✘	✘	✘
parser_meta.psp.syndrome	parser_meta.psp_syndrome		N/A	N/A	✘	N/A	✘	✘	✘
parser_meta.random.value	parser_meta.random		N/A	N/A	✘	N/A	✘	✔	✘
parser_meta.meter.color	parser_meta.meter_color		N/A	N/A	✘	N/A	✘	✘	✘
parser_meta.packet_type.l2_outer	parser_meta.outer_l2_type		N/A	N/A	N/A	N/A	N/A	N/A	N/A
parser_meta.packet_type.l3_outer	parser_meta.outer_l3_type		N/A	N/A	N/A	N/A	N/A	N/A	N/A

`inner.icmp6.code`	`inner.icmp.code`		✘	✘	✘	✘	✘	✘	✘

1. This is a mandatory field for VXLAN-GPE matching.
2. `tun.vxlan_tun_rsvd1` modifications only work for traffic with the default UDP destination port (i.e., 4789 for VXLAN and VXLAN-GBP and 4790 for VXLAN-GPE)

5.4.2.12.2 Non-Matchable Field Strings

Users can modify fields which are not included in `doca_flow_match` structure.

5.4.2.12.2.1 Copy Hash Result

You can copy the the matcher hash calculation into other fields using the `"parser_meta.hash.result"` string.

5.4.2.12.2.2 Copy UTC Timestamp Value

You can copy the NIC hardware timestamp value into other fields using `"parser_meta.utc.time"` string.

5.4.2.12.2.3 Copy GENEVE Options

User can copy GENEVE option type/class/data using the following strings:

- `"tunnel.geneve_opt[i].type"` – Copy from/to option type (only for option configured with `DOCA_FLOW_PARSER_GENEVE_OPT_MODE_MATCHABLE`).
- `"tunnel.geneve_opt[i].class"` – Copy from/to option class (only for option configured with `DOCA_FLOW_PARSER_GENEVE_OPT_MODE_MATCHABLE`).
- `"tunnel.geneve_opt[i].data"` – Copy from/to option data, the bit offset is from the start of the data.

`i` is the index of the option in `tlv_list` array provided in `doca_flow_parser_geneve_opt_create`

5.4.2.13 DOCA Flow Connection Tracking

This guide provides an overview and configuration instructions for the DOCA Flow Connection Tracking (CT) API.

5.4.2.13.1 Introduction

The DOCA Flow Connection Tracking (CT) module is a 5-tuple table designed to efficiently track network connections using hardware resources. It supports the following key features:

- Track zone and 5-tuple sessions – Track and manage network connections based on a 5-tuple (source IP, destination IP, source port, destination port, and protocol) along with zone-based separation
- Zone-based virtual tables – Enable logical isolation using zones
- Aging support – Remove idle connections automatically using configurable timeouts
- Connection metadata – Set and manage metadata for tracked connections
- Bidirectional packet handling – Manage traffic in both directions of a connection
- High connection rate – Efficiently handle a high rate of connections per second (CPS)

The CT module makes it simple and efficient to track connections by leveraging hardware resources.

5.4.2.13.2 Architecture

The DOCA Flow CT Pipe is designed to handle non-encapsulated TCP and UDP packets. It supports two primary actions:

- Forward to next pipe – For packets that match a known 6-tuple connection (5-tuple + zone)
- Miss to next pipe – For packets without a matching connection entry

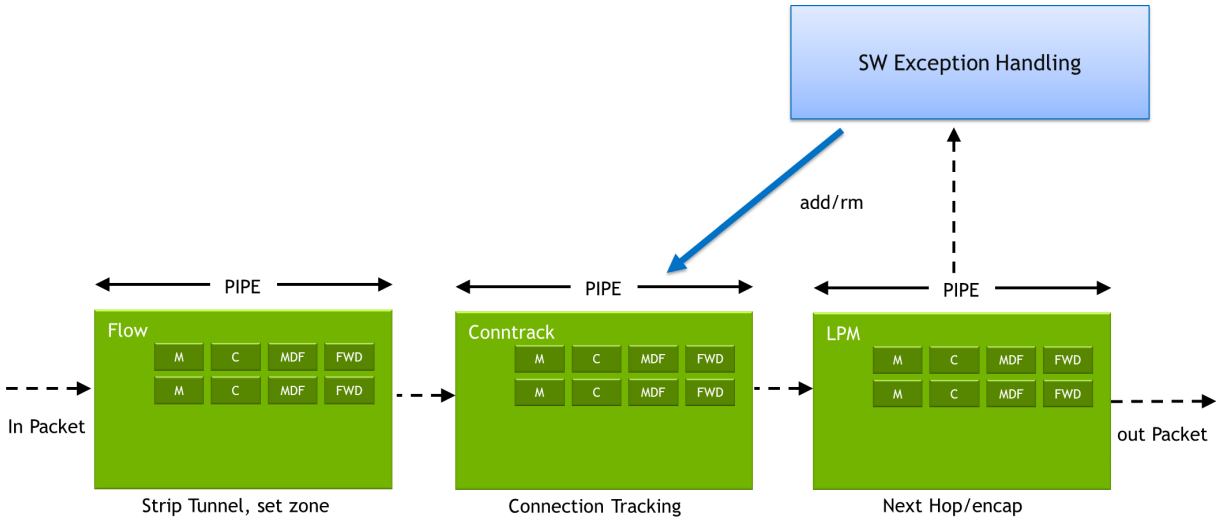
The application is responsible for handling packets based on these outcomes.

The DOCA Flow CT API consists of four major components:

- CT module manipulation – Configure and manage resources within the CT module
- CT connection entry manipulation – Add, remove, or update connection entries efficiently
- Callbacks – Handle asynchronous processing results for connection entries

- Pipe and entry statistics – Monitor connection tracking performance using pipe-level and entry-level statistics

These components provide flexible control over connection tracking and monitoring, allowing applications to adapt to various network scenarios effectively.



5.4.2.13.2.1 Aging

Aging time refers to the maximum duration (in seconds) a session can remain active without detecting any packets. If no packets are observed within this period, the session is terminated.

To support aging, a dedicated aging thread is launched. This thread polls and checks counters for all active connections, ensuring that stale sessions are removed efficiently.

> ⚠ When aging is enabled, either the `counter` flag or a non-zero `timeout` must be set for at least one connection entry to trigger session expiration.

5.4.2.13.2.2 Managed Mode

In Managed Mode, the application is responsible for:

- Managing worker threads
- Parsing and handling connection lifecycles

This mode utilizes DOCA Flow CT management APIs for creating and destroying connections.

The CT aging module automatically notifies the application of aged-out connections by invoking callbacks.

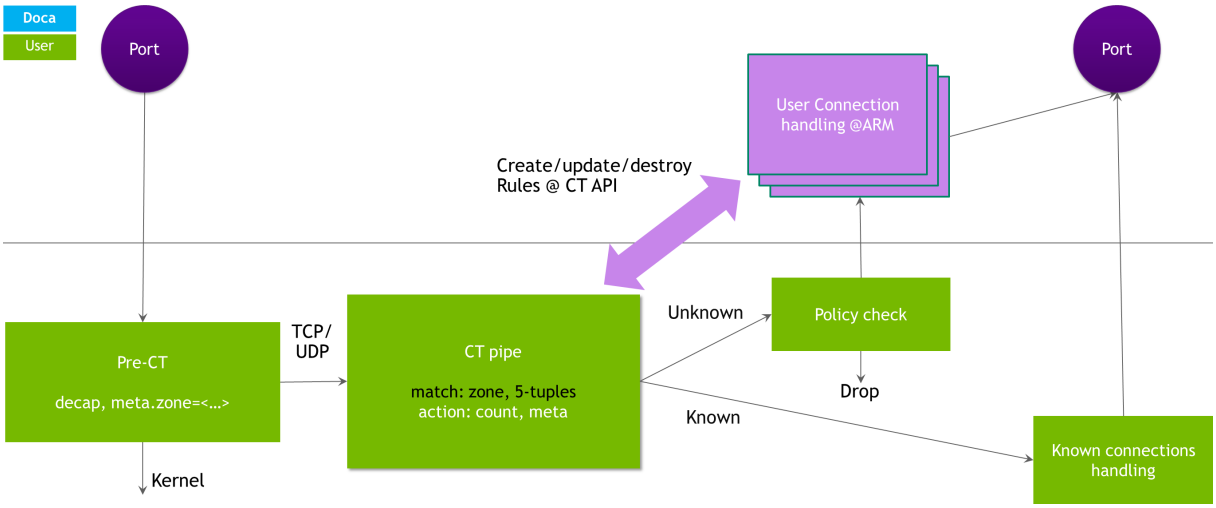
5.4.2.13.2.3 Connection Rules and Management

Users have the flexibility to create connection rules with different patterns, metadata (meta), or counters which can be applied separately for each packet direction.

> ⚠ Users must manually define the appropriate meta and mask values for matching (`match`) and modifying (`modify`) packets.

To create rules in stages:

1. Create one rule for a connection using the standard API.
2. Add a second rule for the opposite packet direction using the `doca_flow_ct_entry_add_dir()` API.



5.4.2.13.2.4 Processing CT Entries

DOCA Flow provides specialized APIs to process CT entries using a dedicated queue:

- `doca_flow_entries_process` – Processes pipe entries in the queue
- `doca_flow_aging_handle` – Handles the aging of pipe entries

> ℹ Some APIs, such as CT entry status queries and pipe miss queries, are not supported in Managed Mode.

5.4.2.13.3 Prerequisites

5.4.2.13.3.1 DPU

To enable DOCA Flow CT on the DPU, perform the following on the Arm:

1. Enable `iommu.passthrough` in Linux boot commands (or disable SMMU from the DPU BIOS):
    a. Run:

    ```
    sudo vim /etc/default/grub
    ```

    b. Set `GRUB_CMDLINE_LINUX="iommu.passthrough=1"`.
    c. Run:

    ```
    sudo update-grub
    sudo reboot
    ```

2. Configure DPU firmware with `LAG_RESOURCE_ALLOCATION=1`:

    ```
    sudo mlxconfig -d <device-id> s LAG_RESOURCE_ALLOCATION=1
    ```

    Retrieve `device-id` from the output of the `mst status -v` command. If, under the MST tab, the value is N/A, run the `mst start` command.

3. Update `/etc/mellanox/mlnx-bf.conf` as follows:

    ```
    ALLOW_SHARED_RQ="no"
    ```

4. Perform power cycle on the host and Arm sides.
5. If working with a single port, set the DPU into e-switch mode:

    ```
    sudo devlink dev eswitch set pci/<pcie-address> mode switchdev
    sudo devlink dev param set pci/<pcie-address> name esw_multiport value false cmode runtime
    ```

    Retrieve `pcie-address` from the output of the `mst status -v` command.

6. If working with two PF ports, set the DPU into multi-port e-switch mode (for the 2 PCIe devices):

    ```
    sudo devlink dev param set pci/<pcie-address> name esw_multiport value true cmode runtime
    ```

    Retrieve `pcie-address` from the output of the `mst status -v` command.

7. Define huge pages (see DOCA Flow prerequisites).

5.4.2.13.3.2 ConnectX

To enable DOCA Flow CT on the NVIDIA® ConnectX®, perform the following:

1. Configure firmware with `LAG_RESOURCE_ALLOCATION=1`:

```
sudo mlxconfig -d <device-id> s LAG_RESOURCE_ALLOCATION=1
```

Retrieve `device-id` from the output of the `mst status -v` command. If, under the MST tab, the value is N/A, run the `mst start` command.

2. Perform power cycle.
3. If working with a single port:

```
sudo devlink dev eswitch set pci/<pcie-address> mode switchdev
sudo devlink dev param set pci/<pcie-address> name esw_multiport value false cmode runtime
```

Retrieve `pcie-address` from the output of the `mst status -v` command.

4. If working with two PF ports:

```
sudo devlink dev eswitch set pci/<pcie-address0> mode switchdev
sudo devlink dev eswitch set pci/<pcie-address1> mode switchdev
sudo devlink dev param set pci/<pcie-address0> name esw_multiport value true cmode runtime
sudo devlink dev param set pci/<pcie-address1> name esw_multiport value true cmode runtime
```

Retrieve `pcie-address` from the output of the `mst status -v` command.

5. Define huge pages (see DOCA Flow prerequisites).

5.4.2.13.4 Actions

DOCA Flow CT supports actions based on meta and NAT operations. Each action can be defined as either shared or non-shared.

Action descriptors are not supported.

5.4.2.13.4.1 Shared Actions

Actions that can be shared between entries. Shared actions are predefined and reused in multiple entries.

The user gets a handle per shared action created and uses this handle as a reference to the action where required.

It is user responsibility to track shared actions and to remove them when they become irrelevant.

Shared actions are defined using a control queue (see struct doca_flow_ct_cfg).

5.4.2.13.4.2 Non-shared Actions

Actions provided with their data during entry create/update.

These actions are completely managed by DOCA Flow CT and cannot be reused in multiple flows (i.e., NAT operations).

5.4.2.13.4.3 Action Sets in Pipe Creation

When creating a DOCA Flow CT pipe, users must define action sets, just as they would for any other pipe.

Fields in the CT pipe must be marked as `CHANGEABLE` during pipe creation. This allows the actual criteria for these fields to be specified later during entry creation.

> Only actions related to meta and NAT, as defined in struct doca_flow_ct_actions, are supported.

During entry creation or update, different actions can be specified for each direction, allowing variations in action content and/or action type.

5.4.2.13.4.4 Feature Enable

To enable user actions, configure the following parameters:

- User action templates during DOCA Flow CT pipe creation
- Maximum number of user actions (`nb_user_actions` on DOCA Flow CT init)

5.4.2.13.4.5 Using Actions in Managed Mode

Init

Configure the following parameters on `doca_flow_ct_init()`:

- `nb_ctrl_queues` – number of control queues for defining shared actions
- `nb_user_actions` – maximum number of user actions. Must align to 64. Both shared control queues and non-shared control queues cache action IDs to speed up ID allocation. Each queue may cache a maximum of 1024 IDs. Users must configure the expected number of actions + total queues * 1024. This number cannot exceed the number of actions hardware supports.

Create DOCA Flow CT Pipe

Configure actions sets on `doca_flow_pipe_create()`.

Create Shared Actions

Use `doca_flow_ct_actions_add_shared()` with one of the control queues.

Shared actions can be added at any time before use.

Add Entry

Entry can be created in one of the following ways:

- Using an action handle of a predefined shared action
- Using action data, which is specific to the flow, not sharable (e.g., for NAT operations)

The entry can have different actions and/or different action types per direction.

Remove Entry

Non-shared actions associated with an entry are implicitly destroyed by DOCA Flow CT.

Shared actions are not destroyed. They can be used by the user until they decide to remove them.

Update Entry

Entry actions can be updated per direction. All combinations of shared/non-shared actions are applicable (e.g., update from shared to non-shared).

5.4.2.13.5 Changeable Forward

DOCA Flow CT allows using a different forward pipe per flow direction.

DOCA Flow CT supports the forward pipe in two levels:

- Pipe level – a single forward pipe defined during DOCA Flow CT pipe creation and used for all entries
- Entry level – forward pipe defined during entry create
- DOCA Flow CT operates in one of the two levels

DOCA CT forward in entry level has the following characteristics:

- Supports only `DOCA_FLOW_FWD_PIPE` (up to 4 different forward pipes)
- Supports forward pipe per flow direction (both directions can have same/different forward pipe)
- Must set forward pipes on each entry create (no default forward pipe)

Turn on the feature:

1. Create DOCA Flow CT pipe with forward type = `DOCA_FLOW_FWD_PIPE` and `next_pipe` = `NULL`.
2. Call `doca_flow_ct_fwd_register` to register forward pipes and get `fwd_handles` in return.

5.4.2.13.5.1 Using Changeable Forward in Managed Mode

1. Initialize DOCA Flow CT (`doca_flow_ct_init`).
2. Register forward pipes (`doca_flow_ct_fwd_register`).
    - Define pipes that can be used for forward
3. Create DOCA Flow CT pipe (`doca_flow_pipe_create`) with definition of possible forward pipes.
4. Add entry (`doca_flow_ct_add_entry`).
    - Set origin and/or reply `fwd_handles` returned from `doca_flow_ct_fwd_register` .
5. Update forward for entry direction (`doca_flow_ct_update_entry`).

> ⚠ Updating forward handle requires setting all other parameters with their previous values.

5.4.2.13.6 API

For the library API reference, refer to DOCA Flow and CT API documentation in the NVIDIA DOCA Library APIs.

> ⚠ DOCA Flow CT is in the DOCA Flow library.

The following sections provide additional details about the library API.

5.4.2.13.6.1 enum doca_flow_ct_flags

Optional DOCA Flow CT configuration flags.

Flag	Description
`DOCA_FLOW_CT_FLAG_STATS = 1u << 0`	Enable internal pipe counters for packet tracking purposes. Call `doca_flow_pipe_dump(<ct_pipe>)` to dump counter values. Each call dumps values changed.
`DOCA_FLOW_CT_FLAG_WORKER_STATS = 1u << 1,`	Enable worker thread internal debug counter periodical dump.
`DOCA_FLOW_CT_FLAG_NO_AGING = 1u << 2,`	Disable aging
`DOCA_FLOW_CT_FLAG_ASYMMETRIC_TUNNEL = 1u << 3,`	Allow Tunnel or non-tunnel in different direction.

Flag	Description
`DOCA_FLOW_CT_FLAG_NO_COUNTER = 1u << 4,`	Disable counter and aging to save aging thread CPU cycles
`DOCA_FLOW_CT_FLAG_CT_PIPE_ONLY = 1u << 5,`	The user must check TCP SYN flags and UDP in CT miss flow to identify ADD type packets.
`DOCA_FLOW_CT_FLAG_WIRE_TO_WIRE = 1u << 6,`	Hint traffic comes from uplink wire and forwards to uplink wire. ⚠ If this flag is set, the direction info must be `DOCA_FLOW_DIRECTION_NETWORK_TO_HOST`.
`DOCA_FLOW_CT_FLAG_DUP_FILTER_UDP_ONLY= 1u << 7,`	Apply the connection duplication filter for UDP connections only

5.4.2.13.6.2 enum doca_flow_ct doca_flow_ct_entry_flags

Optional DOCA Flow CT entry flags.

Flag	Description
`DOCA_FLOW_CT_ENTRY_FLAGS_NO_WAIT = (1 << 0)`	Entry is not buffered; send to hardware immediately
`DOCA_FLOW_CT_ENTRY_FLAGS_DIR_ORIGIN = (1 << 1)`	Apply flags to origin direction
`DOCA_FLOW_CT_ENTRY_FLAGS_DIR_REPLY = (1 << 2)`	Apply flags to reply direction
`DOCA_FLOW_CT_ENTRY_FLAGS_IPV6_ORIGIN = (1 << 3)`	Origin direction is IPv6; origin match union in struct `doca_flow_ct_match` is IPv6
`DOCA_FLOW_CT_ENTRY_FLAGS_IPV6_REPLY = (1 << 4)`	Reply direction is IPv6; reply match union in struct `doca_flow_ct_match` is IPv6
`DOCA_FLOW_CT_ENTRY_FLAGS_COUNTER_ORIGIN = (1 << 5)`	Apply counter to origin direction
`DOCA_FLOW_CT_ENTRY_FLAGS_COUNTER_REPLY = (1 << 6)`	Apply counter to reply direction
`DOCA_FLOW_CT_ENTRY_FLAGS_COUNTER_SHARED = (1 << 7)`	Counter is shared for both direction (origin and reply)
`DOCA_FLOW_CT_ENTRY_FLAGS_FLOW_LOG = (1 << 8)`	Enable flow log on entry removed
`DOCA_FLOW_CT_ENTRY_FLAGS_ALLOC_ON_MISS = (1 << 9)`	Allocate on entry not found when calling `doca_flow_ct_entry_prepare()` API

Flag	Description
`DOCA_FLOW_CT_ENTRY_FLAGS_DUP_FILTER_ORIGIN = (1 << 10)`	Enable duplication filter on origin direction
`DOCA_FLOW_CT_ENTRY_FLAGS_DUP_FILTER_REPLY = (1 << 11)`	Enable duplication filter on reply direction

5.4.2.13.6.3 enum doca_flow_ct_rule_opr

Options for handling flows in autonomous mode with shared actions. The decision is taken on the first flow packet.

Operation	Description
`DOCA_FLOW_CT_RULE_OK`	Flow should be defined in the CT pipe using the required shared actions handles
`DOCA_FLOW_CT_RULE_DROP`	Flow should not be defined in the CT pipe. The packet should be dropped.
`DOCA_FLOW_CT_RULE_TX_ONLY`	Flow should not be defined in the CT pipe. The packet should be transmitted.

5.4.2.13.6.4 struct direction_cfg

Managed mode configuration for origin or reply direction.

Field	Description
`bool match_inner`	5-tuple match pattern applies to packet inner layer
`struct doca_flow_meta *zone_match_mask`	Mask to indicate meta field and bits to match
`struct doca_flow_meta *meta_modify_mask`	Mask to indicate meta field and bits to modify on connection packet match

5.4.2.13.6.5 doca_flow_ct_cfg

DOCA Flow CT configuration manipulation:

```
    struct doca_flow_ct_cfg *ct_cfg;

    ret = doca_flow_ct_cfg_create(&ct_cfg);

    doca_flow_ct_cfg_set_flags(ct_cfg, flags);
    doca_flow_ct_cfg_set_queues(ct_cfg, n_queues);
    doca_flow_ct_cfg_set_connections(ct_cfg, n_v4, n_v6, n_max);
    ...

    ret = doca_flow_ct_init(ct_cfg);

final:
    ret = doca_flow_ct_cfg_destroy(ct_cfg);
```

Where:

Field	Description
`doca_flow_ct_cfg_create(struct doca_flow_ct_cfg **cfg)`	Create CT configuration
`doca_flow_ct_cfg_destroy(struct doca_flow_ct_cfg *cfg)`	Destroy CT configuration
`doca_flow_ct_cfg_set_flags(struct doca_flow_ct_cfg *cfg, uint32_t flags)`	Set CT flags; see `enum doca_flow_ct_flags`
`doca_flow_ct_cfg_set_queues(struct doca_flow_ct_cfg *cfg, uint32_t n_queues)`	Set number of hardware queues to manipulate connections
`doca_flow_ct_cfg_set_queue_depth(struct doca_flow_ct_cfg *cfg, uint32_t queue_depth);`	Set queue depth; default to 512 rules
`doca_flow_ct_cfg_set_ctrl_queues(struct doca_flow_ct_cfg *cfg, uint32_t n_ctrl_queues)`	Number of CT control queues used for defining shared actions
`doca_flow_ct_cfg_set_user_actions(struct doca_flow_ct_cfg *cfg, uint32_t n_user_actions)`	Maximum number of user actions supported (shared and non-shared). Minimum value is 1K * (`nb_ctrl_queues + nb_arm_queues`).
`doca_flow_ct_cfg_set_connections(struct doca_flow_ct_cfg *cfg, uint32_t n_ipv4, uint32_t n_ipv6, uint32_t n_total)`	Maximum number of IPv4, IPv6, and total CT connections
`doca_flow_ct_cfg_set_max_connections_per_zone(struct doca_flow_ct_cfg *cfg, uint32_t max_connections_per_zone)`	Max CT connection per zone
`doca_flow_ct_cfg_set_counter_asymmetric(struct doca_flow_ct_cfg *cfg, uint32_t n_counter_asymmetric)`	Max connections with an asymmetric counter; non-shared counter
`doca_flow_ct_cfg_set_entry_private_data_size(struct doca_flow_ct_cfg *cfg, uint32_t entry_priv_data_size)`	User private data size to allocate per connection
`doca_flow_ct_cfg_set_entry_finalize_cb(struct doca_flow_ct_cfg *cfg, doca_flow_ct_entry_finalize_cb entry_finalize_cb)`	Entry finalize callback to query connection final stats
`doca_flow_ct_cfg_set_status_update_cb(struct doca_flow_ct_cfg *cfg, doca_flow_ct_stats_update_cb stats_update_cb);`	Status update callback to notify on counter changes
`doca_flow_ct_cfg_set_aging_core(struct doca_flow_ct_cfg *cfg, uint32_t aging_core)`	CPU core ID for CT aging thread to bind.

Field	Description
doca_flow_ct_cfg_set_aging_query_delay(struct doca_flow_ct_cfg *cfg, uint32_t aging_query_delay_s)	CT aging query delay for new created connections
doca_flow_ct_cfg_set_aging_plugin_ops(struct doca_flow_ct_cfg *cfg, struct doca_flow_ct_aging_ops *aging_ops)	User-defined aging logic callback functions. Fallback to default aging logic
doca_flow_ct_cfg_set_dup_filter_size(struct doca_flow_ct_cfg *cfg, uint32_t dup_filter_sz)	Number of connections to cache in the duplication filter
doca_flow_ct_cfg_set_direction(struct doca_flow_ct_cfg *cfg, bool direction, bool match_inner, struct doca_flow_meta *zone_match_mask, struct doca_flow_meta *meta_modify_mask	Configuration origin and reply direction

5.4.2.13.6.6 struct doca_flow_ct_actions

This structure is used in the following cases:

- For defining shared actions. In this case, action data is provided by the user. The action handle is returned by DOCA Flow CT.
- For defining an entry with actions. The structure can be filled with two options:
  - With action handle of a previously created shared action
  - With non-shared action data

DOCA Flow CT action structure.

```
enum doca_flow_resource_type  resource_type;
union {
               /* Used when creating an entry with a shared action. */
               uint32_t action_handle;

               /* Used when creating an entry with non-shared action or when creating a shared action. */
               struct {
                         uint32_t action_idx;
                         struct doca_flow_meta meta;
                         struct doca_flow_header_l4_port l4_port;
                         union {
                                   struct doca_flow_ct_ip4 ip4;
                                   struct doca_flow_ct_ip6 ip6;
                          };
               } data;
      };
```

Where:

Field	Description
enum doca_flow_resource_type resource_type	Shared/non-shared action
uint32_t action_handle	Shared action handle
uint32_t action_idx	Actions template index

Field	Description
`struct doca_flow_meta meta`	Modify meta values
`struct doca_flow_header_l4_port l4_port`	UDP or TCP source and destination port
`struct doca_flow_ct_ip4 ip4`	Source and destination IPv4 addresses
`struct doca_flow_ct_ip6 ip6`	Source and destination IPv6 addresses

The value in `meta`, `l4_port`, `ip4`, and `ip6` should start from `bit0`, the least significant bit, regardless of which bits are set in mask. For example, `action_val.meta.u32[0] = DOCA_HTOBE32(0x12)`, `action_mask.meta.u32[0] = DOCA_HTOBE32(0x0000FF00)` sets bits 15-8 to `0x12`.

5.4.2.13.7 DOCA Flow Connection Tracking Samples

This section describes DOCA Flow CT samples based on the DOCA Flow CT pipe.

The samples illustrate how to use the library API to manage TCP/UDP connections.

All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.2.13.7.1 Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - NVIDIA BlueField Platform Software Troubleshooting Guide for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_flow/flow_ct_udp
meson /tmp/build
ninja -C /tmp/build
```

   The binary `doca_flow_ct_udp` is created under `/tmp/build/samples/`.

3. Sample (e.g., `doca_flow_ct_udp`) usage:

```
Usage: doca_<sample_name> [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                            Print a help synopsis
  -v, --version                         Print program version information
  -l, --log-level                       Set the (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                       Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                     Parse command line flags from an input json file

Program Flags:
  -p, --pci_addr <PCI-ADDRESS>          PCIe device address
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/samples/<sample_name> -h
```

The following is a CLI example for running the samples when port `08:00.0` is configured (multi-port e-switch) as manager port:

```
/tmp/build/samples/doca_<sample_name> -- -r pci/08:00.0,pf0vf0 -l 60
```

The following is a CLI example for running the samples when port `08:00.0` is configured (multi-port e-switch) as manager port and `08:00.1` is configured as the representor of the second uplink:

```
/tmp/build/samples/doca_<sample_name> -- -r pci/08:00.1 -l 60
```

To avoid the test being impacted by unexpected packets, it only accepts packets like the following examples:

- IPv4 destination address is `1.1.1.1`
- IPv6 destination address is `0101:0101:0101:0101:0101:0101:0101:0101`

5.4.2.14 DOCA Flow Tune Server

This guide provides an overview and configuration instructions for DOCA Flow Tune Server API.

5.4.2.14.1 Introduction

DOCA Flow Tune Server (TS) is a DOCA Flow subcomponent that collects predefined internal key performance indicators (KPIs) and pipeline information from a running DOCA Flow application. All information is transferred via an inter-process communication channel (Unix domain socket) to the DOCA Flow Tune Tool for further analysis and monitoring.

TS can run in either two modes:

1. Basic: TS uses an internal thread to handle the communication channel.
2. Expert: Server socket polling and thread management are the user's responsibility. The TS API must be invoked whenever the communication channel socket is ready to process a message.

5.4.2.14.2 Prerequisites

DOCA Flow Tune Server API is only available when using the DOCA Flow and DOCA Flow Tune Server trace libraries.

> For more detailed information, refer to section "Debug and Trace Features" under DOCA Flow.

5.4.2.14.3 Configuration

DOCA Flow Tune Server has a configuration file that allows customizing various settings. The configuration file is divided into different sections so to ease its use.

5.4.2.14.3.1 Config File Default Values

If a configuration file was not provided, DOCA Flow Tune Server uses default values for its mandatory fields. List of all default values can be seen in section "Configuration File Example".

5.4.2.14.3.2 Custom Config File

Instead of using the default configuration values, users may create a file of their own and provide a file path using the `doca_flow_tune_server_cfg_set_cfg_file_path()` API call.

Once used, DOCA Flow Tune Server loads all provided values directly from the file, while the rest of the fields (if any) use their respective default values.

5.4.2.14.3.3 Configuration File Example

flow_tune_cfg.json

```
{
    "network": {
        "uds_path": "/tmp/tune_server.sock"
    }
}
```

- `network`

- `uds_path` – Unix Domain Socket (`AF_UNIX`) path for the tune server to bind to. This socket is used for the inter-process-communication (IPC) channel between DOCA Flow Tune Server and DOCA Flow Tune Tool. Default value is `/tmp/tune_server.sock` .

5.4.2.14.4 API

> For more detailed information on DOCA Flow API, refer to NVIDIA DOCA Library APIs.

The following subsections provide additional details about the library API.

5.4.2.14.4.1 enum doca_flow_tune_server_mode

Enum to be used to set the running mode.

5.4.2.14.4.2 struct doca_flow_tune_server_cfg

Opaque configuration struct to use on configuration API calls.

5.4.2.14.4.3 doca_flow_tune_server_cfg_create

Allocates and creates DOCA Flow Tune Server configuration structure.

```
doca_error_t doca_flow_tune_server_cfg_create(struct doca_flow_tune_server_cfg **cfg);
```

5.4.2.14.4.4 doca_flow_tune_server_cfg_set_cfg_file_path

Sets the local configuration file path in the opaque configuration struct, for DOCA Flow Tune Server to use when searching for the JSON configuration file.

Providing a JSON configuration file is optional. If a file is not provided, DOCA Flow Tune Server uses internal defaults.

```
doca_error_t doca_flow_tune_server_cfg_set_bind_path(struct doca_flow_tune_server_cfg *cfg, const char *path);
```

5.4.2.14.4.5 doca_flow_tune_server_cfg_set_mode

Sets the running mode in the opaque configuration struct.

Using this API call is optional. Without the call, DOCA Flow Tune Server runs in Basic mode.

```
doca_error_t doca_flow_tune_server_cfg_set_mode(struct doca_flow_tune_server_cfg *cfg, enum
doca_flow_tune_server_mode mode);
```

5.4.2.14.4.6 doca_flow_tune_server_cfg_set_fd

Sets the user Unix Domain Socket in the opaque configuration struct. This socket is used by DOCA Flow Tune Server to receive messages on the communication channel.

Using this API call is mandatory on Expert mode.

```
doca_error_t doca_flow_tune_server_cfg_set_fd(struct doca_flow_tune_server_cfg *cfg, int fd);
```

5.4.2.14.4.7 doca_flow_tune_server_cfg_destroy

Destroys and deallocates DOCA Flow Tune Server opaque configuration structure.

Should be called after calling `doca_flow_tune_server_init()`.

```
doca_error_t doca_flow_tune_server_cfg_destroy(struct doca_flow_tune_server_cfg *cfg);
```

5.4.2.14.4.8 doca_flow_tune_server_init

Starts DOCA Flow Tune Server main thread.

```
doca_error_t doca_flow_tune_server_init(struct doca_flow_tune_server_cfg *cfg);
```

5.4.2.14.4.9 doca_flow_tune_server_destroy

Stops DOCA Flow Tune Server main thread.

```
void doca_flow_tune_server_destroy(void);
```

5.4.2.14.4.10 doca_flow_tune_server_process_msg

Process communication channel message from the provided Unix Domain Socket. This API call should be used with Expert mode only.

```
doca_error_t doca_flow_tune_server_process_msg(void);
```

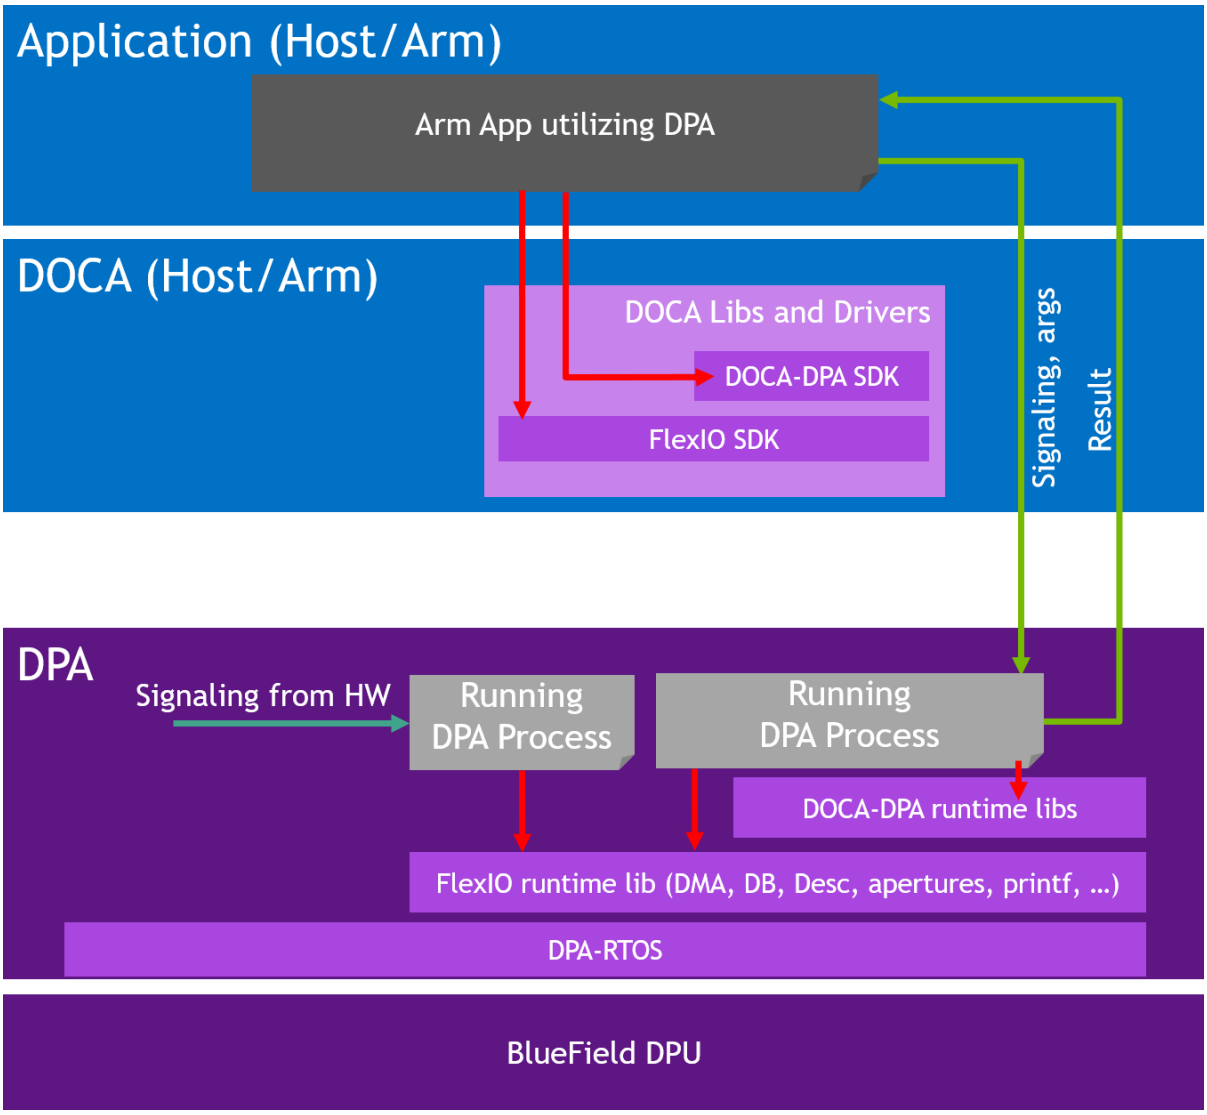
5.4.3 DPA Subsystem

The NVIDIA® BlueField®-3 data-path accelerator (DPA) is an embedded subsystem designed to accelerate workloads that require high-performance access to the NIC engines in certain packet and I/O processing workloads. Applications leveraging DPA capabilities run faster on the DPA than on host. Unlike other programmable embedded

technologies, such as FPGAs, the DPA enables a high degree of programmability using the C programming model, multi-process support, tools chains like compilers and debuggers, SDKs, dynamic application loading, and management.

The DPA architecture is optimized for executing packet and I/O processing workloads. As such, the DPA subsystem is characterized by having many execution units that can work in parallel to overcome latency issues (such as access to host memory) and provide an overall higher throughput.

The following diagram illustrates the DPA subsystem. The application accesses the DPA through the DOCA library (DOCA DPA) or the DOCA driver layer (FlexIO SDK). On the host or DPU side, the application loads its code into the DPA (shown as "Running DPA Process") as well as allocates memory, NIC queues, and more resources for the DPA process to access. The DPA process can use device side libraries to access the resources. The provided APIs support signaling of the DPA process from the host or DPU to explicitly pass control or to obtain results from the DPA.



The threads on the DPA can react independently to incoming messages via interrupts from the hardware, thereby providing full bypass of DPU or Arm CPU for datapath operations.

The following sections provide an overview of the DPA platform design.

5.4.3.1 Multiple Processes on Multiple Execution Units

The DPA platform supports multiple processes with each process having multiple threads. Each thread can be mapped to a different execution unit to achieve parallel execution. The processes operate within their own address spaces and their execution contexts are isolated. Processes are loaded and unloaded dynamically per the user's request. This is achieved by the platform's hardware design (i.e., privilege layers, memory translation units, DMA engines) and a light-weight real-time operating system (RTOS). The RTOS enforces the privileges and isolation among the different processes.

5.4.3.2 DPA RTOS

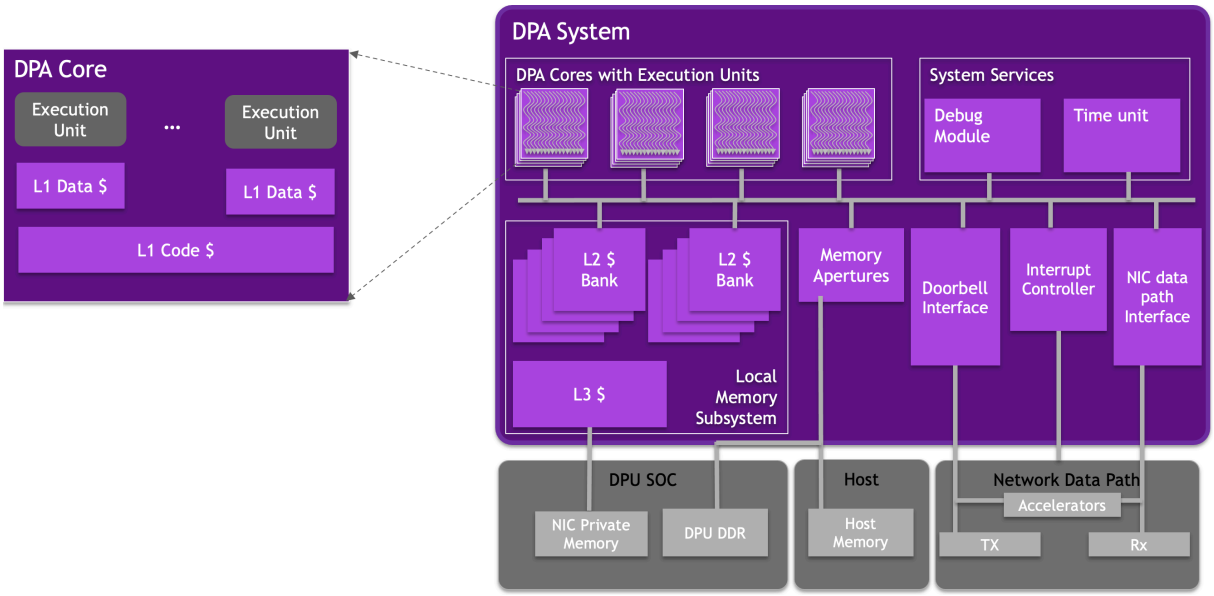
The RTOS is designed to rely on hardware-based scheduling to enable low activation latency for the execution handlers. The RTOS works in a cooperative run-to-completion scheduling model.

Under cooperative scheduling, an execution handler can use the execution unit without interrupts until it relinquishes it. Once relinquished, the execution unit is handed back to the RTOS to schedule the next handler. The RTOS sets a watchdog for the handlers to prevent any handler from unduly monopolizing the execution units.

5.4.3.3 DPA Memory and Caches

The following diagram illustrates the DPA memory hierarchy. Memory accessed by the DPA can be cached at three levels (L1, L2, and L3). Each execution unit has a private L1 data cache. The L1 code cache is shared among all the execution units in a DPA core. The L2 cache is shared among all the DPA cores. The DPA execution units can access external memory via load/store operations through the Memory Apertures.

The external memory that is fetched can be cached directly in L1. The DPA caches are backed by NIC private memory, which is located in the DPU's DDR memory banks. Therefore, the address spaces are scalable and bound only by the size of the NIC's private memory, which in turn is limited only by the DPU's DDR capacity.



See "Memory Model" for more details.

5.4.3.4 DPA Access to NIC Accelerators

The DPA can send and receive any kind of packet toward the NIC and utilize all the accelerators that reside on the BlueField DPU (e.g., encryption/decryption, hash computation, compression/decompression).

The DPA platform has efficient DMA accelerators that enable the different execution units to access any memory location accessible by the NIC in parallel and without contention. This includes both synchronous and asynchronous DMA operations triggered by the execution units. In addition, the NIC can DMA data to the DPA caches to enable low-latency access and fast processing. For example, a packet received from the wire may be "DMA-gathered" directly to the DPA's last level caches.

5.4.3.5 DPA Development

5.4.3.5.1 Overview

5.4.3.5.1.1 DOCA Libs and Drivers

The NVIDIA DOCA framework is the key for unlocking the potential of NVIDIA® BlueField®-3 platforms.

DOCA's software environment allows developers to program the DPA to accelerate workloads. Specifically, DOCA includes:

- DOCA DPA SDK – a high-level SDK for application-level protocol acceleration

- DOCA Flex IO SDK – a low-level SDK to load DPA programs into the DPA, manage the DPA memory, create the execution handlers and the needed hardware rings and contexts
- DPACC – DPA toolchain for compiling and ELF file manipulation of the DPA code

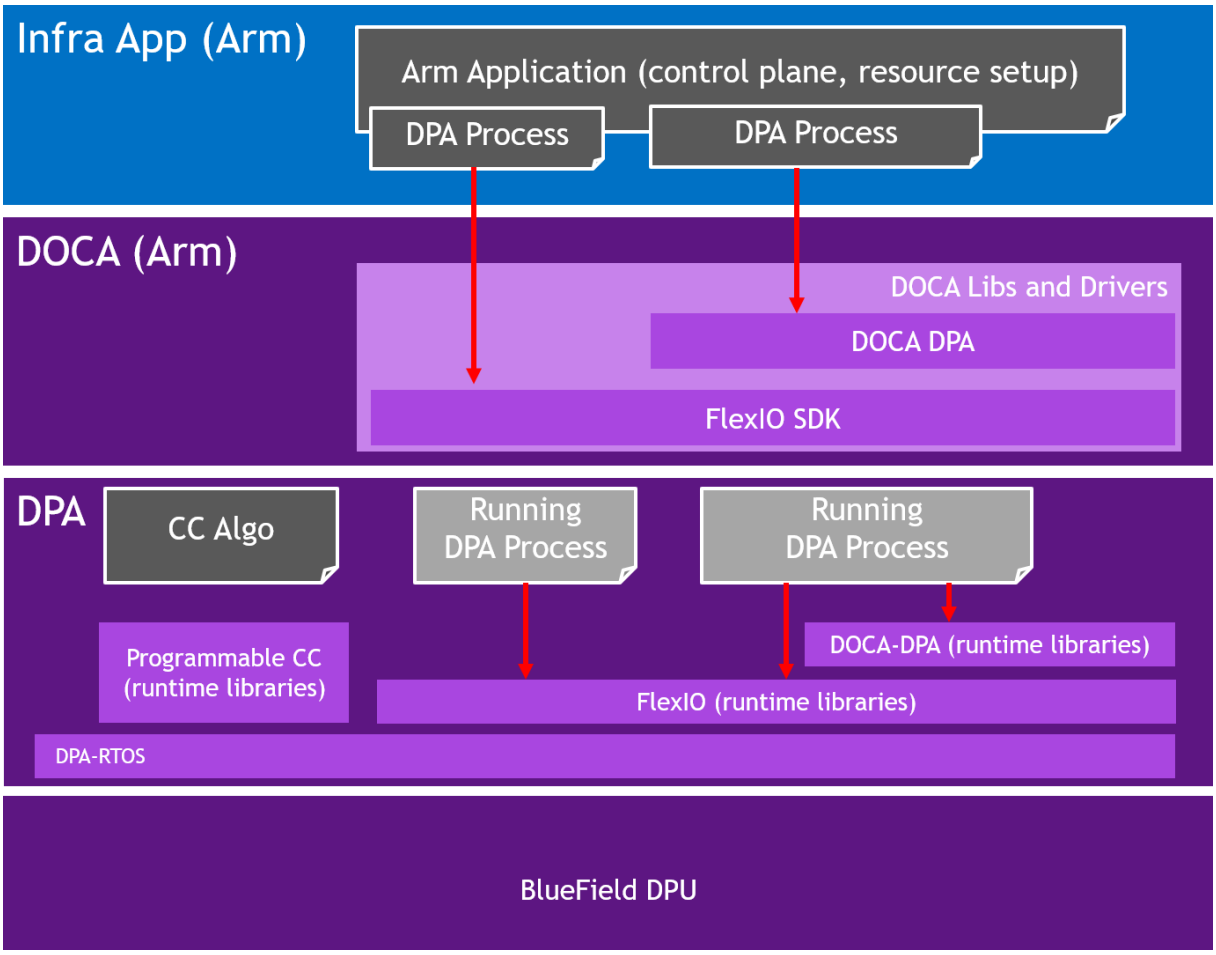
5.4.3.5.1.2 Programming Model

The DPA is intended to accelerate datapath operations for the DPU and host CPU. The accelerated portion of the application using DPA is presented as a library for the host application. The code within the library is invoked in an event-driven manner in the context of a process that is running on the DPA. One or many DPA execution units may work to handle the work associated with network events. The programmer specifies different conditions when each function should be called using the appropriate SDK APIs on the host or DPU.

The DPA cannot be used as a standalone CPU.

Management of the DPA, such as loading processes and allocating memory, is performed from a host or DPU process. The host process discovers the DPA capabilities on the device and drives the control plane to set up the different DPA objects. The DPA objects exist as long as the host process exists. When the host process is destroyed, the DPA objects are freed. The host process decides which functions it wants to accelerate using the DPA: Either its entire data plane or only a part of it.

The following diagram illustrates the different processes that exist in the system:



Compiler

DPACC is a compiler for the DPA processor. It compiles code targeted for the DPA processor into an executable and generates a DPA program. A DPA program is a host library with interfaces encapsulating the DPA executable.

This DPA program is linked with the host application to generate a host executable. The host executable can invoke the DPA code through the DPA SDK's runtime.

Compiler Keywords

DPACC implements the following keywords:

Keyword	Application Usage	Comment
`__dpa_global__`	Annotate all event handlers that execute on the DPA and all common user-defined datatypes (including user-defined structures) which are passed from the host to the DPA as arguments.	Used by the compiler to generate entry points in the DPA executable and automatically replicate user-defined datatypes between the host and DPA.
`__dpa_rpc__`	Annotate all RPC calls which are invoked by the host and execute on the DPA. RPC calls return a value of `uint64_t`.	Used by the compiler to generate RPC specific entry points.

Security Attributes

Security attributes enhance the DPA security model by preventing unauthorized access to hardware DPA resources.

If a DPA application requires non-default security attributes, a security attributes blob must be provided to the DPACC compiler using the `--dpa-proc-attr` option.

For more details, refer to the following documentation:

- DPA Application Security Attributes to Blob – Describes how to create the attributes blob and details the `dpa_attributes` file format.
- DOCA DPACC Compiler – Provides general information about the compiler.

Flex IO SDK

Flex IO SDK is a low-level event-driven library to program and accelerate functions on the DPA.

Flex IO SDK Execution Model

To load an application onto the DPA, the user must create a process on the DPA, called a Flex IO SDK process. Flex IO SDK processes are isolated from each other like standard host OS processes.

Flex IO SDK supports the following options for executing a user-defined function on the DPA:

1. Flex IO SDK event hander – the event handler executes its function each time an event occurs. An event on this context is a completion event (CQE) received on the NIC completion queue (CQ) when the CQ was in the armed state. The event triggers an internal DPA interrupt that activates the event handler. When the event handler is activated, it is provided with a user-defined argument. The argument in most cases is a pointer to the software execution context of the event handler.
   The following pseudo-code example describes how to create an event handler and attach it to a CQ:

```
// Device code
__dpa_global__ void myFunc(flexio_uintptr_t myArg){
      struct my_db *db = (struct my_db *)myArg;
      get_completion(db->myCq)
      work();
      arm_cq(myCq);
      // reschedule the thread
      flexio_dev_thread_reschedule();
}

// Host code
main() {

      /* Load the application code into the DPA */
      flexio_process_create(device, application, &myProcess);

      /* Create event handler to run my_func with my_arg */
      flexio_event_handler_create(myProcess, myFunc, myArg, &myEventHandler);

      /* Associate the event hanlder with a specific CQ */
      create_cq(&myCQ,… , myEventHandler)

      /* Start the event handler */
      flexio_event_handler_run(myEventHandler)
      …
}
```

2. RPC – remote, synchronous, one-time call of a specific function. RPC is mainly used for the control path to update DPA memory contexts of a process. The RPC's return value is reported back to the host application.
   The following pseudo-code example describes how to use the RPC:

```
// Device code
__dpa_rpc__ uint64_t myFunc(myArg) {
      struct my_db *db = (struct my_db *)myArg;
      if (db->flag) return 1;
      db->flag = 1;
      return 0;
}

// Host code
main() {
      …

      /* Load the application code into the DPA */
      flexio_process_create(device, application, &myProcess);

      /* run the function */
      flexio_process_call(myProcess, myFunc, myArg, &returnValue);
      …
}
```

Flex IO SDK Multi-hardware Model

The Flex IO SDK enables building a single DPA application which supports multiple DPA hardware models. DPA hardware models refer to different DPA versions tailored to specific NVIDIA devices, such as NVIDIA® BlueField®-3 and NVIDIA® ConnectX®-8.

When an application is built for multiple hardware models, it generates a copy for each specified hardware model. Users can then select the appropriate Flex IO program (the Flex IO representation of the executable) to load into the Flex IO process by searching for the program by its name and hardware model.

Example implementation:

Flex IO program selection

```
/* Initialize the Flex IO application selection attributes for the device. */

/* Set the application name to match. */
flexio_app_sel_attr.app_name = DEV_APP_NAME_XSTR(DEV_APP_NAME);

/* Set the hardware platform to default - this will automatically select the appropriate program. */
flexio_app_sel_attr.hw_model_id = FLEXIO_HW_MODEL_DEF;

/* Specify the IBV device context to use for the hardware model query. */
flexio_app_sel_attr.ibv_ctx = ctx.ibv_ctx;

/* Retrieve the Flex IO application.
 * The Flex IO application is created per hardware model by DPACC.
 * This function matches the selection attributes (application name and HW model)
 * with the available applications and returns the best match. If no exact match is
 * found, a program built for an older hardware model will be selected.
 */
flexio_app_get(&flexio_app_sel_attr, &ctx.flexio_app);
```

This example demonstrates how to search for the appropriate Flex IO program for a device's hardware model or an older compatible version (as new hardware models maintain backward compatibility with older code). Users can also request a program for a specific hardware model, in which case only a Flex IO program explicitly built for that model will be selected.

Flex IO SDK Memory Management

The DPA process can access several memory locations:

- Global variables defined in the DPA process.
- Stack memory – local to the DPA execution unit. Stack memory is not guaranteed to be preserved between different execution of the same handler. For limitations regarding stack memory, refer to the "Memory Model" section.
- Heap memory – this is the process' main memory. The heap memory contents are preserved as long as the DPA process is active.
- External registered memory – remote to the DPA but local to the server. The DPA can access any memory location that can be registered to the local NIC using the provided API. This includes BlueField DRAM, external host DRAM, GPU memory, and more.

The heap and external registered memory locations are managed from the host process. The DPA execution units can load/store from stack/heap and external memory locations. Note that for external memory locations, the window should be configured appropriately using Flex IO Window APIs.

Flex IO SDK allows the user to allocate and populate heap memory on the DPA. The memory can later be used by in the DPA application as an argument to the execution context (RPC and event handler):

```
/* Load the application code into the DPA */
flexio_process_create(device, application, &myProcess);

/* allocate some memory */
flexio_buf_dev_alloc(process, size, ptr)

/* populate it with user defined data */
flexio_host2dev_memcpy(process, src, size, ptr)

/* run the function */
flexio_process_call(myProcess, function, ptr, &return value);
```

Flex IO SDK allows accessing external registered memory from the DPA execution units using Flex IO Window. Flex IO Window maps a memory region from the DPA process address space to an external registered memory. A memory key for the external memory region is required to be associated with the window. The memory key is used for address translation and protection. Flex IO window is created by the host process and is configured and used by the DPA handler during execution. Once configured, LD/ST from the DPA execution units access the external memory directly.

The access for external memory is not coherent. As such, an explicit memory fencing is required to flush the cached data to maintain consistency. See section "Memory Fences" for more.

The following example code demonstrates the window management:

```
// Device code
__dpa_rpc__ uint64_t myFunc(arg1, arg2, arg3)
{
    struct flexio_dev_thread_ctx *dtctx;
    flexio_dev_get_thread_ctx(&dtctx);
    uint32_t windowId = arg1;
    uint32_t mkey = arg2;
    uint64_t *dev_ptr;
    flexio_dev_window_config(dtctx, windowId, mkey );
    /* get ptr to the external memory (arg3) from the DPA process address space */
    flexio_dev_status status = flexio_dev_window_ptr_acquire (dtctx, arg3, dev_ptr);
    /* will set the external memory */
```

```
    *dev_ptr = 0xff;
    /* flush the data out */
    __dpa_thread_window_writeback();
    return 0;
}

// Host code
main() {
      /* Load the application code into the DPA */
      flexio_process_create(device, application, &myProcess);
      /* define an array on host */
      uint64_t var= {0};
      /* register host buffer  */
      mkey =ibv_reg_mr(&var, …)
      /* create the window */
      flexio_window_create(process, doca_device->pd, mkey, &window_ctx);
      /* run the function */
      flexio_process_call(myProcess, myFunc, flexio_window_get_id(window_ctx), mkey, &var, &returnValue);
}
```

Send and Receive Operation

A DPA process can initiate send and receive operations using the Flex IO outbox object. The Flex IO outbox contains memory-mapped IO registers that enable the DPA application to issue device doorbells to manage the send and receive planes. The DPA outbox can be configured during run time to perform send and receive from a specific NIC function exposed by the DPU. This capability is not available for Host CPUs that can only access their assigned NIC function.

Each DPA execution engine has its own outbox. As such, each handler can efficiently use the outbox without needing to lock to protect against accesses from other handlers. To enforce the required security and isolation, the DPA outbox enables the DPA application to send and receive only for queues created by the DPA host process and only for NIC functions the process is allowed to access.

Like the Flex IO window, the Flex IO outbox is created by the host process and configured and used at run time by the DPA process.

```
// Device code
__dpa_rpc__ uint64_t myFunc(arg1,arg2,arg3) {

    struct flexio_dev_thread_ctx *dtctx;

    flexio_dev_get_thread_ctx(&dtctx);

    uint32_t outbox = arg1;
    flexio_dev_outbox_config (dtctx, outbox);

    /* Create some wqe and post it on sq */

    /* Send DB on sq*/

    flexio_dev_qp_sq_ring_db(dtctx, sq_pi,arg3);

    /* Poll CQ (cq number is in arg2) */
    return 0;
}

// Host code
main() {

      /* Load the application code into the DPA */
      flexio_process_create(device, application, &myProcess);

      /* Allocate uar */
      uar = ibv_alloc_uar(ibv_ctx);

      /* Create queues*/
      flexio_cq_create(myProcess, ibv_ctx, uar, cq_attr, &myCQ);
      my_hwcq = flexio_cq_get_hw_cq (myCQ);

      flexio_sq_create(myProcess, ibv_ctx, myCQ, uar, sq_attr, &mySQ);
      my_hwsq = flexio_sq_get_hw_sq(mySQ);

      /* Outbox will allow access only for queues created with the same UAR*/
      flexio_outbox_create(process, ibv_ctx, uar, &myOutbox);

      /* Run the function */
      flexio_process_call(myProcess, myFunc, myOutbox, my_hwcq->cq_num, my_hwsq->sq_num,  &return_value);
}
```

Synchronization Primitives

The DPA execution units support atomic instructions to protect from concurrent access to the DPA process heap memory. Using those instructions, multiple synchronization primitives can be designed.

Flex IO currently supports basic spin lock primitives. More advanced thread pipelining can be achieved using DOCA DPA events.

DOCA DPA

Supported at beta level.

The DOCA DPA SDK eases DPA code management by providing high-level primitives for DPA work offloading, synchronization, and communication. This leads to simpler code but lacks the low-level control that Flex IO SDK provides.

User-level applications and libraries wishing to utilize the DPA to offload their code may choose DOCA DPA. Use-cases closer to the driver level and requiring access to low-level NIC features would be better served using Flex IO.

The implementation of DOCA DPA is based on the Flex IO API. The higher level of abstraction enables the user to focus on their program logic and not the low-level mechanics.

> Refer to DOCA DPA documentation for more details.

Memory Model

The DPA offers a coherent but weakly ordered memory model. The application is required to use fences to impose the desired memory ordering. Additionally, where applicable, the application is required to write back data for the data to be visible to NIC engines (see the coherency table).

The memory model offers "same address ordering" within a thread. This means that, if a thread writes to a memory location and subsequently reads that memory location, the read returns the contents that have previously been written.

The memory model offers 8-byte atomicity for aligned accesses to atomic datatypes. This means that all eight bytes of read and write are performed in one indivisible transaction.

The DPA does not support unaligned accesses, such as accessing `N` bytes of data from an address not evenly divisible by `N`.

The DPA processes memory can be divided into the following memory spaces:

Memory Space	Definition
Heap	Memory locations within the DPA process heap. Referenced as `__DPA_HEAP` in the code.

Memory Space	Definition
Memory	Memory locations belonging to the DPA process (including stack, heap, BSS and data segment) except the memory-mapped IO. Referenced as `__DPA_MEMORY` in the code.
MMIO (memory-mapped I/O)	External memory outside the DPA process accessed via memory-mapped IO. Window and Outbox accesses are considered MMIO. Referenced as `__DPA_MMIO` in the code.
System	All memory locations accessible to the thread within Memory and MMIO spaces as described above. Referenced as `__DPA_SYSTEM` in the code.

> **Stack Limits**
>
> As with many other real-time operating systems (RTOS), the userspace stack is limited in size, and it is user responsibility to ensure the program does not allocate memory beyond the stack's limits. The overall memory range for the userspace stack is slightly less than 8 KB (8184 bytes), meaning that the user's program and the ABI used by the compiler for the function calls themselves should not cross this limit. DPA programs consuming more memory than the amount allocated for the stack would cause anomalous behavior.

Coherency

The coherency between the DPA threads and NIC engines is described in the following table:

Producer	Observer	Coherency	Comments
DPA thread	NIC engine	Not coherent	Data to be read by the NIC must be written back using the appropriate intrinsic (see section "Memory Fence and Cache Control Usage Examples").
NIC engine	DPA Thread	Coherent	Data written by the NIC is eventually visible to the DPA threads. The order in which the writes are visible to the DPA threads is influenced by the ordering configuration of the memory region (see `IBV_ACCESS_RELAXED_ORDERING`). In a typical example of the NIC writing data and generating a completion entry (CQE), it is guaranteed that when the write to the CQE is visible, the DPA thread can read the data without additional fences.
DPA thread	DPA thread	Coherent	Data written by a DPA thread is eventually visible to the other DPA threads without additional fences. The order in which writes made by a thread are visible to other threads is undefined when fences are not used. Programmers can enforce ordering of updates using fences (see section "Memory Fences").

Memory Fences

Fence APIs are intended to impose memory access ordering. The fence operations are defined on the different memory spaces. See information on memory spaces under section "Memory Model".

The fence APIs apply ordering between the operations issued by the calling thread. As a performance note, the fence APIs also have a side effect of writing back data to the memory space used in the fence operation. However, programmers should not rely on this side effect. See section "Cache Control" for explicit cache control operations. The fence APIs have an effect of a compiler-barrier which means that memory accesses are not reordered around the fence API invocation by the compiler.

A fence applies between the "predecessor" and the "successor" operations. The predecessor and successor ops can be refenced using `__DPA_R`, `__DPA_W`, and `__DPA_RW` in the code.

The generic memory fence operation can operate on any memory space and any set of predecessor and successor operations. The other fence operations are provided as convenient shortcuts that are specific to the use case. It is preferable for programmers to use the shortcuts when possible.

Fence operations can be included using the `dpaintrin.h` header file.

Generic Fence

```
void __dpa_thread_fence(memory_space, pred_op, succ_op);
```

This fence can apply to any DPA thread memory space. Memory spaces are defined under section "Memory Model". The fence ensures that all operations (`pred_op`) performed by the calling thread, before the call to `__dpa_thread_fence()`, are performed and made visible to all threads in the DPA, host, NIC engines, and peer devices as occurring before all operations (`succ_op`) to the memory space after the call to `__dpa_thread_fence()`.

System Fence

```
void __dpa_thread_system_fence();
```

This is equivalent to calling `__dpa_thread_fence(__DPA_SYSTEM, __DPA_RW, __DPA_RW)`.

Outbox Fence

```
void __dpa_thread_outbox_fence(pred_op, succ_op);
```

This is equivalent to calling `__dpa_thread_fence(__DPA_MMIO, pred_op, succ_op)`.

Window Fence

```
void __dpa_thread_window_fence(pred_op, succ_op);
```

This is equivalent to calling `__dpa_thread_fence(__DPA_MMIO, pred_op, succ_op)`.

Memory Fence

```
void __dpa_thread_memory_fence(pred_op, succ_op);
```

This is equivalent to calling `__dpa_thread_fence(__DPA_MEMORY, pred_op, succ_op)`.

Cache Control

Cache control operations allow the programmer to exercise fine-grained control over data resident in the DPA's caches. They have an effect of a compiler-barrier. The operations can be included using the `dpaintrin.h` header file.

Window Read Contents Invalidation

```
void __dpa_thread_window_read_inv();
```

The DPA can cache data that was fetched from external memory using a window. Subsequent memory accesses to the window memory location may return the data that is already cached. In some cases, it is required by the programmer to force a read of external memory (see example under "Polling Externally Set Flag"). In such a situation, the window read contents cached must be dropped.

This function ensures that contents in the window memory space of the thread before the call to `__dpa_thread_window_read_inv()` are invalidated before read operations made by the calling thread after the call to `__dpa_thread_window_read_inv()`.

Window Writeback

```
void __dpa_thread_window_writeback();
```

Writes to external memory must be explicitly written back to be visible to external entities.

This function ensures that contents in the window space of the thread before the call to `__dpa_thread_window_writeback()` are performed and made visible to all threads in the DPA, host, NIC engines, and peer devices as occurring before any write operation after the call to `__dpa_thread_window_writeback()`.

Memory Writeback

```
void __dpa_thread_memory_writeback();
```

Writes to DPA memory space may need to be written back. For example, the data must be written back before the NIC engines can read it. Refer to the coherency table for more.

This function ensures that the contents in the memory space of the thread before the call to `__dpa_thread_writeback_memory()` are performed and made visible to all

threads in the DPA, host, NIC engines, and peer devices as occurring before any write operation after the call to `__dpa_thread_writeback_memory()`.

Memory Fence and Cache Control Usage Examples

These examples illustrate situations in which programmers must use fences and cache control operations.

In most situations, such direct usage of fences is not required by the application using Flex IO or DOCA DPA SDKs as fences are used within the APIs.

Issuing Send Operation

In this example, a thread on the DPA prepares a work queue element (WQE) that is read by the NIC to perform the desired operation.

The ordering requirement is to ensure the WQE data contents are visible to the NIC engines read it. The NIC only reads the WQE after the doorbell (MMIO operation) is performed. Refer to coherency table.

#	User Code - WQE Present in DPA Memory	Comment
1	Write WQE	Write to memory locations in the DPA (memory space = `__DPA_MEMORY`)
2	`__dpa_thread_memory_writeback();`	Cache control operation
3	Write doorbell	MMIO operation via Outbox

In some cases, the WQE may be present in external memory. See the description of `flexio_qmem` below. The table of operations in such a case is below.

#	User Code - WQE Present in External Memory	Comment
1	Write WQE	Write to memory locations in the DPA (memory space = `__DPA_MMIO`)
2	`__dpa_thread_window_writeback();`	Cache control operation
3	Write doorbell	MMIO operation via Outbox

Posting Receive Operation

In this example, a thread on the DPA is writing a WQE for a receive queue and advancing the queue's producer index. The DPA thread will have to order its writes and writeback the doorbell record contents so that the NIC engine can read the contents.

#	User Code - WQE Present in DPA Memory	Comment
1	Write WQE	Write to memory locations in the DPA (memory space = `__DPA_MEMORY`)

#	User Code - WQE Present in DPA Memory	Comment
2	`__dpa_thread_memory_fence(__DPA_W, __DPA_W);`	Order the write to the doorbell record with respect to WQE
3	Write doorbell record	Write to memory locations in the DPA (memory space = `__DPA_MEMORY`)
4	`__dpa_thread_memory_writeback();`	Ensure that contents of doorbell record are visible to the NIC engine

Polling Externally Set Flag

In this example, a thread on the DPA is polling on a flag that will be updated by the host or other peer device. The memory is accessed by the DPA thread via a window. The DPA thread must invalidate the contents so that the underlying hardware performs a read.

User Code - Flag Present in External Memory	Comment
`while (!flag) { __dpa_thread_window_read_inv(); }`	`flag` is a memory location read using a window

Thread-to-thread Communication

In this example, a thread on the DPA is writing a data value and communicating that the data is written to another thread via a flag write. The data and flag are both in DPA memory.

User Code - Thread 1	User Code - Thread 2	Comment
		Initial condition, `flag = 0`
`var1 = x;`	`while(*((volatile int *)&flag) !=1);`	• Thread 1 - write to var1 • Thread 2 - `flag` is accessed as a volatile variable, so the compiler preserves the intended program order of reads
`__dpa_thread_memory_fence(__DPA_W, __DPA_W);`		Thread 1 – write to flag cannot bypass write to `var1`
	`var_t2 = var1;`	
`flag = 1;`	`assert(var_t2 == x);`	`var_t2` must be equal to `x`

Setting Flag to be Read Externally

In this example, a thread on the DPA sets a flag that is observed by a peer device. The flag is written using a window.

User Code - Flag Present in External Memory	Comment
`flag = data;`	`flag` is updated in local DPA memory
`__dpa_thread_window_writeback();`	Contents from DPA memory for the window are written to external memory

Polling Completion Queue

In this example, a thread on the DPA reads a NIC completion queue and updates its consumer index.

First, the DPA thread polls the memory location for the next expected CQE. When the CQE is visible, the DPA thread processes it. After processing is complete, the DPA thread updates the CQ's consumer index. The consumer index is read by the NIC to determine whether a completion queue entry has been read by the DPA thread. The consumer index is used by the NIC to monitor a potential completion queue overflow situation.

User Code - CQE in DPA Memory	Comment
`while(*((volatile uint8_t *)&cq→op_own) & 0x1 == hw_owner);`	Poll CQ owner bit in DPA memory until the value indicates the CQE is in software ownership. Coherency model ensures update to the CQ is visible to the DPA execution unit without additional fences or cache control operations. Coherency model ensures that data in the CQE or referenced by it are visible when the CQE changes ownership to software.
`process_cqe();`	User processes the CQE according to the application's logic.
`cq→cq_index++; // next CQ index. Handle wraparound if necessary`	Calculate the next CQ index taking into account any wraparound of the CQ depth.
`update_cq_dbr(cq, cq_index); // writes cq_index to DPA memory`	Memory operation to write the new consumer index.
`__dpa_thread_memory_writeback();`	Ensures that write to CQ's consumer index is visible to the NIC. Depending on the application's logic, the `__dpa_thread_memory_writeback()` may be coalesced or eliminated if the CQ is configured in overrun ignore mode.
`arm_cq();`	Arm the CQ to generate an event if this handler is going to call `flexio_dev_thread_reschedule()`. Arming the CQ is not required if the handler calls `flexio_dev_thread_finish()`.

DPA-specific Operations

The DPA supports some platform-specific operations. These can be accessed using the functions described in the following subsections. The operations can be included using the `dpaintrin.h` header file.

Clock Cycles

```
uint64_t __dpa_thread_cycles();
```

Returns a counter containing the number of cycles from an arbitrary start point in the past on the execution unit the thread is currently scheduled on.

Note that the value returned by this function in the thread is meaningful only for the duration of when the thread remains associated with this execution unit.

This function also acts as a compiler barrier, preventing the compiler from moving instructions around the location where it is used.

Timer Ticks

```
uint64_t __dpa_thread_time();
```

Returns the number of timer ticks from an arbitrary start point in the past on the execution unit the thread is currently scheduled on.

Note that the value returned by this function in the thread is meaningful only for the duration of when the thread remains associated with this execution unit.

This intrinsic also acts as a compiler barrier, preventing the compiler from moving instructions around the location where the intrinsic is used.

Instructions Retired

```
uint64_t __dpa_thread_inst_ret();
```

Returns a counter containing the number of instructions retired from an arbitrary start point in the past by the execution unit the thread is currently scheduled on.

Note that the value returned by this function in the software thread is meaningful only for the duration of when the thread remains associated with this execution unit.

This intrinsic also acts as a compiler barrier, preventing the compiler from moving instructions around the location where the intrinsic is used.

Fixed Point Log2

```
int __dpa_fxp_log2(unsigned int);
```

This function evaluates the fixed point Q16.16 base 2 logarithm. The input is an unsigned integer.

Fixed Point Reciprocal

```
int __dpa_fxp_rcp(int);
```

This function evaluates the fixed point Q16.16 reciprocal (1/x) of the value provided.

Fixed Point Pow2

```
int __dpa_fxp_pow2(int);
```

This function evaluates the fixed point Q16.16 power of 2 of the provided value.

DPA Attributes

DPA programs should make sure to enable the necessary DPA features for their application:

Feature	Description
Programmable_Congestion_Control	Enables application to serve Programmable Congestion Control events
Device_Emulation	Enables application to emulate a PCIe device
Generating_Empty_CQE	Enables application to generate Empty CQE on a given CQ (e.g., for triggering other software entries).
Congestion_Control_Flow_Context_Access	Enables application to access Congestion Control Flow Context

Enabling these features is done using a dedicated tool. See the DPA Application Security Attributes to Blob guide for details.

5.4.3.5.2 Flex IO SDK

⚠ The quality status of DOCA libraries is listed here.

This chapter provides an overview and configuration instructions for DOCA Flex IO SDK API.

The DPA processor is an auxiliary processor designed to accelerate packet processing and other data-path operations. The Flex IO SDK exposes an API for managing the DPA device and executing native code over it.

The DPA processor is supported on NVIDIA® BlueField®-3 DPUs and later generations.

After DOCA installation, Flex IO SDK headers may be found under `/opt/mellanox/flexio/include` and libraries may be found under `/opt/mellanox/flexio/lib/`.

5.4.3.5.2.1 Prerequisites

DOCA Flex IO applications can run either on the host machine or on the target DPU.

Developing programs over Flex IO SDK requires knowledge of DPU networking queue usage and management.

5.4.3.5.2.2 Architecture

Flex IO SDK library exposes a few layers of functionality:

- `libflexio` – library for Host-side operations. It is used for resource management.
- `libflexio-dev` – library for DPA-side operations. It is used for data path implementation.
- `libflexio-libc` – a lightweight C library for DPA device code. `libflexio_libc` may expose very partial functionality compared to a standard `libc`.

A typical application is composed of two parts: One running on the host machine or the DPU target and another running directly over the DPA.

5.4.3.5.2.3 API

Please refer to the DOCA API References.

5.4.3.5.2.4 Resource Management

DPA programs cannot create resources. The responsibility of creating resources, such as Flex IO process, thread, outbox and window, as well as queues for packet processing (completion, receive and send), lies on the DPU program. The relevant information should be communicated (copied) to the DPA side and the address of the copied information should be passed as an argument to the running thread.

Example

Host side:

1. Declare a variable to hold the DPA buffer address.

```
flexio_uintptr_t app_data_dpa_daddr;
```

2. Allocate a buffer on the DPA side.

```
flexio_buf_dev_alloc(flexio_process, sizeof(struct my_app_data), &app_data_dpa_daddr);
```

3. Copy application data to the DPA buffer.

```
flexio_host2dev_memcpy(flexio_process, (uintptr_t)app_data, sizeof(struct my_app_data),
app_data_dpa_daddr);
```

`struct my_app_data` should be common between the DPU and DPA applications so the DPA application can access the struct fields.
The event handler should get the address to the DPA buffer with the copied data:

```
flexio_event_handler_create(flexio_process, net_entry_point, app_data_dpa_daddr, NULL, flexio_outbox,
&app_ctx.net_event_handler)
```

DPA side:

```
__dpa_rpc__ uint64_t event_handler_init(uint64_t thread_arg)
{
      struct my_app_data *app_data;
```

```
        app_data = (my_app_data *)thread_arg;
        ...
}
```

5.4.3.5.2.5 DPA Memory Management

As mentioned previously, the DPU program is responsible for allocating buffers on the DPA side (same as resources). The DPU program should allocate device memory in advance for the DPA program needs (e.g., queues data buffer and rings, buffers for the program functionality, etc).

The DPU program is also responsible for releasing the allocated memory. For this purpose, the Flex IO SDK API exposes the following memory management functions:

```
flexio_status flexio_buf_dev_alloc(struct flexio_process *process, size_t buff_bsize, flexio_uintptr_t
*dest_daddr_p);
flexio_status flexio_buf_dev_free(flexio_uintptr_t daddr_p);
flexio_status flexio_host2dev_memcpy(struct flexio_process *process, void *src_haddr, size_t buff_bsize,
flexio_uintptr_t dest_daddr);
flexio_status flexio_buf_dev_memset(struct flexio_process *process, int value, size_t buff_bsize, flexio_uintptr_t
dest_daddr);
```

Allocating NIC Queues for Use by DPA

The Flex IO SDK exposes an API for allocating work queues and completion queues for the DPA. This means that the DPA may have direct access and control over these queues, allowing it to create doorbells and access their memory.

When creating a Flex IO SDK queue, the user must pre-allocate and provide memory buffers for the queue's work queue elements (WQEs). This buffer may be allocated on the DPU or the DPA memory.

To this end, the Flex IO SDK exposes the `flexio_qmem` struct, which allows the user to provide the buffer address and type (DPA or DPU).

Memory Allocation Best Practices

To optimize process device memory allocation, it is recommended to use the following allocation sizes (or closest to it):

- Up to 1 page (4KB)
- 2^6 pages (256KB)
- 2^{11} pages (8MB)
- 2^{16} pages (256MB)

Using these sizes minimizes memory fragmentation over the process device memory heap. If other buffer sizes are required, it is recommended to round the allocation up to one of the listed sizes and use it for multiple buffers.

5.4.3.5.2.6 DPA Window

DPA windows are used to access external memory, such as on the DPU's DDR or host's memory. DPA windows are the software mechanism to use the Memory Apertures

mentioned in section "DPA Memory and Caches". To use the window functionality, DPU or host memory must be registered for the device using the `ibv_reg_mr()` call.

Both the address and size provided to this call must be 64 bytes aligned for the window to operate. This alignment may be obtained using the `posix_memalign()` allocation call.

5.4.3.5.2.7 DPA Event Handler

Default Window/Outbox

The DPA event handler expects a DPA window and DPA outbox structs upon creation. These are used as the default for the event handler thread. Users may choose to set one or both to NULL, in which case there would be no valid default value for one/both of them.

Upon thread invocation on the DPA side, the thread context is set for the provided default IDs. If, at any point, the outbox/window IDs are changed, then the thread context on the next invocation is restored to the default IDs. This means that the DPA Window MKey must be configured each time the thread is invoked, as it has no default value.

Execution Unit Management

DPA execution units (EUs) are the equivalent to logical cores. For a DPA program to execute, it must be assigned an EU.

It is possible to set EU affinity for an event handler upon creation. This causes the event handler to execute its DPA program over specific EUs (or a group of EUs).

DPA supports three types of affinity: `none`, `strict`, `group`.

The affinity type and ID, if applicable, are passed to the event handler upon creation using the `affinity` field of the `flexio_event_handler_attr` struct.

For more information, please refer to Single Point of Resource Distribution.

Execution Unit Partitions

To work over DPA, an EU partition must be created for the used device. A partition is a selection of EUs marked as available for a device. For the DPU ECPF, a default partition is created upon boot with all EUs available in it. For any other device (i.e., function), the user must create a partition. This means that running an application on a non-ECPF function without creating a partition would result in failure.

Flex IO SDK uses `strict` and `none` affinity for internal threads, which require a partition with at least one EU for the participating devices. Failing to comply with this assumption may cause failures.

Virtual Execution Units

Users should be aware that beside the default EU partition, which is exposed to the real EU numbers, all other partitions created use virtual EUs.

For example, if a user creates a partition with the range of EUs 20-40, querying the partition info from one of its virtual HCAs (vHCAs) it would display EUs from 0-20. So, the real EU number, 39 in this example, would correspond to the virtual EU number 19.

5.4.3.5.2.8 Version API and Backward Compatibility

Flex IO SDK supports partial backward compatibility. This may follow one of the following options:

1. Work only with the latest version. The user must align their entire code according to the changes in the Flex IO SDK API listed in the document accompanying each version.
2. Ensure partial backward compatibility for the working code. The user must inform the SDK which version they intend to work with. The SDK provides a set of tools that ensure backward compatibility. The set consists of compile-time and runtime tools.

Version API Toolkit

To support backward compatibility, the Flex IO SDK uses the macros `FLEXIO_VER` for the host and `FLEXIO_DEV_VER` for the DPA device. The macros have 3 parameters, where the first is the major version (year), the second is the minor version (month), and the third is the sub-minor version (not used, always 0).

Compile-time

This toolkit is available for both the host and DPA device. The header files `flexio_ver.h` and `flexio_dev_ver.h` contain the macros `FLEXIO_VER` and `FLEXIO_VER_LATEST` for the host and `FLEXIO_DEV_VER` and `FLEXIO_DEV_VER_LATEST` for the DPA device. For example, to set backward compatibility for version 24.04, the user must declare the following construct for the host:

```
#include <libflexio/flexio_ver.h>
#define FLEXIO_VER_USED FLEXIO_VER(24, 4, 0)
#include <libflexio/flexio.h>
```

And the user must declare the following construct for the DPA device:

```
#include <libflexio-dev/flexio_dev_ver.h>
#define FLEXIO_DEV_VER_USED FLEXIO_DEV_VER(24, 4, 0)
#include <libflexio-dev/flexio_dev.h>
```

Where `24` is the major version, and `4` is the minor version.

The files `flexio.h` and `flexio_dev.h` have the macros `FLEXIO_CURRENT_VERSION` and `FLEXIO_LAST_SUPPORTED_VERSION` for the host `FLEXIO_DEV_CURRENT_VERSION` and `FLEXIO_DEV_LAST_SUPPORTED_VERSION` for the DPA device. These versions are provided for internal use and user information. The user should not use these macros.

Runtime

This toolkit is only present for the host. For backward compatibility in runtime, the user can call the function `flexio_status flexio_version_set(uint64_t version);` in `flexio.h` once before calling any other function from the API, with the version parameter they wish to work with. The function returns an error in the following cases:

- If the specified version is less than `FLEXIO_LAST_SUPPORTED_VERSION`
- If it exceeds `FLEXIO_CURRENT_VERSION`
- If the function is called again with a version value different from the previous one

```
status = flexio_version_set(FLEXIO_VER(24, 4, 0));
if (status == FLEXIO_STATUS_FAILED)
{
    return ERROR;
}
```

It is recommended to use the `FLEXIO_VER_USED` macro as a parameter:

```
flexio_version_set(FLEXIO_VER_USED);
```

End of Backward Compatibility

The backward compatibility tools are designed to have an endpoint. With each new version, it is possible to gradually raise the value of `FLEXIO_LAST_SUPPORTED_VERSION` for the host and `FLEXIO_DEV_LAST_SUPPORTED_VERSION` for the DPA device. If `FLEXIO_VER_USED` equals `FLEXIO_LAST_SUPPORTED_VERSION`, then the compiler will issue a warning. This is a sign for the user to start transitioning to a newer version. This way the user has time at least until the next version to modify their code to comply with the older version. If `FLEXIO_VER_USED` is lower than `FLEXIO_LAST_SUPPORTED_VERSION`, then the compiler will issue errors. This is a sign for the user to immediately transition to a newer version. The same behavior for the DPA device.

DPA Device-to-Host Capabilities

A common challenge in DPA-based SDKs is binary compatibility, as the host-side components are often provided as shared objects (`.so`) while the device-side components are statically linked into the DPA application.

The DPA "CAPS" (capabilities) mechanism is designed to solve this. It allows the DPA application to embed information (such as version or feature support) that the host application can query at runtime and adjust its behavior accordingly.

This is implemented in two parts:

1. On the DPA (device side): A variable of any type is defined and placed into a custom ELF section using the standard C library `__attribute__` annotation. This is processed at build time.

```
// Example DPA-side capability
__attribute__((section("<section_name>"), used))
my_cap_t my_dpa_capabilities = { .version = 2, .feature_x = true };
```

2. On the host side: At runtime, the host application uses the FlexIO SDK `flexio_app_extract_symbol` API to retrieve the contents of that variable from the custom section by name.

> ⚠ This process relies on a build-time/runtime distinction. The DPA variable is embedded into the DPA binary at build time, and the host-side FlexIO API reads this static information at runtime.

5.4.3.5.2.9 Application Debugging

Because application execution is divided between the host side and the DPA processor services, debugging may be somewhat challenging, especially since the DPA side does not have a terminal allowing the use of the C stdio library printf services.

Using DPA GDB

See DOCA DPA GDB Server Tool for information.

Using Device Messaging Stream API

Another logging (messaging) option is to use Flex IO SDK infrastructure to send strings or formatted text in general, from the DPA side to the host side console or file. The host side's `flexio.h` file provides the `flexio_msg_stream_create` API function for initializing the required infrastructures to support this. Once initialized, the DPA side must have the thread context, which can be obtained by calling `flexio_dev_get_thread_ctx`. `flexio_dev_msg` can then be called to write a string generated on the DPA side to the stream created (using its ID) on the host side, where it is directed to the console or a file, according to user configuration in the creation stage.

It is important to call `flexio_msg_stream_destroy` when exiting the DPU application to ensure proper clean-up of the print mechanism resources.

Device messages use an internal QP for communication between the DPA and the DPU. When running over an InfiniBand fabric, the user must ensure that the subnet is well-configured, and that the relevant device's port is in `active` state.

Message Stream Functionality

The user can create as many streams as they see fit, up to a maximum of `FLEXIO_MSG_DEV_MAX_STREAMS_AMOUNT` as defined in `flexio.h`.

Every stream has its own messaging level which serves as a filter where messages with a level below that of the stream are filtered out.

The first stream created is the `default_stream` gets stream ID 0, and it is created with messaging level `FLEXIO_MSG_DEV_INFO` by default.

The stream ID defined by `FLEXIO_MSG_DEV_BROADCAST_STREAM` serves as a broadcast stream which means it messagaes all open streams (with the proper messaging level).

A stream can be configured with a synchronization mode attribute according to the following options:

- `sync` – displays the messages as soon as they are sent from the device to the host side using the verb SEND.
- `async` – uses the verb RDMA write. When the programmer calls the stream's flush functionality, all the messages in the buffer are displayed (unless there was a wraparound due to the size of messages being bigger than the size allocated for them). In this synchronization mode, the flush should be called at the end of the run.
- `batch` – uses RDMA write and RDMA write with immediate. It works similarly to the async mode, except the fact each batch size of messages is being flushed and therefore displayed automatically in every batch. The purpose is to allow the host to use fewer resources for device messaging.

Device Messaging Assumptions

Device messaging uses RPC calls to create, modify, and destroy streams. By default, these RPC calls run with affinity `none`, which requires at least one available EU on the default group. If the user wants to set the management affinity of a stream to a different option (any affinity option is supported, including forcing `none`, which is the default behavior) they should specify this in the stream attributes using the `mgmt_affinity` field.

Printf Support

FlexIO SDK provides limited `printf` functionality, which is not a full implementation of the standard libc `printf`. The `printf` functions are operational only after the message stream mechanism is enabled and will cease to function after it is destroyed.

The following format specifiers and modifiers are supported:

- Format specifiers: `%c`, `%s`, `%d`, `%u`, `%i`, `%x`, `%X`, `%o`, `%p`, `%%`
- Flags: `0`, `-`, `+`, `#`, space
- Width: `*`, numeric values
- Precision: `.*`, `.number`
- Length modifiers: `hh`, `h`, `l`, `ll`

The following modifiers are not supported:

- Floating-point modifiers: `%a`, `%A`, `%e`, `%E`, `%f`, `%lf`, `%LF`
- Writing the number of characters written so far: `%n`

For I/O purposes, it is recommended to use the internal device messaging stream API instead of `printf`.

Core Dump

If the DPA process encounters a fatal error, the user can create a core dump file to review the application's status at that point using a GDB app.

Creating a core dump file can be done after the process has crashed (as indicated by the `flexio_err_status` API) and before the process is destroyed by calling the `flexio_coredump_create` API.

Recommendations for opening DPA core dump file using GDB:

- Use the `gdb-multiarch` application
- The `Program` parameter for GDB should be the device-side ELF file
    - Use the `dpacc-extract` tool (provided with the DPACC package) to extract the device-side ELF file from the application's ELF file

5.4.3.5.2.10 Application Flow Analysis (dTrace)

FlexIO provides a tracing mechanism designed to capture code flow information with minimal impact on performance. This feature is known as dTrace.

dTrace Concepts

Concept	Explanation
Trace points (TPs)	Developers place TPs within the DEV code. When dTrace is active, passing these points triggers a report.
Identification	Every TP is identified by a `u32` number.
Arguments	Every TP can optionally include up to five `u64` arguments.
Sequencing	Every TP event is assigned a unique, sequential number.
Report Structure	A report contains the TP number, arguments (if provided), sequence number, reporting thread ID, and a timestamp.

Concept	Explanation
Lossy Collection	• Collisions: Data collection is lossy. In the case of a collision (simultaneous TP reporting from different threads), the conflicting event is dropped. A gap in the sequence numbers indicates dropped reports. • Transport: Transportation of reports from DEV to HOST is also lossy; unreliable connections are used to minimize overhead. • Host Processing: Reports may be dropped on the HOST side if the receiver is stuck or overwhelmed.

5.4.3.5.2.11 Tracing vs. Printing

It is crucial to understand the differences between Tracing (dTrace) and Printing.

- Printing (e.g., using `flexio_dev_print()`) guarantees that data is delivered to the viewer. However, the cost is execution time. If a print statement is placed in a critical path, it will significantly impact performance.
- Tracing (TP) does not guarantee the delivery of every report. However, because the overhead is minimal, TPs can be left in released code (used judiciously). This allows users to analyze real code flow under real traffic conditions.

> **Guideline**
>
> If you need to report an error case, use Print. The speed penalty is acceptable for errors. If you need to analyze high-frequency code flow, use Trace. Be aware that some reports may be lost.

Tool Comparison

Feature	Print	dTrace
Ease of Use	Very easy. Results are displayed in a human-readable format.	Challenging. Requires reading abstract data or using additional visualization tools.
Delivery Guarantee	Lossless. Delivery is guaranteed.	Lossy. Data may be dropped during collisions or transport.
Long-term Execution	Impossible/Useless. Not suitable for continuous reporting to the console.	Supported. Can run indefinitely without stopping the application.
Output Format	Human-readable text to screen or file.	Binary file, CSV file, or user callback. Post-processing tools are required for visualization.
On/Off Mode	generally supported, but problematic for long durations.	Supported. Preferred mode. Collect data only when analysis is required.
Management	Not supported via system console.	Supported. Tracing can be activated/deactivated from the host console without modifying user code.
Severity Levels	Supported (ERR / WARN / INFO / DBG).	Not supported. Errors and debug messages should be reported using `print()`.

dTrace Usage (HOST)

The following minimal code is required to initialize and start dTrace with the default configuration:

C code. Host.

```c
/* Initialize dTrace */
flexio_dtrace_init(flexio_process);

/* Optional: Change dTrace parameters here if non-default config is needed */
flexio_dtrace_create(flexio_process);

/* Start dTrace - trace points are now active */
flexio_dtrace_start(flexio_process);

/* ... Application Runtime ... */

/* Destroy dTrace to release allocated resources */
flexio_dtrace_destroy(ctx.flexio_process);
```

Refer to `libflexio/flexio.h` for extended dTrace API information and defaults.

dTrace Usage (DEV)

Place Trace Points (TPs) at desired locations in your code. During development, TPs can be used as a substitute for standard prints.

Performance Warning

Even if dTrace is OFF, every TP in the code adds at least one assembly instruction and requires a read from common memory. On some platforms, this memory read may introduce latency. Remove unnecessary TPs before committing production code.

Example of TP placement:

C code. DEV

```c
#define START_TP_NUMBER 1981

/* Basic timestamp/start marker */
flexio_dev_ts(START_TP_NUMBER);
...
/* Trace point with function name and return address */
flexio_dev_tp(__func__, (uint64_t)__builtin_return_address(0));
...
/* Trace point with string and line number */
flexio_dev_tp("Point 2", __LINE__);
...
/* Trace point with string, line number, and variable */
flexio_dev_tp("Wrong argument", __LINE__, count);
...
/* Trace point with formatted arguments */
flexio_dev_tp("Arguments %lu %lu %lu %lu", count, arg1, arg2, arg3);
...
/* Trace point with raw numeric ID and 5 arguments */
flexio_dev_tp(5, count, arg1, arg2, arg3, i);
...
/* Termination trace point */
flexio_dev_tp("Finish");
```

These examples demonstrate various aspects of TP usage. Combining these variations allows for efficient debugging.

dTrace Output Analysis

dTrace outputs information as binary data (via file or user callback) or as a CSV file. Both contain identical information. The CSV format is shown below for readability:

CSV output file

```
# line, seq_number,     timestamp,  tid,        TP#,         a1,  a2,  a3,  a4,  a5
     0,          0, 6543090767984, 8010, 0x400033e1, 0x40002458,    ,    ,    ,
     1,          1, 6543090767986, 8010, 0x4000347b,       0x12,    ,    ,    ,
     2,        252, 6543090768005, 8006, 0x40003388,          0, 0x1, 0x2, 0x3,
     3,        653, 6543090768006, 800d, 0x40003328,          0, 0x1, 0x2, 0x3,
     4,        654, 6543090768007, 800d, 0x4000347b,       0x27,    ,    ,    ,
     5,       7586, 6543090768009, 8010,       0x2a,       0x28,    ,    ,    ,
     6,      37654, 6543090768023, 8013, 0x40003351,          ,    ,    ,    ,
```

While the CSV contains all necessary raw data, it is recommended to use external utilities to convert this file into a more user-friendly text format. Currently, a specific converter is not provided as part of the FlexIO package.

5.4.3.5.2.12 Experimental Flex IO APIs

Flex IO APIs are now marked as experimental which requires adjustment of users' build definitions as follows:

- For host-side projects, users must add the compilation flag `-DFLEXIO_ALLOW_EXPERIMENTAL_API` to their projects. For example:
  - If using meson, add the command `add_project_arguments('-DFLEXIO_ALLOW_EXPERIMENTAL_API', language: 'c', native: true)`
  - If using a makefile, add `-DFLEXIO_ALLOW_EXPERIMENTAL_API` to the compiler flags
- For device-side projects, add the following when launching the DPACC application:
  - Add `-DFLEXIO_ALLOW_EXPERIMENTAL_API` to the `--hostcc_args` flag
  - Add `-DFLEXIO_DEV_ALLOW_EXPERIMENTAL_API` to the `--devicecc_options` flag

The absence of these macros would result in compilation warnings or errors if the `-Werror` flag is used.

If the host-side project uses the pkg-config mechanism for working with libflexio, such as `dependency('libflexio', required: true)` for `meson.build` or `CFLAGS := $(shell pkg-config --cflags 'libflexio')` for a makefile, there is no need to add the compilation flag as this is done automatically.

An example of adding these flags to launch DPACC can be found in the `doca_build_dpacc.sh` script in the `flexio-samples` package.

5.4.3.5.2.13 Flex IO Samples

This section describes samples based on the Flex IO SDK. These samples illustrate how to use the Flex IO API to configure and execute code on the DPA.

Running Flex IO Sample

The Flex IO SDK samples serve as a reference for building and running Flex IO-based DPA applications. They provide a collection of out-of-the-box working DPA applications that encompass the basic functionality of the Flex IO SDK.

Documentation

- Refer to DOCA Installation Guide for Linux for details on how to install BlueField-related software
- Refer to DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples

Minimal Requirements

The user must have the following installed:

- DOCA DPACC package
- DOCA RDMA package
- pkg-config package
- Python3 package
- Gcc with version 7.0 or higher
- Meson package with version 0.53.0 or higher
- Ninja package
- DOCA Flex IO SDK

Sample Structure

Each sample is situated in its own directory and is accompanied by a corresponding description in README files. Every sample comprises two applications:

- The first, located in the `dev` directory, is designed for DPA
- The second, found in the `host` directory, is intended for execution on the DPU or host in a Linux OS environment

Additionally, there is a `common` directory housing libraries for the examples. These libraries are further categorized into `dev` and `host` directories to facilitate linking with similar applications. Beyond containing functions and macros, these libraries also serve as illustrative examples for how to use them.

The list of the samples:

- `flexio_rpc` – sample demonstrating how to run RPC functions from DPA
- `packet_processor` – sample demonstrating how to process packets over DPA

Building the Samples

```
cd /opt/mellanox/flexio/samples/
./build.sh --check-compatibility --rebuild
```

Flex IO samples support building for multiple hardware models. Users can specify one or more hardware models to include in the build using the `--cpu` flag.

To build Flex IO samples for specific hardware models, use the following example commands:

```
cd /opt/mellanox/flexio/samples/
./build.sh --check-compatibility --rebuild --cpu bf3,cx8
```

This process generates builds optimized for the requested hardware models.

Samples

flexio_rpc

This sample application executes Flex IO with a remote process call.

The device program calculates the sum of 2 input parameters, prints the result, and copies the result back to the host application.

This sample demonstrates how applications are built (DPA and host), how to create processes and message streams, how to open the IBV device, and how to use RPC from the host to DPA function.

Compilation

```
cd /opt/mellanox/flexio/samples/
./build.sh --check-compatibility --rebuild
```

The output path:

```
/opt/mellanox/flexio/samples/build/flexio_rpc/host/flexio_rpc
```

Usage

```
<sample_root>/build/flexio_rpc/host/flexio_rpc <mlx5_device> <arg1> <arg2>
```

Where:

- `mlx5_device` – IBV device with DPA
- `arg1` – first numeric argument
- `arg2` – second numeric argument

Example:

```
$/opt/mellanox/flexio/samples/build/flexio_rpc/host/flexio_rpc mlx5_0 44 55
Welcome to 'Flex IO RPC' sample
Registered on device mlx5_0
/  2/Calculate: 44 + 55 = 99
```

```
Result: 99
Flex IO RPC sample is done
```

flexio_packet_process

This example demonstrates packet processing handling.

The device application implements a handler for `flexio_pp_dev` that receives packets from the network, swaps MAC addresses, inserts some text into the packet, and sends it back.

This allows the user to send UDP packets (with a packet length of 65 bytes) and check the content of returned packets. Additionally, the console displays the execution of packet processing, printing each new packet index. Device messaging operates in synchronous mode (i.e., each message from the device received by the host is output immediately).

This sample illustrates how applications work with libraries (DPA and host), how to create SQ, RQ, CQ, memory keys, and doorbell rings, how to create and use DPA memory buffers, how to use UAR, and how to create and run event handlers.

Compilation

```
cd /opt/mellanox/flexio/samples/
./build.sh --check-compatibility --rebuild
```

The output path:

```
/opt/mellanox/flexio/samples/build/packet_processor/host/flexio_packet_processor
```

Usage

```
<sample_root>/build/packet_processor/host/flexio_packet_processor <mlx5_device>
```

Where:

- `mlx5_device` – name of IB device with DPA
- `--nic-mode` – optional parameter indicating that the application is run from the host. If the application is run from DPU, then the parameter should not be used.

For example

```
$sudo /build/packet_processor/host/flexio_packet_processor mlx5_0
```

The application must run with root privileges.

Debug

When running the application, the output will display a debug token. This token can be used to connect to the DPA GDB server for debugging purposes.

```
$sudo build/packet_processor/host/flexio_packet_processor mlx5_0
```

```
Welcome to 'Flex IO SDK packet processing' sample app.
Use the token >>> 0x790478344927513b <<< for debugging
```

See DOCA DPA GDB Server Tool for instructions on using DPA GDB.

Running with Traffic

Run host-side sample:

```
$ cd <sample_root>
$ sudo ./build/packet_processor/host/flexio_packet_processor mlx5_0
```

Use another machine connected to the setup running the application. Bring the interface used as packet generator up:

```
$ sudo ifconfig my_interface up
```

Use `scapy` to run traffic to the device the application is running on:

```
$ python

>>> from scapy.all import *
>>> from scapy.layers.inet import IP, UDP, Ether

>>> sendp(Ether(src="02:42:7e:7f:eb:02", dst='52:54:00:79:db:d3')/IP()/UDP()/Raw(load="================12345678"),
iface="my_interface")
```

⚠ Source MAC must be same as above as the application defines a steering rule for it. Destination MAC can be anything.

⚠ The load should be kept the same as above, as the application looks for this pattern and changes it during processing.

⚠ Interface name should be changed to the interfaced used for traffic generation.

The packets can be viewed using `tcpdump`:

```
$ sudo tcpdump -i my_interface -en host 127.0.0.1 -X
```

Example output

```
Example output:
11:53:51.422075 02:42:7e:7f:eb:02 > 52:54:00:12:34:56, ethertype IPv4 (0x0800), length 65: 127.0.0.1.domain >

5.4.3.5.2.14 Flex IO SDK Packages

The Flex IO SDK contains the following packages:

- `flexio-sdk` – this package contains Flex IO SDK header and library files for both the host and device sides. The library files for the device side are divided by chip type (i.e., some are for NVIDIA® BlueField®-3, while others are for NVIDIA® ConnectX®-8).
- `flexio-samples` – this package contains Flex IO samples for both the host and device sides
- `dpa-gdbserver` – this package contains Flex IO binary files for both the host and device sides and is used as a gdbserver to debug DPA applications

5.4.3.5.3 DPA Application Authentication

DPA Application Authentication is supported at beta level for BlueField-3.

DPA Application Authentication is currently only supported with statically linked libraries. Dynamically linked libraries are currently not supported.

This section provides instructions for developing, signing, and using authenticated BlueField-3 data-path accelerator (DPA) applications. It includes information on:

- Principles of root of trust and structures supporting it
- Device ownership transfer/claiming flow (i.e., how the user should configure the device so that it will authenticate the DPA applications coming from the user)
- Crypto signing flow and ELF file structure and tools supporting it

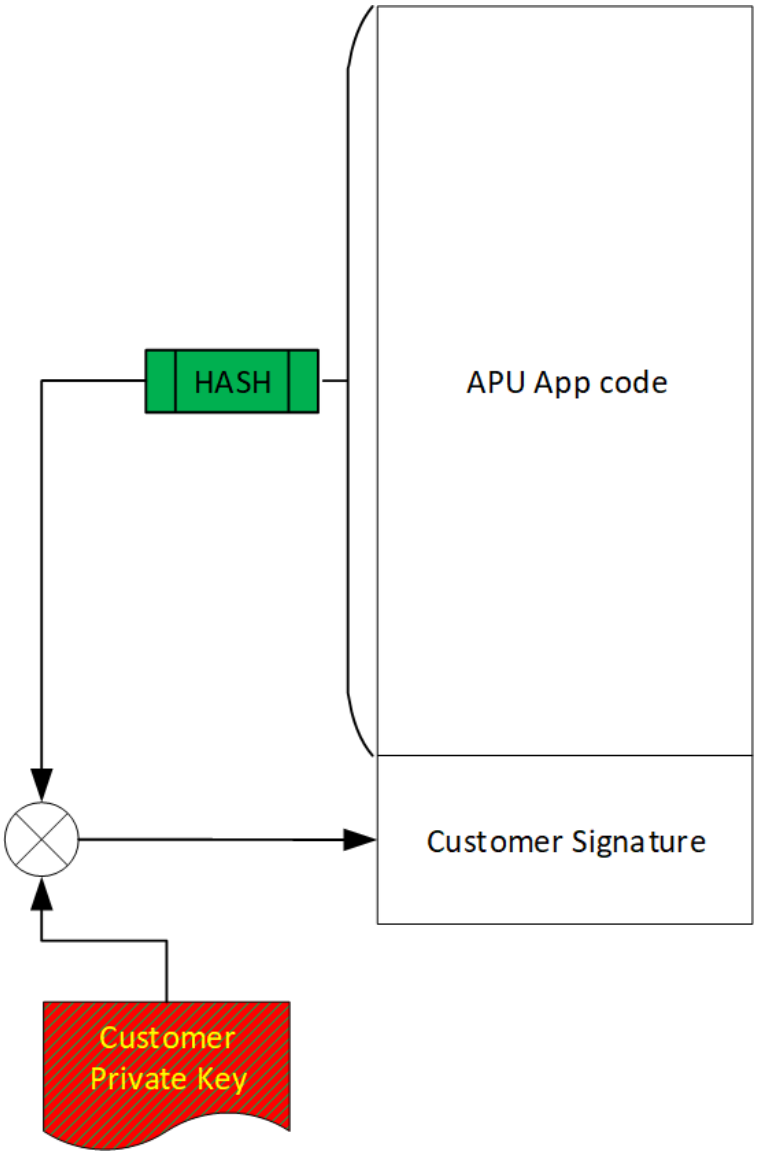
5.4.3.5.3.1 Root of Trust Principles

Signing of 3rd Party DPA App Code

NVIDIA® BlueField®-3 introduces the ability for customers/device owners to sign applications running on the DPA with their private key and have it authenticated by a device-embedded certificate chain. This provides the benefit of ensuring that only code permitted by the customer can run on the DPA. The customer can be any party writing code intended to run on the DPA (e.g., a cloud service provider, OEM, etc).

The following figure illustrates the signature of customer code. This signature will allow NVIDIA firmware to authenticate the source of the application's code.

Example of Customer DPA Code Signed by Customer for Authentication



The high-level scheme is as follows (see figure "Loading of Customer Keys and CA Certificates and Provision of DPA Firmware to BlueField-3 Device"):

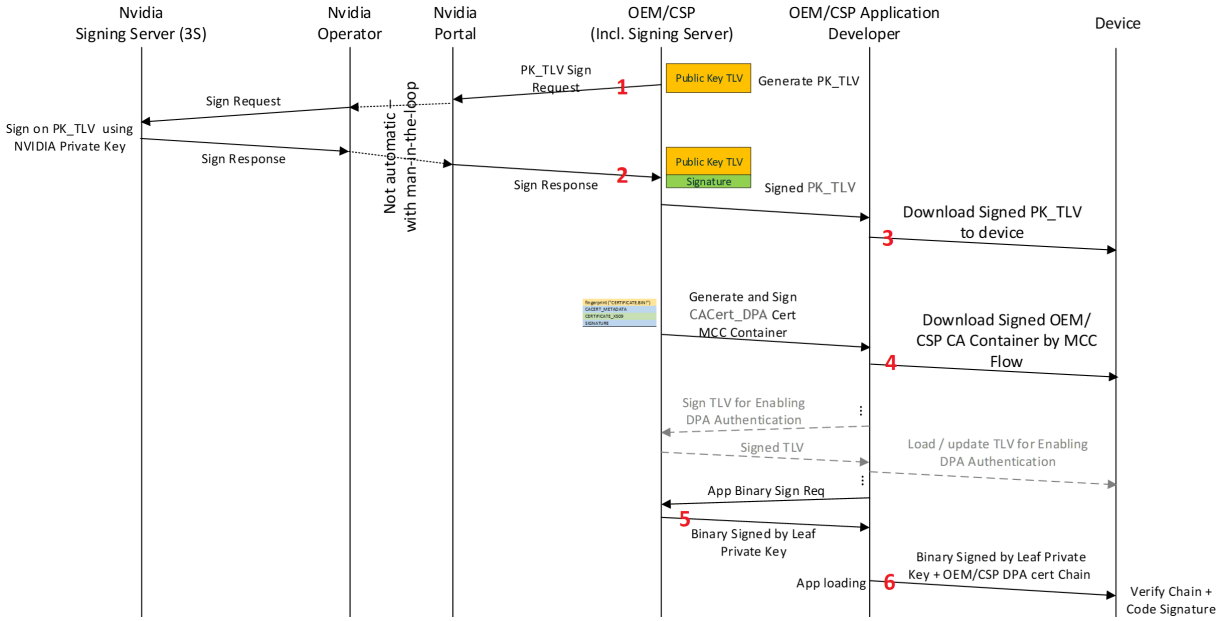
The numbers of these steps correspond to the numbers indicated in the figure below.

1. Customer provides NVIDIA Enterprise Support the public key for device ownership.
2. NVIDIA signs the customer's public key and sends it back to the customer.
3. Customer uploads the NVIDIA-signed public key to the device, enabling "Transfer of Ownership" to the customer (from NVIDIA).
4. Using the private key corresponding to the public key uploaded to the device, the customer can now enable DPA authentication and load the root certificate used for authentication of DPA App code.
5. DPA app code crypto-signed by the customer serves to authenticate the source of the app code.

The public key used to authenticate the DPA app is provided as part of the certificate chain (leaf certificate), together with the DPA firmware image.

6. App code and the owner signature serves to authorize the app execution by the NVIDIA firmware (similar to NVIDIA own signature).

Loading of Customer Keys and CA Certificates and Provision of DPA Firmware to BlueField-3 Device



The following sections provide more details about this high-level process.

Verification of Authenticity of DPA App Code

Authentication of application firmware code before authorization to execute shall consist of validation of the customer certificate chain and customer signature using the customer's public key.

Public Keys (Infrastructure, Delivery, and Verification)

For the purposes of the authentication verification of the application firmware, the public key must be securely provided to the hardware. To do so, a secure Management Component Control (MCC) Flow shall be used. Using this, the content of the downloaded certificate is enveloped in an MCC Download Container and signed by NVIDIA Private Key.

The following is an example of how to use the MCC flow describes in detail the procedures, tools and structures supporting this (Section "Loading of CSP CA Certificates and Keys and Provisioning of DPA Firmware to Device" describes the high-level flow for this).

The following command burns the certificate container:

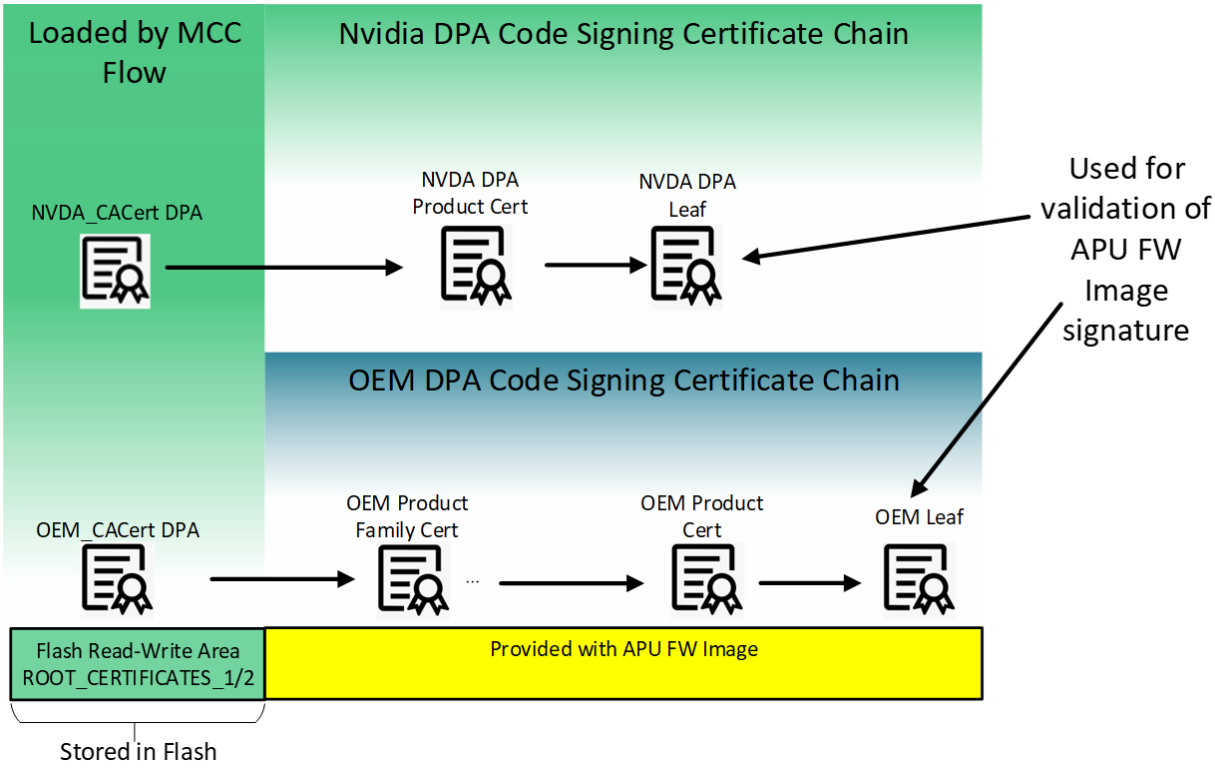
```
flint -d <mst device> -i <signed-certificate-container> burn
```

Two use cases are possible:

- The DPA application is developed internally in NVIDIA, and the authentication is based on internal NVIDIA keys and signing infrastructure
- The DPA application is developed by a customer, and the authentication is based on the customer certificate chain

In either case, the customer must download the relevant CA certificate to the device.

ROT Certificate Chain



This figure illustrates the build of the certificate chain used for validation of DPA app images. The leaf certificate of these chains is used to validate the DPA application supplied by the customer (with ROT from customer CA). The NVIDIA certificate chain for validation of DPA applications (built internally in NVIDIA) is structured in a very similar way. OEMDpaCert CA is the root CA which can be used by the customer to span their certificate chain up to the customer leaf certificate which is used for validating the signature of the application's image. Similarly, NVDADpaCert CA is the root CA used internally in NVIDIA to build the DPA certificate chain for validation of NVIDIA DPA apps.

Customer private keys must be kept secure and are the sole responsibility of the customer to maintain. It is recommended to have a set of keys ready and usable by customer for redundancy purposes.The whole customer certificate chain, including root CA and leaf, must not exceed 4 certificates.

The `NVDA_CACert_DPA` and `OEM_CACert_DPA` certificates are self-signed and trusted because they are loaded by the secure MCC flow and authenticated by the firmware.

The customer certificate chain beyond `OEM_CACert_DPA` is delivered with the DPA image, including the leaf certificate that is used for validating the cryptographic signature of the DPA firmware (see table "ELF Crypto Data Section Fields Description").

For more details on the certificates and their location in the flash, contact NVIDIA Enterprise Support to obtain the *Flash Application Note*. The rest of the certificate chain used for the DPA firmware authentication includes:

- For NVIDIA-signed images (e.g., figure "ROT Certificate Chain"): NVDA DPA root certificate (`NVDA_CACert_DPA` can be downloaded here)
- For customer-signed images (e.g., figure "ROT Certificate Chain"): Customer CA certificate, customer product, and customer leaf certificates

In both cases (NVIDIA internal and customer-signed) these parts of the certificate chain are attached to the DPA firmware image.

Loading of CSP CA Certificates and Keys and Provisioning of DPA Firmware to Device

The figure "Loading of Customer Keys and CA Certificates and Provision of DPA Firmware to BlueField-3 Device" shows, at high-level, the procedures for loading user public keys to the device, signing and loading of customer certificates MCC container, and downloading the DPA firmware images.

For clarity, the hierarchy of ROT validation is as follows:

1. Customer public key to be used for customer TLVs and `CACert_DPA` certificate validation, `PK_TLV` (i.e., `NV_LC_NV_PUBLIC_KEY`):
    a. For a device whose DPA authentication ability the customer wishes to enable for the first time, the customer must get it signed and authenticated by NVIDIA keys by reaching out to NVIDIA Enterprise Support. The complete flow is described in "Device Ownership Claiming Flow".
    b. After `PK_TLV` is loaded, it can be updated by authenticating the update using either the same `PK_TLV`. The complete flow is described in "Device Ownership Claiming Flow".
    c. Authentication of TLV for enabling/disabling DPA authentication is also validated by the `PK_TLV`. The complete flow is described in section "DPA Authentication Enablement".
2. Loading of CA certificate (`CACert_DPA`) to be used for DPA code validation. It is authenticated using the same `PK_TLV`.
   The complete flow is described in "Uploading DPA Root CA Certificate".
3. The public key in the leaf of the certificate chain anchored by `CACert_DPA` is used for authentication of the DPA firmware Image.
   The structure of the ELF file containing the DPA app and the certificate chain is described in "ELF File Structure".

A scalable and reliable infrastructure is required to support many users. The customer must also have an infrastructure to support their own code signing process according to their organization's security policy. Both matters are out of the scope of this document.

> ⚠ Trying to utilize the DPA signing flow in a firmware version prior to DOCA 2.2.0 is not supported.

Device Ownership Claiming Flow

NVIDIA networking devices allow the user of the device to customize the configurations, and in some cases change the behavior of the device. This set of available customizations is controlled by higher level NVIDIA configurations that come either as part of the device firmware or as a separate update file. To allow customers/device owners to change the set of available configurations and allowed behaviors, each device can have a device owner who is allowed to change the default behaviors and configurations of the device, and to change what configurations are exposed to the user.

The items controlled by the customer/device owner are:

- Device configurations: The customer/device owner can change the default value of any configuration available to users. They can also prevent users from changing the value.
- Trusted root certificates: The customer/device owner can control what root certificates the device trusts. These certificates control various behaviors (e.g., what 3rd party code the BlueField DPA accepts).

After the device has the public key of the owner, whenever an NVconfig file is signed with this key, one of two things must be true:

- The `nv_file_id` field in the NVconfig file must have the parameter `keep_same_priority` as `True`; or
- The NVconfig file must contain the public key itself (so the public key is rewritten to the device)

Otherwise, the public key is removed from the device, and as such will not accept files signed by the matching private key.

Detailed Ownership Claiming Flow

1. Customer generates a private-public key pair, and a UUID for the key pair.
    a. Generating UUID for the key pair:

    ```
    uuidgen -t
    ```

    Example output:

    ```
    77dd4ef0-c633-11ed-9e20-001dd8b744ff
    ```

b. Generating an RSA key pair:

```
openssl genrsa -out OEM.77dd4ef0-c633-11ed-9e20-001dd8b744ff.pem 4096
```

Example output:

```
Generating RSA private key, 2048 bit long modulus
...........+++
..............+++
e is 65537 (0x10001)
```

c. Extracting the public key file from the RSA key pair:

```
openssl rsa -in OEM.77dd4ef0-c633-11ed-9e20-001dd8b744ff.pem -out OEM.77dd4ef0-
c633-11ed-9e20-001dd8b744ff.public -pubout -outform PEM
```

Output:

```
writing RSA key
```

The public key should look similar to the following:

```
-----BEGIN PUBLIC KEY-----
MIICIjANBgkqhkiG9w0BAQEFAAOCAg8AMIICCgKCAgEAxfijde+27A3pQ7MoZnlm
mtpyuHO1JY9AUeKaHUXkWRiopL9Puswx1KcGfWJSNzlEPZRevTHraYlLQCru4ofr
W9NBE/qIwS2n7kiFwCCvZK6FKUUqZAuMJTpfuNtv9o4C4v0ZiX4TQqWDND8hy+1L
hPf3QLRiJ/ux4G6uHIFwENSwagershuKD0RI6BaZ1g9S9IxdXcD0vTdEuDPqQ0m4
CwEs/3xnksNRLUM+TiPEZoc5MoEoKyJv4GFbGttabhDCt5sr9RqAqTNUSDI9B0jr
XoQBQQpqRgYd3lQ31Fhh3G9GjtoAcUQ6l0Gct3DXKFTAADV3Lyo1vjFNrOKUhdhT
pjDKzNmZAsxyIZI0buc24TCgj1yPyFboJtpnHmltyxfm9e+EJsdSIpRiX8YTWwkN
aIzNj08VswULwbKow5Gu5FFpE/uXDE3cXjLOUNnKihszFv4qkqsQjKaK4GszXge+
jfiEwsDKwS+cuWd9ihnyLrIWF23+OX0S5xjFXDJE8UthOD+3j3gGmP3kze1Iz2YP
Qvh3ITPRsqQltaiYh+CivqaCHC0voIMOP1ilAEZ/rW85pi6LA8EsudNMG2ELrUyl
SznBzZI/OxMk4qKx9nGgjaP2YjmcPw2Ffc9zZcwl57ThEOhlyS6w3E9xwBvZINLe
gMuOIWsu1FK3lIGxMSCUZQsCAwEAAQ==
-----END PUBLIC KEY-----
```

2. Customer provides NVIDIA Enterprise Support the public key for device ownership with its UUID.
3. NVIDIA generates a signed NVconfig file with this public key and sends it to the customer. This key may only be applied to devices that do not have a device ownership key installed yet.
4. Customer uses `mlxconfig` to install the OEM key on the needed devices.

```
mlxconfig -d /dev/mst/<dev> apply oem_public_key_nvconfig.bin
```

To check if the upload process has been successful, the customer can use `mlxconfig` to query the device and check if the new public key has been applied. The relevant parameters to query are `LC_NV_PUB_KEY_EXP`, `LC_NV_PUB_KEY_UUID`, and `LC_NV_PUB_KEY_0_255`.

Example of query command and expected response:

```
mlxconfig -d <dev>-e q LC_NV_PUB_KEY_0_255
```

Uploading DPA Root CA Certificate

After uploading a device ownership public key to the device, the owner can upload DPA root CA certificates to the device. There can be multiple DPA root CA certificates on the device at the same time.

If the owner wants to upload authenticated DPA apps developed by NVIDIA, they must upload the NVIDIA DPA root CA certificate found here.

If the owner wants to sign their own DPA apps, they must create another public-private key pair (in addition to the device ownership key pair), create a certificate containing the DPA root CA public key, and create a container with this certificate using `mlxdpa`.

To upload a signed container with a DPA root CA certificate to the device, `mlxdpa` must be used. This can be done both for either NVIDIA or customer-created certificates.

Generating DPA Root CA Certificate

1. Create a DER encoded certificate containing the public key used to validate DPA apps.
    a. Generating a certificate and a new key pair:

```
openssl req -x509 -newkey rsa:4096 -keyout OEM-DPA-root-CA-key.pem -outform der -out OEM-DPA-root-CA-cert.crt -sha256 -nodes -subj "/C=XX/ST=OEMStateName/L=OEMCityName/O=OEMCompanyName/OU=OEMCompanySectionName/CN=OEMCommonName" -days 3650
```

> ⚠ Both SHA256 and SHA512 are supported in cert. Only a RSA 4096 key is supported. The size of each certificate in DER format must be less than 1792 bytes.

    Output:

```
Generating a 4096 bit RSA private key
......++
.....................++
writing new private key to 'OEM-DPA-root-CA-key.pem'
-----
```

2. Create a container for the certificate and sign it with the device ownership private key.
    a. To create and add a container:

```
mlxdpa --cert_container_type add -c <cert.der> -o <path to output> --life_cycle_priority <Nvidia/OEM/User> create_cert_container
```

    Output example:

```
Certificate container created successfully!
```

    b. To sign a container:

```
mlxdpa --cert_container <path to container> -p <key file> --keypair_uuid <uuid> --cert_uuid <uuid> --life_cycle_priority <Nvidia/OEM/User> -o <path-to-output> sign_cert_container

Certificate container signed successfully!
```

Manually Signing Container

If the server holding the private key cannot run `mlxdpa`, it is possible to manually sign the certificate container and add the signature to the container. In that case, the following process should be followed:

1. Generate unsigned cert container:

```
mlxdpa --cert_container_type add -c <.DER-formatted-certificate> -o <unsigned-container-path> --
keypair_uuid <uuid> --cert_uuid <uuid> --life_cycle_priority OEM create_cert_container
```

2. Generate signature field header:

```
echo "90 01 02 0C 10 00 00 00 00 00 00 00" | xxd -r -p - <signature-header-path>
```

3. Generate signature of container (in whatever way, this is an example only):

```
openssl dgst -sha512 -sign <private-key-pem-file> -out <container-signature-path> <unsigned-container-path>
```

4. Concatenate unsigned container, signature header, and signature into one file:

```
cat <unsigned-container-path> <signature-header-path> <container-signature-path> > <signed-container-path>
```

Uploading Certificates

Upload each signed container containing the desired certificates for the device.

```
flint -d <dev> -i  <signed-container> -y b
```

Output example:

```
-I- Downloading FW ...
FSMST_INITIALIZE -   OK
Writing DIGITAL_CACERT_REMOVAL component -   OK
-I- Component FW burn finished successfully.
```

Removing Certificates

To remove root CA certificates from the device, the user must apply a certificate removal container signed by the device ownership private key.

There are two ways to remove certificates, either removing all certificates, or removing all installed certificates:

- Removing all root CA certificates from the device:
    a. Generate a signed container to remove all certificates.
        i. Created certificate container:

```
mlxdpa --cert_container_type remove --remove_all_certs -o <path-to-container> --
life_cycle_priority <Nvidia/OEM/User> create_cert_container
```

Output example:

```
Certificate container created successfully!
```

ii. Sign certificate container:

```
mlxdpa --cert_container <path-to-container> -p <key-file> --keypair_uuid <uuid> --
life_cycle_priority <Nvidia/OEM/User> -o <path-to-signed-container> sign_cert_container
```

Output example:

```
Certificate container signed successfully!
```

b. Apply the container to the device.

```
flint -d <dev> -i <signed-container> -y b
```

Output example:

```
-I- Downloading FW ...
FSMST_INITIALIZE -   OK
Writing DIGITAL_CACERT_REMOVAL component -   OK
-I- Component FW burn finished successfully.
```

- Removing specific root CA certificates according to their UUID:
  a. Generate a signed container to remove certificate based on UUID.
     i. Create the container.

```
mlxdpa --cert_container_type remove--cert_uuid <uuid> -o <path-to-container> --
life_cycle_priority <Nvidia/OEM/User> create_cert_container
```

Output example:

```
Certificate container created successfully!
```

ii. Sign the container:

```
mlxdpa --cert_container <path-to-container> -p <key-file> --keypair_uuid <uuid> --cert_uuid
<uuid> --life_cycle_priority <Nvidia/OEM/User> -o <path to output> sign_cert_container
```

Output example:

```
Certificate container signed successfully!
```

b. Apply the container to the device:

```
flint -d <dev> -i <signed container> -y b
```

Output:

```
-I- Downloading FW ...
FSMST_INITIALIZE -   OK
Writing DIGITAL_CACERT_REMOVAL component -   OK
-I- Component FW burn finished successfully.
```

DPA Authentication Enablement

After the device has a device ownership key and DPA root CA certificates installed, the owner of the device can enable DPA authentication. To do this, they must create an

NVconfig file, sign it with the device ownership private key, and upload the NVconfig to the device.

Generating NVconfig Enabling DPA Authentication

1. Create XML with TLVs to enable DPA authentication.
    a. Get list of available TLVs for this device:

```
mlxconfig -d /dev/mst/<dev> gen_tlvs_file enable_dpa_auth.txt
```

Output:

```
Saving output...
Done!
```

Example part of the generated text file:

```
file_applicable_to                              0
file_comment                                    0
file_signature                                  0
file_dbg_fw_token_id                            0
file_cs_token_id                                0
file_btc_token_id                               0
file_mac_addr_list                              0
file_public_key                                 0
file_signature_4096_a                           0
file_signature_4096_b                           0
…
```

    b. Edit the text file to contain the following TLVs:

```
file_applicable_to                              1
nv_file_id_vendor                               1
nv_dpa_auth                                     1
```

    c. Convert the `.txt` file to XML format with another mlxconfig command:

```
mlxconfig -a gen_xml_template enable_dpa_auth.txt enable_dpa_auth.xml
```

Output:

```
Saving output...
Done!
```

The generated `.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<config xmlns="http://www.mellanox.com/config">
<file_applicable_to ovr_en='1' rd_en='1' writer_id='0'>
     <psid></psid>
     <psid_branch></psid_branch>
 </file_applicable_to>

<nv_file_id_vendor ovr_en='1' rd_en='1' writer_id='0'>

    <!-- Legal Values: False/True -->
    <disable_override></disable_override>

    <!-- Legal Values: False/True -->
    <keep_same_priority></keep_same_priority>

    <!-- Legal Values: False/True -->
    <per_tlv_priority></per_tlv_priority>

    <!-- Legal Values: False/True -->
    <erase_lower_priority></erase_lower_priority>
    <file_version></file_version>
    <day></day>
    <month></month>
    <year></year>
    <seconds></seconds>
    <minutes></minutes>
```

```
    <hour></hour>

</nv_file_id_vendor>

<nv_dpa_auth ovr_en='1' rd_en='1' writer_id='0'>
    <!-- Legal Values: False/True -->
    <dpa_auth_en></dpa_auth_en>

</nv_dpa_auth>
</config>
```

d. Edit the XML file and add the information for each of the TLVs, as seen in the following example XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<config xmlns="http://www.mellanox.com/config">

<file_applicable_to ovr_en='0' rd_en='1' writer_id='0'>
    <psid>TODO</psid>
    <psid_branch>TODO</psid_branch>
</file_applicable_to>

<nv_file_id_vendor ovr_en='0' rd_en='1' writer_id='0'>
    <disable_override>False</disable_override>
    <keep_same_priority>True</keep_same_priority>
    <per_tlv_priority>False</per_tlv_priority>
    <erase_lower_priority>False</erase_lower_priority>
    <file_version>TODO</file_version>
    <day>TODO</day>
    <month>TODO</month>
    <year>TODO</year>
    <seconds>TODO</seconds>
    <minutes>TODO</minutes>
    <hour>TODO</hour>
</nv_file_id_vendor>

<nv_dpa_auth ovr_en='0' rd_en='1' writer_id='0'>
    <dpa_auth_en>True</dpa_auth_en>
</nv_dpa_auth>
</config>
```

⚠ In `nv_file_id_vendor`, `keep_same_priority` must be `True` to avoid removing the ownership public key from the device. More information they can be found in section "Device Ownership Claiming Flow".

⚠ The `ovr_en` should be set to 0. This can ignore user priority changing `nv_dpa_auth`.

2. Convert XML file to binary NVconfig file and sign it using `mlxconfig`:

```
mlxconfig -p OEM.77dd4ef0-c633-11ed-9e20-001dd8b744ff.pem -u 77dd4ef0-c633-11ed-9e20-001dd8b744ff
create_conf enable_dpa_auth.xml enable_dpa_auth.bin
```

Output of `create_conf` command:

```
Saving output...
Done!
```

3. Upload NVconfig file to device by writing the file to the device:

```
mlxconfig -d /dev/mst/<dev> apply enable_dpa_auth.bin
```

Output:

```
Saving output...
```

```
Done!
```

4. Verify that the device has DPA authentication enabled by reading the status of DPA authentication from the device:

```
mlxconfig -d /dev/mst/<dev> -e q DPA_AUTHENTICATION
```

Output:

```
Device #1:
----------

Device type:    BlueField3
…
…
Configurations:                                 Default         Current         Next Boot
 RO     DPA_AUTHENTICATION                      True(1)         True(1)         True(1)
```

The DPU's factory default setting is configured with `dpa_auth_en=0` (i.e., DPA applications can run without authentication). To prevent configuration change by any user, it is strongly recommended for the customer to generate and install NVconfig with `dpa_auth_en=0/1`, according to their preferences, with `ovr_en=0`.

Manually Signing NVconfig File

If the server holding the private key cannot run mlxconfig, it is possible to manually sign the binary NVconfig file and add the signature to the file. In this case, the following process should be followed instead of step 2:

1. Generate unsigned NVconfig bin file from the XML file:

```
mlxconfig create_conf <xml-nvconfig-path> <unsigned-nvconfig-path>
```

2. Generate random UUID for signature:

```
uuidgen -r | xxd -r -p - <signature-uuid-path>
```

3. Generate signature of NVconfig bin file (in whatever way, this is an example only):

```
openssl dgst -sha512 -sign <private-key-pem-file> -out <nvconfig-signature-path> <unsigned-nvconfig-path>
```

4. Split the signature into two parts:

```
head -c 256 <nvconfig-signature-path> > <signature-part-1-path> && tail -c 256 <nvconfig-signature-path> >
<signature-part-2-path>
```

5. Add signing key UUID:

```
echo "<signing-key-UUID>" | xxd -r -p - <signing-key-uuid-path>
```

Use the signing key UUID, which must have a length of exactly 16 bytes, in a format like `aa9c8c2f-8b29-4e92-9b76-2429447620e0`.

6. Generate headers for signature struct:

```
echo "03 00 01 20 06 00 00 0B 00 00 00 00" | xxd -r -p - <signature-1-header-path>
echo "03 00 01 20 06 00 00 0C 00 00 00 00" | xxd -r -p - <signature-2-header-path>
```

7. Concatenate everything:

```
cat <unsigned-nvconfig-path> <signature-1-header-path> <signature-uuid-path> <signing-key-uuid-path>
<signature-part-1-path> <signature-2-header-path> <signature-uuid-path> <signing-key-uuid-path> <signature-
part-2-path> > <signed-nvconfig-path>
```

Device Ownership Transfer

The device owner may change the device ownership key to change the owner of the device or to remove the owner altogether.

First Installation

To install the first `OEM_PUBLIC_KEY` on the device, the user must upload an NVCONFIG file signed by NVIDIA. This file would contain the 3 `FILE _OEM_PUBLIC_KEY` TLVs of the current user.

Removing Device Ownership Key

Before completely removing the device ownership key, it is recommended that the device owner reverts any changes made to the device, as these changes cannot be undone afterward. Specifically, the root CA certificates installed by the owner should be removed.

1. To remove device ownership key completely, follow the steps in section "Generating NVconfig Enabling DPA Authentication" to create an XML file with TLVs.
2. Edit the XML file to contain the following TLVs:

```
<?xml version="1.0" encoding="UTF-8"?>
<config xmlns="http://www.mellanox.com/config">

<file_applicable_to ovr_en='0' rd_en='1' writer_id='0'>
    <psid> MT_0000000911</psid>
    <psid_branch> </psid_branch>
</file_applicable_to>

<nv_file_id_vendor ovr_en='0' rd_en='1' writer_id='0'>
    <disable_override>False</disable_override>
    <keep_same_priority>False</keep_same_priority>
    <per_tlv_priority>False</per_tlv_priority>
    <erase_lower_priority>False</erase_lower_priority>
    <file_version>0</file_version>
    <day>17</day>
    <month>7</month>
    <year>7e7</year>
    <seconds>1</seconds>
    <minutes>e</minutes>
    <hour>15</hour>
</nv_file_id_vendor>
</config>
```

   The TLVs in this file are the only TLVs that will have OEM priority after this file is applied, and as the device ownership key will no longer be on the device, the OEM will no longer be able to change the TLVs. To have OEM priority TLVs on the device after removing the device ownership key, add to this XML any TLV that must stay as default on the device.
3. Convert the XML file to a binary NVconfig TLV file signed by the device ownership key as described in section "Generating NVconfig Enabling DPA Authentication".
4. Apply the NVconfig file to the device as described in section "Generating NVconfig Enabling DPA Authentication".

Changing Device Ownership Key

To transfer ownership of the device to another entity, the previous owner can change the device ownership public key to the public key of the new owner.

To do this, they can use an NVconfig file, and include in it the following TLVs:

```
<nv_ls_nv_public_key_0 ovr_en='0' rd_en='1' writer_id='0'>
    <public_key_exp>65537</public_key_exp>
    <keypair_uuid>77dd4ef0-c633-11ed-9e20-001dd8b744ff</keypair_uuid>
</nv_ls_nv_public_key_0>

<nv_ls_nv_public_key_1 ovr_en='0' rd_en='1' writer_id='0'>
    <key>
    c5:f8:a3:75:ef:b6:ec:0d:e9:43:b3:28:66:79:

    de:80:cb:8e:21:6b:2e:d4:52:b7:94:81:b1:31:20:
    94:65:0b
    </key>
</nv_ls_nv_public_key_2>
```

If the transfer is internal, the owner should set `keep_same_priority=True in nv_file_id_vendor` TLV and only include the 3 `nv_ls_nv_public_key_*` TLVs, `file_applicable_to` and `nv_file_id_vendor` TLVs in the NVconfig file.

If the transfer is to another OEM/CSP, the owner should clean the device (similarly to removing the device ownership key) and set `keep_same_priority=False` in `nv_file_id_vendor` TLV.

5.4.3.5.3.2 ELF File Structure

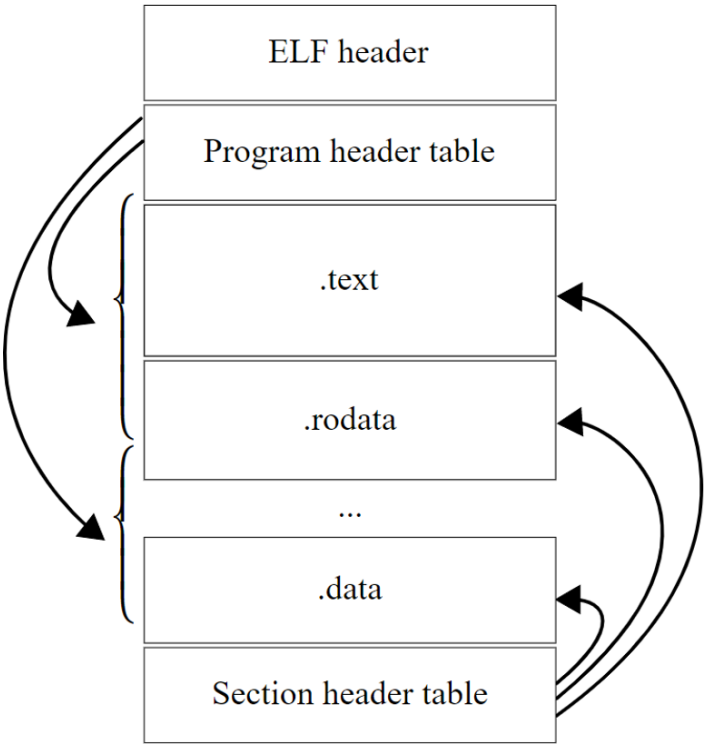
For maximal firmware code reuse, the format of the DPA image loaded from driver should be the same as for the file loaded from flash. As for files loaded from the host, ELF is the default file format. This is chosen as the format for the DPA image, both for flash and for files loaded from the host.

The following figure shows, schematically, a generic ELF file structure.

To support DPA Code authentication additional information needs to be presented to firmware. This info must include:

- Cryptographic signature of the DPA code
- Customer certificate chain including a Leaf Certificate with the public key to be used for signature validation (as described in section "Public Keys (Infrastructure, Delivery, and Verification)")

ELF File Structure Schematic



Crypto Signing Flow

The host ELF includes parts which run on the host, and those that run on DPA. DPA code files are incorporated in the "big" host ELF as binaries. Each host file may include several DPA applications.

When it is required to sign the DPA applications, the following steps need to be performed by the MFT Signing Tool (also see figure "Crypto Signing Flow"):

1. Using ELF manipulation library APIs of DPACC, extract Apps List Table
    a. Input – host ELF
    b. Output – apps list data table to include:
        i. DPA app index
        ii. DPA app name
        iii. Offset in host ELF
        iv. Size of app
        v. Name of corresponding crypto data section

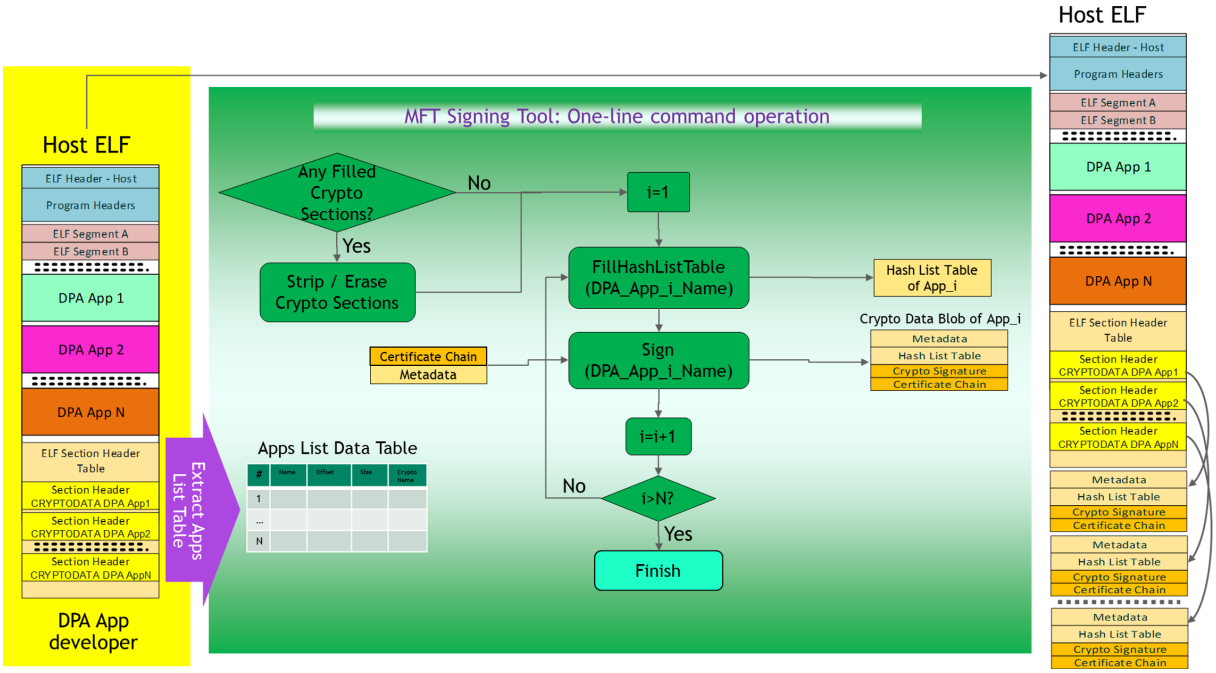
For each DPA application (from i=1 to i=N, N- number of DPA apps in the host ELF) run steps 2 and 3.

2. Fill hash list table:
    - Input: `Dpa_App_i`
    - Output: Hash list table
3. Sign the crypto data:
    - Input: {Metadata, Hash List Table}, key handle (e.g., UUID from leaf of the Certificate Chain)
    - Output: `Crypto_Data` "Blob", including: Metadata, Hash List Table, Crypto Signature, Certificate Chain
4. Add crypto data section to host ELF:
    - Inputs: Host ELF, crypto data section name to use
    - Output: File name of host ELF with signature added

The structures used in the flow (hash list table, metadata, etc.) are described in sections "ELF Crypto Data Section Content" and "Hash List Table Layout".

Signing the crypto data may be done using a signing server or a locally stored key.

Crypto Signing Flow



ELF Cryptographic Data Section

This figure shows, schematically, the layout of the cryptographic data section, and the following subsections provide details about the ELF section header and the rest of the structures.

ELF Cryptographic Data Section Layout

Crypto Data ELF Section Header

Defined according to the ELF section header format.

ELF Section Header

Name	Offset	Range	Description
`sh_name`	0x0	4B	&("Cryptographic Data Section DPA App X") An offset to a string (in the `.shstrtab` section of ELF) which represents the name of this section
`sh_type`	0x4	4B	0x70000666 `SHT_CRYPTODATA` – the section is proprietary and holds crypto information defined in this document
`sh_flags`	0X8	8B	0 – no flags
`sh_addr`	0x10	8B	Virtual address of the section in memory, for sections that are loaded
`sh_offset`	0x18	8B	Offset of the section in the file image
`sh_size`	0x20	8B	Size in bytes of the section in the file image. Depends on the content (e.g., presence and type of public key certificate chain and signature).
`sh_link`	0x28	4B	0 – `=SHN_UNDEF`, no link information
`sh_info`	0x2C	4B	0 – no extra information about the section
`sh_addralign`	0x30	8B	Contains the required alignment of the section. This field must be a power of two.
`sh_entsize`	0x38	8B	0
	0x40		End of section header (size)

ELF Crypto Data Section Content

ELF Crypto Data Section Fields Description

Name	Offset	Range	Description
metadata_version	0x0	15:0	Version metadata structure format. Initial version is 0.
Reserved (`DPA_fw_type`)	0x4	15:8	Reserved
Reserved	0x8	31:0	Reserved
Reserved	0xC	31:0	Reserved. Shall be set to all zeros.
Reserved	0x10	16B	Reserved. Shall be set to all zeros.
Reserved	0x20	4 bytes	Reserved. Shall be set to all zeros.
Reserved	0x24	24B	Reserved. Shall be set to all zeros.
signature_type	0x3c	15:0	Signature Type. Only relevant for signed firmware: • 0, 1 – Reserved • 2 – RSA_ SHA_512 • >3 – Reserved
Hash List Table	0x40	HashTable Length	
Crypto Signature	0x40 + HashTableLength	Signature_ Length	Signature_Length depends on the signature_type.
Certificate_Chain	0x40 + HashTableLength + Signature_Length	CrtChain_ Length	Structure given the table under section "Certificate Chain Layout".
Padding			FF-padding to align the full size of the data to multiples of DWords (DWs)

The full length of the ELF crypto data section shall be a multiple of DWs (due to firmware legacy implementation). Thus, the MFT (as part of the flow described in figure "Crypto Signing Flow") shall add FF-padding for this structure to align to multiple of DW.

Hash List Table Layout

This table specifies the hash table layout (proposal).

The table contains two parts:

- The 1st part corresponds to the segments of the ELF file, as referenced by the Program Header Table of the EFL file
- The 2nd part corresponds to the sections of the ELF file, as referenced by the Section Header Table

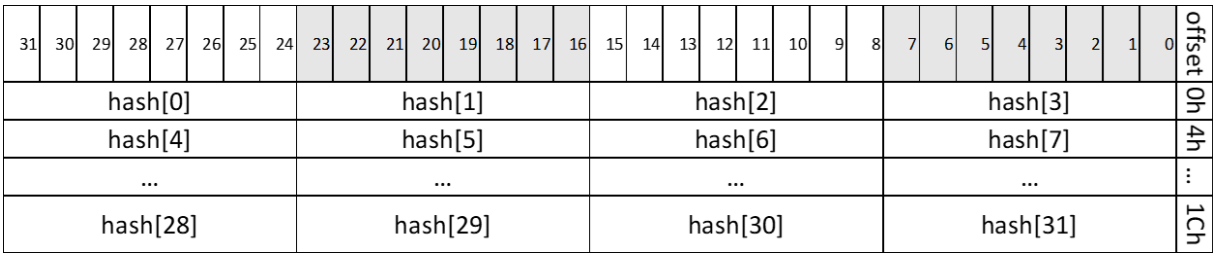
The hash algorithm to be used is SHA-256.

Hash List Table Layout (Proposal)

Name	Offset	Range	Description
Hash Table Magic Pattern	0x0	8 bytes	ASCII "HASHLIST' string: 0x0: 31:24 – "H", 23:16 – "A", 15:8 – "S", 7:0 – "H" 0x4: 31:24 – "L", 23:16 – "I", 15:8 – "S", 7:0 – "T"
Number of Entries – Segments	0x8	7:0	Number of entries in Hashes Segments part, N_Segments.
Reserved	0x8	31:8	Reserved
Number of Entries – Sections	0xc	7:0	Number of entries in Hashes Sections part, N_Sections. Minimum – 0
Reserved	0xc	31:8	Reserved
Reserved	0x10	16 bytes	Reserved
DPA Application ELF Hash	0x20	32 bytes	Hash of the full ELF App file
ELF Header Hash	0x40	32 bytes	Hash of the ELF Header
Program Header Hash	0x60	32 bytes	Hash of the program header
Hash of 1st Segment referenced in the Program Header Table	0x80	32 bytes	Hash of 1st segment referenced in the Program Header Table
Hash of 2nd Segment referenced in the Program Header Table	0xA0	32 bytes	Hash of 2nd Segment referenced in the Program Header Table
.....	.....	.....	.....
Hash of N_Segments (last) Segment referenced in the Program Header Table	0x60 + N_Segments*0x20	32 bytes	Hash of 2nd segment referenced in the Program Header Table
Section Header Table Hash	0x80 + N_Segments*0x20	32 bytes	Hash of the Section Header Table
Hash of 1st Section referenced in the Section Header Table	+ 0x20	32 bytes	Hash of 1st section referenced in the Section Header Table
Hash of 2nd Section referenced in the Section Header Table	+ 0x20	32 bytes	Hash of 2nd section referenced in the Section Header Table
.....	.....	.....	.....
Hash of N_Sections (last) Section referenced in the Section Header Table	+ 0x20	32 bytes	Hash of N_Sections (last) section referenced in the Section Header Table

The 32-bytes hash fields of different sections/segments in the previous table shall follow Big-Endian convention, as illustrated here:

Hash Fields (Big Endian) Bytes Alignment



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset
hash[0]								hash[1]								hash[2]								hash[3]								0h
hash[4]								hash[5]								hash[6]								hash[7]								4h
...								...								...								...								...
hash[28]								hash[29]								hash[30]								hash[31]								1Ch

Certificate Chain Layout

The following table specifies the certificate chain layout. The leaf (the last certificate) of the chain is used as the public key for authentication of the DPA code. This structure is aligned with the certificate chain layout as defined in the *Flash Application Note*.

Certificate Chain Layout

Name	Offset	Range	Description
Type	0x0	3:0	Chain type. Shall be set to 1. 3rd party code authentication certificate chain.
Count	0x0	7:4	Number of certificates in this chain
Length	0x0	23:8	Total length of the certificate chain, in bytes, including all fields in this table
Reserved	0x4	31:0	31:0 – Reserved
CRC	0x8	15:0	The CRC of the header, for header integrity check, covering DWs in 0x0, 0x4
Certificates	0xC-0x1000		One or more ASN.1 DER-encoded X509v3 certificates. The ASN.1 DER encoding of each individual certificate can be analyzed to determine its length. The certificates shall be listed in hierarchical order, with the leaf certificate being the last on the list.

5.4.3.5.4 Distribution of Execution Units Across Multiple Applications

Managing DPA execution units across multiple applications is challenging due to the variability in available units and running applications. To address this, administrators can define a subset of execution units (EUs) for each application to run on, as described in the Single Point of Resource Distribution page.

This approach is supported by the following applications:

- DOCA PCC application
- DPA basic initiator sample

To implement this, create a YAML file describing the DPA resource allocation before running the application.

Applications receive their EU allocation through the following command-line arguments:

- `--dpa-resources` – Path to the YAML file containing DPA resource definitions

- `--dpa-app-key` – Name of the application as defined in the resources YAML file

When properly configured, execution units are assigned to the application according to the YAML file's resource specifications.

> ⚠ Execution Unit Groups (EUGs) are currently unsupported.

> ⚠ The PCC application still accepts the `--threads` command line argument for backward compatibility, but it cannot be used alongside the new DPA resources flags. This argument will be removed in future versions.

5.4.3.5.5 Known Limitations

5.4.3.5.5.1 Supported Devices

- BlueField-3 based DPUs
- ConnectX-8 based NICs
- Only ECPF/PF may be used for loading DPA applications

5.4.3.5.5.2 Supported Host OS

- Windows is not supported

5.4.3.5.5.3 Supported SDKs

- DOCA Flex IO at GA level
- DOCA DPA at beta level

5.4.3.5.5.4 Toolchain

- DPA image-signing and signature-verification are not currently supported

5.4.3.5.5.5 Flex IO

- When `flexio_dev_outbox_config_uar_extension` API is called with a `device_id` parameter different than PF/ECPF ID (i.e., move to SF/VF outbox) and the APIs `flexio_dev_yield()`, `flexio_dev_print()`, or `flexio_dev_msg()` are called, then when either of those 3 APIs return, the user cannot work with the SF/VF queues.
- Flex IO SDK tracer might suffer from data loss and ordering issues when working under high load (multithread/high rate).
- Functions that copy data from the host to the DPA use WQEs and may be blocked for an extended period under heavy high-priority traffic. To mitigate this, it is recommended to configure a 99/1 weight between high-priority traffic and TC7.

- The following Flex IO SDK API functions are directly affected:
  - `flexio_memcpy()`
  - `flexio_host2dev_memcpy()`
  - `flexio_buf_dev_memset()`
  - `flexio_copy_from_host()`
- Additionally, the following API functions use copy operations and are indirectly affected:
  - `flexio_cq_create()`
  - `flexio_event_handler_create()`
  - `flexio_event_handler_run()`
  - `flexio_process_call()`
  - `flexio_cmdq_create()`
  - `flexio_log_dev_init()`

5.4.3.6 DOCA DPA

5.4.3.6.1 Introduction

The quality status of DOCA libraries is listed here.

This chapter provides an overview and configuration instructions for DOCA DPA API.

The DOCA DPA libraries offer a programming model for offloading communication-centric user code to run on the DPA processor on NVIDIA® BlueField®-3 networking platform. DOCA DPA provides a high-level programming interface to the DPA processor.

DOCA DPA offers:

- Full control over DPA threads –
  - The user can control the thread function (kernel) that runs on DPA and their placement on DPA EUs
  - The user can associate a DPA thread with a DPA Completion Context. When the completion context receives a notification, the DPA thread is scheduled.
- Abstraction to allow a DPA thread to issue asynchronous operations
- Abstraction to execute a blocking one-time call from host application to execute the kernel on the DPA from the host application (RPC)
- Abstraction for memory services
- Abstraction for remote communication primitives (integrated with remote event signaling)
- Full control on execution-ordering and notifications/synchronization of the DPA and host/Target BlueField

- A set of debugging APIs that allow diagnosing and troubleshooting any issue on the device, as well as accessing real-time information from the running application
- C API for application developers

DPACC is used to compile and link kernels with DOCA DPA device libraries to get DPA applications that can be loaded from the host program to execute on the DPA (similar to CUDA usage with NVCC). For more information on DPACC, refer to the DOCA DPACC Compiler.

5.4.3.6.2 Prerequisites

DOCA DPA applications can run either on the host or on the Target BlueField. Running on the host machine requires EU pre-configuration using the `dpaeumgmt` tool. For more information, please refer to NVIDIA DOCA DPA EU Management Tool.

5.4.3.6.3 Library Changes From Previous Releases

5.4.3.6.3.1 Changes in 2.9.0

The following subsection(s) detail the `doca_dpa` library updates in version 2.9.0.

Added

- `doca_dpa_dev.h`
  - Added `enum doca_dpa_dev_submit_flag` to be used in the new parameter `uint32_t flags` in DPA RDMA device and DPA memcpy APIs

Removed

- `doca_dpa_dev_rdma.h`
  - `void doca_dpa_dev_rdma_synchronize(doca_dpa_dev_rdma_t rdma);`
  - `void doca_dpa_dev_rdma_srq_post_receive(doca_dpa_dev_rdma_srq_t rdma_srq, uint32_t next_index);`
  - `void doca_dpa_dev_rdma_srq_receive_ack(doca_dpa_dev_rdma_srq_t rdma_srq, uint32_t num_acked);`

Changed

- `doca_dpa_dev_rdma.h`
  - Added `uint32_t connection_id` parameter to all DPA RDMA device APIs
  - Changed `uint32_t completion_requested` parameter to `uint32_t flags` in all DPA RDMA APIs
- `doca_dpa_dev_buf.h`

- Changed `uint32_t completion_requested` parameter to `uint32_t flags` in all DPA memcpy APIs

5.4.3.6.4 Development Flow

DOCA enables developers to program the DPA processor using both DOCA DPA libraries and a suite of other tools (mainly DPACC).

The following are the main steps to start DPA offload programming:

1. Write DPA device code, or kernels, (`.c` files) with:
   - The `__dpa_global__` keyword before DPA thread function (see "Examples" section)
   - The `__dpa_rpc__` keyword before RPC function (see "Examples" section)
2. Use DPACC to build a DPA program (i.e., a host library which contains an embedded device executable). Inputs for DPACC are:
   - Kernels from the previous step
   - DOCA DPA device libraries
3. Build host executable using a host compiler. Inputs for the host compiler are:
   - DPA program from the previous step
   - User host application source files
   - DOCA DPA host library

DPACC is provided by the DOCA SDK installation. For more information, please refer to the DOCA DPACC Compiler.

5.4.3.6.4.1 DPA Queries

- Before invoking the DPA API, make sure that DPA is indeed supported on the relevant device. The API which checks whether a device supports DPA is:

```
doca_error_t doca_devinfo_get_is_dpa_supported(const struct doca_devinfo *devinfo)
```

> Only if this call returns `DOCA_SUCCESS` can the user invoke DOCA DPA API on the device.

- To use a valid EU ID for the DPA EU Affinity of a DPA thread, use the following APIs to query EU ID and core valid values:

```
doca_error_t doca_dpa_get_core_num(struct doca_dpa *dpa, unsigned int *num_cores)
doca_error_t doca_dpa_get_num_eus_per_core(struct doca_dpa *dpa, unsigned int *eus_per_core)
doca_error_t doca_dpa_get_total_num_eus_available(struct doca_dpa *dpa, unsigned int *total_num_eus)
```

- There is a limitation on the maximum number of DPA threads that can run a single kernel. This can be retrieved by calling the host API:

```
doca_error_t doca_dpa_get_max_threads_per_kernel(struct doca_dpa *dpa, unsigned int *value)
```

- Each kernel launched into the DPA has a maximum DPA kernel time alive supported by the DOCA device. During the DPA process creation, the host application should read the cap and adjust the parameters of the DPA threads, such as batch size and loop iterations, to ensure they remain within the specified limits.

```
doca_error_t doca_dpa_cap_get_max_kernel_time_alive_supported(const struct doca_devinfo *devinfo, uint64_t
*value)
```

> ⚠ If the kernel execution time on the DPA exceeds this maximum runtime limit, it may be terminated and cause a fatal error. To recover, the application must destroy the DPA context and create a new one.

> ⚠ DEPRECATED API, will be removed in future release.

- Each kernel launched into the DPA has a maximum runtime limit. This can be retrieved by calling the host API:

```
doca_error_t doca_dpa_get_kernel_max_run_time(struct doca_dpa *dpa, unsigned long long *value)
```

5.4.3.6.4.2 Initialization

The DPA context encapsulates the DPA device and a DPA process (program). Within this context, the application creates various DPA SDK objects and controls them. After verifying DPA is supported for the chosen device, the DPA context is created.

Use the following host-side APIs to create/set the DPA context and it is expected to be the first programming step:

- To create/destroy DPA context:

```
doca_error_t doca_dpa_create(struct doca_dev *dev, struct doca_dpa **dpa)
doca_error_t doca_dpa_destroy(struct doca_dpa *dpa)
```

> ⚠ Please note that the `dev` used to create the "base" DPA context must be a PF DOCA device.

- To start/stop DPA context:

```
doca_error_t doca_dpa_start(struct doca_dpa *dpa)
doca_error_t doca_dpa_stop(struct doca_dpa *dpa)
```

5.4.3.6.4.3 Interface to DPACC

DPA Application

To associate a DPA program (app) with a DPA context, use the following host-side APIs:

```
doca_error_t doca_dpa_set_app(struct doca_dpa *dpa, struct doca_dpa_app *app)
doca_error_t doca_dpa_get_app(struct doca_dpa *dpa, struct doca_dpa_app **app)
doca_error_t doca_dpa_app_get_name(struct doca_dpa_app *app, char *app_name, size_t *app_name_len)
```

The `app` variable name used in `doca_dpa_set_app()` API must be the token passed to DPACC `--app-name` parameter.

Example (Pseudo Code)

For example, when using the following `dpacc` command line:

```
dpacc \
    kernels.c \
    -o dpa_program.a \
    -hostcc=gcc \
    -hostcc-options="..." \
    --devicecc-options="..." \
    -device-libs="-L/opt/mellanox/doca/include -ldoca_dpa_dev -ldoca_dpa_dev_comm" \
    --app-name="dpa_example_app"
```

The user must use the following commands to set the `app` of a DPA context:

```
extern struct doca_dpa_app *dpa_example_app;
doca_dpa_create(&dpa);
doca_dpa_set_app(dpa, dpa_example_app);
doca_dpa_start(dpa);
```

5.4.3.6.5 Software Architecture

5.4.3.6.5.1 DOCA DPA Software Objects

Term	Definition
DPA context	Software construct for the host process that encapsulates the state associated with a DPA process (on a specific device). DPA context must be associated with a PF device.
Extended DPA context	A DPA context associated with a VF/SF device to be used for RDMA utilities. This to allow creation of DPA resources such as RDMA/DPA completion/DPA Async ops... contexts on the VF/SF device.
DPA Application	Interface with the DPACC compiler to produce a DPA program (app) which is obtained by the DPA context to begin working on DPA.
Kernel	User function (and its arguments) to be executed on DPA. A kernel may be executed by one or more DPA threads.
DPA EU Affinity	An object used to control which EU to use for DPA thread.
DPA Thread	DOCA DPA provides APIs to create/manage DPA thread which runs a given kernel.

Term	Definition
DPA Completion Context	An object used to receive/handle a completion notification. The user can associate a DPA thread with a completion context. When the completion context receives a notification, DPA thread is scheduled.
DPA Thread Notification	A mechanism for one DPA thread to notify another DPA thread.
DPA Async Ops	An object used to allow a DPA thread to issue asynchronous operations, like memcpy or post_wait operations.
DPA RPC	A blocking one-time call from host application to execute a kernel on DPA. RPC is mainly used for control path. The RPC's return value is reported back to the host application.
DPA Memory	DOCA DPA provides an API to allocate/manage DPA memory, as well as handling host/Target BlueField memory that has been exported to DPA.
Sync Event	Data structure in either CPU, Target BlueField, GPU, or DPA-heap. An event contains a counter that can be updated and waited on.
RDMA	Abstraction around a network transport object. Allows executing various RDMA operations.
DPA Hash Table	DOCA DPA provides an API to create a Hash Table on DPA. This data structure is managed on DPA using relevant device APIs.
DPA Logger/Tracer	DOCA DPA provides a set of debugging APIs to allow the user to diagnose and troubleshoot any issue on the device, as well as accessing real-time information from the running application.

5.4.3.6.5.2 Deployment View

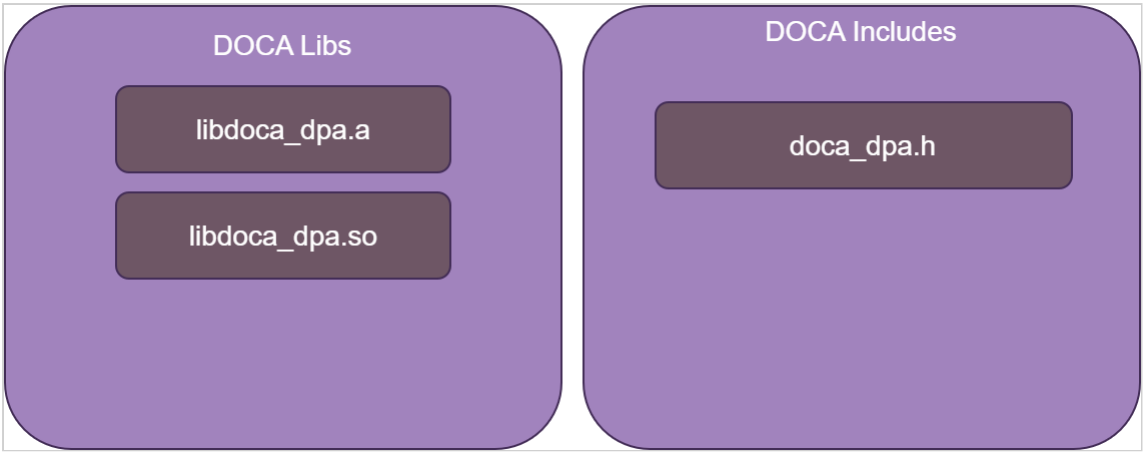
DOCA DPA comprises two main components which are part of the DOCA SDK installation package:

- DOCA DPA host library
- DOCA DPA device library

> ⚠ The DOCA DPA SDK does not use any means of multi-thread synchronization primitives. All DOCA DPA objects are non-thread-safe. Developers should make sure the user program and kernels are written to avoid race conditions.

DOCA DPA Host Library

Host library and header files:



The host library offers an interface for managing the following components:

Affinity

Users can control which EU is assigned to a DPA thread by using a DPA EU affinity object.

A DPA EU affinity object can be configured to target a single EU ID at a time.

Use the following host-side APIs to manage it:

- To create/destroy DPA EU affinity object:

```
doca_error_t doca_dpa_eu_affinity_create(struct doca_dpa *dpa, struct doca_dpa_eu_affinity **affinity)
doca_error_t doca_dpa_eu_affinity_destroy(struct doca_dpa_eu_affinity *affinity)
```

- To set/clear EU ID in DPA EU affinity object:

```
doca_error_t doca_dpa_eu_affinity_set(struct doca_dpa_eu_affinity *affinity, unsigned int eu_id)
doca_error_t doca_dpa_eu_affinity_clear(struct doca_dpa_eu_affinity *affinity)
```

- To get EU ID of a DPA EU affinity object:

```
doca_error_t doca_dpa_eu_affinity_get(struct doca_dpa_eu_affinity *affinity, unsigned int *eu_id)
```

DPA Resources

The DPA Resources API provides a mechanism to parse and query pre-defined DPA resource configurations. This enables applications to discover and utilize the Execution Units (EUs) allocated to them in the Single Point of Resource Distribution (SPRD) file.

The SPRD is a YAML-formatted configuration file that defines DPA application resources. It maps application names (keys) to specific resources, specifying:

- The number of allocated EUs per application.
- The specific EU IDs assigned to each application.

For file syntax and examples, refer to Single Point of Resource Distribution documentation.

DPA Thread

DOCA DPA thread used to run a user function “DPA kernel” on DPA.

You can control which EU to run DPA kernel by attaching a DPA EU affinity object to the thread.

The thread can be triggered on DPA using two methods:

1. DPA thread notification – Notifying one DPA thread from another DPA thread.
2. DPA completion context – A completion is arrived at a DPA completion context which is attached to the thread.

DPA thread operations:

- To create/destroy DPA thread:

```
doca_error_t doca_dpa_thread_create(struct doca_dpa *dpa, struct doca_dpa_thread **dpa_thread)
doca_error_t doca_dpa_thread_destroy(struct doca_dpa_thread *dpa_thread)
```

- To set/get thread user function and its argument:

```
doca_error_t doca_dpa_thread_set_func_arg(struct doca_dpa_thread *thread, doca_dpa_func_t *func, uint64_t
arg)
doca_error_t doca_dpa_thread_get_func_arg(struct doca_dpa_thread *dpa_thread, doca_dpa_func_t **func,
uint64_t *arg)
```

- To set/get DPA EU Affinity:

```
doca_error_t doca_dpa_thread_set_affinity(struct doca_dpa_thread *thread, struct
doca_dpa_eu_thread_affinity *eu_affinity)
doca_error_t doca_dpa_thread_get_affinity(struct doca_dpa_thread *dpa_thread, const struct
doca_dpa_eu_affinity **affinity)
```

- Thread Local Storage (TLS)
  You can ask to store an opaque for a DPA thread in host side application using the following API:

```
doca_error_t doca_dpa_thread_set_local_storage(struct doca_dpa_thread *dpa_thread, doca_dpa_dev_uintptr_t
dev_ptr)
doca_error_t doca_dpa_thread_get_local_storage(struct doca_dpa_thread *dpa_thread, doca_dpa_dev_uintptr_t
*dev_ptr)
```

  `dev_ptr` is a pre-allocated DPA memory.
  In kernel, user can retrieve the stored opaque using the relevant device API (see below API).
  This opaque is stored/retrieved using the Thread Local Storage (TLS) mechanism.

- To start/stop DPA thread:

```
doca_error_t doca_dpa_thread_start(struct doca_dpa_thread *thread)
doca_error_t doca_dpa_thread_stop(struct doca_dpa_thread *dpa_thread)
```

- To run DPA thread:

```
doca_error_t doca_dpa_thread_run(struct doca_dpa_thread *dpa_thread)
```

This API sets the thread to run state. This function must be called after DPA thread is:

a. Created, set, and started.

b. If a DPA thread is attached to a DPA completion context, the completion context must be started first.

Example (host-side pseudo code):

```
extern doca_dpa_func_t hello_kernel;

// create DPA thread
doca_dpa_thread_create(&dpa_thread);

// set thread kernel
doca_dpa_thread_set_func_arg(dpa_thread, &hello_kernel, func_arg);

// set thread affinity
doca_dpa_eu_affinity_create(&eu_affinity);
doca_dpa_eu_affinity_set(eu_affinity, 10 /* EU ID */);
doca_dpa_thread_set_affinity(dpa_thread, eu_affinity);

// set thread local storage
doca_dpa_mem_alloc(&tls_dev_ptr);
doca_dpa_thread_set_local_storage(dpa_thread, tls_dev_ptr);

// start thread
doca_dpa_thread_start(dpa_thread);

// create and initialize DPA Completion Context
doca_dpa_completion_create(&dpa_comp);
doca_dpa_completion_set_thread(dpa_comp, dpa_thread);
doca_dpa_completion_start(dpa_comp);

// run thread only after both thread is started and the attached completion context is started
doca_dpa_thread_run(dpa_thread);
```

Completion Context

The DPA Completion Context integrates user applications with the DPA's native event-driven scheduling model. It functions as a generic mechanism shared across Message Queues, RDMA, Ethernet, and DPA Async Operations.

Operational modes:

- Event-driven: A DPA Thread is associated with a completion context. When the context receives a notification, the DPA Thread is automatically triggered.
- Polling: The application creates a completion context without an associated DPA Thread and polls for events manually.

Additionally, the system provides control over notification delivery, allowing the application to enable or suppress incoming notifications as needed

- To create/destroy DPA Completion Context:

```
doca_error_t doca_dpa_completion_create(struct doca_dpa *dpa, unsigned int queue_size, struct
doca_dpa_completion **dpa_comp)

doca_error_t doca_dpa_completion_destroy(struct doca_dpa_completion *dpa_comp)
```

- To get queue size:

```
doca_error_t doca_dpa_completion_get_queue_size(struct doca_dpa_completion *dpa_comp, unsigned int *size)
```

- To attach to a DPA Thread:

```
doca_error_t doca_dpa_completion_set_thread(struct doca_dpa_completion *dpa_comp, struct doca_dpa_thread
*thread)

doca_error_t doca_dpa_completion_get_thread(struct doca_dpa_completion *dpa_comp, struct doca_dpa_thread
**thread)
```

Attaching to a thread is only required if the user wants triggering of the thread when a completion is arrived at the completion context.

- To start/stop DPA Completion Context:

```
doca_error_t doca_dpa_completion_start(struct doca_dpa_completion *dpa_comp)

doca_error_t doca_dpa_completion_stop(struct doca_dpa_completion *dpa_comp)
```

- To get DPA handle:

```
doca_error_t doca_dpa_completion_get_dpa_handle(struct doca_dpa_completion *dpa_comp,
doca_dpa_dev_completion_t *handle)
```

Use output parameter `handle` for below device APIs which can be used in thread kernel.

Thread Notification

Thread Activation is a mechanism for one DPA thread to trigger another DPA Thread.

Thread activation is done without receiving a completion on the attached thread. Therefore it is expected that user of this method of thread activation passes the message in another fashion – such as shared memory.

Thread Activation can be achieved using DPA Notification Completion object.

- To create/destroy DPA Notification Completion:

```
doca_error_t doca_dpa_notification_completion_create(struct doca_dpa *dpa, struct doca_dpa_thread
*dpa_thread, struct doca_dpa_notification_completion **notify_comp)

doca_error_t doca_dpa_notification_completion_destroy(struct doca_dpa_notification_completion *notify_comp)
```

Attaching DPA Notification Completion to a DPA Thread is done using the given parameter `dpa_thread`.

- To get attached DPA Thread:

```
doca_error_t doca_dpa_notification_completion_get_thread(struct doca_dpa_notification_completion
*notify_comp, struct doca_dpa_thread **dpa_thread)
```

- To start/stop DPA Notification Completion:

```
doca_error_t doca_dpa_notification_completion_start(struct doca_dpa_notification_completion *notify_comp)

doca_error_t doca_dpa_notification_completion_stop(struct doca_dpa_notification_completion *notify_comp)
```

- To get DPA handle:

```
doca_error_t doca_dpa_notify_completion_get_dpa_handle(struct doca_dpa_notification_completion
*notify_comp, doca_dpa_dev_notification_completion_t *comp_handle)
```

  Use output parameter `comp_handle` for below device API which can be used in thread kernel.

Example (host-side pseudo code):

```
extern doca_dpa_func_t hello_kernel;

// create DPA thread
doca_dpa_thread_create(&dpa_thread);

// set thread kernel
doca_dpa_thread_set_func_arg(dpa_thread, &hello_kernel, func_arg);

// start thread
doca_dpa_thread_start(dpa_thread);

// create and start DPA notification completion
doca_dpa_notification_completion_create(dpa, dpa_thread, &notify_comp);

doca_dpa_notification_completion_start(notify_comp);

// get its DPA handle
doca_dpa_notification_completion_get_dpa_handle(notify_comp, &notify_comp_handle);

// run thread only after both thread is started and attached notification completion is started
doca_dpa_thread_run(dpa_thread);
```

Asynchronous Ops

DPA Async Ops allows DPA Thread to issue asynchronous operations, like memcpy or post_wait.

This feature requires the user to create an “asynchronous ops” context and attach to a completion context.

User is expected to adhere to `queue_size` limit on the device when posting operations.

The completion context can raise activation if it is attached to a DPA Thread.

User can also choose to progress the completion context via polling it manually.

User can provide DPA Async Ops `user_data`, and retrieve this metadata in device using relevant device API.

- To create/destroy DPA Async Ops:

```
doca_error_t doca_dpa_async_ops_create(struct doca_dpa *dpa, unsigned int queue_size, uint64_t user_data,
struct doca_dpa_async_ops **async_ops)

doca_error_t doca_dpa_async_ops_destroy(struct doca_dpa_async_ops *async_ops)
```

  Please use the following define for valid user_data values:

```
#define DOCA_DPA_COMPLETION_LOG_MAX_USER_DATA   (24)
```

- To get queue size/user_data:

```
doca_error_t doca_dpa_async_ops_get_queue_size(struct doca_dpa_async_ops *async_ops, unsigned int
 *queue_size)

doca_error_t doca_dpa_async_ops_get_user_data(struct doca_dpa_async_ops *async_ops, uint64_t *user_data)
```

- To attach to a DPA Completion Context:

```
doca_error_t doca_dpa_async_ops_attach(struct doca_dpa_async_ops *async_ops, struct doca_dpa_completion
*dpa_comp)
```

- To start/stop DPA Async Ops:

```
doca_error_t doca_dpa_async_ops_start(struct doca_dpa_async_ops *async_ops)

doca_error_t doca_dpa_async_ops_stop(struct doca_dpa_async_ops *async_ops)
```

- To get DPA handle:

```
doca_error_t doca_dpa_async_ops_get_dpa_handle(struct doca_dpa_async_ops *async_ops,
doca_dpa_dev_async_ops_t *handle)
```

  Use output parameter `handle` for below device API which can be used in thread kernel.

Example (host-side pseudo code):

```
doca_dpa_thread_create(&dpa_thread);
doca_dpa_thread_set_func_arg(dpa_thread);
doca_dpa_thread_start(dpa_thread);

doca_dpa_completion_create(&dpa_comp);
doca_dpa_completion_set_thread(dpa_comp, dpa_thread);
doca_dpa_completion_start(dpa_comp);

doca_dpa_thread_run(dpa_thread);

doca_dpa_async_ops_create(&async_ops);
doca_dpa_async_ops_attach(async_ops, dpa_comp);
doca_dpa_async_ops_start(async_ops);

doca_dpa_async_ops_get_dpa_handle(async_ops, &handle); // use this handle in relevant Async Ops device APIs
```

Thread Group

Thread group is used to aggregate individual DPA threads to a single group.

- To create/destroy DPA Thread Group:

```
doca_error_t doca_dpa_thread_group_create(struct doca_dpa *dpa, unsigned int num_threads, struct
doca_dpa_tg **tg)

doca_error_t doca_dpa_thread_group_destroy(struct doca_dpa_tg *tg)
```

- To get number of threads:

```
doca_error_t doca_dpa_thread_group_get_num_threads(struct doca_dpa_tg *tg, unsigned int *num_threads);
```

- To set DPA Thread at 'rank' in DPA Thread Group:

```
doca_error_t doca_dpa_thread_group_set_thread(struct doca_dpa_tg *tg, struct doca_dpa_thread *thread,
unsigned int rank)
```

  Thread rank is an index of the thread (between 0 and (num_threads - 1)) within the group.

- To start/stop DPA Thread Group:

```
doca_error_t doca_dpa_thread_group_start(struct doca_dpa_tg *tg)
```

```
doca_error_t doca_dpa_thread_group_stop(struct doca_dpa_tg *tg)
```

Memory Subsystem

The user can allocate (from the host API) and access (from both the host and device API) several memory locations using the relevant DOCA DPA API.

DOCA DPA supports access from the host/Target BlueField to DPA heap memory and also enables device access to host memory (e.g., kernel writes to host memory).

The normal memory usage flow would be to:

1. Allocate memory (Host/Target BlueField/DPA).
2. Register the memory.
3. Get a DPA handle for the registered memory so it can be accessed by DPA kernels.
4. Access/use the memory from the kernel (see relevant device-side APIs).

Operations:

- To allocate DPA heap memory:

```
doca_dpa_mem_alloc(doca_dpa_t dpa, size_t size, doca_dpa_dev_uintptr_t *dev_ptr)
```

- To free previously allocated DPA memory:

```
doca_dpa_mem_free(doca_dpa_dev_uintptr_t dev_ptr)
```

- To copy previously allocated memory from a host pointer to a DPA heap device pointer:

```
doca_dpa_h2d_memcpy(doca_dpa_t dpa, doca_dpa_dev_uintptr_t src_ptr, void *dst_ptr, size_t size)
```

- To copy previously allocated memory from a DOCA Buffer to a DPA heap device pointer:

```
doca_error_t doca_dpa_h2d_buf_memcpy(struct doca_dpa *dpa, doca_dpa_dev_uintptr_t dst_ptr, struct doca_buf
*buf, size_t size)
```

- To copy previously allocated memory from a DPA heap device pointer to a host pointer:

```
doca_dpa_d2h_memcpy(doca_dpa_t dpa, void *dst_ptr, doca_dpa_dev_uintptr_t src_ptr, size_t size)
```

- To copy previously allocated memory from a DPA heap device pointer to a DOCA Buffer:

```
doca_error_t doca_dpa_d2h_buf_memcpy(struct doca_dpa *dpa, struct doca_buf *buf, doca_dpa_dev_uintptr_t
src_ptr, size_t size)
```

- To set memory:

```
doca_dpa_memset(doca_dpa_t dpa, doca_dpa_dev_uintptr_t dev_ptr, int value, size_t size)
```

- To get a DPA handle to use in kernels, the user must use a DOCA Core Memory Inventory Object in the following manner (refer to "DOCA Memory Subsystem"):
  - When the user wants to use device APIs with DOCA Buffer, use the following pseudo code:

    ```
    doca_buf_arr_create(&buf_arr);
    doca_buf_arr_set_target_dpa(buf_arr, doca_dpa);
    doca_buf_arr_start(buf_arr);
    doca_buf_arr_get_dpa_handle(buf_arr, &handle);
    ```

    Use output parameter `handle` in relevant device APIs in thread kernel.
  - When the user wants to use device APIs with DOCA Mmap, use the following pseudo code:

    ```
    doca_mmap_create(&mmap);
    doca_mmap_set_dpa_memrange(mmap, doca_dpa, dev_ptr, dev_ptr_len); // dev-ptr is a pre-allocated DPA memory
    doca_mmap_start(mmap);
    doca_mmap_dev_get_dpa_handle(mmap, doca_dev, &handle);
    ```

    Use output parameter `handle` in relevant device APIs in thread kernel.

Extended DOCA DPA Context

A base DOCA DPA context is a context created on a PF DOCA device using:

```
doca_dpa_create(pf_doca_dev, &base_dpa_ctx);
```

To enable creating DPA resources (e.g., RDMA/DPA completion/DPA Async ops contexts) on VF/SF DOCA device, an extended DOCA DPA context is required.

DOCA DPA provides the following host API to extend a base DOCA DPA context (created on a PF DOCA device) to an SF/VF DOCA device:

```
doca_error_t doca_dpa_device_extend(struct doca_dpa *dpa, struct doca_dev *other_dev, struct doca_dpa **extended_dpa)
```

The extended DPA context can be used later on for creation of DPA resources (e.g., as RDMA/DPA completion/DPA Async ops contexts) on the other DOCA device (SF/VF).

Note that:

- The extended DPA context is already started.
- The extended DPA context can be used later for all DOCA DPA APIs (e.g., creating DPA memory, DPA completion context) or within kernel launch flow.

> ⚠ When running from the DPU, DOCA RDMA context (on DPA datapath) must be created on SF DOCA device. Therefore, it must be created using an extended DOCA DPA context (created on the same SF DOCA device).

To obtain a DPA handle for a DOCA DPA context (both base or extended):

```
doca_error_t doca_dpa_get_dpa_handle(struct doca_dpa *dpa, doca_dpa_dev_t *handle)
```

Use output parameter `handle` in the relevant device's APIs in the thread kernel.

> ⚠ When creating a DOCA RDMA context with an extended DOCA DPA context and that RDMA context is attached to a DPA completion context and a DPA thread, all DOCA RDMA, DPA completion context, and the DPA thread must be created on the same extended DOCA DPA context.

Example (host-side pseudo code):

```
// create a base DPA context
doca_dpa_create(pf_doca_dev, &base_dpa_ctx);
// call base_dpa_ctx setters
doca_dpa_start(base_dpa_ctx);

// create an extended DPA context
doca_dpa_device_extend(base_dpa_ctx, sf_doca_dev, &extended_dpa_ctx);
doca_dpa_get_dpa_handle(extended_dpa_ctx, &extended_dpa_ctx_handle);

// create DPA thread on extended DPA context
doca_dpa_thread_create(extended_dpa_ctx, &dpa_thread);
// call dpa_thread setters
doca_dpa_thread_start(dpa_thread);

// create DPA completion context on extended DPA context
doca_dpa_completion_create(extended_dpa_ctx, &dpa_completion);
doca_dpa_completion_set_thread(dpa_completion, dpa_thread);
doca_dpa_completion_start(dpa_completion);

// create DOCA RDMA context on SF DOCA device and extended DPA context
doca_rdma_create(sf_doca_dev, &rdma);
doca_ctx_set_datapath_on_dpa(rdma_as_ctx, extended_dpa_ctx);
doca_rdma_dpa_completion_attach(rdma, dpa_completion);
// other rdma setters
doca_ctx_start(rdma_as_ctx);
doca_rdma_get_dpa_handle(rdma, rdma_dpa_handle);
```

Data Structures

Hash Table

DOCA DPA provides an API to create a hash table on DPA. This data structure is managed on DPA using relevant device APIs.

- To create a hash table on DPA:

  ```
  doca_error_t doca_dpa_hash_table_create(struct doca_dpa *dpa, unsigned int num_entries, struct
  doca_dpa_hash_table **ht)
  ```

- To destroy a hash table:

  ```
  doca_error_t doca_dpa_hash_table_destroy(struct doca_dpa_hash_table *ht)
  ```

- To obtain a DPA handle:

  ```
  doca_error_t doca_dpa_hash_table_get_dpa_handle(struct doca_dpa_hash_table *ht, doca_dpa_dev_hash_table_t
  *handle)
  ```

  Use output parameter `handle` in relevant device APIs in the thread kernel.

RPC

A blocking one-time call from the host application to execute a kernel on DPA.

RPC is mainly used for control path.

The RPC's return value is reported back to the host application.

```
doca_error_t doca_dpa_rpc(struct doca_dpa *dpa, doca_dpa_func_t *func, uint64_t *retval, … /* func arguments */)
```

Example:

- Device-side – DPA device `func` must be annotated with `__dpa_rpc__` annotation, such as:

```
__dpa_rpc__ uint64_t hello_rpc(int arg)
{
    ...
}
```

- Host-side:

```
extern doca_dpa_func_t hello_rpc;

uint64_t retval;
doca_dpa_rpc(dpa, &hello_rpc, &retval, 10);
```

Kernel Launch

DOCA DPA provides an API which enables full control for launching and monitoring kernels.

Since DOCA DPA libraries are not thread-safe, it is up to the programmer to make sure the kernel is written to allow it to run in a multi-threaded environment. For example, to program a kernel that uses RDMAs with 16 concurrent threads, the user should pass an array of 16 RDMAs to the kernel so that each thread can access its RDMA using its rank (`doca_dpa_dev_thread_rank()`) as an index to the array.

```
doca_dpa_kernel_launch_update_<add|set>(struct doca_dpa *dpa, struct doca_sync_event *wait_event, uint64_t
wait_threshold, struct doca_sync_event *comp_event, uint64_t comp_count, unsigned int num_threads, doca_dpa_func_t
*func, ... /* args */)
```

- This function asks DOCA DPA to run `func` in DPA by `num_threads` and give it the supplied list of arguments (variadic list of arguments).
- This function is asynchronous so when it returns, it does not mean that `func` started/ended its execution.
- To add control or flow/ordering to these asynchronous kernels, two optional parameters for launching kernels are available:
    - `wait_event` – the kernel does not start its execution until the event is signaled (if NULL, the kernel starts once DOCA DPA has an available EU to run on it) which means that DOCA DPA would not run the kernel until the event's counter is bigger than `wait_threshold` .

> ⚠ Please note that the valid values for `wait_threshold` and `wait_event` counter and are [0-254]. Values out of this range might cause anomalous behavior.

  - `comp_event` – once the last thread running the kernel is done, DOCA DPA updates this event (either sets or adds to its current counter value with `comp_count`).
- DOCA DPA takes care of packing (on host/Target BlueField) and unpacking (in DPA) the kernel parameters.
- `func` must be prefixed with the `__dpa_global__` macro for DPACC to compile it as a kernel (and add it to DPA executable binary) and not as part of host application binary.
- The programmer must declare `func` in their application also by adding the line `extern doca_dpa_func_t func`.

> ⚠ The following APIs are only relevant for a kernel used in `kernel_launch` APIs. These APIs are not relevant in `doca_dpa_thread` kernel.

- To retrieve the running thread's rank for a given kernel on the DPA. If, for example, a kernel is launched to run with 16 threads, each thread running this kernel is assigned a rank ranging from 0 to 15 within this kernel. This is helpful for making sure each thread in the kernel only accesses data relevant for its execution to avoid data-races:

```
unsigned int doca_dpa_dev_thread_rank()
```

- To return the number of threads running current kernel:

```
unsigned int doca_dpa_dev_num_threads()
```

- To yield the thread which runs the kernel:

```
void doca_dpa_dev_yield(void)
```

Examples

Linear Execution Example

Device-side pseudo code:

```
#include "doca_dpa_dev.h"
#include "doca_dpa_dev_sync_event.h"

__dpa_global__ void
linear_kernel(doca_dpa_dev_sync_event_t wait_ev, doca_dpa_dev_sync_event_t comp_ev)
{
    if (wait_ev)
        doca_dpa_dev_sync_event_wait_gt(wait_ev, wait_th = 0);
```

```
    doca_dpa_dev_sync_event_update_add(comp_ev, comp_count = 1);
}
```

Host-side pseudo code:

```
#include <doca_dev.h>
#include <doca_error.h>
#include <doca_sync_event.h>
#include <doca_dpa.h>

int main(int argc, char **argv)
{

    /*
        A
        |
        B
        |
        C
    */

    /* Open DOCA device */
    open_doca_dev(&doca_dev);
    /* Create doca dpa conext */
    doca_dpa_create(doca_dev, dpa_linear_app, &dpa_ctx, 0);

    /* Create event A - subscriber is DPA and publisher is CPU */
    doca_sync_event_create(&ev_a);
    doca_sync_event_add_publisher_location_cpu(ev_a, doca_dev);
    doca_sync_event_add_subscriber_location_dpa(ev_a, dpa_ctx);
    doca_sync_event_start(ev_a);

    /* Create event B - subscriber and publisher are DPA */
    doca_sync_event_create(&ev_b);
    doca_sync_event_add_publisher_location_dpa(ev_b, dpa_ctx);
    doca_sync_event_add_subscriber_location_dpa(ev_b, dpa_ctx);
    doca_sync_event_start(ev_b);

    /* Create event C - subscriber and publisher are DPA */
    doca_sync_event_create(&ev_c);
    doca_sync_event_add_publisher_location_dpa(ev_c, dpa_ctx);
    doca_sync_event_add_subscriber_location_dpa(ev_c, dpa_ctx);
    doca_sync_event_start(ev_c);

    /* Create completion event for last kernel - subscriber is CPU and publisher is DPA */
    doca_sync_event_create(&comp_ev);
    doca_sync_event_add_publisher_location_dpa(comp_ev, dpa_ctx);
    doca_sync_event_add_subscriber_location_cpu(comp_ev, doca_dev);
    doca_sync_event_start(comp_ev);

    /* Export kernel events and acquire their handles */
    doca_sync_event_get_dpa_handle(ev_b, dpa_ctx, &ev_b_handle);
    doca_sync_event_get_dpa_handle(ev_c, dpa_ctx, &ev_c_handle);
    doca_sync_event_get_dpa_handle(comp_ev, dpa_ctx, &comp_ev_handle);

    /* Launch kernels */
    doca_dpa_kernel_launch_update_add(wait_ev = ev_a, wait_threshold = 1, num_threads = 1, &linear_kernel,
kernel_args: NULL, ev_b_handle);
    doca_dpa_kernel_launch_update_add(wait_ev = NULL,  num_threads = 1, &linear_kernel, kernel_args: ev_b_handle,
ev_c_handle);
    doca_dpa_kernel_launch_update_add(wait_ev = NULL, &linear_kernel, num_threads = 1, kernel_args: ev_c_handle,
comp_ev_handle);

    /* Update host event to trigger kernels to start executing in a linear manner */
    doca_sync_event_update_set(ev_a, 1)

    /* Wait for completion of last kernel */
    doca_sync_event_wait_gt(comp_ev, 0);

    /* Tear Down... */
    teardown_resources();
}
```

Diamond Execution Example

Device-side pseudo code:

```
#include "doca_dpa_dev.h"
#include "doca_dpa_dev_sync_event.h"

__dpa_global__ void
diamond_kernel(doca_dpa_dev_sync_event_t wait_ev, uint64_t wait_th, doca_dpa_dev_sync_event_t comp_ev1,
doca_dpa_dev_sync_event_t comp_ev2)
{
    if (wait_ev)
        doca_dpa_dev_sync_event_wait_gt(wait_ev, wait_th);

    doca_dpa_dev_sync_event_update_add(comp_ev1, comp_count = 1);
    if (comp_ev2)    // can be 0 (NULL)
        doca_dpa_dev_sync_event_update_add(comp_ev2, comp_count = 1);
}
```

Host-side pseudo code:

```
#include <doca_dev.h>
#include <doca_error.h>
#include <doca_sync_event.h>
#include <doca_dpa.h>

int main(int argc, char **argv)
{
    /*
         A
        / \
       C   B
      /   /
     D   /
      \ /
       E
    */

    /* Open DOCA device */
    open_doca_dev(&doca_dev);
    /* Create doca dpa conext */
    doca_dpa_create(doca_dev, dpa_diamond_app, &dpa_ctx, 0);

    /* Create root event A that will signal from the host the rest to start */
    doca_sync_event_create(&ev_a);
    // set publisher to CPU, subscriber to DPA and start event

    /* Create events B,C,D,E */
    doca_sync_event_create(&ev_b);
    doca_sync_event_create(&ev_c);
    doca_sync_event_create(&ev_d);
    doca_sync_event_create(&ev_e);
    // for events B,C,D,E, set publisher & subscriber to DPA and start event

    /* Create completion event for last kernel */
    doca_sync_event_create(&comp_ev);
    // set publisher to DPA, subscriber to CPU and start event

    /* Export kernel events and acquire their handles */
    doca_sync_event_get_dpa_handle(&ev_b_handle, &ev_c_handle, &ev_d_handle, &ev_e_handle, &comp_ev_handle);

    /* wait threshold for each kernel is the number of parent nodes */
    constexpr uint64_t wait_threshold_one_parent {1};
    constexpr uint64_t wait_threshold_two_parent {2};

    /* launch diamond kernels */
    doca_dpa_kernel_launch_update_set(wait_ev = ev_a, wait_threshold = 1, num_threads = 1, &diamond_kernel,
kernel_args: NULL, 0, ev_b_handle, ev_c_handle);
    doca_dpa_kernel_launch_update_set(wait_ev = NULL, num_threads = 1, &diamond_kernel, kernel_args: ev_b_handle,
wait_threshold_one_parent, ev_e_handle, NULL);
    doca_dpa_kernel_launch_update_set(wait_ev = NULL, num_threads = 1, &diamond_kernel, kernel_args: ev_c_handle,
wait_threshold_one_parent, ev_d_handle, NULL);
    doca_dpa_kernel_launch_update_set(wait_ev = NULL, num_threads = 1, &diamond_kernel, kernel_args: ev_d_handle,
wait_threshold_one_parent, ev_e_handle, NULL);
    doca_dpa_kernel_launch_update_set(wait_ev = NULL, num_threads = 1, &diamond_kernel, kernel_args: ev_e_handle,
wait_threshold_two_parent, comp_ev_handle, NULL);

    /* Update host event to trigger kernels to start executing in a diamond manner */
    doca_sync_event_update_set(ev_a, 1);
    /* Wait for completion of last kernel */
    doca_sync_event_wait_gt(comp_ev, 0);

    /* Tear Down... */
    teardown_resources();
}
```

Performance Optimizations

- The time interval between a kernel launch call from the host and the start of its execution on the DPA is significantly optimized when the host application calls `doca_dpa_kernel_launch_update_<add|set>()` repeatedly to execute with the same number of DPA threads. So, if the application calls `doca_dpa_kernel_launch_update_<add|set>(..., num_threads = x)`, the next call with `num_threads = x` would have a shorter latency (as low as ~5-7 microseconds) for the start of the kernel's execution.
- Applications calling for kernel launch with a wait event (i.e., the completion event of a previous kernel) also have significantly lower latency in the time between the host launching the kernel and the start of the execution of the kernel on the DPA. So, if the application calls `doca_dpa_kernel_launch_update_<add|set>( ...,`

`completion event = m_ev, ...)` and then `doca_dpa_kernel_launch_update_<add|set>( wait event = m_ev, ...)`, the latter kernel launch call would have shorter latency (as low as ~3 microseconds) for the start of the kernel's execution.

Limitations

- The order in which kernels are launched is important. If an application launches K1 and then K2, K1 must not depend on K2's completion (e.g., wait on its wait event that K2 should update).
  Not following this guideline leads to unpredictable results (at runtime) for the application and might require restarting the DOCA DPA context (i.e., destroying, reinitializing, and rerunning the workload).
- DPA threads are an actual hardware resource and are, therefore, limited in number to 256 (including internal allocations and allocations explicitly requested by the user as part of the kernel launch API)
  - DOCA DPA does not check these limits. It is up to the application to adhere to this number and track thread allocation across different DPA contexts.
  - Each `doca_dpa_dev_rdma_t` consumes one thread.
- The DPA has an internal watchdog timer to make sure threads do not block indefinitely. Kernel execution time must be finite and not exceed the time returned. by `doca_dpa_get_kernel_max_run_time`.
- The `num_threads` parameter in the `doca_dpa_kernel_launch` call cannot exceed the maximum allowed number of threads to run a kernel returned.
  by `doca_dpa_get_max_threads_per_kernel`.

Logging and Tracing

DOCA DPA provides a set of debugging APIs to allow diagnosing and troubleshooting any issues on the device, as well as accessing real-time information from the running application.

Logging in the data path has significant impact on an application's performance. While the tracer provided by the library is of high-frequency and is designed to prevent significant impact on the application's performance.

Therefore, it is recommended to use:

- Logging in the control path
- Tracing in the data path

You can control the log/trace file path and device log verbosity.

- To set/get the trace file path:

```
doca_error_t doca_dpa_trace_file_set_path(struct doca_dpa *dpa, const char *file_path)
doca_error_t doca_dpa_trace_file_get_path(struct doca_dpa *dpa, char *file_path, uint32_t *file_path_len);
```

- To set/get the log file path:

```
doca_error_t doca_dpa_log_file_set_path(struct doca_dpa *dpa, const char *file_path)
doca_error_t doca_dpa_log_file_get_path(struct doca_dpa *dpa, char *file_path, uint32_t *file_path_len)
```

- To set/get device log verbosity:

```
doca_error_t doca_dpa_set_log_level(struct doca_dpa *dpa, doca_dpa_dev_log_level_t log_level)
doca_error_t doca_dpa_get_log_level(struct doca_dpa *dpa, doca_dpa_dev_log_level_t *log_level)
```

Error Handling

DPA context can enter an error state caused by the device flow. The application can check this error state by calling the following host API:

```
doca_error_t doca_dpa_peek_at_last_error(const struct doca_dpa *dpa)
```

If a fatal error core dump and crash occur, data is written to the file path `/tmp/doca_dpa_fatal` or to the file path set by the API `doca_dpa_log_file_set_path()`, with the suffixes `.PID.core` and `.PID.crash` respectively, where PID is the process ID. The data written to the file would include a memory snapshot at the time of the crash, which would contain instrumental information in pinpointing the cause of a crash (e.g., the program's state, variable values, and the call stack).

Creating core dump files can be done after the DPA application has crashed.

This call does not reset the error state.

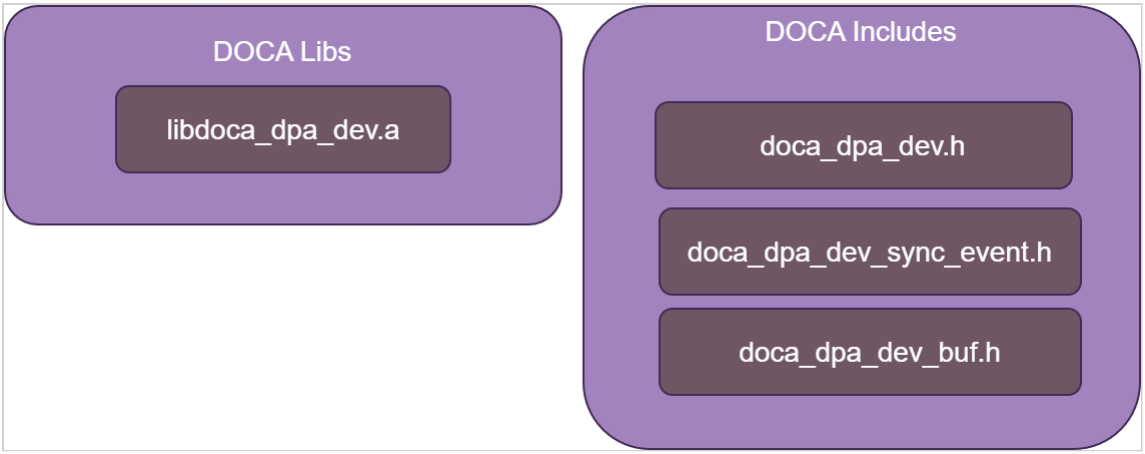
If an error occurred, DPA context enters a fatal state and must be destroyed by the user.

DOCA DPA Device Library

DOCA DPA device library offers an interface for common utilities such as:

- Managing DPA thread
- Managing DPA completion context
- Managing DPA hash table
- Log and trace
- Managing DPA sync event
- Managing DPA DOCA buf and mmap

DPA device library and header files:



DPA Thread

- Thread restart APIs
  DPA thread can ends its run using one of the following device APIs:
  - Reschedule API:

    ```
    void doca_dpa_dev_thread_reschedule(void)
    ```

    - DPA thread is still active
    - DPA thread resources are back to RTOS
    - DPA thread can be triggered again
  - Finish API:

    ```
    void doca_dpa_dev_thread_finish(void)
    ```

    - DPA thread is marked as finished
    - DPA thread resources are back to RTOS
    - DPA thread cannot be triggered again
- To get TLS:

  ```
  doca_dpa_dev_uintptr_t doca_dpa_dev_thread_get_local_storage(void)
  ```

  This function returns DPA thread local storage previously set using the host API `doca_dpa_thread_set_local_storage()`.

⚠ DPA thread device APIs cannot be used in the user's written kernel which is used in the DOCA DPA kernel launch API.

Completion Context

Kernels get `doca_dpa_dev_completion_t` handle and invoke the following API:

- To get a completion element:

```
int doca_dpa_dev_get_completion(doca_dpa_dev_completion_t dpa_comp_handle,
doca_dpa_dev_completion_element_t *comp_element)
```

Use the returned `comp_element` to retrieve completion info using the APIs below.

- To get completion element type:

```
typedef enum {
    DOCA_DPA_DEV_COMP_SEND = 0x0,                /**< Send completion */
    DOCA_DPA_DEV_COMP_RECV_RDMA_WRITE_IMM = 0x1, /**< Receive RDMA Write with Immediate completion */
    DOCA_DPA_DEV_COMP_RECV_SEND = 0x2,           /**< Receive Send completion */
    DOCA_DPA_DEV_COMP_RECV_SEND_IMM = 0x3,       /**< Receive Send with Immediate completion */
    DOCA_DPA_DEV_COMP_SEND_ERR = 0xD,            /**< Send Error completion */
    DOCA_DPA_DEV_COMP_RECV_ERR = 0xE             /**< Receive Error completion */
} doca_dpa_dev_completion_type_t;

doca_dpa_dev_completion_type_t doca_dpa_dev_get_completion_type(doca_dpa_dev_completion_element_t
comp_element)
```

- To get completion element user data:

```
uint32_t doca_dpa_dev_get_completion_user_data(doca_dpa_dev_completion_element_t comp_element)
```

This API returns user data which:

  - Was set previously in host API `doca_dpa_async_ops_create(..., user_data, ...)`
    When DPA completion context is attached to the DPA async ops.
  - Equivalent to `connection_id` in `doca_error_t doca_rdma_connection_get_id(const struct doca_rdma_connection *rdma_connection, uint32_t *connection_id)`
    When DPA completion context is attached to DOCA RDMA context.

- To get completion element immediate data:

```
uint32_t doca_dpa_dev_get_completion_immediate(doca_dpa_dev_completion_element_t comp_element)
```

This API returns immediate data for a completion element of type:

  - `DOCA_DPA_DEV_COMP_RECV_RDMA_WRITE_IMM`
  - `DOCA_DPA_DEV_COMP_RECV_SEND_IMM`

- To acknowledge that the completions have been read on the DPA completion context:

```
void doca_dpa_dev_completion_ack(doca_dpa_dev_completion_t dpa_comp_handle, uint64_t num_comp)
```

This API releases resources of the acked completion elements in the completion context. This acknowledgment enables receiving new `num_comp` completions.

- To request notification on the DPA completion context:

```
void doca_dpa_dev_completion_request_notification(doca_dpa_dev_completion_t dpa_comp_handle)
```

This API enables requesting new notifications on the DPA completion context. If this function is not called, the DPA completion context is not notified on newly arrived completion elements. Therefore, new completions are not populated in DPA completion context.

Example (device-side pseudo code):

```
__dpa_global__ void hello_kernel(uint64_t arg)
{
    // User is expected to pass in some way the attached completion context handle "dpa_comp_handle" to kernel such
as func_arg or a shared memory.
    DOCA_DPA_DEV_LOG_INFO("Hello from kernel\n");

    doca_dpa_dev_completion_element_t comp_element;
    found = doca_dpa_dev_get_completion(dpa_comp_handle, &comp_element);
    if (found) {
        comp_type = doca_dpa_dev_get_completion_type(comp_element);
        // process the completion according to completion type...

        // ack on 1 completion
        doca_dpa_dev_completion_ack(dpa_comp_handle, 1);

        // enable getting more completions and triggering the thread
        doca_dpa_dev_completion_request_notification(dpa_comp_handle);
  }

    // reschedule thread
    doca_dpa_dev_thread_reschedule();
}
```

Thread Notification

Kernels get `doca_dpa_dev_notification_completion_t` handle and invoke the following API:

```
void doca_dpa_dev_thread_notify(doca_dpa_dev_notification_completion_t comp_handle)
```

Calling this API triggers the attached DPA Thread (the one that is specified in `dpa_thread` parameter in host-side API `doca_dpa_notification_completion_create()`).

Asynchronous Ops

Kernels get the `doca_dpa_dev_async_ops_t` handle and invoke the APIs listed below.

Users may control work request submit configuration using the following enum:

```
/**
 * @brief DPA submit flag type
 */
__dpa_global__ enum doca_dpa_dev_submit_flag {
    DOCA_DPA_DEV_SUBMIT_FLAG_NONE = 0U,
    DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH = (1U << 0),          /**
                                * Use flag to inform related DPA context
                                * (such as RDMA or DPA Async ops) to flush related
                                * operation and previous operations to HW,
                                * otherwise the context may aggregate the operation
                                * and not flush it immediately
                                */
    DOCA_DPA_DEV_SUBMIT_FLAG_OPTIMIZE_REPORTS = (1U << 1), /**
                                * Use flag to inform related DPA context that it may
                                * defer completion of the operation to a later time. If
                                * flag is not provided then a completion will be raised
                                * as soon as the operation is finished, and any
                                * preceding completions that were deferred will also be
                                * raised. Use this flag to optimize the amount of
                                * completion notifications it receives from HW when
                                * submitting a batch of operations, by receiving a
                                * single completion notification on the entire batch.
                                */
};
```

This enum can be used in the `flags` parameter in the following device APIs:

- To post a memcpy operation using `doca_buf`:

  ```
  void doca_dpa_dev_post_buf_memcpy(doca_dpa_dev_async_ops_t async_ops_handle, doca_dpa_dev_buf_t
  dst_buf_handle, doca_dpa_dev_buf_t src_buf_handle, uint32_t flags)
  ```

This API copies data between two DOCA buffers. The destination buffer, specified by `dst_buf_handle`, will contain the copied data after memory copy is complete. This is a non-blocking routine.

- To post a memcpy operation using `doca_mmap` and an explicit address:

```
void doca_dpa_dev_post_memcpy(doca_dpa_dev_async_ops_t async_ops_handle,
                              doca_dpa_dev_mmap_t dst_mmap_handle,
                              uint64_t dst_addr,
                              doca_dpa_dev_mmap_t src_mmap_handle,
                              uint64_t src_addr,
                              size_t length,
                              uint32_t flags)
```

This API copies data between two DOCA Mmaps. The destination DOCA Mmap (`dst_addr`), specified by `dst_mmap_handle`, will contain the copied data in source DOCA Mmap specified by `src_mmap_handle`, `src_addr`, and `length` after memory copy is complete. This is a non-blocking routine.

> Use this API for memcpy instead of using the `doca_buf memcpy` API to gain better performance.

- To post a wait greater operation on a DOCA Sync Event:

```
void doca_dpa_dev_sync_event_post_wait_gt(doca_dpa_dev_async_ops_t async_ops_handle,
doca_dpa_dev_sync_event_t wait_se_handle, uint64_t value)
```

This function posts a wait operation on the DOCA Sync Event using DPA async ops to obtain DPA thread activation. The attached thread is activated when the value of a DOCA Sync Event is greater than a given value. This is a non-blocking routine.

> Valid values must be in the range [0, 254] and can be called for an event with a value in the range [0, 254]. Invalid values leads to anomalous behavior.

- To post a wait not equal operation on a DOCA Sync Event:

```
void doca_dpa_dev_sync_event_post_wait_ne(doca_dpa_dev_async_ops_t async_ops_handle,
doca_dpa_dev_sync_event_t wait_se_handle, uint64_t value)
```

This function posts a wait operation on the DOCA Sync Event using the DPA async ops to obtain DPA thread activation. The attached thread is activated when the value of DOCA Sync Event is not equal to a given value. This is a non-blocking routine.

Memory Subsystem

Memory APIs supplied by the DOCA DPA SDK are all asynchronous (i.e., non-blocking).

The user can acquire either:

1. Pre-configured DOCA Buffers (previously configured with `doca_buf_arr_set_params`).

2. Non-configured DOCA Buffers and use below device setters to configure them.

Device-side API operations:

- To obtain a single buffer handle from the buf array handle:

```
doca_dpa_dev_buf_t doca_dpa_dev_buf_array_get_buf(doca_dpa_dev_buf_arr_t buf_arr, const uint64_t buf_idx)
```

- To set/get the address pointed to by the buffer handle:

```
void doca_dpa_dev_buf_set_addr(doca_dpa_dev_buf_t buf, uintptr_t addr)
uintptr_t doca_dpa_dev_buf_get_addr(doca_dpa_dev_buf_t buf)
```

- To set/get the length of the buffer:

```
void doca_dpa_dev_buf_set_len(doca_dpa_dev_buf_t buf, size_t len)
uint64_t doca_dpa_dev_buf_get_len(doca_dpa_dev_buf_t buf)
```

- To set/get the DOCA Mmap associated with the buffer:

```
void doca_dpa_dev_buf_set_mmap(doca_dpa_dev_buf_t buf, doca_dpa_dev_mmap_t mmap)
doca_dpa_dev_mmap_t doca_dpa_dev_buf_get_mmap(doca_dpa_dev_buf_t buf)
```

- To get a pointer to external memory registered on the host using DOCA Buffer:

```
doca_dpa_dev_uintptr_t doca_dpa_dev_buf_get_external_ptr(doca_dpa_dev_buf_t buf)
```

> After calling this API, users can read/write the memory indicated by the returned pointer from the DPA kernel.

- To get a pointer to external memory registered on the host using an explicit address and DOCA Mmap:

```
doca_dpa_dev_uintptr_t doca_dpa_dev_mmap_get_external_ptr(doca_dpa_dev_mmap_t mmap_handle, uint64_t addr)
```

> After calling this API, users can read/write the memory indicated by the returned pointer from the DPA kernel.

Sync Events

Sync events fulfill the following roles:

- DOCA DPA execution model is asynchronous and sync events are used to control various threads running in the system (allowing order and dependency)
- DOCA DPA supports remote sync events, so the programmer is capable of invoking remote nodes by means of DOCA sync events

> For host-side APIs, refer to "DOCA Sync Event".

- To get the current event value:

```
doca_dpa_dev_sync_event_get(doca_dpa_dev_sync_event_t event, uint64_t *value)
```

- To add/set to the current event value:

```
doca_dpa_dev_sync_event_update_<add|set>(doca_dpa_dev_sync_event_t event, uint64_t value)
```

- To wait until event is greater than threshold:

```
doca_dpa_dev_sync_event_wait_gt(doca_dpa_dev_sync_event_t event, uint64_t value, uint64_t mask)
```

  Use mask to apply bitwise AND on the DOCA Sync Event value for comparison with the wait threshold.

Extended DOCA DPA Context

To work with a DPA resource created on an extended DOCA DPA context, DOCA DPA offers the following device API:

```
void doca_dpa_dev_device_set(doca_dpa_dev_t dpa_handle)
```

This function must be called before calling any related device API of a DPA resource (e.g., DPA RDMA) created on an extended DOCA DPA context.

> When creating only a DPA base context without an extended DPA context in this application, there is no need to call this API.

> When creating DPA resources on both base and extended DPA contexts, the proper DPA device (and DPA context) must be set before calling the relevant DPA resource API.

Example (device-side pseudo code):

```
__dpa_global__ void kernel(uint64_t thread_arg)
{
    // parse completion...

    // set extended device before executing RDMA operation
    doca_dpa_dev_device_set(thread_arg->extended_dpa_ctx_handle);
    doca_dpa_dev_rdma_post_send(rdma_dpa_handle);
    ...
}
```

Data Structures

Hash Table

This data structure is managed on DPA using the following device APIs:

- To add a new entry to the hash table:

```
void doca_dpa_dev_hash_table_add(doca_dpa_dev_hash_table_t ht_handle, uint32_t key, uint64_t value)
```

> ⚠ Adding a new key when the hash table is full causes anomalous behavior.

- To remove an entry from the hash table:

```
void doca_dpa_dev_hash_table_remove(doca_dpa_dev_hash_table_t ht_handle, uint32_t key)
```

- To return the value to which the specified key is mapped in the hash table:

```
int doca_dpa_dev_hash_table_find(doca_dpa_dev_hash_table_t ht_handle, uint32_t key, uint64_t *value)
```

Logging and Tracing

- Log to host:

```
typedef enum doca_dpa_dev_log_level {
    DOCA_DPA_DEV_LOG_LEVEL_DISABLE = 10, /**< Disable log messages */
    DOCA_DPA_DEV_LOG_LEVEL_CRIT = 20,    /**< Critical log level */
    DOCA_DPA_DEV_LOG_LEVEL_ERROR = 30,   /**< Error log level */
    DOCA_DPA_DEV_LOG_LEVEL_WARNING = 40, /**< Warning log level */
    DOCA_DPA_DEV_LOG_LEVEL_INFO = 50,    /**< Info log level */
    DOCA_DPA_DEV_LOG_LEVEL_DEBUG = 60,   /**< Debug log level */
} doca_dpa_dev_log_level_t;

void doca_dpa_dev_log(doca_dpa_dev_log_level_t log_level, const char *format, ...)
```

- Log macros:

```
DOCA_DPA_DEV_LOG_CRIT(...)
DOCA_DPA_DEV_LOG_ERR(...)
DOCA_DPA_DEV_LOG_WARN(...)
DOCA_DPA_DEV_LOG_INFO(...)
DOCA_DPA_DEV_LOG_DBG(...)
```

- To create a trace message entry with arguments:

```
void doca_dpa_dev_trace(uint64_t arg1, uint64_t arg2, uint64_t arg3, uint64_t arg4, uint64_t arg5)
```

- To flush the trace message buffer to host:

```
void doca_dpa_dev_trace_flush(void)
```

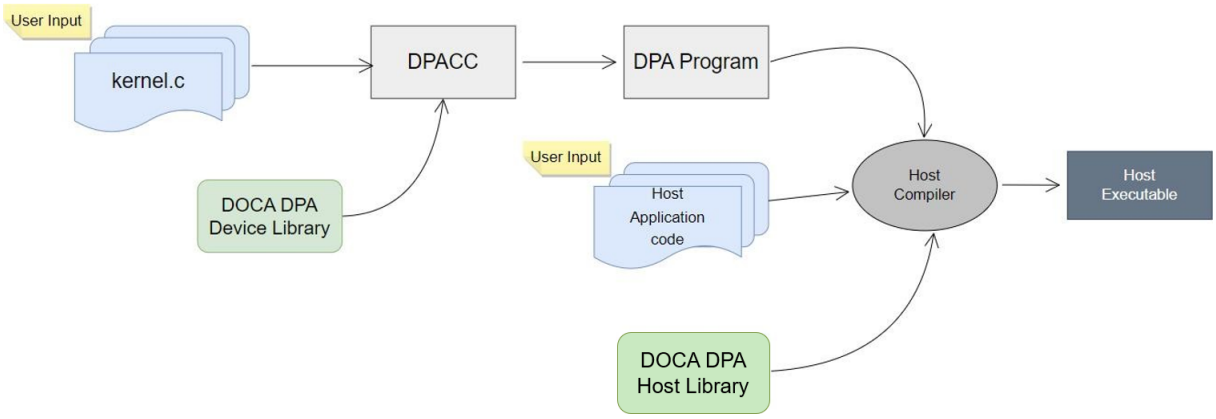
5.4.3.6.6 Hello World Example

> ⚠ The provided example code demonstrates the basic functionality and flow of the DPA but is not intended to be executed as-is due to missing initializations. For complete and runnable DPA examples, refer to the full samples in the Samples section.

5.4.3.6.6.1 Procedure Outline

1. Write DPA device code (i.e., kernels or `.c` files).

2. Use DPACC to build a DPA program (i.e., a host library which contains an embedded device executable). Input for DPACC:
    a. Kernels from step 1.
    b. DOCA DPA device library.
3. Build host executable using a host compiler. Input for the host compiler:
    a. DPA program.
    b. User host application `.c` / `.cpp` files.
4. Run host executable.



5.4.3.6.6.2 Procedure Steps

The following code snippets show a basic DPA code that eventually prints "Hello World" to `stdout`.

This is achieved using:

- A DPA Thread which prints the string and signals a DOCA Sync Event to indicate completion to host application
- A DPA RPC to notify DPA Thread

The steps are elaborated in the following subsections.

Prepare Kernels Code

```
#include "doca_dpa_dev.h"
#include "doca_dpa_dev_sync_event.h"

__dpa_global__ void hello_world_thread_kernel(uint64_t arg)
{
    DOCA_DPA_DEV_LOG_INFO("Hello World From DPA Thread!\n");
    doca_dpa_dev_sync_event_update_set(arg, 1);
    doca_dpa_dev_thread_finish();
}

__dpa_rpc__ uint64_t hello_world_thread_notify_rpc(doca_dpa_dev_notification_completion_t comp_handle)
{
    DOCA_DPA_DEV_LOG_INFO("Notifying DPA Thread From RPC\n");
    doca_dpa_dev_thread_notify(comp_handle);
    return 0;
}
```

Prepare Host Application Code

```
#include <stdio.h>
```

```c
#include <unistd.h>
#include <doca_dev.h>
#include <doca_error.h>
#include <doca_sync_event.h>
#include <doca_dpa.h>

/**
 * A struct that includes all needed info on registered kernels and is initialized during linkage by DPACC.
 * Variable name should be the token passed to DPACC with --app-name parameter.
 */
extern struct doca_dpa_app *dpa_hello_world_app;

/**
 * kernel declaration that the user must declare for each kernel and DPACC is responsible to initialize.
 * Only then, user can use this variable in relevant host APIs
 */
doca_dpa_func_t hello_world_thread_kernel;
doca_dpa_func_t hello_world_thread_notify_rpc;

int main(int argc, char **argv)
{
    struct doca_dev *doca_dev = NULL;
    struct doca_dpa *dpa_ctx = NULL;
    struct doca_sync_event *cpu_se = NULL;
    doca_dpa_dev_sync_event_t cpu_se_handle = 0;
    struct doca_dpa_thread *dpa_thread = NULL;
    struct doca_dpa_notification_completion *notify_comp = NULL;
    doca_dpa_dev_notification_completion_t notify_comp_handle = 0;
    uint64_t retval = 0;

    printf("\n----> Open DOCA Device\n");
    /* Open appropriate DOCA device doca_dev */

    printf("\n----> Initialize DOCA DPA Context\n");
    doca_dpa_create(doca_dev, &dpa_ctx);
    doca_dpa_set_app(dpa_ctx, dpa_hello_world_app);
    doca_dpa_start(dpa_ctx);

    printf("\n----> Initialize DOCA Sync Event\n");
    doca_sync_event_create(&cpu_se);
    doca_sync_event_add_publisher_location_dpa(cpu_se, dpa_ctx);
    doca_sync_event_add_subscriber_location_cpu(cpu_se, doca_dev);
    doca_sync_event_start(cpu_se);
    doca_sync_event_get_dpa_handle(cpu_se, dpa_ctx, &cpu_se_handle);

    printf("\n----> Initialize DOCA DPA Thread\n");
    doca_dpa_thread_create(dpa_ctx, &dpa_thread);
    doca_dpa_thread_set_func_arg(dpa_thread, &hello_world_thread_kernel, cpu_se_handle);
    doca_dpa_thread_start(dpa_thread);

    printf("\n----> Initialize DOCA DPA Notification Completion\n");
    doca_dpa_notification_completion_create(dpa_ctx, dpa_thread, &notify_comp);
    doca_dpa_notification_completion_start(notify_comp);
    doca_dpa_notification_completion_get_dpa_handle(notify_comp, &notify_comp_handle);

    printf("\n----> Run DOCA DPA Thread\n");
    doca_dpa_thread_run(dpa_thread);

    printf("\n----> Trigger DPA RPC\n");
    doca_dpa_rpc(dpa_ctx, &hello_world_thread_notify_rpc, &retval, notify_comp_handle);

    printf("\n----> Waiting For hello_world_thread_kernel To Finish\n");
    doca_sync_event_wait_gt(cpu_se, 0, 0xFFFFFFFFFFFFFFFF);

    printf("\n----> Destroy DOCA DPA Notification Completion\n");
    doca_dpa_notification_completion_destroy(notify_comp);

    printf("\n----> Destroy DOCA DPA Thread\n");
    doca_dpa_thread_destroy(dpa_thread);

    printf("\n----> Destroy DOCA DPA event\n");
    doca_sync_event_destroy(cpu_se);

    printf("\n----> Destroy DOCA DPA context\n");
    doca_dpa_destroy(dpa_ctx);

    printf("\n----> Destroy DOCA device\n");
    doca_dev_close(doca_dev);

    printf("\n----> DONE!\n");
    return 0;
}
```

Build DPA Program

```
/opt/mellanox/doca/tools/dpacc \
    kernel.c \
    -o dpa_program.a \
    -hostcc=gcc \
    -hostcc-options="-Wno-deprecated-declarations -Werror -Wall -Wextra -W" \
    --devicecc-options="-D__linux__ -Wno-deprecated-declarations -Werror -Wall -Wextra -W" \
    --app-name="dpa_hello_world_app" \
    --mcpu=nv-dpa-bf3 \
    --device-libs="-L/opt/mellanox/doca/lib/x86_64-linux-gnu/ -ldoca_dpa_dev" \
    -I/opt/mellanox/doca/include/
```

Build Host Application

```
gcc hello_world.c -o hello_world \
    dpa_program.a \
    -I/opt/mellanox/doca/include/ \
    -DDOCA_ALLOW_EXPERIMENTAL_API \
    -L/opt/mellanox/doca/lib/x86_64-linux-gnu/ -ldoca_dpa -ldoca_common \
    -L/opt/mellanox/flexio/lib/ -lflexio \
    -lstdc++ -libverbs -lmlx5
```

Execution

```
$  ./hello_world

----> Open DOCA Device

----> Initialize DOCA DPA Context

----> Initialize DOCA Sync Event

----> Initialize DOCA DPA Thread

----> Initialize DOCA DPA Notification Completion

----> Run DOCA DPA Thread

----> Trigger DPA RPC
/ 10/[DOCA][DPA DEVICE][INF] Notifying DPA Thread From RPC
/  8/[DOCA][DPA DEVICE][INF] Hello World From DPA Thread!

----> Waiting For hello_world_thread_kernel To Finish

----> Destroy DOCA DPA Notification Completion

----> Destroy DOCA DPA Thread

----> Destroy DOCA DPA event

----> Destroy DOCA DPA context

----> Destroy DOCA device

----> DONE!
```

5.4.3.6.7 Samples

This section provides DPA sample implementation on top of the BlueField-3 networking platform.

> All DOCA samples in this section are provided under the BSD-3 software license and are also available on GitHub.

DPA samples can be executed from either the host or the DPU.

When running from the DPU and using RDMA utilities, the RDMA DOCA device (SF device) must be provided as a parameter. If not specified, a random RDMA device is selected.

In this case:

- The DOCA DPA context is created on the PF device.
- An extended DPA context is created on the SF device.
- The DOCA RDMA context is created on the SF device.

> All DPA resources (e.g., DPA threads, DPA completion contexts) associated with the SF RDMA instance must be created using the extended DPA context.

To run DPA samples:

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - *NVIDIA BlueField Platform Software Troubleshooting Guide* for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_dpa/<sample_name>
meson /tmp/build
ninja -C /tmp/build
```

   The binary `doca_<sample_name>` is created under `/tmp/build/`.

3. Sample (e.g., `dpa_initiator_target`) usage:

```
Usage: doca_dpa_initiator_target [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -pf_dev, --pf-device <PF DOCA device name> PF device name that supports DPA (optional). If not provided
then a random device will be chosen
-rdma_dev, --rdma-device <RDMA DOCA device name> device name that supports RDMA (optional). If not provided
then a random device will be chosen
  --dpa-resources <DPA resources file> Path to a DPA resources .yaml file
  --dpa-app-key <DPA application key> Application key in specified DPA resources .yaml file
  -g, --gid-index                   GID index for DOCA RDMA (optional)
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name> -h
```

5.4.3.6.7.1 Basic Initiator Target

This sample illustrates how to trigger DPA Thread using DPA Completion Context attached to DOCA RDMA.

This sample consists of initiator and target endpoints.

In the initiator endpoint, a DOCA RDMA executes RDMA post send operation using DPA RPC.

In the target endpoint, a DOCA RDMA, attached to DPA Completion Context, executes RDMA post receive operation using DPA RPC.

Completion on the post receive operation triggers DPA Thread which prints completion info and sets DOCA Sync Event to release the host application that waits on that event before destroying all resources and finish.

The sample logic includes:

1. Allocating DOCA DPA and DOCA RDMA resources for both initiator and target endpoints.
2. Target – Attaching DOCA RDMA to DPA Completion Context which is attached to DPA Thread.
3. Running DPA thread.
4. Target – DPA RPC to execute RDMA post receive operation.
5. Initiator – DPA RPC to execute RDMA post send operation.
6. The completion on the post receive operation triggers DPA Thread.
7. Waiting on completion event to be set from DPA Thread.
8. Destroying all resources.

5.4.3.6.7.2 Advanced Initiator Target

This sample illustrates how to trigger DPA threads using both DPA Notification Completion and DPA Completion Context which is attached to a DOCA RDMA context with 2 connections.

This sample consists of initiator and target endpoints.

In the initiator endpoint, two DOCA RDMA connections execute an RDMA post send operation using DPA RPC in the following order:

1. Connection #0 executes the RDMA post send operation on buffer with value 1.
2. Connection #1 executes the RDMA post send operation on buffer with value 2.
3. Connection #0 executes the RDMA post send operation on buffer with value 3.
4. Connection #1 executes the RDMA post send operation on buffer with value 4.

In the target endpoint, DOCA RDMA context with two connections is attached to a single DPA Completion Context which is attached to DPA Thread #1.

Target RDMA executes the initial RDMA post receive operation using DPA RPC.

Completions on the post receive operations trigger DPA Thread #1 which:

1. Prints completion info including user data.
2. Updates a local data base with the receive buffer value.
3. Repost RDMA receive operation.
4. Ack, request completion and reschedule.

Once target DPA Thread #1 receives all expected values "1, 2, 3, 4", it notifies DPA Thread #2 and finishes.

Once DPA Thread #2 is triggered, it sets DOCA Sync Event to release the host application that waits on that event before destroying all resources and finishing.

The sample logic includes:

1. Allocating DOCA DPA and DOCA RDMA resources for both initiator and target endpoints.
2. Target: Attaching DOCA RDMA to DPA Completion Context which is attached to DPA Thread #1.
3. Target: Attaching DPA Notification Completion to DPA Thread #2.
4. Run DPA threads.
5. Target: DPA RPC to execute the initial RDMA post receive operation.
6. Initiator: DPA RPC to execute all RDMA post send operations.
7. Completions on the post receive operations (4 completions) trigger DPA Thread #1.
8. Once all expected values are received, DPA Thread #1 notifies DPA Thread #2 and finishes.
9. Waiting on completion event to be set from DPA Thread #2.

10. Destroying all resources.

5.4.3.6.7.3 Ping Pong

This sample illustrates the functionality of the following DPA objects:

- DPA Thread
- DPA Completion Context
- DOCA RDMA

This sample consists of ping and pong endpoints which run for 100 iterations. On each iteration, DPA threads (ping and pong) post RDMA receive and send operations for data buffers with values [0-99].

Once all expected values are received on each DPA thread, it sets a DOCA Sync Event to release the host application waiting on that event before destroying all resources and finishes.

To trigger DPA threads, the sample uses a DPA RPC.

The sample logic includes:

1. Allocating DOCA DPA and DOCA RDMA resources.
2. Attaching DOCA RDMA to DPA completion context which is attached to DPA thread.
3. Run DPA threads.
4. DPA RPC to trigger DPA threads.
5. 100 ping pong iterations of RDMA post receive and send operations.
6. Waiting on completion events to be set from DPA threads.
7. Destroying all resources.

5.4.3.6.7.4 Kernel Launch

This sample illustrates how to launch a DOCA DPA kernel with wait and completion DOCA sync events.

The sample logic includes:

1. Allocating DOCA DPA resources.
2. Initializing wait and completion DOCA sync events for the DOCA DPA kernel.
3. Running `hello_world` DOCA DPA kernel that waits on the wait event.
4. Running a separate thread that triggers the wait event.
5. `hello_world` DOCA DPA kernel prints "Hello from kernel".
6. Waiting for the completion event of the kernel.
7. Destroying the events and resources.

Reference:

- `/opt/mellanox/doca/samples/doca_dpa/dpa_wait_kernel_launch/dpa_wait_kernel_launch_main.c`

- `/opt/mellanox/doca/samples/doca_dpa/build_dpacc_samples.sh`

5.4.3.6.7.5 NVQual

This sample illustrates a stressor for DOCA DPA by running multiple DPA threads on all available EUs simultaneously. Some EUs perform arithmetic operations, and some perform memory stress operations while measuring the total DPA run time.

The sample logic includes:

1. Allocating DOCA DPA resources, including:
    a. Initializing DOCA sync event to synchronize host and DPA between iterations.
    b. Initializing and configuring DPA threads for each available EU.
    c. Initializing a notification completion for each thread to schedule the thread on available EU in every iteration.

2. Running the following loop, while sufficient time remains:
    a. Notify DPA threads by DPA RPC.
    b. Threads perform memory and arithmetic operations according to their assigned kernels.
    c. Wait for all the completion events of all threads.
    d. Calculate average latency of copying a single byte to/from the DPA heap.
3. Printing sample data summary.
4. Destroying all resources.

Sample usage:

```
Usage: dpa_nvqual [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -pf_dev, --pf-device <PF DOCA device name> PF device name that supports DPA (mandatory).
  -test_dur, --test-duration-sec <test duration sec> test duration seconds (mandatory).
  -user_fac, --user-factor [user factor] user factor from type float (optional). If not provided then 0.75f be
chosen.
  -ex_eu, --excluded-eus [excluded eus] excluded eus list, devided by ',' with no spaced (optional). If not
provided then no eu will be excluded.
```

Use smaller user factor value (e.g., 0.6) when running the sample on NVIDIA® ConnectX®-8 and use higher user factor value (e.g., 0.8) when running it on NVIDIA® ConnectX®-9.

- `/opt/mellanox/doca/samples/doca_dpa/build_dpacc_samples.sh`

5.4.3.6.7.6 Verbs Initiator Target

This sample illustrates how to perform RDMA operations using DOCA Verbs API.

Sample logic:

1. Allocating DOCA DPA resources:

- Initializing and configuring DPA threads and kernels.
- Initializing a buffer on the DPA heap for Verbs operations and attaching mmap.
- Initializing a DPA completion context to replace CQ.
- Initializing a DOCA sync event to synchronize the host and DPA when the data path is finished.

2. Allocating Verbs resources:
    - Verbs context
    - Verbs QP attached to the DPA completion context
    - Verbs PD
    - Verbs AH
3. Establishing a connection between the initiator and target using a TCP socket.
4. Exchanging RDMA parameters:
    - Local buffer addresses
    - MKEYs
    - QP numbers
    - GID addresses
5. Configuring QP attributes and modifying QP states from Reset to Ready to Send.
6. Data path:
    - Initiator:
        - Waits for completion
        - Polls the local buffer value to sync with the target's Write operation
        - Increments the buffer value
        - Posts a Send work request
        - Acknowledges completion
    - Target:
        - Waits for completions
        - Posts a Receive work request
        - Increments the buffer value
        - Posts a Write work request
        - Acknowledges 2 completions
7. Verifying the final buffer value (initiator).
8. Updating the sync event to threshold value (both initiator and target).
9. Printing sample data summary.
10. Destroying all resources.

Sample usage:

```
Usage: dpa_verbs_initiator_target [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>

Program Flags:
  -i, --initiator <Sample is initiator, requires target OOB IP> Sample is initiator, requires target OOB IP
  -d, --device <PF device name>     PF device name
```

```
  -sf_dev, --sf-device <SF device name> SF device name that supports RDMA.
  -gid, --gid-index                GID index for DOCA RDMA (optional)
```

5.4.3.7 DOCA PCC

This guide provides an overview and configuration instructions for the DOCA Programmable Congestion Control (PCC) API.

5.4.3.7.1 Introduction

⚠ The quality status of DOCA libraries is listed here.

The DOCA PCC library offers a high-level programming interface that enables users to implement customized congestion control (CC) algorithms. By leveraging the NVIDIA® BlueField®-3 platform hardware acceleration, it facilitates efficient network congestion management while abstracting away hardware complexities.

With the DOCA PCC API, users can:

- Configure probe packets for sending and receiving
- Retrieve CC events or packets and access their fields
- Set flow rate limits to regulate network traffic
- Maintain per-flow contexts for individualized management
- Initiate and configure CC algorithms tailored to application needs

- Process incoming request packets and generate appropriate response packets

This streamlined API allows developers to focus on designing and implementing congestion control logic without worrying about low-level hardware operations.

5.4.3.7.2 Prerequisites

DOCA PCC-based applications can run on either the host machine or the NVIDIA BlueField-3 Platform (or later) target.

> Currently, DOCA PCC is supported only for the ETHERNET link type.

5.4.3.7.2.1 Enabling DOCA PCC

To enable DOCA PCC RP:

1. On the host/VM, run:

```
mlxconfig -d <mlx_device> -y s USER_PROGRAMMABLE_CC=1
```

2. Perform a graceful shutdown and then power cycle the host.

To enable DOCA PCC NP:

1. On the host/VM, run:

```
mlxconfig -d <mlx_device> -y s PCC_INT_EN=0
```

2. Perform a graceful shutdown and then power cycle the host.

5.4.3.7.2.2 Configuration Notes

- Setting `PCC_INT_EN=1` blocks the creation of DOCA PCC NP context and enables the legacy NP solution. It also only supports DOCA PCC RP context for setting Congestion Control Message After Drop (CCMAD) probe packet format.
- For IFA2.0 support, enable both DOCA PCC RP and DOCA PCC NP on all cluster nodes.
- The DOCA PCC NP process requires root access.
- For BlueField-3 devices in DPU mode, executing the DOCA PCC NP process on an x86 host is not supported.
- When running from an x86 host in NIC mode, privileged permissions are required. Check the privilege level using `mlxprivhost -d <mlx_device> q`.
- To enable the injection of response timestamp information into probe response payloads, you must set `FLEX_PARSER_PROFILE_ENABLE=10` in the device's non-volatile (NV) configuration.

```
mlxconfig -d <mlx_device> -y s FLEX_PARSER_PROFILE_ENABLE=10
```

5.4.3.7.2.3 DPACC Tool

The DPACC tool compiles and links user algorithms and device code with the DOCA PCC device library to create loadable applications. DPACC is included in the DOCA SDK installation package. For more information, refer to DOCA DPACC Compiler documentation.

5.4.3.7.3 Changes From Previous Releases

5.4.3.7.3.1 Changes in 3.3.0

Added

- Support for injecting response timestamp in DOCA PCC NP.

5.4.3.7.4 Dependencies

The library requires firmware version 32.38.1000 and higher.

5.4.3.7.5 Architecture

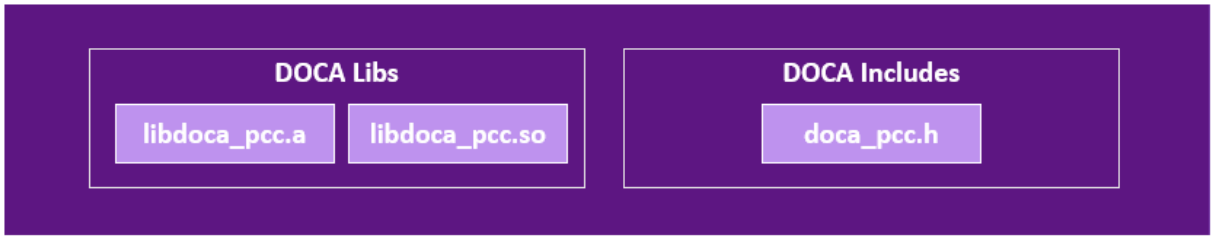
DOCA PCC comprises three main components which are part of the DOCA SDK installation package.

5.4.3.7.5.1 Host Library

The host library offers a unified interface for managing the DOCA PCC context configuration.

As part of the control path, the host library integrates passively within the application, orchestrating congestion control activities without directly handling data transmission.

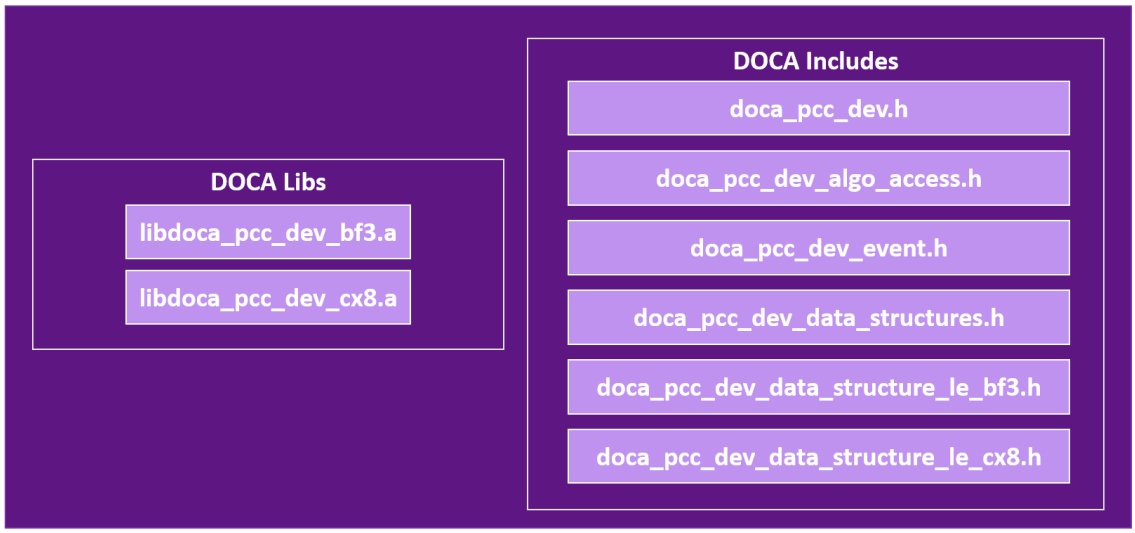
Host/device library and header files:



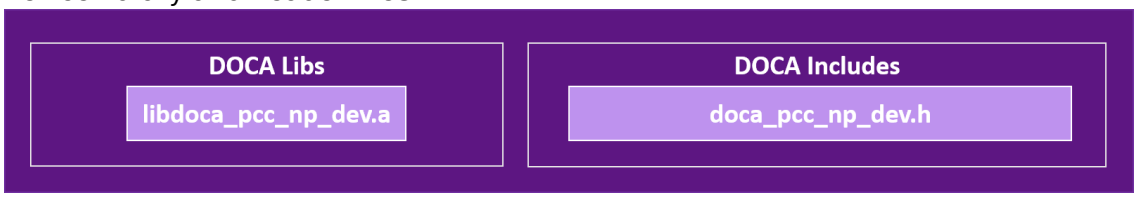
5.4.3.7.5.2 Device Libraries

The DOCA PCC context assumes one of two roles:

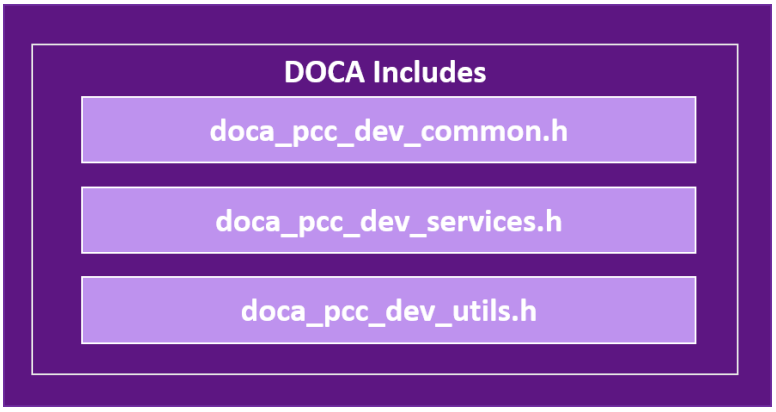
- Reaction point (RP): Monitors network conditions actively, dynamically adjusting data transmission rates to alleviate congestion promptly. RP context is global per NIC.
  Device library and header files:



- Notification point (NP): Passively receives congestion notifications from external sources, processing them intelligently to facilitate informed decisions within the application. NP context is global per e-switch owner.
  Device library and header files:



Both RP and NP device libraries share common headers:



Currently, the device library and the user algorithm are implemented and managed over the BlueField's data-path accelerator (DPA) subsystem.

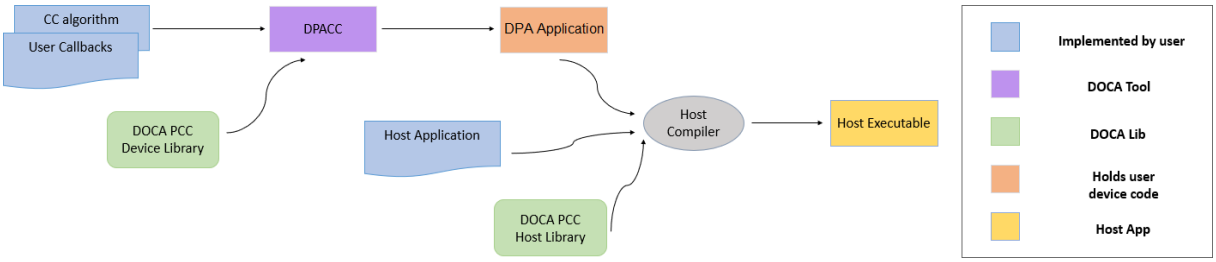
For more info on DPA, refer to DPA Subsystem.

5.4.3.7.5.3 Development Flow

DOCA enables developers to program the congestion control algorithm into the system using the DOCA PCC library.

The following are the required steps to start programming:

1. Implement CC algorithms and probe packet handling using the API provided by the device header files.
2. Implement the user callbacks defined by the library for DataPath:
   - For RP: `doca_pcc_dev_user_init()`, `doca_pcc_dev_user_set_algo_params()`, `doca_pcc_dev_user_algo()`.
   - For NP: `doca_pcc_dev_np_user_packet_handler()`
3. Use DPACC to build a DPA application (i.e., a host library which contains an embedded device executable). Input for DPACC are the files containing the implementation of the previous steps.
4. Build host executable using a host compiler. Inputs for the host compiler are the DPA application generated in the previous step and the user application host source files.
5. In the host executable, create and start a DOCA PCC context which is set with the DPA application containing the device code.

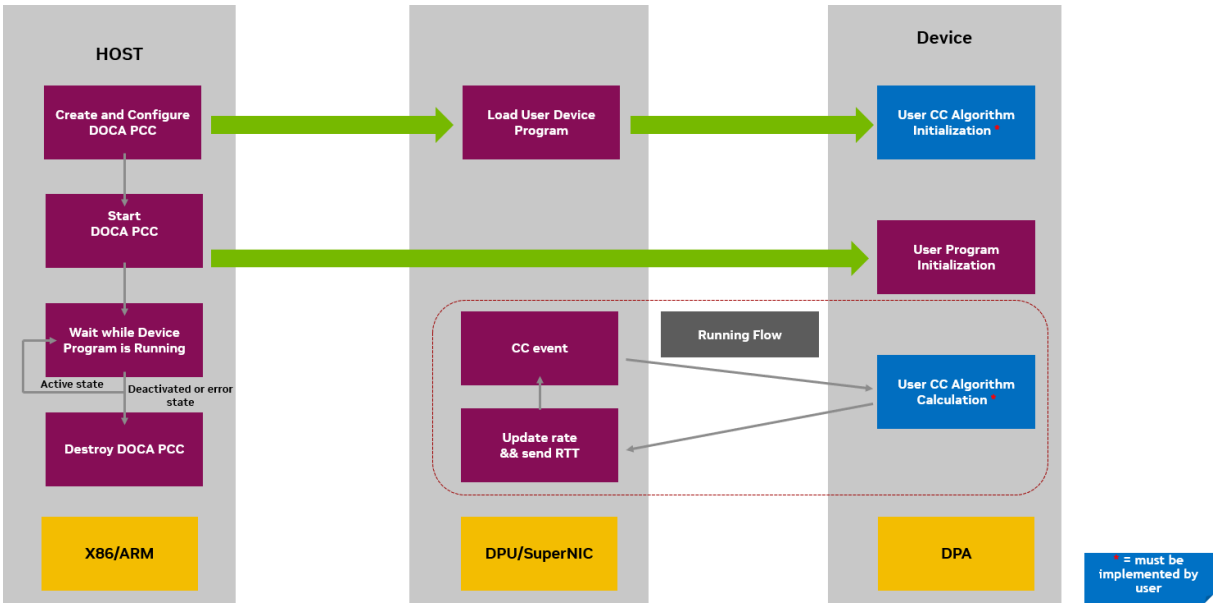


For a more descriptive example, refer to *NVIDIA DOCA PCC Application Guide*.

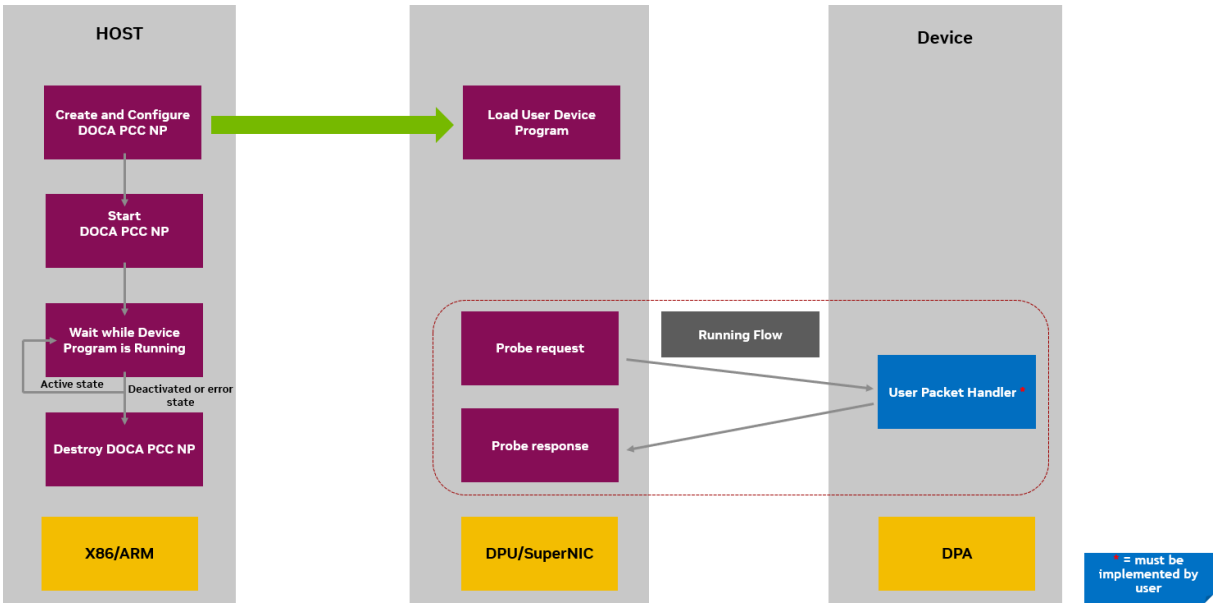
> **Initialization Sequence**
>
> The PCC program must be loaded before the QP is created. If the QP is created first, it will not be able to access the PCC program context. This dependency is strict; reversing the order causes PCC features to fail or result in undefined library behavior.

5.4.3.7.5.4 System Design

DOCA PCC flow for implementing an RP program:



DOCA PCC flow for implementing an NP program:



5.4.3.7.6 API

For the library API reference, refer to PCC API documentation in the API References.

The following sections provide additional details about the library API.

5.4.3.7.6.1 Host API

The host library API consists of calls to set the PCC context attributes and observe availability of the process.

Selecting and Opening DOCA Device

To perform PCC operations, a device must be selected. To select a device, users may iterate over all DOCA devices using `doca_devinfo_list_create()` and check whether the device supports the desired PCC role either via `doca_devinfo_get_is_pcc_supported()` for RP, or `doca_pcc_np_cap_is_supported()` for NP.

Setting Up and Starting DOCA PCC Context

After selecting a DOCA device, a PCC context can be created.

As described in the Architecture section, The DOCA PCC library provides APIs to leverage Reaction Points (RP) and Notification Points (NP) to implement programmable congestion control strategies.

Call `doca_pcc_create()` to create a DOCA PCC RP context, and `doca_pcc_np_create()` to create a DOCA PCC NP context.

Afterwards, the following attributes must be set for the PCC context:

- Context app – the name of the DPA application compiled using DPACC, consisting of the device algorithm and code. This is set using the call `doca_pcc_set_app()`.
- Context threads – the affinity of DPA threads to be used to handle CC events. This is set using the call `doca_pcc_set_thread_affinity()`. The number of threads to be used must be constrained between the minimum and maximum number of threads allowed to run the PCC process (see `doca_pcc_get_min_num_threads()` and `doca_pcc_get_max_num_threads()`). The availability and usage of the threads for PCC is dependent on the complexity of the CC algorithm, link rate, and other potential DPA users.

  > ⚠ Users can manage DPA threads in the system using EU pre-configuration with the `dpaeumgmt` tool. For more information, refer to Single Point of Resource Distribution.

After setting up the context attributes, the context can be started using `doca_pcc_start()`. Starting the context initiates the CC algorithm supplied by the user.

Configuring Probe Packets

The DOCA PCC library provides APIs to configure the probe packet settings to tailor congestion control behaviors according to specific network conditions.

The probe packet serves to probe the network for congestion and gather essential feedback for congestion control algorithms.

The DOCA PCC Library supports the following probe packet types:

- CCMAD – Provides information about the network's round-trip time so the algorithm can detect and adapt to congestion proactively
- IFA1 – In-band Flow Analyzer 1 packets provide in-band congestion feedback for proactive congestion control
- IFA2 – In-band Flow Analyzer 2 packets offer an alternative method for in-band congestion feedback, optimized for specific network environments

Configuring Dedicated Fields for Different Probe Types

The DOCA PCC library provides APIs to configure specific fields in different supported probe packet types.

- IFA1 – support to configure probe marker
- IFA2 – support to configure gns and hop limit

Configuring Remote NP Handler

To enable Reaction Point contexts to interact with remote Notification Point contexts, the DOCA PCC library provides an API to set the expected remote handler type.

When the DOCA PCC RP process expects CCMAD probe packet responses from a DOCA PCC NP process, it should set it as so using the API `doca_pcc_rp_set_ccmad_remote_sw_handler()`. If not set, the DOCA PCC RP process expects that no remote DOCA PCC NP process is activated, and that responses are handled by the remote node's hardware. Note that if using probe types other than CCMAD, probe packet responses are always expected to be generated from a remote DOCA Notification Point process.

RTC Timestamps for PCC

To use the real-time clock (RTC) as the timetable for both DOCA PCC RP (requesting party) and DOCA PCC NP (notifying party), the clocks on both endpoints must be synchronized (e.g., using PTP). Synchronization details are outside the scope of this documentation.

By default, RTT probe packet timestamps are taken from the device's free-running clock. The steps below describe how to configure and use RTC-based timestamps.

Configuring RTC in DOCA PCC RP

1. Enable RTC on the device.

```
mlxconfig -d <mlx_device> -y s REAL_TIME_CLOCK_ENABLE=1
```

2. Configure RTT timestamp format to use RTC (value 2).

```
mlxconfig -d <mlx_device> -y s ROCE_CC_RTT_TIMESTAMP_FORMAT=2
```

This NV config setting requires MFT version 4.34 or newer.

3. retrieve the RTT request timestamp (T1) using the API `doca_pcc_dev_get_rtt_req_recv_timestamp();`. This function is compatible with both RTC and free-running clock sources.

Configure RTC in DOCA PCC NP

1. Enable RTC on the device.

```
mlxconfig -d <mlx_device> -y s REAL_TIME_CLOCK_ENABLE=1
```

2. In the host-side code, configure the NP to use the RTC timestamp source using the following APIs:
   - `doca_pcc_np_cap_is_ts_source_supported()`: Verifies if the device supports the specific timestamp source (defined in `doca_pcc_np_ts_source_t`).
   - `doca_pcc_np_set_ts_source()`: Sets the NP to use the specified timestamp source.

     > ⚠ Configuring the timestamp source in the DOCA PCC NP requires `flexio-sdk` version 25.10.xxxx or newer.

3. In the device code, retrieve the RTT request receive timestamp (T2) using `doca_pcc_np_dev_get_t2_ns()`.

   > ⚠ This API returns a 30-bit value for nanoseconds in little-endian format. It is compatible with both RTC and free-running clock sources.

DOCA PCC Notification Point: Response Timestamp

Response timestamp allows the DOCA PCC Notification Point (NP) to inject timestamp information directly into probe response payloads. This facilitates precise timing measurements in congestion control scenarios by capturing a timestamp at the moment the probe response is transmitted from the port.

When enabled, the timestamp is automatically inserted into the least-significant bits of the last DWORD of the Congestion Control (CC) probe response payload. This allows the Reaction Point (RP) to calculate accurate round-trip times (RTT) and make informed congestion control decisions.

Configuring Response Timestamp

To enable the injection of response timestamps, you must set the Flex Parser profile to 10 in the device's non-volatile (NV) configuration.

```
mlxconfig -d <mlx_device> -y s FLEX_PARSER_PROFILE_ENABLE=10
```

- `doca_pcc_np_cap_is_resp_ts_supported()` – Queries whether the device supports injecting response timestamps into probe response payloads for Notification Point operations.
- `doca_pcc_np_set_resp_ts_size()` – Configures the number of bits (`ts_size`) used for the timestamp within the last DWORD of the payload.
  - `0` : Response timestamp injection is disabled (Default).
  - `1-32` : The timestamp is injected into the least-significant `ts_size` bits of the last DWORD.

    > ⚠ Larger sizes provide higher precision but consume more payload space. Use `doca_pcc_np_set_resp_ts_resolution()` to adjust the time scale if the value range is insufficient.
- `doca_pcc_np_set_resp_ts_resolution()` – Sets the granularity of the timestamp by configuring a right-bit shift applied to the raw timestamp before injection. This allows trading precision for an extended time range.
  - `0` : No shift applied (maximum precision) (Default).
  - `N` : The raw timestamp is right-shifted by `N` bits (effectively dividing by 2^N).
- `doca_pcc_np_set_ts_source()` – Selects the hardware clock source. This setting applies globally to NP operations, affecting both the response timestamp injection and the `doca_pcc_np_dev_get_t2_ns()` device API.

> **Deprecation of Default Timestamp Source**
>
> The `DOCA_PCC_NP_TS_SOURCE_DEFAULT` enum value is deprecated in this release and will be removed in an upcoming version. Applications must explicitly select a valid timestamp source (e.g., `FREE_RUNNING` or `REAL_TIME`).

```
typedef enum {
    DOCA_PCC_NP_TS_SOURCE_FREE_RUNNING = 0,                    /**< Free running timestamp. */
    DOCA_PCC_NP_TS_SOURCE_DEFAULT DOCA_DEPRECATED_ENUM = 0x1, /**< @deprecated Deprecated in this
release; will be removed in an upcoming release. */
    DOCA_PCC_NP_TS_SOURCE_REAL_TIME = 0x2,                     /**< Real time timestamp. */
} doca_pcc_np_ts_source_t;
```

Debuggability

The DOCA PCC library provides a comprehensive set of debugging APIs. These tools allow you to diagnose issues, pinpoint bottlenecks, and access real-time information from your running device-side application.

PCC Tracer

The library's tracer is optimized for high-frequency use. It allows you to observe device algorithm behavior and diagnose issues with negligible impact on application performance.

⚠ PCC tracing is enabled by default when `doca_pcc_start()` is called. By default, trace output is routed to `stdout`.

Tracer API reference:

Category	API Function	Description
State control	`doca_pcc_deactivate_tracer()`	Disables runtime trace printing.
	`doca_pcc_activate_tracer()`	Re-enables tracing dynamically without restarting the PCC context.
Destination config	`doca_pcc_trace_buf_set()`	Routes trace output to a user-supplied buffer. [1]
	`doca_pcc_trace_file_set()`	Routes trace output to a specified file. [1]
	`doca_pcc_trace_buf_get()`	Queries the currently configured destination buffer.
	`doca_pcc_trace_file_get()`	Queries the currently configured destination file. Returns `DOCA_ERROR_BAD_CONFIG` if no file is set.
Formatting and handling	`doca_pcc_set_trace_message()`	Sets the specific trace message string used for device printing. [1]
	`doca_pcc_register_trace_handler()`	Registers a custom callback function for programmatic handling. The callback receives a user context pointer and an array of arriving device trace reports.

1. Must be set before `doca_pcc_start()`.

PCC Logger

The logger handles explicit messages generated by the device API `doca_pcc_dev_printf()`.

⚠ **Performance**

Unlike the tracer, device-side prints incur measurable performance overhead. Use them sparingly for short-term debugging or targeted diagnostics. For ongoing observability, use the PCC Tracer.

Logger API reference:

- `doca_pcc_set_print_buffer_size()` – Configures the size of the buffer used to accumulate device-side print data (`doca_pcc_dev_printf()`) before sending it to the host.

Incurs measurable performance overhead; use sparingly.

Must be set before `doca_pcc_start()`.

Device Coredump File

The coredump utility captures crucial device crash data when an unrecoverable error occurs on the device side of the application. The resulting file includes a memory snapshot at the exact time of the crash, detailing the program's state, variable values, and the call stack.

Coredump API reference:

- `doca_pcc_set_dev_coredump_file()` – Configures the host-side file path to capture device crash data (memory snapshot, call stack, variables) when an unrecoverable error occurs on the device side.

Device Mailbox

The DOCA PCC library provides a set of APIs for sending and receiving messages through a mailbox. This service allows communication between the host and device:

- `doca_pcc_set_mailbox()` – API to set the mailbox attributes for the process.
- `doca_pcc_mailbox_get_request_buffer()` and `doca_pcc_mailbox_get_response_buffer()` – API to get the buffers with which the communication will be handled. User can set the request he wants to send to the device, and get a response back.
- `doca_pcc_mailbox_send()` – API to send the mailbox request to the device. This is a blocking call which invokes a callback on the device `doca_pcc_dev_user_mailbox_handle()` which user can handle.

High Availability

The DOCA PCC library supports High Availability (HA) to ensure continuous operation and recovery if the running PCC process malfunctions. You can achieve this by running multiple PCC processes in parallel.

Process Lifecycle and Failover

1. Call `doca_pcc_start()` to register multiple PCC processes in parallel with the NIC firmware.
2. The firmware designates the first process to register as the ACTIVE process (running on the DPA and handling Congestion Control events). All subsequent processes are automatically placed in STANDBY mode.

3. Continuously observe the status of your processes using `doca_pcc_get_process_state()`. If a state change occurs, the `doca_pcc_wait()` function will return.
4. If the currently ACTIVE process encounters an error or stops processing events, the firmware automatically promotes one of the STANDBY processes to become the new ACTIVE process.
5. The defunct (failed) process must explicitly call `doca_pcc_destroy()` to safely free its allocated resources.

> ⚠ Configuration state is not replicated across processes. When a failover occurs, the replacement process does not automatically receive new algorithm configurations, and any user-applied PPCC commands are lost and must be re-applied manually.

Process States (`doca_pcc_process_state_t`)

The following table details the possible states of a PCC process at any given time:

State Enum	Value	Description	Action Required
`DOCA_PCC_PS_ACTIVE`	`0`	The process is actively handling CC events.	None (Only one process is active at a time).
`DOCA_PCC_PS_STANDBY`	`1`	The process is waiting in standby mode.	None (Another process is currently ACTIVE).
`DOCA_PCC_PS_DEACTIVATED`	`2`	The process was deactivated by the NIC Firmware.	Must call `doca_pcc_destroy()`.
`DOCA_PCC_PS_ERROR`	`3`	The process has encountered an error.	Must call `doca_pcc_destroy()`.

PCC Resources

The PCC Resources API provides a mechanism to parse and query pre-defined PCC resource configurations. This enables applications to discover and utilize the Execution Units (EUs) allocated to them in the Single Point of Resource Distribution (SPRD) file.

The SPRD file is a YAML-formatted configuration file that defines PCC application resources. It specifies:

- Application names (keys).
- The number of allocated EUs per application.
- The specific EU IDs assigned to each application.

> ℹ For file syntax and examples, refer to the Single Point of Resource Distribution documentation.

Key functions:

Function	Description
`doca_pcc_resources_create`	Creates a PCC resources object by parsing an SPRD buffer and extracting the configuration for a specific application
`doca_pcc_resources_get_num_eus`	Releases all resources associated with a PCC resources object
`doca_pcc_resources_get_eus`	Retrieves the number of EUs allocated to the application in the PCC resources object
`doca_pcc_resources_destroy`	Retrieves the array of EU IDs allocated to the application

5.4.3.7.6.2 Device API

The device library API provides the necessary calls to set up and manage your congestion control (CC) algorithms so they can handle CC events arriving directly on the hardware.

Counter Sampling

These APIs allow you to sample NIC byte counters to monitor the amount of data transmitted and received through the NIC.

> **Best Practice**
>
> It is highly recommended to configure the counters inside the `doca_pcc_dev_user_port_info_changed()` callback, as this indicates the correct port state to sample from.

API Function	Description
`doca_pcc_dev_nic_counters_config()`	Prepares the list of counters you want to read.
`doca_pcc_dev_nic_counters_sample()`	Samples and retrieves the new counter values.

Algorithm Access

The Reaction Point (RP) device library supports running multiple PCC algorithms, useful for fast A/B testing and comparative runs. You can utilize the default library algorithm alongside your own custom algorithms.

Category	API Function	Description
Core	`doca_pcc_dev_default_internal_algo()`	Loads the default CC algorithm (can be used fully or partially).
	`doca_pcc_dev_init_algo_slot()`	Assigns a specific algorithm to run on a designated device port (slot).

Category	API Function	Description
Initialization	`doca_pcc_dev_algo_init_param()`	Initiates the algorithm's parameters.
	`doca_pcc_dev_algo_init_counter()`	Initiates the algorithm's counters.
	`doca_pcc_dev_algo_init_metadata()`	Initiates the algorithm's metadata base.

Algorithm Selection

Algorithms are enabled or disabled on specific "algo slots" using either `doca_pcc_dev_init_algo_slot()` or the `mlxreg` command (`cmd_type` 1 and 2).

The algorithm that is ultimately selected for traffic depends on the negotiation between the two connection endpoints:

- Successful negotiation (with ECE): Occurs if both endpoints support Enhanced Congestion Control (ECE). Each Queue Pair (QP) specifies its CC algo slot via ECE. If multiple algorithms are enabled, the one with the lowest shared slot index is selected.
- No negotiation (without ECE): If ECE is not supported or not enabled, no negotiation occurs. The system defaults to the default algorithm slot.
    - For example, When testing with `ib_write_bw`, algorithm negotiation only executes if you pass the `--rdma_cm` parameter on both the client and server (which enables ECE).

Events

The RP device library provides optimized helper functions to access CC events. These supply the runtime data needed to analyze and inspect hardware events and build out your CC algorithm logic.

Utilities

A set of optimized utility macros (such as fixed-point math operations, memory space fences, etc.) are included to streamline the programming of your CC algorithm on the device.

User Callbacks

The library relies on specific user-implemented callbacks to initiate the CC algorithm and handle packet I/O.

> ⚠ These callbacks must be implemented in your code and compiled by DPACC to be properly provided to the DOCA PCC context in your DPA application.

Reaction point (RP) callbacks:

Callback Function	Trigger/Purpose
`doca_pcc_dev_user_init()`	Called on PCC process load. Use this to initialize the data for all user algorithms.
`doca_pcc_dev_user_algo()`	The primary entry point to your custom user algorithm handling code.
`doca_pcc_dev_user_set_algo_params()`	Called whenever an algorithm parameter change is triggered externally.

Notification point (NP) callbacks:

Callback Function	Trigger/Purpose
`doca_pcc_dev_np_user_packet_handler()`	Called immediately upon the arrival of probe packets.

Debuggability

PCC Tracer

The device-side tracer is the preferred method for ongoing observability, designed to minimize performance impact compared to standard prints.

> ⚠ The message format must be pre-configured on the host using `doca_pcc_set_trace_message()`.

API Function	Description
`doca_pcc_dev_trace_5()`	Emits formatted trace records containing up to five arguments.
`doca_pcc_dev_trace_flush()`	Forces a partially filled trace buffer to the host. ⛔ Avoid frequent use; typically reserved for the end of a run.

PCC Logger

Intended strictly for short-term debugging convenience.

API Function	Description
`doca_pcc_dev_printf()`	Prints device-side messages directly to the host `stdout`. ⛔ Frequent use degrades performance, and dropped messages may occur due to limited host buffering.

5.4.3.8 DOCA DPA Comms

5.4.3.8.1 Introduction

> ⚠ This feature is supported at the beta level.

The DOCA DPA device communication library provides a set of communication utilities (e.g., RDMA) to facilitate data transfers between nodes using efficient communication primitives.

The primary communication object is called an RDMA DPA handle. It represents a unidirectional communication pipe between two nodes and is exclusively accessible from the kernel. These handles are established by setting a DOCA RDMA context on the DPA data path.

> ℹ For more information on configuring and using RDMA contexts, refer to DOCA RDMA documentation.

To monitor the completion of communication operations, users can attach a DOCA RDMA context to a DPA Completion Context.

There are two options for tracking completion events:

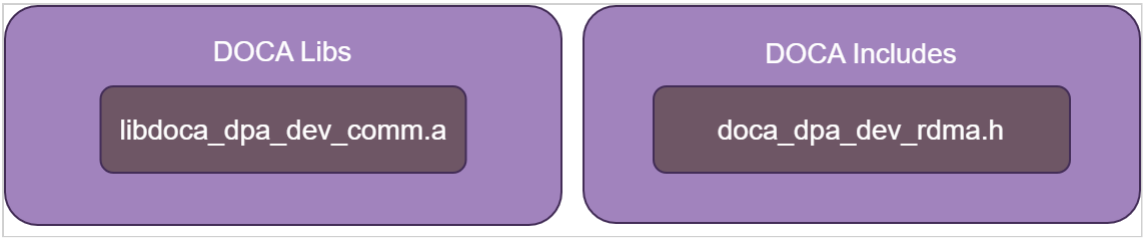
- DPA thread association – Users can associate the Completion Context with a DPA Thread, which is automatically triggered when a communication operation completes.
- Manual polling – Alternatively, users may manually poll the Completion Context without assigning it to a DPA Thread. This approach provides greater control in scenarios where asynchronous event management is not required.

This flexible design allows users to optimize their applications based on specific performance and operational needs.

5.4.3.8.2 Architecture

> ⚠ The DOCA DPA SDK does not implement any multi-thread synchronization primitives. All DOCA DPA objects are non-thread-safe. Developers must ensure that both the user program and kernels are designed to prevent race conditions.

DOCA Comms library and header files:



5.4.3.8.2.1 Relevant Host-side APIs

- To create a DOCA RDMA context on DPA, the following API must be used for the DOCA RDMA context:

```
doca_error_t doca_ctx_set_datapath_on_dpa(struct doca_ctx *ctx, struct doca_dpa *dpa)
```

> ⚠ When running from BlueField and creating DOCA RDMA using an SF DOCA device, or when creating a DOCA RDMA context on DPA, an extended DPA context (created on the same SF DOCA device) must be provided to the `doca_ctx_set_datapath_on_dpa()` API.

- To attach a DOCA RDMA context to a DPA completion context:

```
doca_error_t doca_rdma_dpa_completion_attach(struct doca_rdma *rdma, struct doca_dpa_completion *dpa_comp)
```

- To obtain a DPA RDMA handle and a connection ID:

```
doca_error_t doca_rdma_get_dpa_handle(struct doca_rdma *rdma, doca_dpa_dev_rdma_t *dpa_rdma)
doca_error_t doca_rdma_connection_get_id(const struct doca_rdma_connection *rdma_connection, uint32_t
*connection_id)
```

Use output parameters `dpa_handle` and `connection_id` in relevant device APIs in the thread kernel.

> ⚠ DPA RDMAs are not thread safe and, therefore, must not be used from different kernels/threads concurrently.

- To support multiple DOCA RDMA connection management in DPA, DOCA offers the following APIs:
  - To get the RDMA connection ID using the host API:

    ```
    doca_error_t doca_rdma_connection_get_id(const struct doca_rdma_connection *rdma_connection,
    uint32_t *connection_id)
    ```

    This can also be retrieved in the device using the completion API:

    ```
    uint32_t doca_dpa_dev_get_completion_user_data(doca_dpa_dev_completion_element_t comp_element)
    ```

    The returned value should be used to distinguish which DOCA RDMA connection has triggered this completion.
  - To retrieve the RDMA work request index for an RDMA completion:

```
uint32_t doca_dpa_dev_rdma_completion_get_wr_index(doca_dpa_dev_completion_element_t comp_element)
```

`work request index` should be used to get the operation index of the DOCA RDMA context which triggered this completion.

5.4.3.8.2.2 Device-side APIs

DOCA DPA offers two work models for each device RDMA operation:

- An API for RDMA operation using DOCA buffer
- An API for RDMA operation using DOCA mmap and an explicit memory address

The user may control `work request submit` configuration using the following enum:

```
/**
 * @brief DPA submit flag type
 */
__dpa_global__ enum doca_dpa_dev_submit_flag {
    DOCA_DPA_DEV_SUBMIT_FLAG_NONE = 0U,
    DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH = (1U << 0),          /**
                                * Use flag to inform related DPA context
                                * (such as RDMA or DPA Async ops) to flush related
                                * operation and previous operations to HW,
                                * otherwise the context may aggregate the operation
                                * and not flush it immediately
                                */
    DOCA_DPA_DEV_SUBMIT_FLAG_OPTIMIZE_REPORTS = (1U << 1), /**
                                * Use flag to inform related DPA context that it may
                                * defer completion of the operation to a later time. If
                                * flag is not provided then a completion will be raised
                                * as soon as the operation is finished, and any
                                * preceding completions that were deferred will also be
                                * raised. Use this flag to optimize the amount of
                                * completion notifications it receives from HW when
                                * submitting a batch of operations, by receiving a
                                * single completion notification on the entire batch.
                                */
};
```

This enum can be used in the `flags` parameter in the following device APIs:

- To aggregate multiple operations and flush them at once to hardware using the `DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH` flag:

```
doca_dpa_dev_rdma_post_write(..., DOCA_DPA_DEV_SUBMIT_FLAG_NONE); // This operation is not flushed to HW as
DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH was not used
doca_dpa_dev_rdma_post_write(..., DOCA_DPA_DEV_SUBMIT_FLAG_NONE); // This operation is not flushed to HW as
DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH was not used
doca_dpa_dev_rdma_post_write(..., DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH); // This operation is flushed to HW
together with all non-flushed previous operations as DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH was used
```

- To defer completion of an operation to a later time using the `DOCA_DPA_DEV_SUBMIT_FLAG_OPTIMIZE_REPORTS` flag:

```
doca_dpa_dev_rdma_post_write(..., DOCA_DPA_DEV_SUBMIT_FLAG_OPTIMIZE_REPORTS); // This operation is not
flushed to HW as DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH was not used
                                                                               // and will not trigger a
completion as DOCA_DPA_DEV_SUBMIT_FLAG_OPTIMIZE_REPORTS was used
doca_dpa_dev_rdma_post_write(..., DOCA_DPA_DEV_SUBMIT_FLAG_OPTIMIZE_REPORTS); // This operation is not
flushed to HW as DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH was not used
                                                                               // and will not trigger a
completion as DOCA_DPA_DEV_SUBMIT_FLAG_OPTIMIZE_REPORTS was used
doca_dpa_dev_rdma_post_write(..., DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH); // This operation is flushed to HW
together with all non-flushed previous operations as
                                                                  // DOCA_DPA_DEV_SUBMIT_FLAG_FLUSH was
used.
                                                                  // in addition this operation will
trigger a completion once its done as DOCA_DPA_DEV_SUBMIT_FLAG_OPTIMIZE_REPORTS was NOT used
```

- To read to a local buffer from the remote side buffer:

```
void doca_dpa_dev_rdma_post_read(doca_dpa_dev_rdma_t rdma,
                                 uint32_t connection_id,
                                 doca_dpa_dev_mmap_t dst_mmap_handle,
                                 uint64_t dst_addr,
                                 doca_dpa_dev_mmap_t src_mmap_handle,
                                 uint64_t src_addr,
                                 size_t length,
                                 uint32_t flags)
void doca_dpa_dev_rdma_post_buf_read(doca_dpa_dev_rdma_t rdma,
                                     uint32_t connection_id,
                                     doca_dpa_dev_buf_t dst_buf_handle,
                                     doca_dpa_dev_buf_t src_buf_handle,
                                     uint32_t flags)
```

- To write local memory to the remote side buffer:

```
void doca_dpa_dev_rdma_post_write(doca_dpa_dev_rdma_t rdma,
                                  uint32_t connection_id,
                                  doca_dpa_dev_mmap_t dst_mmap_handle,
                                  uint64_t dst_addr,
                                  doca_dpa_dev_mmap_t src_mmap_handle,
                                  uint64_t src_addr,
                                  size_t length,
                                  uint32_t flags)
void doca_dpa_dev_rdma_post_buf_write(doca_dpa_dev_rdma_t rdma,
                                      uint32_t connection_id,
                                      doca_dpa_dev_buf_t dst_buf_handle,
                                      doca_dpa_dev_buf_t src_buf_handle,
                                      uint32_t flags)
```

- To write local memory to the remote buffer and include immediate data which can be retrieved upon receiving a completion for this operation:

```
void doca_dpa_dev_rdma_post_write_imm(doca_dpa_dev_rdma_t rdma,
                                      uint32_t connection_id,
                                      doca_dpa_dev_mmap_t dst_mmap_handle,
                                      uint64_t dst_addr,
                                      doca_dpa_dev_mmap_t src_mmap_handle,
                                      uint64_t src_addr,
                                      size_t length,
                                      uint32_t immediate,
                                      uint32_t flags)
void doca_dpa_dev_rdma_post_buf_write_imm(doca_dpa_dev_rdma_t rdma,
                                          uint32_t connection_id,
                                          doca_dpa_dev_buf_t dst_buf_handle,
                                          doca_dpa_dev_buf_t src_buf_handle,
                                          uint32_t immediate,
                                          uint32_t flags)
// use the following API to retrieve immediate data on completion
uint32_t doca_dpa_dev_get_completion_immediate(doca_dpa_dev_completion_element_t comp_element)
```

- To send local memory:

```
void doca_dpa_dev_rdma_post_send(doca_dpa_dev_rdma_t rdma,
                                 uint32_t connection_id,
                                 doca_dpa_dev_mmap_t mmap_handle,
                                 uint64_t addr,
                                 size_t length,
                                 uint32_t flags)
void doca_dpa_dev_rdma_post_buf_send(doca_dpa_dev_rdma_t rdma,
                                     uint32_t connection_id,
                                     doca_dpa_dev_buf_t send_buf_handle,
                                     uint32_t flags)
```

- To send local memory with an immediate data which can be retrieved when receiving a completion for this operation:

```
void doca_dpa_dev_rdma_post_send_imm(doca_dpa_dev_rdma_t rdma,
                                     uint32_t connection_id,
                                     doca_dpa_dev_mmap_t mmap_handle,
                                     uint64_t addr,
                                     size_t length,
                                     uint32_t immediate,
                                     uint32_t flags)
void doca_dpa_dev_rdma_post_buf_send_imm(doca_dpa_dev_rdma_t rdma,
                                         uint32_t connection_id,
                                         doca_dpa_dev_buf_t send_buf_handle,
                                         uint32_t immediate,
                                         uint32_t flags)
// use the following API to retrieve immediate data on completion
uint32_t doca_dpa_dev_get_completion_immediate(doca_dpa_dev_completion_element_t comp_element)
```

- To handle posting an RDMA receive operation, use the following APIs:

- To post RDMA receive operation:

```
void doca_dpa_dev_rdma_post_receive(doca_dpa_dev_rdma_t rdma, doca_dpa_dev_mmap_t mmap_handle,
uint64_t addr, size_t length)
void doca_dpa_dev_rdma_post_buf_receive(doca_dpa_dev_rdma_t rdma, doca_dpa_dev_buf_t
receive_buf_handle)
```

- To acknowledge that post receive operations are done (data has been received on associated data buffers):

```
void doca_dpa_dev_rdma_receive_ack(doca_dpa_dev_rdma_t rdma, uint32_t num_acked)
```

  This operation frees `num_acked` entries in the DOCA RDMA context.

- To perform an atomic add operation on the remote buffer:

```
void doca_dpa_dev_rdma_post_atomic_fetch_add(doca_dpa_dev_rdma_t rdma,
                                             uint32_t connection_id,
                                             doca_dpa_dev_mmap_t dst_mmap_handle,
                                             uint64_t dst_addr,
                                             uint64_t value,
                                             uint32_t flags)
void doca_dpa_dev_rdma_post_buf_atomic_fetch_add(doca_dpa_dev_rdma_t rdma,
                                                 uint32_t connection_id,
                                                 doca_dpa_dev_buf_t dst_buf_handle,
                                                 uint64_t value,
                                                 uint32_t flags)
```

- To signal a remote event:

```
doca_dpa_dev_rdma_signal_<add|set>(doca_dpa_dev_rdma_t rdma, uint32_t connection_id,
doca_dpa_dev_sync_event_remote_t remote_sync_event, uint64_t count)
```

5.4.3.9 DOCA DPA Verbs

5.4.3.9.1 Overview

The DOCA DPA Device Verbs library provides RDMA operations support for DPA applications, enabling high-performance RDMA operations (Send, Receive, Read, Write, Atomic) directly on the DPA device without CPU involvement.

The library follows an RDMA-core/ibverbs-like API design pattern, making it intuitive for developers experienced with traditional RDMA programming. It maintains the same conceptual model of work requests, queue pairs, and completion queues but is optimized for execution within DPA kernels.

5.4.3.9.1.1 Work Request Model

The library uses a work request (WR) based model for posting RDMA operations:

- Send Work Requests (`doca_dpa_dev_verbs_send_wr`): For outbound RDMA operations, including Send, RDMA Write, RDMA Read, and Atomic operations.
- Receive Work Requests (`doca_dpa_dev_verbs_recv_wr`): For posting receive buffers for incoming data.

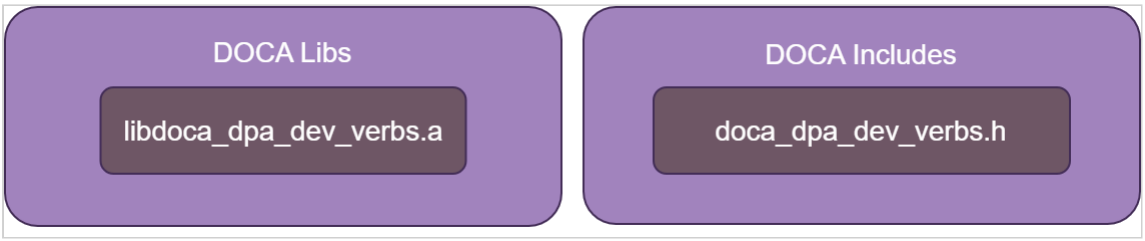
5.4.3.9.1.2 Key Features

- DPA-native RDMA operations: Execute RDMA operations directly on the DPA device.
- RDMA-core compatible interface: Familiar API design following rdma-core/ibverbs patterns.
- Work request based model: Post send and receive work requests similar to traditional RDMA programming.
- Support for QP and SRQ: Enable Queue Pairs and Shared Receive Queues.
- Scatter-gather (SG) operations: Support complex memory layouts with multiple regions per operation.

5.4.3.9.2 Deployment

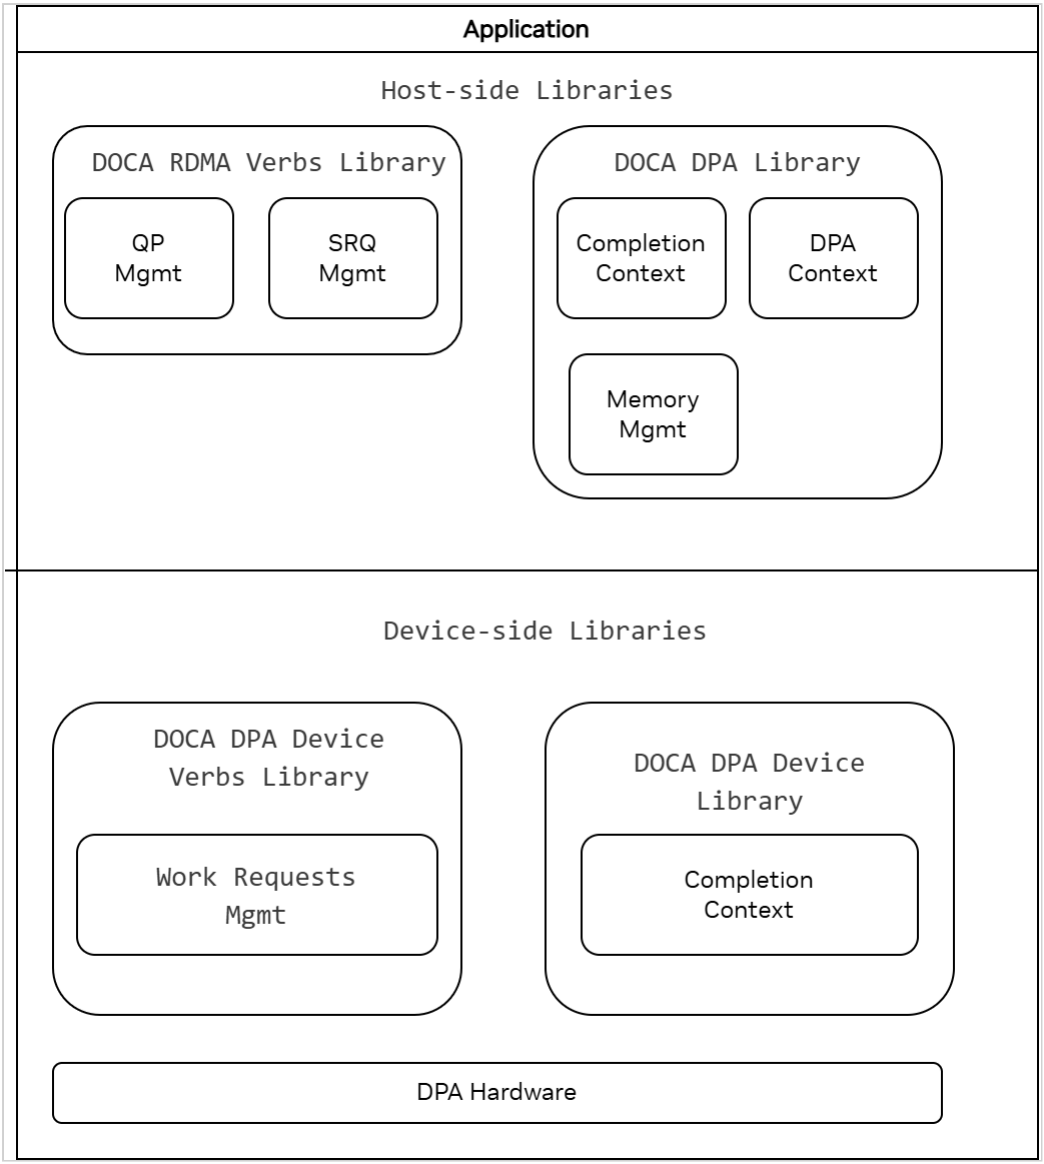
The DOCA DPA Verbs library and header files are:

- `libdoca_dpa_dev_verbs.a` (DOCA Libs)
- `doca_dpa_dev_verbs.h` (DOCA Includes)



5.4.3.9.3 Architecture

The DOCA DPA SDK does not implement multi-thread synchronization primitives, and all DOCA DPA objects are non-thread-safe. Developers must ensure that both the user program and kernels are designed to prevent race conditions.



Component breakdown:

1. Host-side libraries:
    - DOCA RDMA Verbs Library: Handles QP/SRQ creation, configuration, and lifecycle management.
    - DOCA DPA Library: Manages DPA context creation, DPA completion contexts, threads, memory management, and overall DPA orchestration.
2. DPA device libraries:
    - DPA Device Verbs Library: Device-side library for direct RDMA operations.
    - DPA Device Library: Device-side completion context processing and completion element handling.
3. DPA hardware: The underlying DPA device that executes operations.

5.4.3.9.4 Core Concepts

5.4.3.9.4.1 DPA Device Handles

The DOCA DPA Verbs library uses specific handles to represent DPA device resources:

- `doca_dpa_dev_verbs_qp_t`: Handle for a Queue Pair on the DPA device.
- `doca_dpa_dev_verbs_srq_t`: Handle for a Shared Receive Queue on the DPA device.
- `doca_dpa_dev_completion_t`: Handle for a Completion Queue on the DPA device.

5.4.3.9.4.2 Work Request Structures

The library defines structures for work requests:

- `doca_dpa_dev_verbs_send_wr`: Structure for send work requests.
- `doca_dpa_dev_verbs_recv_wr`: Structure for receive work requests.
- `doca_dpa_dev_verbs_sge`: SG element for describing memory regions.

These structures are used to configure and post work requests to Queue Pairs or Shared Receive Queues.

5.4.3.9.4.3 Operation Types

The DOCA DPA Verbs library supports various RDMA operation types:

- Send operations: `SEND` and `SEND_WITH_IMM`
- RDMA operations: `RDMA_WRITE`, `RDMA_WRITE_WITH_IMM`, and `RDMA_READ`
- Atomic operations: `ATOMIC_FETCH_ADD`

5.4.3.9.4.4 DPA Completion Context Management

The library provides a completion context management system that spans both host and device sides:

- Host-side completion contexts (`struct doca_dpa_completion`): Managed by the DOCA DPA Library, with configurable queue size, thread attachment, and lifecycle control.
- Device-side completion context processing: Utilizes the `doca_dpa_dev_completion_t` handle for processing completions on the DPA device.
- DPA completion elements (`doca_dpa_dev_completion_element_t`): Represent individual completion events containing metadata about completed operations.
- Supported completion types include send, receive (RDMA Write with Immediate, Send, Send with Immediate), and error completions.

5.4.3.9.5 API Reference

5.4.3.9.5.1 Enumerations and Constants

The `doca_dpa_dev_verbs.h` header file contains complete enum definitions and values.

Send Work Request Opcodes

The `enum doca_dpa_dev_verbs_send_wr_opcode` defines RDMA operation types:

- `WRITE`: One-sided RDMA write operation.
- `WRITE_WITH_IMM`: RDMA write with immediate data, generating a completion on the receiver.
- `SEND`: Two-sided send operation requiring a posted receive buffer on the remote side.
- `SEND_WITH_IMM`: Send operation with immediate data attached.
- `READ`: One-sided RDMA read operation retrieving data from remote memory.
- `ATOMIC_FETCH_ADD`: Atomic fetch-and-add operation on a remote memory location.

Send Work Request Flags

The `enum doca_dpa_dev_verbs_send_wr_flags` controls work request behavior:

- `SIGNALED`: Generates a completion queue entry (CQE) when the operation completes.
- `SOLICITED`: Requests a solicited event on the remote side (used with send operations).

Fence Modes

The `enum doca_dpa_dev_verbs_send_wr_fm` controls ordering and synchronization between work requests:

- `NO_FENCE`: No ordering constraints for maximum performance.
- `INITIATOR_SMALL_FENCE`: Light ordering constraint for local operations.
- `FENCE`: Standard fence ensuring previous operations complete before this one.
- `STRONG_ORDERING_FENCE`: Strongest ordering guarantee for critical operations.
- `FENCE_AND_INITIATOR_SMALL_FENCE`: Combined fence modes for specific use cases.

SRQ Types

The `enum doca_dpa_dpa_dev_verbs_srq_type` defines Shared Receive Queue implementation types:

- `LINKED_LIST`: SRQ implemented as a linked list structure.
- `CONTIGUOUS`: SRQ implemented as a contiguous memory buffer.

SG Element (SGE) Structure

The `struct doca_dpa_dev_verbs_sge` represents a memory region for data transfer:

- `addr`: Virtual address of the memory region (`uint64_t`).
- `length`: Length of the memory region in bytes (`uint32_t`).
- `lkey`: Local key for the memory region (`uint32_t`).

For non-fully occupied SG lists, set the last entry's `lkey` field to `DOCA_DPA_DEV_VERBS_SGE_TERMINATING_LKEY` (0x100) to indicate the end of valid entries.

5.4.3.9.5.2 Send Work Request Configuration

See `doca_dpa_dev_verbs_send_wr_set_*` and `doca_dpa_dev_verbs_send_wr_get_*` functions in `doca_dpa_dev_verbs.h` for complete API signatures.

These APIs configure send work requests before posting them to a queue pair. Configuration must be completed before posting.

Operation Type

`doca_dpa_dev_verbs_send_wr_set/get_opcode()` : Sets/gets the RDMA operation type (`SEND` , `WRITE` , `READ` , `ATOMIC_FETCH_ADD`), determining the work request's fundamental behavior

Memory Settings

- `doca_dpa_dev_verbs_send_wr_set/get_sg_list()` : Sets/gets the SG list pointing to local memory regions containing the data to send
- `doca_dpa_dev_verbs_send_wr_set/get_sg_num_sge()` : Sets/gets the number of SG elements in the list

Control and Synchronization

- `doca_dpa_dev_verbs_send_wr_set/get_send_flags()` : Sets/gets completion generation and solicited event control flags
- `doca_dpa_dev_verbs_send_wr_set/get_fence_mode()` : Sets/gets ordering constraints between work requests

Optional Data

- `doca_dpa_dev_verbs_send_wr_set/get_imm_data()` : Sets/gets immediate data for `SEND_WITH_IMM` and `WRITE_WITH_IMM` operations

- `doca_dpa_dev_verbs_send_wr_set/get_invalidate_rkey()` : Sets/gets remote key to invalidate for `SEND_WITH_INV` operations

RDMA-specific Configuration

Required for RDMA WRITE and READ operations:

- `doca_dpa_dev_verbs_send_wr_set/get_rdma_remote_addr()` : Sets/gets the target memory address on the remote node
- `doca_dpa_dev_verbs_send_wr_set/get_rdma_rkey()` : Sets/gets the remote memory key for accessing the target memory region

Atomic Operations Configuration

Required for atomic operations:

- `doca_dpa_dev_verbs_send_wr_set/get_atomic_remote_addr()` : Sets/gets the target memory address for the atomic operation
- `doca_dpa_dev_verbs_send_wr_set/get_atomic_rkey()` : Sets/gets the remote memory key for the atomic operation
- `doca_dpa_dev_verbs_send_wr_set/get_atomic_compare_add()` : Sets/gets the value to add in fetch-and-add operations
- `doca_dpa_dev_verbs_send_wr_set/get_atomic_swap()` : Sets/gets the swap value for compare-and-swap operations

5.4.3.9.5.3 Receive Work Request Configuration

See `doca_dpa_dev_verbs_recv_wr_set_*` and `doca_dpa_dev_verbs_recv_wr_get_*` functions in `doca_dpa_dev_verbs.h` for complete API signatures.

These APIs configure and query receive work requests before posting them to a queue pair or SRQ. Receive work requests prepare buffers to receive incoming data from remote nodes. All configuration must be completed before calling the posting APIs.

Configuration

- `doca_dpa_dev_verbs_recv_wr_set/get_sg_list()` : Sets/gets the SG list pointing to local memory regions where incoming data will be stored
- `doca_dpa_dev_verbs_recv_wr_set/get_sg_num_sge()` : Sets/gets the number of SG elements in the list

The receive work request configuration is simpler than send work requests since receive operations are passive - they only specify where to store incoming data.

5.4.3.9.5.4 Work Request Posting

> See `doca_dpa_dev_verbs_qp_post_*` functions in `doca_dpa_dev_verbs.h` for complete API signatures.

This section provides APIs for posting send and receive work requests to queue pairs. All posting functions return a work request counter that can be matched with completion events.

Standard Work Request Posting

- `doca_dpa_dev_verbs_qp_post_send_wr()` : Posts a configured send work request to the send queue. Returns the send work request counter for completion tracking.
- `doca_dpa_dev_verbs_qp_post_recv_wr()` : Posts a receive work request to the receive queue. Prepares the queue to receive incoming data. Returns the send work request counter for completion tracking.

Raw WQE Posting

- `doca_dpa_dev_verbs_qp_post_send_raw_wqe()` : Posts a custom-built send Work Queue Element directly to hardware, bypassing high-level work request processing.
- `doca_dpa_dev_verbs_qp_post_recv_raw_wqe()` : Posts a custom-built receive WQE with specified size.

SG List Usage

When using a SG list (`sg_list`) that is not fully occupied, set the last entry's `lkey` field to `DOCA_DPA_DEV_VERBS_SGE_TERMINATING_LKEY` to indicate the end of valid entries.

5.4.3.9.5.5 Commit Operations

> See `doca_dpa_dev_verbs_qp_*commit*` functions in `doca_dpa_dev_verbs.h` for complete API signatures.

This section provides APIs for committing posted work requests to hardware, making them available for processing by the DPA device. Work requests must be committed for the hardware to process them.

Standard Commit Operations

- `doca_dpa_dev_verbs_qp_commit_send()` : Commits all pending send work requests to hardware with internal memory fence for ordering guarantees.

- `doca_dpa_dev_verbs_qp_commit_recv()` : Commits all pending receive work requests to hardware with internal memory fence.

Lightweight Commit Operations

> ⚠ User must perform memory fence operations before calling these functions.

- `doca_dpa_dev_verbs_qp_lw_commit_send()` : Lightweight send commit without internal memory fence. Higher performance but requires manual memory synchronization.
- `doca_dpa_dev_verbs_qp_lw_commit_recv()` : Lightweight receive commit without internal memory fence. User responsible for proper memory ordering.

5.4.3.9.5.6 Shared Receive Queue (SRQ) Operations

Basic SRQ Operations

- `doca_dpa_dev_verbs_srq_post_recv_wr()` : Posts a receive work request to the SRQ, specifying the SRQ type and receive work request structure.
- `doca_dpa_dev_verbs_srq_commit_recv()` : Commits pending receive work requests to the SRQ with internal memory fence.
- `doca_dpa_dev_verbs_srq_lw_commit_recv()` : Lightweight commit for SRQ receive work requests without internal memory fence. User responsible for memory fence operations.

SRQ Raw WQE Operations

`doca_dpa_dev_verbs_srq_post_recv_raw_wqe()` : Posts a custom-built receive WQE to the SRQ with specified type and size. Follows same principles as QP raw WQE posting.

SG List Usage

When providing a SG list (`sg_list`) that is not fully occupied, the user must set the last entry's lkey field to `DOCA_DPA_DEV_VERBS_SGE_TERMINATING_LKEY` to indicate the end of the valid entries.

SRQ Management

> ⚠ This API is relevant only for Linked-List SRQ.

`doca_dpa_dev_verbs_srq_linked_list_ack_wr()` : Acknowledges processed receive work request in linked list SRQ implementation, specifying the receive work request count (`doca_dpa_dev_completion_element_get_wqe_counter()` return value) to acknowledge.

5.4.3.9.5.7 Query APIs

> ⚠ The following APIs are for debug and inspection purposes only. Do not modify the returned WQ buffers or DBR addresses, as this can cause undefined behavior and system instability.

Queue Pair Query APIs

- `doca_dpa_dev_verbs_qp_get_wq()` : Retrieves work queue attributes, including SQ/RQ buffer addresses, entry counts, and receive WQE size. The returned buffers are read-only; modifying them can cause undefined behavior.
- `doca_dpa_dev_verbs_qp_get_dbr_addr()`: Returns the doorbell record address for the queue pair. The returned address is read-only; modifying it can cause undefined behavior.
- `doca_dpa_dev_verbs_qp_get_qpn()` : Gets the queue pair number.
- `doca_dpa_dev_verbs_qp_get_user_index()` : Retrieves the user-assigned index for the queue pair.

SRQ Query APIs

- `doca_dpa_dev_verbs_srq_get_srqn()` : Gets the SRQ number.
- `doca_dpa_dev_verbs_srq_get_wq()`: Retrieves SRQ work queue attributes, including buffer address, entry count, and WQE size. The returned buffers are read-only; modifying them can cause undefined behavior.

5.4.3.9.6 Integration with Host-side DOCA RDMA Verbs

The DPA Device Verbs library integrates with host-side DOCA RDMA Verbs to provide a complete RDMA solution.

5.4.3.9.6.1 QP/SRQ Configuration Modes

Two mutually exclusive modes are available for configuring Queue Pairs (QP) and Shared Receive Queues (SRQ) with DPA integration.

Mode 1: DPA Context Integration (Basic)

This mode provides full DPA integration, where the DPA context manages all DPA-related resources:

- Set the DPA context using `doca_verbs_qp_init_attr_set_dpa_ctx()` for QPs or `doca_verbs_srq_init_attr_set_dpa_ctx()` for SRQs.
- The DPA context automatically handles memory allocation, doorbell records, and user access regions.

- This is the basic mode for DPA applications due to simplified resource management.

Mode 2: External Resource Management (Advanced)

This mode provides fine-grained control over DPA resources:

- Set external user memory (UMEM) for the work queue buffer using `doca_verbs_qp_init_attr_set_external_umem()` or `doca_verbs_srq_init_attr_set_external_umem()`.
- Set external doorbell record (DBR) using `doca_verbs_qp_init_attr_set_external_dbr_umem()` or `doca_verbs_srq_init_attr_set_external_dbr_umem()`.
- Set external user access region (UAR) using `doca_verbs_qp_init_attr_set_external_uar()`.
- The application is responsible for manual management of all DPA resources.
- This mode requires a deep understanding of DPA resource management and memory allocation.
- It is used for scenarios requiring custom resource allocation strategies and full user control.

Notes:

- These two modes are mutually exclusive; you cannot mix DPA context mode with external resource mode.
- Mode 1 is the basic mode for applications.
- Mode 2 should only be used when custom resource management is required.
- All resources in Mode 2 must be properly aligned and configured according to DPA hardware requirements.

5.4.3.9.6.2 Host-side Setup Requirements

For Mode 1 (DPA Context Integration)

1. Create a DOCA RDMA Verbs context and protection domain.
2. Retrieve the DOCA device from the Verbs PD.
3. Create a DPA context using `doca_dpa_create()`.
4. Configure queue pair initialization attributes.
5. Set the DPA context for the queue pair/SRQ.
6. Create and configure DPA completion contexts.
7. Associate completion contexts with queue pairs.

For Mode 2 (External Resource Management)

1. Create a DOCA RDMA Verbs context and protection domain.
2. Retrieve the DOCA device from the Verbs PD.
3. Allocate and configure external WQ UMEM.

4. Allocate and configure external DBR UMEM.
5. Allocate and configure external UAR.
6. Configure queue pair initialization attributes.
7. Set external resources for the queue pair/SRQ.
8. Create and configure DPA completion contexts.
9. Associate completion contexts with queue pairs.

5.4.3.9.7 Usage Patterns

5.4.3.9.7.1 Basic DPA QP Setup Pattern

```
// Create DOCA RDMA Verbs context and PD
doca_verbs_context_create(devinfo, 0, &verbs_ctx);
doca_verbs_pd_create(verbs_ctx, &pd);

// Retrieve DOCA device from Verbs PD
doca_verbs_pd_as_doca_dev(pd, &dev);

// Create DPA context and completion contexts
doca_dpa_create(dev, &dpa_ctx);
doca_dpa_completion_create(dpa_ctx, 256, &send_completion);
doca_dpa_completion_create(dpa_ctx, 256, &recv_completion);

// Configure QP with DPA completions
doca_verbs_qp_init_attr_create(&qp_init_attr);
doca_verbs_qp_init_attr_set_pd(qp_init_attr, pd);
doca_verbs_qp_init_attr_set_external_datapath_en(qp_init_attr, 1);
doca_verbs_qp_init_attr_set_dpa_ctx(qp_init_attr, dpa_ctx);
doca_verbs_qp_init_attr_set_send_dpa_completion(qp_init_attr, send_completion);
doca_verbs_qp_init_attr_set_receive_dpa_completion(qp_init_attr, recv_completion);

// Create queue pair
doca_verbs_qp_create(verbs_ctx, qp_init_attr, &qp);

// Get DPA handles
doca_dpa_dev_verbs_qp_t dpa_qp;
doca_dpa_dev_completion_t send_comp, recv_comp;

doca_verbs_qp_get_dpa_handle(qp, dpa_ctx, &dpa_qp);
doca_dpa_completion_get_dpa_handle(send_completion, &send_comp);
doca_dpa_completion_get_dpa_handle(recv_completion, &recv_comp);
```

5.4.3.9.7.2 Advanced DPA QP Setup Pattern

```
// Create DOCA RDMA Verbs context and PD
doca_verbs_context_create(devinfo, 0, &verbs_ctx);
doca_verbs_pd_create(verbs_ctx, &pd);

// Retrieve DOCA device from Verbs PD
doca_verbs_pd_as_doca_dev(pd, &dev);

// Create DPA context and completion contexts
doca_dpa_create(dev, &dpa_ctx);
doca_dpa_completion_create(dpa_ctx, 256, &send_completion);
doca_dpa_completion_create(dpa_ctx, 256, &recv_completion);

// Allocate external UMEM for QP using DPA heap addresses
uint64_t qp_wq_dpa_addr = doca_dpa_mem_alloc(dpa_ctx, qp_umem_size);
doca_umem_dpa_create(dpa_ctx, qp_wq_dpa_addr, &qp_umem);

uint64_t dbr_dpa_addr = doca_dpa_mem_alloc(dpa_ctx, qp_dbr_umem_size);
doca_umem_dpa_create(dpa_ctx, dbr_dpa_addr, &qp_dbr_umem);

// Create UAR for doorbell access
doca_uar_dpa_create(dpa_ctx, &dpa_uar);

// Configure QP with external resources
doca_verbs_qp_init_attr_create(&qp_init_attr);
doca_verbs_qp_init_attr_set_pd(qp_init_attr, pd);
doca_verbs_qp_init_attr_set_external_datapath_en(qp_init_attr, 1);
doca_verbs_qp_init_attr_set_external_umem(qp_init_attr, qp_umem, 0);
doca_verbs_qp_init_attr_set_external_dbr_umem(qp_init_attr, qp_dbr_umem, 0);
doca_verbs_qp_init_attr_set_external_uar(qp_init_attr, dpa_uar);
doca_verbs_qp_init_attr_set_send_dpa_completion(qp_init_attr, send_completion);
doca_verbs_qp_init_attr_set_receive_dpa_completion(qp_init_attr, recv_completion);
```

```
// Create queue pair
doca_verbs_qp_create(verbs_ctx, qp_init_attr, &qp);

// Get DPA handles
doca_dpa_dev_verbs_qp_t dpa_qp;
doca_dpa_dev_completion_t send_comp, recv_comp;

doca_dpa_dev_verbs_qp_t dpa_qp;
doca_verbs_qp_get_dpa_handle(qp, dpa_ctx, &dpa_qp);
```

5.4.3.9.7.3 SRQ Setup Pattern

```
// Create SRQ with DPA context
doca_verbs_srq_init_attr_create(&srq_init_attr);
doca_verbs_srq_init_attr_set_pd(srq_init_attr, pd);
doca_verbs_srq_init_attr_set_dpa(srq_init_attr, dpa_ctx);
doca_verbs_srq_create(verbs_ctx, srq_init_attr, &srq);

// Get SRQ handle and post receives
doca_dpa_dev_verbs_srq_t dpa_srq;
doca_verbs_srq_get_dpa_handle(srq, dpa_ctx, &dpa_srq);
```

5.4.3.9.7.4 RDMA Write Operation (Data path example)

```
__dpa_global__ void dpa_rdma_write_example(doca_dpa_dev_verbs_qp_t qp_handle,
                                           uint64_t local_addr,
                                           uint32_t length,
                                           uint32_t lkey,
                                           uint64_t remote_addr,
                                           uint32_t rkey)
{
    struct doca_dpa_dev_verbs_send_wr send_wr;
    struct doca_dpa_dev_verbs_sge sge;

    // Configure scatter-gather element
    sge.addr = local_addr;
    sge.length = length;
    sge.lkey = lkey;

    // Configure RDMA write work request
    doca_dpa_dev_verbs_send_wr_set_opcode(&send_wr, DOCA_DPA_DEV_VERBS_SEND_WR_OPCODE_WRITE);
    doca_dpa_dev_verbs_send_wr_set_sg_list(&send_wr, &sge);
    doca_dpa_dev_verbs_send_wr_set_sg_num_sge(&send_wr, 1);
    doca_dpa_dev_verbs_send_wr_set_rdma_remote_addr(&send_wr, remote_addr);
    doca_dpa_dev_verbs_send_wr_set_rdma_rkey(&send_wr, rkey);
    doca_dpa_dev_verbs_send_wr_set_fence_mode(&send_wr, DOCA_DPA_DEV_VERBS_SEND_WR_FM_NO_FENCE);
    doca_dpa_dev_verbs_send_wr_set_send_flags(&send_wr, DOCA_DPA_DEV_VERBS_SEND_WR_FLAGS_SIGNALED);

    // Post and commit
    uint32_t wr_count = doca_dpa_dev_verbs_qp_post_send_wr(qp_handle, &send_wr);
    doca_dpa_dev_verbs_qp_commit_send(qp_handle);
}
```

5.4.3.9.8 Optimizing Performance with Compile-Time Constants

For better performance:

- Use compile-time constant values for the `opcode` parameter in `doca_dpa_dev_verbs_send_wr_set_opcode()`. This allows the compiler to optimize the code path.
- Use compile-time constant values for the `srq_type` parameter in `doca_dpa_dev_verbs_srq_post_recv_wr()`. This enables the compiler to generate more efficient code paths for SRQ operations.

Example: Use enum values like `DOCA_DPA_DEV_VERBS_SEND_WR_OPCODE_WRITE`, `DOCA_DPA_DEV_VERBS_SRQ_TYPE_LINKED_LIST`, or `DOCA_DPA_DEV_VERBS_SRQ_TYPE_CONTIGUOUS` as literal constants instead of passing them through variables.

5.4.4 DOCA DMA

This guide provides instructions on building and developing applications that require copying memory using Direct Memory Access (DMA).

5.4.4.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

DOCA DMA provides an API to copy data between DOCA buffers using hardware acceleration, supporting both local and remote memory regions.

The library provides an API for executing DMA operations on DOCA buffers, where these buffers reside either in local memory (i.e., within the same host) or host memory accessible by the DPU. See DOCA Core for more information about the memory subsystem.

Using DOCA DMA, complex memory copy operations can be easily executed in an optimized, hardware-accelerated manner.

This document is intended for software developers wishing to accelerate their application's memory I/O operations and access memory that is not local to the host.

5.4.4.2 Prerequisites

This library follows the architecture of a DOCA Core Context, it is recommended read the following sections before:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

5.4.4.3 Library Changes From Previous Releases

5.4.4.3.1 Changes in 2.9.0

N/A

5.4.4.4 Environment

DOCA DMA-based applications can run either on the host machine or on the NVIDIA® BlueField® DPU target.

Copying from Host to DPU and vice versa only works with a DPU configured running in DPU mode as described in BlueField Modes of Operation.

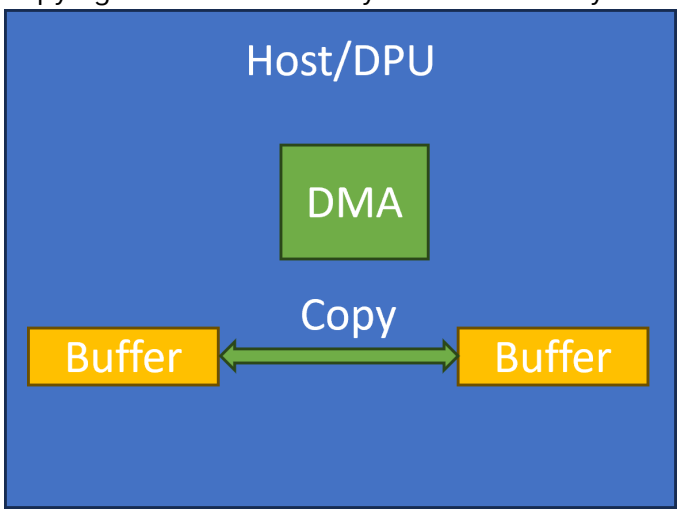
5.4.4.5 Architecture

DOCA DMA is a DOCA Context as defined by DOCA Core. See DOCA Core Context for more information.

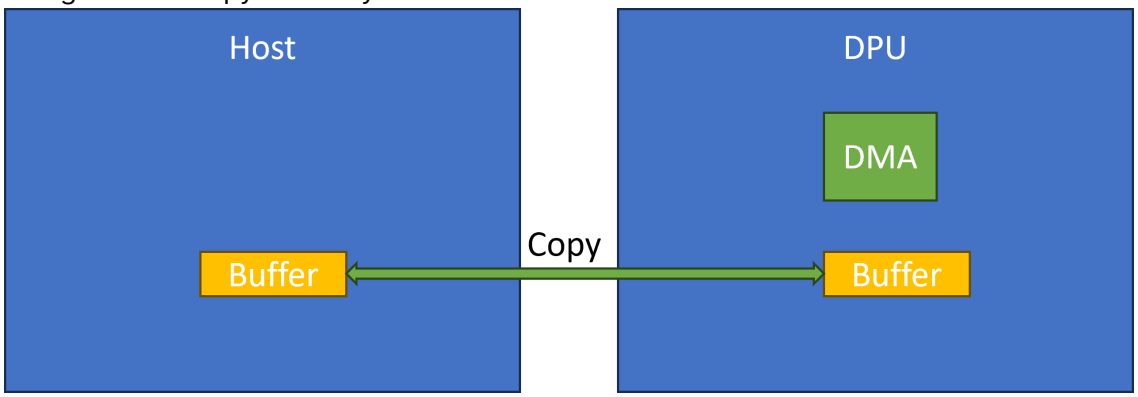
DOCA DMA leverages DOCA Core architecture to expose asynchronous tasks/events that are offloaded to hardware.

DMA can be used to copy data as follows:

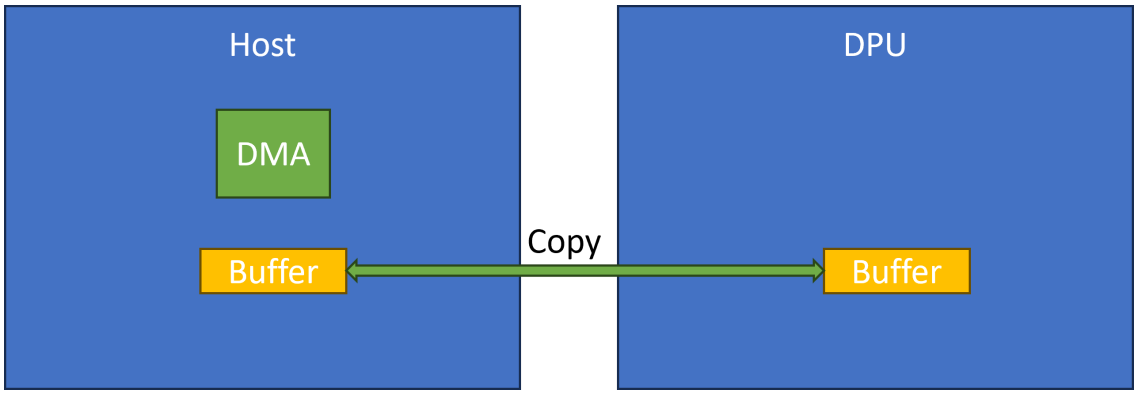
- Copying from local memory to local memory:



- Using DPU to copy memory between host and DPU:



- Using host to copy memory between host and DPU:



5.4.4.5.1 Objects

5.4.4.5.1.1 Device and Device Representor

The DMA library needs a DOCA device to operate. The device is used to access memory and perform the actual copy. See DOCA Core Device Discovery.

For same BlueField DPU, it does not matter which device is used (PF/VF/SF), as all these devices utilize the same hardware component. If there are multiple DPUs, then it is possible to create a DMA instance per DPU, providing each instance with a device from a different DPU.

To access memory that is not local (from the host to the DPU or vice versa), the DPU side of the application must select a device with an appropriate representor. See DOCA Core Device Representor Discovery.

The device must stay valid for as long as the DMA instance is not destroyed.

5.4.4.5.1.2 Memory Buffers

The memory copy task requires two DOCA buffers containing the destination and the source. Depending on the allocation pattern of the buffers, refer to the table in the "Inventory Types" section. To find what kind of memory is supported, refer to the table in section "Buffer Support".

Buffers must not be modified or read during the memory copy operation.

5.4.4.6 Configuration Phase

To start using the library, users must go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context, to allow execution of tasks and retrieval of events.

5.4.4.6.1 Configurations

The context can be configured to match the application use case.

To find if a configuration is supported, or what the min/max value for it is, refer to section "Device Support".

5.4.4.6.1.1 Mandatory Configurations

These configurations are mandatory and must be set by the application before attempting to start the context:

- At least one task/event type must be configured. See configuration of tasks and/or events in sections "Tasks" and "Events" respectively for information.
- A device with appropriate support must be provided upon creation

5.4.4.6.2 Device Support

DOCA DMA requires a device to operate. To select a device, refer to "DOCA Core Device Discovery".

As device capabilities may change (see DOCA Core Device Support), it is recommended to select your device using the following method:

- `doca_dma_cap_task_memcpy_is_supported`

Some devices can allow different capabilities as follows:

- The maximum number of tasks
- The maximum buffer size

5.4.4.6.3 Buffer Support

Tasks support buffers with the following features:

Buffer Type	Source Buffer	Destination Buffer
Local mmap buffer	Yes	Yes
mmap from PCIe export buffer	Yes	Yes
mmap From RDMA export buffer	No	No
Linked list buffer	Yes	Yes

5.4.4.7 Execution Phase

This section describes execution on CPU using DOCA Core Progress Engine.

5.4.4.7.1 Tasks

DOCA DMA exposes asynchronous tasks that leverage the DPU hardware according to the DOCA Core architecture. See DOCA Core Task.

5.4.4.7.1.1 Memory Copy Task

The memory copy task allows copying memory from one location to another. Using buffers as described in Buffer Support.

Task Configuration

Description	API to set the configuration	API to query support
Enable the task	`doca_dma_task_memcpy_set_conf`	`doca_dma_cap_task_memcpy_is_supported`
Number of tasks	`doca_dma_task_memcpy_set_conf`	`doca_dma_cap_get_max_num_tasks`
Maximal buffer size	–	`doca_dma_cap_task_memcpy_get_max_buf_size`
Maximum buffer list size	–	`doca_dma_cap_task_memcpy_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer that points to the memory to be copied	Only the data residing in the data segment is copied
Destination buffer	Buffer that points to where memory is copied	The data is copied to the tail segment extending the data segment

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task is completed successfully:

- The data is copied from the source to the destination
- The destination buffer data segment is extended to include the copied data

Task Completion Failure

If the task fails midway:

- The context may enter stopping state, if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, then the source and destination should not be read/written to
- Source and destination must not overlap
- Other limitations are described in DOCA Core Task

5.4.4.7.2 Events

DOCA DMA exposes asynchronous events to notify on changes that happen unexpectedly, according to DOCA Core architecture.

The only event DMA exposes is common events as described in DOCA Core Event.

5.4.4.8 State Machine

The DOCA DMA library follows the Context state machine as described in DOCA Core Context State Machine.

The following section describes how to move states and what is allowed in each state.

5.4.4.8.1 Idle

In this state it is expected that application:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to section "Configurations"
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all tasks have been freed
Stopping	Call progress until all tasks are completed and freed

5.4.4.8.2 Starting

This state cannot be reached.

5.4.4.8.3 Running

In this state it is expected that application:

- Allocates and submits tasks
- Calls progress to complete tasks and/or receive events

Allowed operations:

- Allocating a previously configured task
- Submitting a task
- Calling stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

5.4.4.8.4 Stopping

In this state it is expected that application:

- Calls progress to complete all inflight tasks (tasks complete with failure)
- Frees any completed tasks

Allowed operations:

- Call progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without freeing all tasks

5.4.4.9 Alternative Datapath Options

DOCA DMA allows data path to be run on the CPU or GPU.

> For the CPU data path, see Execution Phase.

5.4.4.9.1 GPU Datapath

DOCA offers the DOCA GPUNetIO library which provides a programming model for offloading the orchestration of the communication to a GPU CUDA kernel.

The user may run a DMA operation on the GPU data path by configuring the DOCA DMA context used by the application in the following manner:

1. Obtain DOCA CTX by calling `doca_dma_as_ctx()`.
2. Set the datapath of the context to GPU by calling `doca_ctx_set_datapath_on_gpu()`. For additional information, refer to DOCA Core Alternative Data Path.
3. Finish context configuration and start the context by calling `doca_ctx_start()`. For additional information, refer to DOCA Core Context.

After configuring the datapath, the user can obtain a GPU handle for the DOCA RDMA context by calling `doca_dma_get_gpu_handle()`. The GPU handle must be passed to a GPU CUDA kernel so the DOCA GPUNetIO CUDA device functions can execute datapath operations. For additional information, refer to section "GPU Functions – RDMA" under "DOCA GPUNetIO" under DOCA GPUNetIO library documentation.

5.4.4.10 DOCA DMA Samples

This section describes DOCA DMA samples based on the DOCA DMA library.

The samples illustrate how to use the DOCA DMA API to do the following:

- Copy contents of a local buffer to another buffer
- Use DPU to copy contents of buffer on the host to a local buffer

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.4.10.1 Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_dma/dma_local_copy
meson /tmp/build
ninja -C /tmp/build
```

The binary `doca_dma_local_copy` is created under `/tmp/build/`.

3. Sample (e.g., `doca_dma_local_copy`) usage:

```
Usage: doca_<sample_name> [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                            Print a help synopsis
  -v, --version                         Print program version information
  -l, --log-level                       Set the (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                     Parse command line flags from an input json file

Program Flags:
  -p, --pci_addr <PCI-ADDRESS>          PCI device address
  -t, --text                            Text to DMA copy
  -ns, --num-src-buf                    Number of doca_buf for source buffer
  -nd, --num-dst-buf                    Number of doca_buf for destination buffer
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/<sample_name> -h
```

- The command line option "--num-src-buf" and "--num-dst-buf" are used to show linked-list usage of `doca-buf`.
- The maximum supported number of elements is 64.
- And they are only available for `doca_dma_local_copy` and `doca_dma_copy_dpu`, because `doca_dma_copy_host` does not need to construct any `doca_dma_task_memcpy`.

5.4.4.10.2 Samples

These samples are also available on GitHub.

5.4.4.10.2.1 DMA Local Copy

This sample illustrates how to locally copy memory with DMA from one buffer to another on the DPU. This sample should be run on the DPU.

The sample logic includes:

1. Locating DOCA device.
2. Initializing needed DOCA core structures.
3. Populating DOCA memory map with two relevant buffers.
4. Allocating element in DOCA buffer inventory for each buffer.
5. Initializing DOCA DMA memory copy task object.
6. Submitting DMA task.
7. Handling task completion once it is done.

8. Checking task result.
9. Destroying all DMA and DOCA core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_dma/dma_local_copy/dma_local_copy_sample.c`
- `/opt/mellanox/doca/samples/doca_dma/dma_local_copy/dma_local_copy_main.c`
- `/opt/mellanox/doca/samples/doca_dma/dma_local_copy/meson.build`

5.4.4.10.2.2 DMA Copy DPU

> ⚠ This sample should run only after DMA Copy Host is run and the required configuration files (descriptor and buffer) have been copied to the DPU.

This sample illustrates how to copy memory (which contains user defined text) with DMA from the x86 host into the DPU. This sample should be run on the DPU.

The sample logic includes:

1. Locating DOCA device.
2. Initializing needed DOCA core structures.
3. Reading configuration files and saving their content into local buffers.
4. Allocating the local destination buffer in which the host text is to be saved.
5. Populating DOCA memory map with destination buffer.
6. Creating the remote memory map with the export descriptor file.
7. Creating memory map to the remote buffer.
8. Allocating element in DOCA buffer inventory for each buffer.
9. Initializing DOCA DMA memory copy task object.
10. Submitting DMA task.
11. Handling task completion once it is done.
12. Checking DMA task result.
13. If the DMA task ends successfully, printing the text that has been copied to log.
14. Printing to log that the host-side sample can be closed.
15. Destroying all DMA and DOCA core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_dma/dma_copy_dpu/dma_copy_dpu_sample.c`
- `/opt/mellanox/doca/samples/doca_dma/dma_copy_dpu/dma_copy_dpu_main.c`
- `/opt/mellanox/doca/samples/doca_dma/dma_copy_dpu/meson.build`

5.4.4.10.2.3 DMA Copy Host

> ⚠ This sample should be run first. It is user responsibility to transfer the two configuration files (descriptor and buffer) to the DPU and provide their path to the DMA Copy DPU sample.

This sample illustrates how to allow memory copy with DMA from the x86 host into the DPU. This sample should be run on the host.

The sample logic includes:

1. Locating DOCA device.
2. Initializing needed DOCA core structures.
3. Populating DOCA memory map with source buffer.
4. Exporting memory map.
5. Saving export descriptor and local DMA buffer information into files. These files should be transferred to the DPU before running the DPU sample.
6. Waiting until DPU DMA sample has finished.
7. Destroying all DMA and DOCA core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_dma/dma_copy_host/dma_copy_host_sample.c`
- `/opt/mellanox/doca/samples/doca_dma/dma_copy_host/dma_copy_host_main.c`
- `/opt/mellanox/doca/samples/doca_dma/dma_copy_host/meson.build`

5.4.5 DOCA Comch

This guide provides instructions on building and developing applications that require communication channels between the x86 host and the BlueField Arm cores.

5.4.5.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

DOCA Comch provides a communication channel between client applications on the host and servers on the BlueField Arm. It introduces features such as high-performance data path over the consumer-producer API, as well as working with DOCA progress engine and other standard DOCA Core objects.

Benefits of using DOCA Comch:

- Security – the communication channel is isolated from the network
- Network independent – the state of the communication channel does not depend on the state and configuration of the network
- Ease of use

DOCA Comch provides two different data path APIs:

- Basic DOCA Comch send/receive for control messages
- High bandwidth, low latency, zero-copy, multi-producer, multi-consumer API

The following table summarizes the differences between the two data path APIs:

Features	Basic Send/Receive	Fast Path (using doca_comch_consumer/ doca_comch_producer)
Zero-copy	No	Yes
Takes network bandwidth	Yes	No
Isolated from network	Yes	Yes
Max msg size	Fixed	1GB or more (depends on hardware cap)
Multi-threaded	Safe for a single thread	Allows creation of consumer/producers per thread.
Multi-consumer	No	Yes
Multi-producer	Yes – allows multiple clients per server	Yes – allow multiple producers/consumers per connection
Requires `doca_mmap` and `doca_buf`	No	Yes

DOCA Comch does not support event-triggered completions.

5.4.5.2 Prerequisites

This library follows the architecture of a DOCA Core Context, it is recommended to read the following sections before:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem (fast path only)

5.4.5.3 Changes From Previous Release

N/A

5.4.5.4 Environment

DOCA Comch based applications can run either on the host machine or on the NVIDIA BlueField Arm.

Sending messages between the host and BlueField Arm can only be run with a BlueField configured with a mode as described in BlueField Modes of Operation.

For basic DOCA Comch send and receive, the following configuration is required:

- `doca_comch_server` context must run on the BlueField Arm cores
- `doca_comch_client` context must run on the host machine

> ⚠ Producer and consumer objects can run on both the host and BlueField Arm cores. However, there must be a valid client/server connection already established on the channel.

5.4.5.5 Architecture

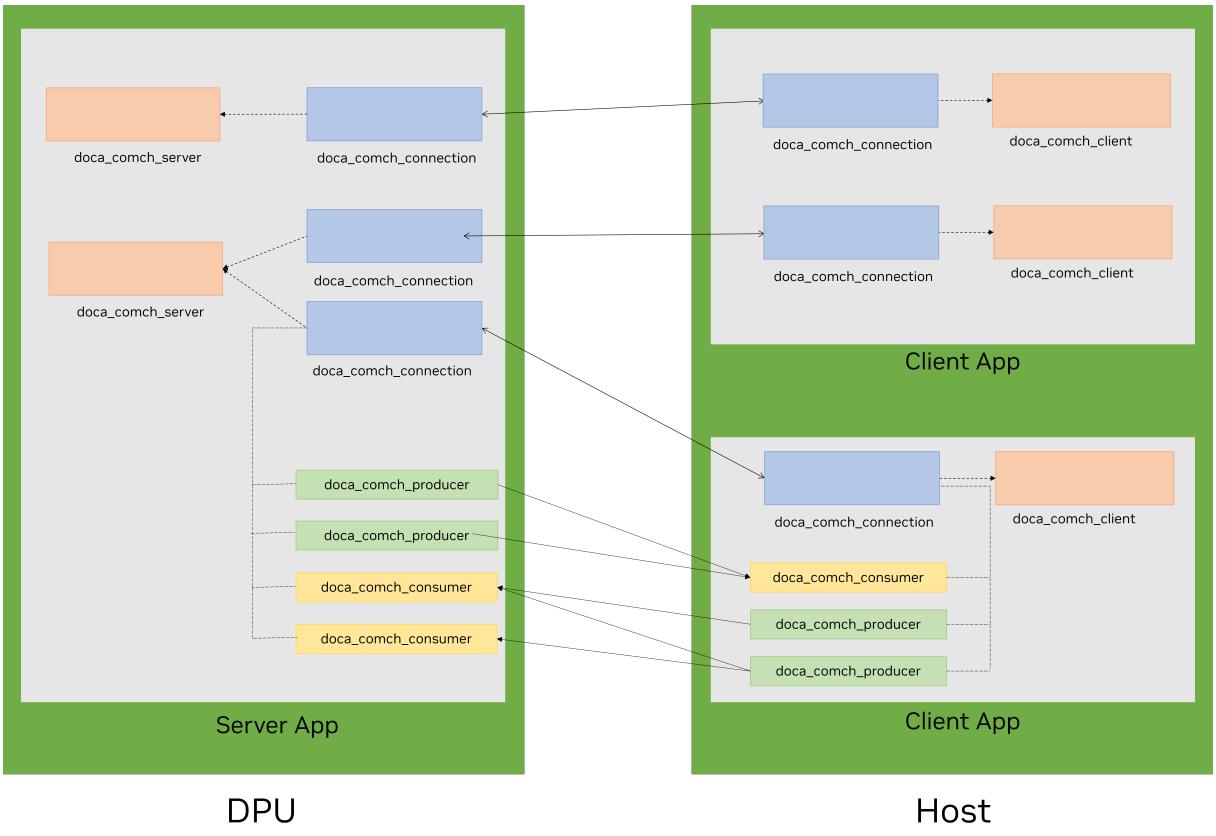
DOCA Comch is comprised of four DOCA Core Contexts. All DOCA Comch contexts leverage DOCA Core architecture to expose asynchronous tasks/events that are offloaded to hardware.

A `doca_comch_server` context runs on the BlueField Arm and listens for incoming connections from the host side. Such host side connections are initiated by a `doca_comch_client` context.

Servers can receive connections from multiple clients in parallel, however, a client can only connect with one server. An established 1-to-1 connection between a client and a server is represented by a `doca_comch_connection`.

Once an established connection exists between a client and a server, the `doca_comch_producer` and `doca_comch_consumer` contexts can be used to run fast path channels.

The following diagram provides examples of the contexts use:



5.4.5.5.1 Objects

	Description	Location	Scope
`doca_comch_server`	Allows applications on the BlueField Arm cores to listen on a specific server name and accept new incoming connection from the host	BlueField Arm only	Per host PCIe function (`doca_dev` + `doca_dev_rep`)
`doca_comch_client`	Allows client applications to connect to a specific server name on the BlueField Arm cores	Host only	Per host PCIe function (`doca_dev`)
`doca_comch_connection`	A connection handle created on the client side or the server side when a new connection is established. This handle is used to send/receive messages or to create `doca_comch_consumer` s and `doca_comch_producer` s.	BlueField Arm and host	Per client server pair
`doca_comch_producer`	A handle for a FIFO-like send queue that provides a zero-copy API to send messages to a specific `doca_comch_consumer` on the same `doca_comch_connection` . Multiple `doca_comch_producer` s can be created per `doca_comch_connection` .	BlueField Arm and host	Per `doca_comch_connection`

	Description	Location	Scope
`doca_comch_consumer`	A handle for a FIFO-like receive queue that provides a zero-copy API to receive messages from a `doca_comch_producer`	BlueField Arm and host	Per `doca_comch_connection`

5.4.5.5.2 Security Considerations

- DOCA Comch guarantees:
  - The client is connected to the server by providing the exact server name on the client side
  - Only clients on the PF/VF/SF represented by the `doca_dev_rep` provided upon server creation can connect to the server
  - The connection requests and data path are isolated from the network
- DOCA Comch does not provide security at the application level:
  - It is up to the user to implement application-level security and verify the identity of the client application
  - A server handles applications from a single PF/VF/SF. If a server application detects a compromised client application, the server app should consider all clients (from that PF/VF/SF) compromised.

5.4.5.5.3 Initialization Flow

5.4.5.5.3.1 doca_comch_server Initialization Flow

1. A `doca_comch_server` is created on a specific `doca_dev` and a specific `doca_dev_rep`.
2. A `doca_comch_server` must have a unique name per `doca_dev/doca_dev_rep` (i.e., two servers on the same `doca_dev` and `doca_dev_rep` cannot have the same name).
3. Once `doca_ctx_start()` is called, the `doca_comch_server` can start receiving new connection requests.
4. For the `doca_comch_server` to process new connection requests and messages, the user must periodically call `doca_pe_progress()`.
5. When a new connection request arrives, `doca_comch_server` calls the connection request handler function and passes a `doca_comch_connection` object.

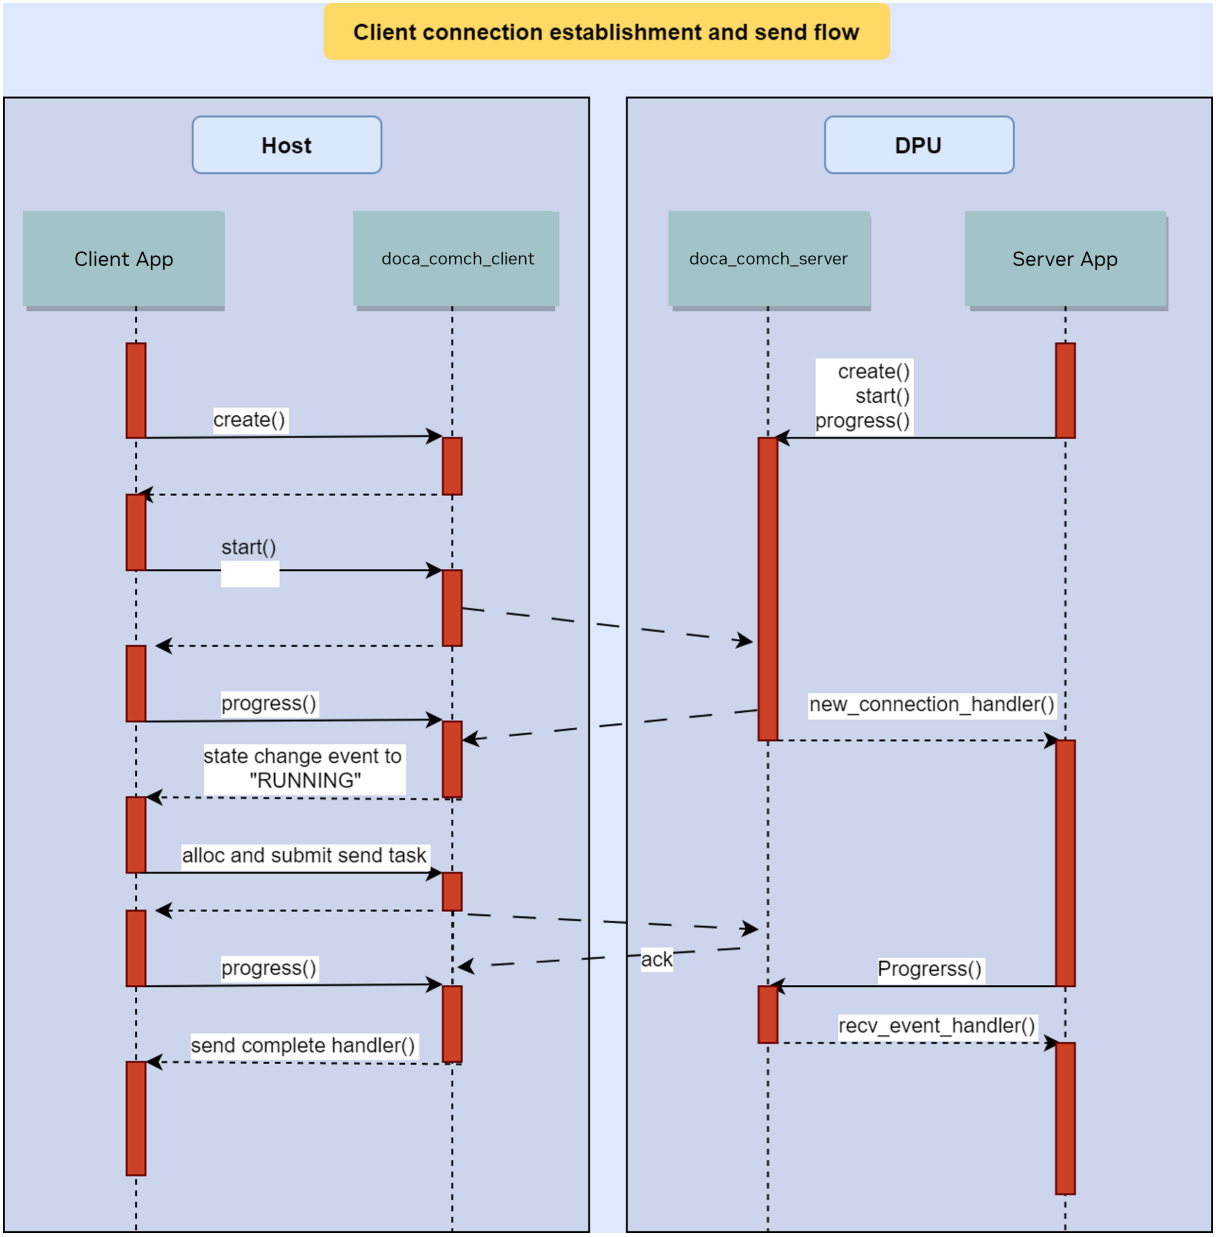
The server can now send and receive messages on the connection represented by `doca_comch_connection`.

5.4.5.5.3.2 doca_comch_client Initialization Flow

1. A `doca_comch_client` is created on a specific `doca_dev` is targeting a specific `doca_comch_server`.
2. Once `doca_ctx_start()` is called, `doca_comch_client` asynchronously tries to connect to the server.
3. To establish the connection and receive messages, the user must periodically call `doca_pe_progress()`.
4. When the connection is established, `doca_comch_client` calls the state change callback indicating state change to "RUNNING".

The client can now send a receive messages.

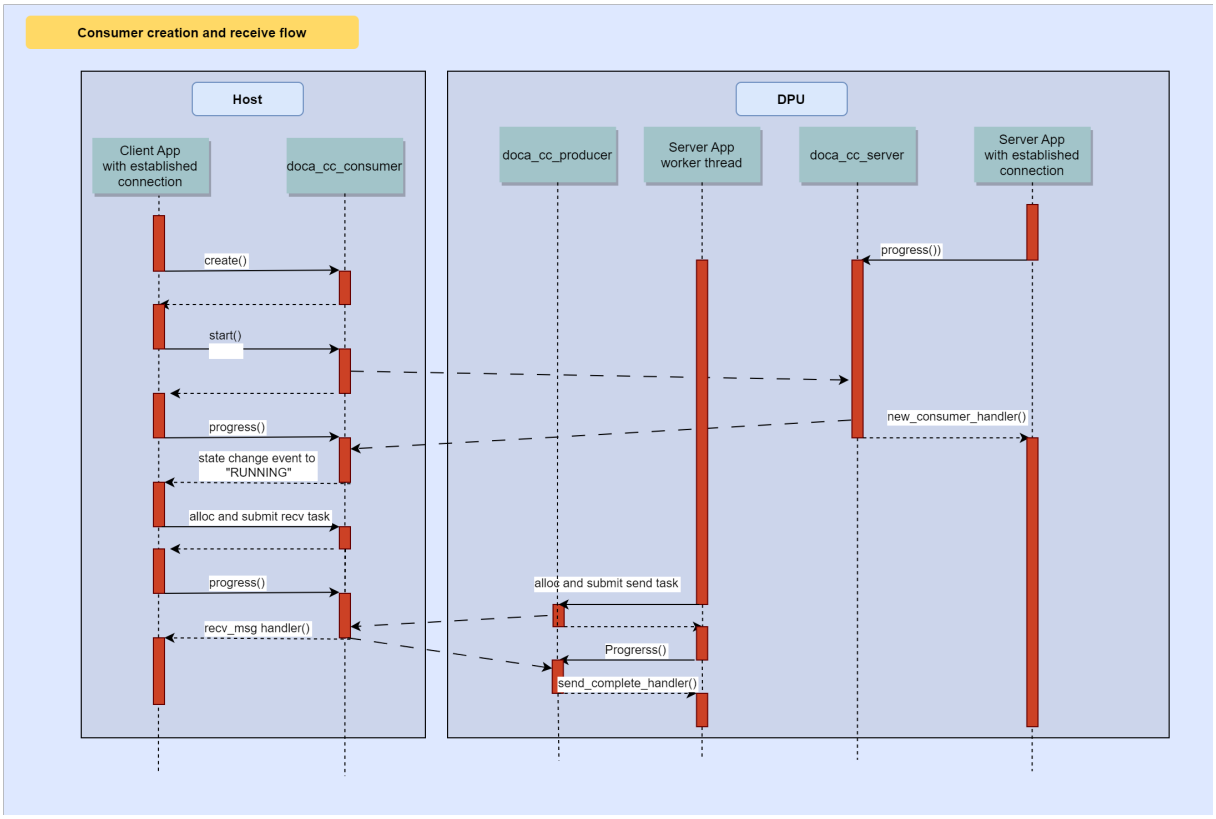
The following diagram describes the initialization of a basic client/server connection on DOCA Comch:



5.4.5.5.3.3 doca_comch_consumer Initialization Flow

1. A `doca_comch_consumer` is created on a specific `doca_comch_connection`.
2. `doca_pe_progress()` must be periodically called on the client/server PE to allow registration of the consumer.
3. After the `doca_comch_consumer` moves to "RUNNING" state:
    a. `doca_comch_consumer` notifies its existence to the peer (invoking a new consumer event).
    b. The application can start posting receive tasks.
    c. A `doca_comch_producer` on the peer side can start sending messages to that consumer.

The initialization flow is described in the following diagram:



5.4.5.5.4 Teardown Flow

The teardown flow must be executed in the following order, otherwise errors may occur.

5.4.5.5.4.1 Disconnecting Specific Connection

The proper disconnection process for a specific connection consists of the following steps:

1. Stop all consumers and producers linked to the connection.
2. Server/client:
    a. For server, a connection can be disconnected using `doca_comch_server_disconnect()`. If there are any active producers/consumers linked to the connection, the disconnect would fail. A disconnection notifies the client and initiates teardown on that side too.
    b. For client, since there is only one connection at any given time, the connection can be disconnected by calling `doca_ctx_stop()`. If there are any active producers/consumers, the command would fail. Stopping the client context notifies the server of the disconnection and causes a disconnection of the connection on it.

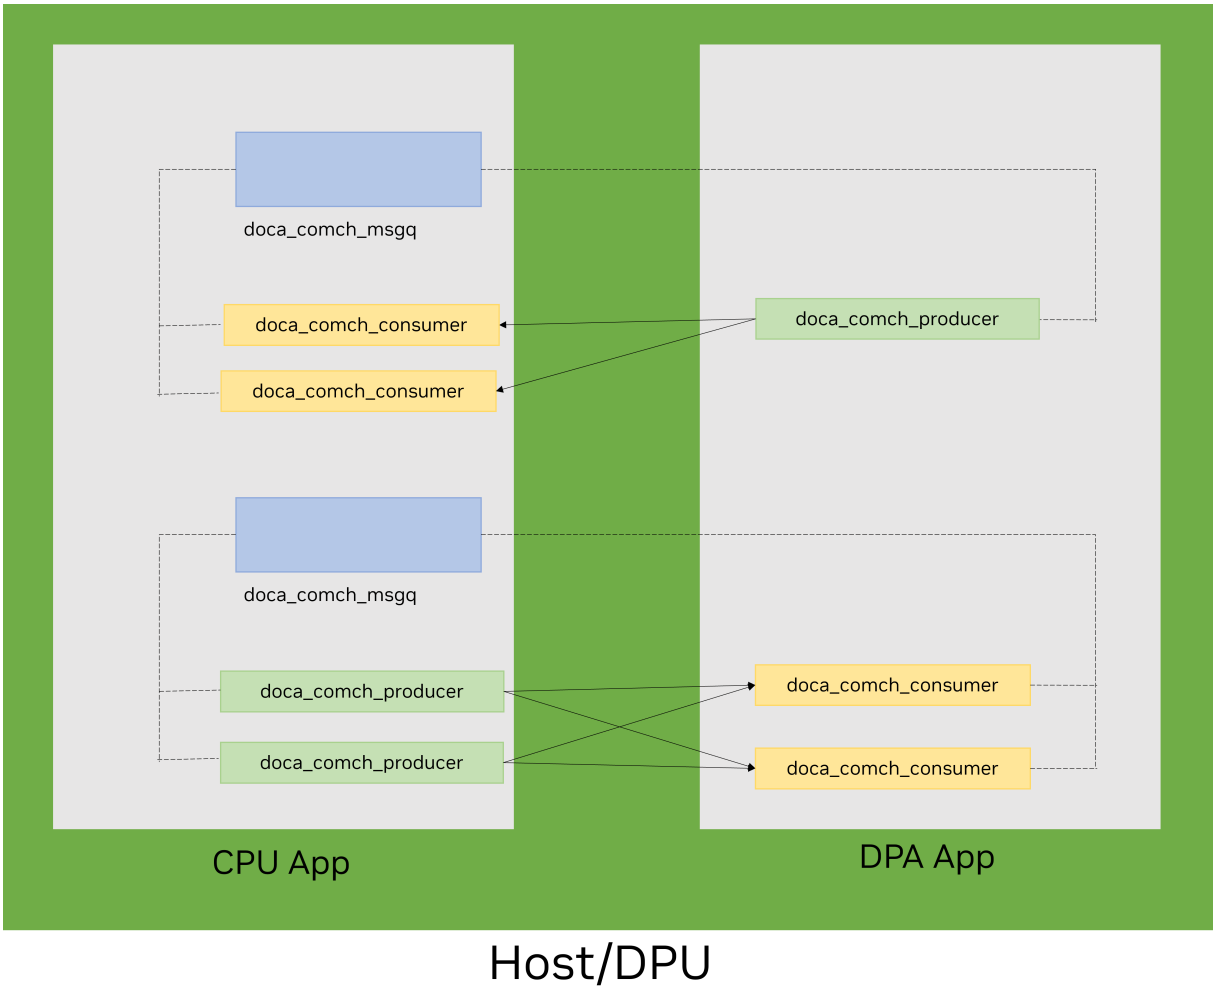
5.4.5.5.4.2 Tearing Down DOCA Comch

The proper teardown for a DOCA Comch context consists of the following:

1. Stop all consumers and producers linked to the context.
2. Call `doca_ctx_stop()`. If there are any active connections, they would all be disconnected. If there are any active consumers/producers, the command would fail. Disconnecting/stopping the context informs all active peers of the disconnection, and causes teardown (on clients) or disconnection (on server). Calling `doca_ctx_stop()` successfully moves the context to "stopping" state.
3. After moving to stopping state, `doca_pe_progress()` must be called until the context moves to idle state.

5.4.5.5.5 MsgQ (DPA Communication)

DOCA Comch MsgQ leverages the existing consumer/producer model to allow communication between host/BlueField and DPA.



Since communication between the host/BlueField and DPA is local, there is no need to create a server, client, or connection. Instead the user can create a MsgQ and use it to create producers and consumers directly.

When creating a consumer/producer using the MsgQ, it becomes possible to use them in the DPA application as well as the CPU application:

- The CPU application can utilize existing consumer/producer APIs for communication
- The DPA application has a different set of APIs that are usable within a DPA application

5.4.5.5.5.1 Communication Direction

Every instance of a MsgQ can only support a single communication direction as follows:

- Communication from host/BlueField to DPA
  - This direction may be specified using `doca_comch_msgq_set_dpa_consumer`
  - Consumers created from this MsgQ are referred to as DPA consumers, while producers are CPU producers
- Communication from DPA to host/BlueField
  - This direction may be specified using `doca_comch_msgq_set_dpa_producer`
  - Consumers created from this MsgQ are referred to as CPU consumers, while producers are DPA producers

To support bidirectional communication in an application, the user has to create 2 MsgQ instances, as shown in the above diagram.

5.4.5.6 Configuration Phase

To start using the library, users must go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context to allow execution of tasks and retrieval of events.

5.4.5.6.1 Configurations

The context can be configured to match the application use case.

To find out if a certain configuration is supported, or what the min/max value for it is, refer to Device Support.

5.4.5.6.1.1 Mandatory Configurations

These configurations are mandatory and must be set by the application before attempting to start the context:

- For a basic send/receive client or server:
  - A send task callback
  - A receive event callback
  - A device with appropriate support must be provided on creation
  - A valid server name must be provided on creation (for clients this is the server to connect to)
  - A connection event callback (server only)
- For fast path producer or consumer:
  - A device with appropriate support must be provided on creation
  - An established client to server connection must be provided on creation
  - A `doca_mmap` with PCIe read/write permissions of where data should be received must be provided on creation (consumer only)
  - A post receive task callback (consumer only)
  - A send task callback (producer only)
  - A new consumer callback (triggered upon creation/destruction of a remove consumer)
- For MsgQ fast path producer or consumer:
  - A started MsgQ must be provided on creation
  - A DPA instance must be provided (DPA consumer/producer only)
  - A DPA consumer completion context must be connected (DPA consumer only)
  - A DPA completion context must be attached (DPA producer only)
  - A post receive task callback (CPU consumer only)
  - The number of receive operations (DPA consumer only)
  - A send task callback (CPU producer only)
  - The number of send operations (DPA producer only)

5.4.5.6.1.2 Optional Configurations

The following configurations are optional, if they are not set then a default value will be used:

For basic send/receive client:

- `doca_comch_(server|client)_set_max_msg_size` – set the maximum size of message that can be sent. If set, it must be matching between server and client.
- `doca_comch_(server|client)_set_recv_queue_size` – set the size of the queue to receive new messages on

For fast path consumers:

- `doca_comch_consumer_set_imm_data_len` – set the length of immediate data that a consumer can receive.

5.4.5.6.2 Device Support

DOCA Comch requires a device to operate. For instructions on picking a device, see DOCA Core Device Discovery.

As device capabilities are subject to change (see DOCA Core Device Support), it is recommended to select a device using the following methods:

- For basic client and server:
  - `doca_comch_cap_server_is_supported`
  - `doca_comch_cap_client_is_supported`
- For extended fast path functionality:
  - `doca_comch_producer_cap_is_supported`
  - `doca_comch_consumer_cap_is_supported`

Some devices can allow different capabilities as follows:

- The maximum length server name
- The maximum message size
- The maximum receive queue length
- The maximum clients that can connect to a server
- The maximum number of send tasks or post receive tasks
- The maximum buffer length for fast path
- The maximum immediate data supported by a fast path consumer

5.4.5.6.3 Buffer Support

Basic send and receive between a client and server does not use DOCA buffers and so has no restrictions on buffer type.

- For producers, supplied buffers need only be from a local mmap
- For consumers, post receive buffers are required to be from a PCIe export mmap

> ⚠ Chained buffers are not supported in DOCA Comch.

5.4.5.7 Execution Phase

This section describes execution on CPU using DOCA Core Progress Engine. For additional execution environments, refer to section "Alternative Datapath Options".

5.4.5.7.1 Tasks

DOCA Comch exposes asynchronous tasks that leverage the BlueField hardware according to DOCA Core architecture.

5.4.5.7.1.1 Control Channel Send Task

This task allows the sending of messages between connected client and server objects.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Number of tasks	`doca_comch_server_task_send_set_conf` `doca_comch_client_task_send_set_conf`	`doca_comch_cap_get_max_send_tasks`
Maximal message size	`doca_comch_server_set_max_msg_size` `doca_comch_client_set_max_msg_size`	`doca_comch_server_get_max_msg_size` `doca_comch_client_get_max_msg_size`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Peer	Established client/server connection	–
Message	Data string to send to remote client/server	The is no requirement for the message to be in DOCA mmap registered memory
Length	Number of bytes in the message	Must not exceed configured max size

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully:

- The message is delivered to the connections remote client/server
- A receive event is triggered on the remote side

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The message is not delivered to the remote side

Task Limitations

- The operation is not atomic

- Once the task has been submitted, then the message should not be updated
- Other limitations are described in DOCA Core Task

5.4.5.7.1.2 Consumer Post Receive Task

This task allows consumer objects to publish buffers which are available for remote producers to write to.

> ⚠ A Post Receive task may have a NULL buffer if it only wishes to receive immediate data.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_comch_consumer_task_post_recv_set_conf`	`doca_comch_consumer_cap_is_supported`
Number of tasks	`doca_comch_consumer_task_post_recv_set_conf`	`doca_comch_consumer_cap_get_max_num_tasks`
Maximal buffer size	–	`doca_comch_consumer_cap_get_max_buf_size`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Buffer	Buffer that the consumer can receive data on	Data is appended to the tail of the buffer ℹ Buffers `doca_mmap` must have `DOCA_ACCESS_FLAG_PCI_READ_WRITE` flag set.

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

The task only completes once a producer has written to the advertised buffer (or immediate data, or both), not when the post receive has completed.

Upon successful completion, the buffer contains the data written by the producer and its length is updated appropriately.

Task Completion Failure

Task failure occurs if a buffer has not been successfully posted to receive data.

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- Producers are not aware of the buffer so would not write to it

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the buffer should not be read/written to
- Buffer must come from memory with PCIe read/write access
- Chained buffer lists are not supported
- MsgQ consumer does not support providing `doca_buf`, and can only receive immediate data
- Other limitations are described in DOCA Core Task

5.4.5.7.1.3 Producer Send Task

This task allows producer objects to copy buffers for use by remote consumers.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_comch_producer_task_send_set_conf`	`doca_comch_producer_cap_is_supported`
Number of tasks	`doca_comch_producer_task_send_set_conf`	`doca_comch_producer_cap_get_max_num_tasks`
Maximal buffer Size	–	`doca_comch_producer_cap_get_max_buf_size`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Buffer	Buffer that should be copied to a consumer	Only the data residing in the data segment is copied
Immediate data	Short byte array to add to the post receive completion entry	This is not a zero copy operation but does improve latency for small payloads
Immediate data length	Length of data immediate data pointed to	Maximum length is determined/set by individual consumers
Consumer ID	Identifier for the target consumer to write to	Active consumers and their IDs are advertised through consumer events

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task is completed successfully:

- The data is copied form the buffer to the next free buffer posted by the given consumer
- Consumers process buffers from a given consumer in the order they are sent

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination memory may be modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the buffer should not be read/written to
- The buffer length should not be greater than consumer post receive buffers (an invalid value is returned otherwise)
- MsgQ producer does not support providing `doca_buf`, and can only send immediate data
- All limitations described in DOCA Core Task

5.4.5.7.2 Events

DOCA Comch exposes asynchronous events to notify about changes that happen out of the blue, according to the DOCA Core architecture. See DOCA Core Event.

Common events as described in DOCA Core Event.

5.4.5.7.2.1 Control Channel Receive Event

This event triggers whenever a remote client/server has sent a message to the local client/server object.

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_comch_server_event_msg_recv_register` `doca_comch_client_event_msg_recv_register`	–

Event Trigger Condition

The event is triggered when a remote message is received on any currently active connection associated with the client or server.

Event Output

Upon event detection, the registered callback is triggered, passing the following parameters:

- A pointer to the message data

  > The data is only valid in the context of the callback.

- The length in bytes of the message
- The active connection on which the message was received

5.4.5.7.2.2 Connection Status Changed Event (Server Only)

This event provides asynchronous updates on the state of any connections associated with a server.

> A client object can only connect to a single server, so its connection state can be tracked through its `doca_ctx` state and the generic `doca_ctx_set_state_changed_cb` function.

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_comch_server_event_connection_status_changed_register`	–

Event Trigger Condition

The event is triggered when a new connection is either established or a current connection disconnected on a server.

Event Output

Separate callbacks are registered for connection or disconnection events with the appropriate one triggered based on the specific event.

Both callbacks contain a Boolean indicating if the connection or disconnection was successful.

5.4.5.7.2.3 Consumer Event

This event indicates that a new consumer object has been created or an existing consumer object has been destroyed.

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_comch_server_event_consumer_register` `doca_comch_client_event_consumer_register`	–

Event Trigger Condition

The event is triggered whenever a new consumer is created or a current consumer destroyed on the remote side of an established DOCA Comch connection.

Event Output

The event hits a separate callback for either the creation or destruction of a consumer.

Callback parameters include:

- The established DOCA Comch connection on which the consumer is connected (on the remote side)
- The ID of the consumer (a unique value per Comch connection)

5.4.5.8 State Machine

The DOCA Comch library follows the Context state machine described in DOCA Core Context State Machine.

The following section describes how to move to the state and what is allowed in each state.

5.4.5.8.1 Idle

In this state it is expected that the application either:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to Configurations
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all tasks have been freed
Stopping	Call progress until all tasks are completed and freed

5.4.5.8.2 **Starting**

In this state it is expected that the application will:

- Call progress to allow transition to next state (e.g., when a connection attempt completes)

Allowed operations:

- Call progress

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

5.4.5.8.3 Running

In this state, it is expected that the application:

- Allocates and submit tasks
- Calls progress to complete tasks and/or receive events

Allowed operations:

- Allocate a previously configured task
- Submit an allocated task
- Call stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration
Starting	Call progress until context state transitions

5.4.5.8.4 Stopping

In this state, it is expected that the application will:

- Free any completed tasks

Allowed operations:

- Allocate previously configured task
- Submit an allocated task
- Call stop

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without freeing all tasks

5.4.5.9 Alternative Datapath Options

DOCA Comch can be run on as part of DPA data path, using the MsgQ.

5.4.5.9.1 DPA Support

Using the MsgQ it is possible to create consumer/producer on the DPA. They follow the definition described in DOCA Core DPA.

Since these objects can be used in DPA, they have DPA APIs that can be used to perform the data path operations expanded on in the following subsections.

5.4.5.9.1.1 Consumer Ack

The `doca_dpa_dev_comch_consumer_ack` API prepares the DPA consumer to receive a number of immediate messages from CPU producers.

Configuration

Description	API to Set the Configuration	API to Query Support
Queue Size	`doca_comch_consumer_set_dev_max_num_recv`	–

Input

Name	Description	Notes
Number of Messages	A number describing how many additional immediate messages this consumer can receive	Must not exceed the queue size

Completion

Whenever a message is received from the CPU producer a completion element is generatedand can be polled using `doca_dpa_dev_comch_consumer_get_completion`.

Using the generated completion, it is possible to get the following outputs:

Name	Description	Notes
Immediate Message	A pointer to the immediate message that the CPU producer sent	The message lifetime is the same as the completion element lifetime. That is, once the completion is acked using `doca_dpa_dev_comch_consumer_completion_ack`, the pointer is no longer valid. To retain the message past the completion lifetime, the user must copy the contents of the message.
Immediate Message Length	The length in bytes of the immediate message that the CPU producer sent	
Producer ID	The ID of the CPU producer that sent the message	User can find the IDs of each producer by using `doca_comch_producer_get_id`

Limitations

- The maximal immediate message size is 32 bytes

5.4.5.9.1.2 Producer Post Send Immediate Only

The `doca_dpa_dev_comch_producer_post_send_imm_only` API sends an immediate message to the CPU consumer. Once the message arrives at the CPU consumer side, the CPU consumer receive task completes.

The CPU producer must have posted a receive task prior to this. The user can verify if the consumer can receive the message using `doca_dpa_dev_comch_producer_is_consumer_empty`. Note, however, that this may add overhead.

Configuration

Description	API to Set the Configuration	API to Query Support
Queue Size	`doca_comch_producer_set_dev_max_num_send`	–

Input

Name	Description	Notes
Immediate Message	Short byte array to be sent to the CPU consumer	This is not a zero copy operation but does improve latency for small payloads
Immediate Message Length	Length of the message the immediate message points to	The maximum length is 32 bytes
Consumer ID	Identifier for the target CPU consumer to write to	User can find the IDs of each consumer by using `doca_comch_consumer_get_id`
Completion Requested	Flag indicating whether to generate a completion once the send is completed	This refers to the DPA producer completion which is separate from the completion the CPU consumer receives • 0 – no completion • 1 – otherwise

Completion

Once the message arrives to the CPU consumer, a completion element is generated, indicating that the send is complete (this is separate from the completion the CPU consumer receives) and can be polled using `doca_dpa_dev_get_completion`.

Using the generated completion, it is possible to get the following outputs:

Name	Description	Notes
Producer User Data	Producer user data provided during configuration of the producer	User data previously set using `doca_ctx_set_user_data` when configuring this producer. User data which is returned belongs to the DPA producer this completion has been generated for, and can be used to identify the specific producer.

Limitations

- The maximal immediate message size is 32 bytes

5.4.5.9.1.3 Producer DMA Copy

The `doca_dpa_dev_comch_producer_dma_copy` API performs a DMA copy operation and, once the copy operation is done, sends an immediate message to the CPU consumer. Once the message arrives at the CPU consumer side, the CPU consumer receive task completes.

The CPU producer must have posted a receive task prior to this. The user can verify if the consumer can receive the message using `doca_dpa_dev_comch_producer_is_consumer_empty`. Note, however, that this may add overhead.

Configuration

Description	API to Set the Configuration	API to Query Support
Queue Size	`doca_comch_producer_set_dev_num_recv`	–

Input

Name	Description	Notes
Destination Mmap	Mmap representing the memory to be used as the destination of the copy operation	This mmap must have `LOCAL_READ_WRITE` access enabled
Destination Address	The address to be used as the destination of the copy operation	The address and copy length must be within the range of the destination mmap's memory range
Source Mmap	Mmap representing the memory to be used as the source of the copy operation	This mmap must have `LOCAL_READ` access enabled
Source Address	The address to be used as the source of the copy operation	The address and copy length must be within the range of the source mmap's memory range
Length	The length of the copy operation	Source and destination addresses must not overlap
Immediate Message	Short byte array to be sent to the CPU consumer once the copy operation is done	This is not a zero copy operation but does improve latency for small payloads
Immediate Message Length	Length of the message the immediate message points to	The maximum length is 32 bytes
Consumer ID	Identifier for the target CPU consumer to write to	User can find the IDs of each consumer using `doca_comch_consumer_get_id`

Name	Description	Notes
Completion Requested	Flag indicating whether to generate a completion once the send is completed	This refers to the DPA producer completion which is separate from the completion the CPU consumer receives • 0 – no completion • 1 – otherwise

Completion

Once copy is complete and the message arrives to the CPU consumer, a completion element is generated, indicating that the copy is complete (this is separate from the completion the CPU consumer receives) and can be polled using `doca_dpa_dev_get_completion`.

Using the generated completion, it is possible to get the following outputs:

Name	Description	Notes
Producer User Data	Producer user data provided during configuration of the producer	The user data set using `doca_ctx_set_user_data` when configuring this producer. The user data which is returned belongs to the DPA producer this completion has been generated for, and can be used to identify the specific producer.

Limitations

- The maximal immediate message size is 32 bytes

5.4.5.9.2 GPU Datapath Support

DOCA offers the DOCA GPUNetIO library, which provides a programming model for running DOCA Comch producers and consumers on a GPU CUDA Kernel.

5.4.5.9.2.1 Key Requirements and Limitations

- Client-only support: The GPU datapath is currently supported only for `doca_comch_client` objects and their associated producers/consumers. It is not supported for `doca_comch_server`.
- No mixed datapaths: Once a `doca_comch_client` is configured for the GPU datapath, all producers or consumers created from that client must also use the GPU datapath.
- Progress engine required: All GPU datapath contexts must still be connected to a Progress Engine (`doca_pe_connect_ctx()`). The PE is required to handle connection management events, such as remote Producers or Consumers connecting or disconnecting.

5.4.5.9.2.2 Configuration

Configuring the GPU datapath requires setting the datapath on both the parent client object and the individual Producer/Consumer contexts.

Configure the DOCA Comch Client

1. Obtain the DOCA Context from the client by calling `doca_comch_client_as_ctx()`.
2. Set the context's datapath to GPU by calling `doca_ctx_set_datapath_on_gpu()`. (For details, see DOCA Core Alternative Data Path.)
3. Finish context configuration and start it by calling `doca_ctx_start()`. (For details, see DOCA Core Context.)

Configure the DOCA Comch Producer or Consumer

1. Obtain the DOCA Context from the Producer or Consumer by calling `doca_comch_producer_as_ctx()` or `doca_comch_consumer_as_ctx()`.
2. Set the context's datapath to GPU by calling `doca_ctx_set_datapath_on_gpu()`. (For details, see DOCA Core Alternative Data Path.)
3. Finish context configuration and start the context by calling `doca_ctx_start()`. (For details, see DOCA Core Context.)

5.4.5.9.2.3 Obtaining the GPU Handle

After the Producer or Consumer context is in the "running" state, the application can retrieve a GPU handle by calling `doca_comch_producer_get_gpu_handle()` or `doca_comch_consumer_get_gpu_handle()`.

This handle must be passed to a GPU CUDA kernel, which allows the DOCA GPUNetIO CUDA device functions to execute datapath operations. For more information, refer to the "GPU Functions – Comch" section in the DOCA GPUNetIO library documentation.

5.4.5.10 DOCA Comch Samples

This section describes DOCA Comch samples based on the DOCA Comch library.

The samples illustrate how to use the DOCA Comch API to do the following:

- Set up a client/server between host and BlueField Arm cores and use it to send text messages
- Configure fast path producers and consumers, and send messages between them

All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.5.10.1 Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

   ```
   cd /opt/mellanox/doca/samples/doca_comch/<sample_name>
   meson /tmp/build
   ninja -C /tmp/build
   ```

   The binary `doca_<sample_name>` is created under `/tmp/build/`.
3. All DOCA Comch samples accept the same input arguments:

Sample	Argument	Description

`doca_comch_ctrl_path_server`
`doca_comch_ctrl_path_client`
`doca_comch_data_path_high_speed_server`
`doca_comch_data_path_high_speed_client`
	`-p`, `--pci-addr`	DOCA Comch device PCIe address

	`-r`, `--rep-pci`	DOCA Comch device representor PCIe address (required only on BlueField Arm)
	`-t`, `--text`	Text to be sent to the other side of channel (overwrites default)

4. For additional information per sample, use the `-h` option:

   ```
   /tmp/build/<sample_name> -h
   ```

5.4.5.10.2 Samples

These samples are also available on GitHub.

5.4.5.10.2.1 DOCA Comch Control Path Client/Server

> ⚠ `doca_comch_ctrl_path_server` must be run on the BlueField Arm side and started before `doca_comch_ctrl_path_client` is started on the host.

This sample sets up a client server connection between the host and BlueField Arm cores.

The connection is used to pass two messages, the first sent by the client when the connection is established and the second by the server on receipt of the client's message.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the core DOCA structures.
3. Initializing and configuring client/server contexts.
4. Registering tasks and events for sending/receiving messages and tracking connection changes.
5. Allocating and submitting tasks for sending control path messages.
6. Handling event completions for receiving messages.
7. Stopping and destroying client/server objects.

References:

- `/opt/mellanox/doca/samples/doca_comch/comch_ctrl_path_client/comch_ctrl_path_client_main.c`
- `/opt/mellanox/doca/samples/doca_comch/comch_ctrl_path_client/comch_ctrl_path_client_sample.c`
- `/opt/mellanox/doca/samples/doca_comch/comch_ctrl_path_server/comch_ctrl_path_server_main.c`
- `/opt/mellanox/doca/samples/doca_comch/comch_ctrl_path_server/comch_ctrl_path_server_sample.c`
- `/opt/mellanox/doca/samples/doca_comch/comch_ctrl_path_common.c`
- `/opt/mellanox/doca/samples/doca_comch/comch_ctrl_path_common.h`

5.4.5.10.2.2 DOCA Comch Data Path Client/Server

> ⚠ `doca_comch_data_path_high_speed_server` should be run on the BlueField Arm cores and should be started before `doca_comch_data_path_high_speed_client` is started on the host.

This sample sets up a client server connection between host and BlueField Arm.

The connection is used to create a producer and consumer on both sides and pass a message across the two fastpath connections.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the core DOCA structures.
3. Initializing and configuring client/server contexts.
4. Initializing and configuring producer/consumer contexts on top of an established connection.
5. Submitting post receive tasks for population by producers.
6. Submitting send tasks from producers to write to consumers.
7. Stopping and destroying producer/consumer objects.
8. Stopping and destroying client/server objects.

5.4.6 DOCA UROM

This guide provides an overview and configuration instructions for DOCA Unified Resources and Offload Manager (UROM) API.

5.4.6.1 Introduction

The quality status of DOCA libraries is listed here.

The DOCA Unified Resource and Offload Manager (UROM) offers a framework for offloading a portion of parallel computing tasks, such as those related to HPC or AI workloads and frameworks, from the host to the NVIDIA DPUs. This framework includes the UROM service which is responsible for resource discovery, coordination between the host and DPU, and the management of UROM workers that execute parallel computing tasks.

When an application utilizes the UROM framework for offloading, it consists of two main components: the host part and the UROM worker on the DPU. The host part is responsible for interacting with the DOCA UROM API and operates as part of the application with the aim of offloading tasks to the DPU. This component establishes a connection with the UROM service and initiates an offload request. In response to the offload request, the UROM service provides network identifiers for the workers, which are spawned by the UROM service. If the UROM service is running as a Kubernetes POD, the workers are spawned within the POD. Each worker is responsible for executing either a single offload or multiple offloads, depending on the requirements of the host application.

5.4.6.2 Prerequisites

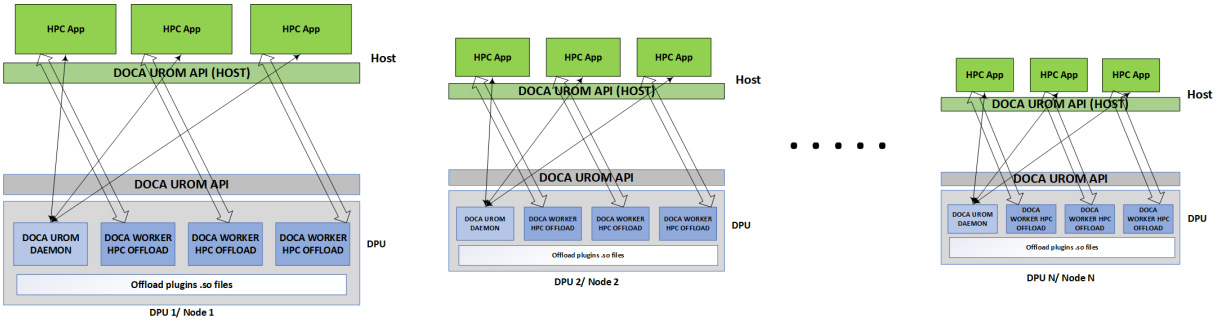
UCX is required for the communication channel between the host and DPU parts of DOCA UROM based on TCP socket transport. This is a mechanism to transfer commands from the host to the UROM service on the DPU and receive responses from the DPU.

By default, UCX scans all available devices on the machine and selects the best ones based on performance characteristics. The environment variable `UCX_NET_DEVICES=<dev1>,<dev2>,...` would restrict UCX to using only the specified devices. For example, `UCX_NET_DEVICES=eth2` uses the Ethernet device `eth2` for TCP socket transport.

For more information about UCX, refer to DOCA UCX Programming Guide.

5.4.6.3 Architecture

5.4.6.3.1 UROM Deployment



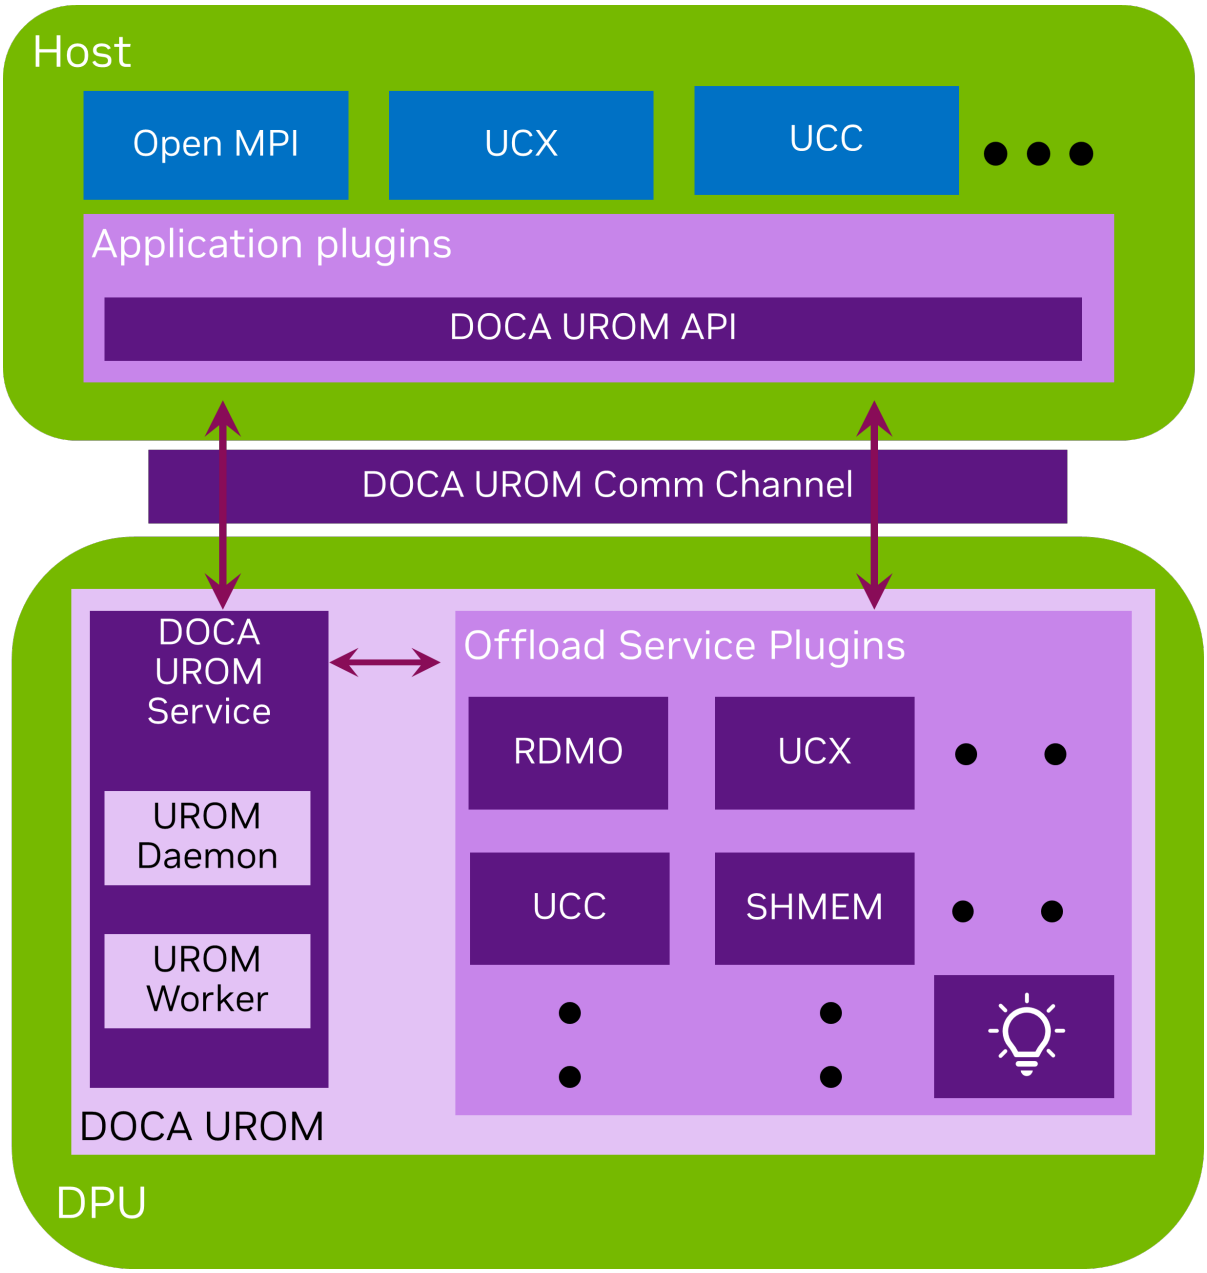
The diagram illustrates a standard UROM deployment where each DPU is required to host both a service process instance and a group of worker processes.

The typical usage of UROM services involves the following steps:

1. Every process in the parallel application discovers the UROM service.
2. UROM handles authentication and provides service details.
3. The host application receives the available offloading plugins on the local DPU through UROM service.
4. The host application picks the desired plugin info and triggers UROM worker plugin instances on the DPU through the UROM service.
5. The application delegates specific tasks to the UROM workers.
6. UROM workers execute these tasks and return the results.

5.4.6.3.2 UROM Framework

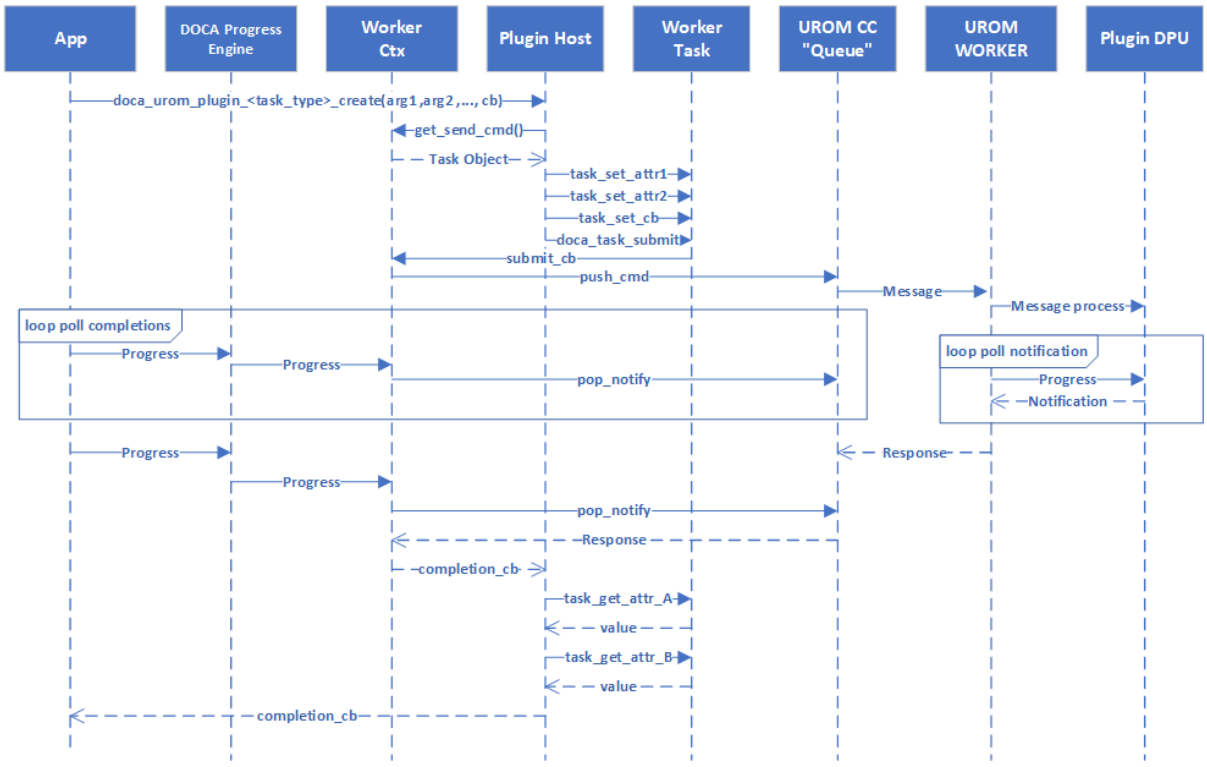
This diagram shows a high-level overview of the DOCA UROM framework.



A UROM offload plugin is where developers of AI/HPC offloads implement their own offloading logic while using DOCA UROM as the transport layer and resource manager. Each plugin defines commands to execute logic on the DPU and notifications that are returned to the host application. Each type of supported offload corresponds to a distinct type of DOCA UROM plugin. For example, a developer may need a UCC plugin to offload UCC functionality to the DPU. Each plugin implements a DPU-side plugin API and exposes a corresponding host-side interface.

A UROM daemon loads the plugin DPU version (`.so` file) in runtime as part of the discovery of local plugins.

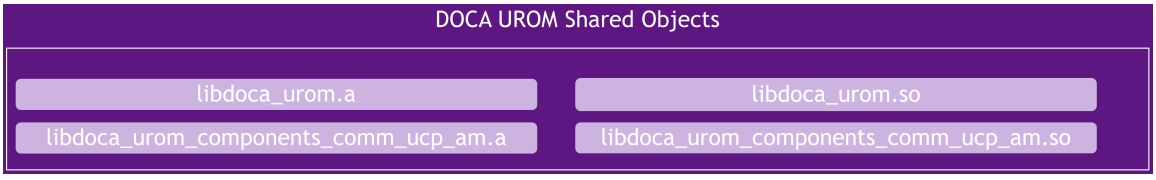
5.4.6.3.2.1 Plugin Task Offloading Flow



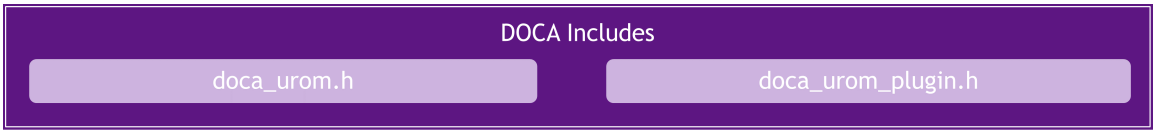
5.4.6.3.3 UROM Installation

DOCA UROM is an integral part of the DOCA SDK installation package. Depending on your system architecture and enabled offload plugins, UROM is comprised by several components, which can be categorized into two main parts: those on the host and those on the DPU.

- DOCA UROM library components:
  - `libdoca_urom` shared object – contains the DOCA UROM API
  - `libdoca_urom_components_comm_ucp_am` – includes the UROM communication channel interface API



- DOCA UROM headers:

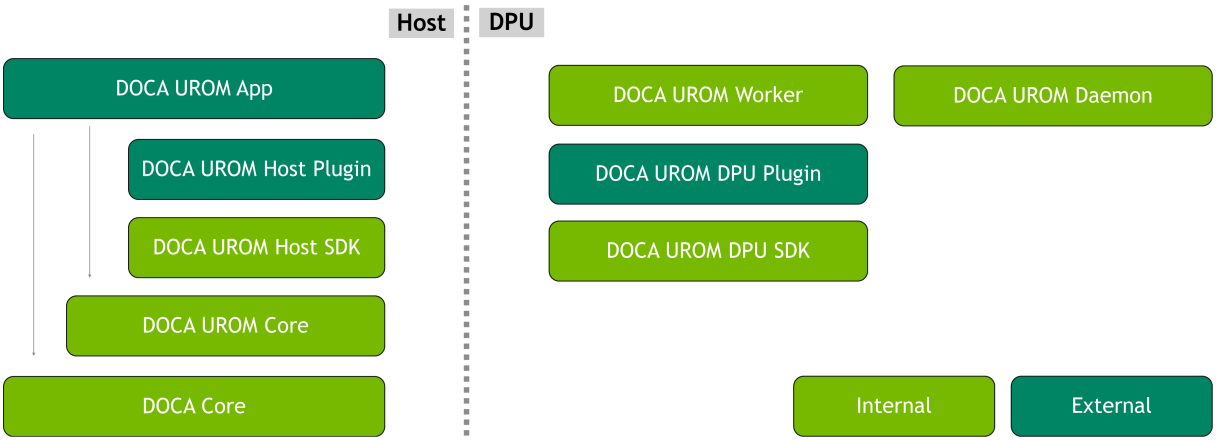


The header files include definitions for DOCA UROM as described in the following:

- DOCA UROM host interface (`doca_urom.h`) – this header includes three essential components: contexts, tasks, and plugins.
  - Service context (`doca_urom_service`) – this context serves as an abstraction of the UROM service process. Tasks posted within this context include the authentication, spawning, and termination of workers on the DPU.
  - Worker context (`doca_urom_worker`) – this context abstracts the DPU UROM worker, which operates on behalf of host application plugins (offload). Tasks posted within this context involve relaying commands from the host application to the worker on behalf of a specific offload plugin, such as offloaded functionality for communication operations.
  - Domain context (`doca_urom_domain`) – this context encapsulates a group of workers belonging to the same host application. This concept is similar to the MPI (message passing interface) communicator in the MPI programming model or PyTorch's process groups. Plugins are not required to use the UROM Domain.
- DOCA UROM plugin interface (`doca_urom_plugin.h`) – this header includes the main structure and definitions that the user can use to build both the host and DPU components of their own offloading plugins
  - UROM plugin interface structure (`urom_plugin_iface`) – this interface includes a set of operations to be executed by the UROM worker
  - UROM worker command structure (`urom_worker_cmd`) – this structure defines the worker instance command format
  - UROM worker notification structure (`urom_worker_notify`) – this structure defines the worker instance notification format

The following diagram shows various software components of DOCA UROM:

- DOCA Core – involves DOCA device discovery, DOCA progress engine, DOCA context, etc.
- DOCA UROM Core – includes the UROM library functionality
- DOCA UROM Host SDK – UROM API for the host application to use
- DOCA UROM DPU SDK – UROM API for the NVIDIA® BlueField® networking platform (DPU or SuperNIC) to use
- DOCA UROM Host Plugin – user plugin host version
- DOCA UROM DPU Plugin – user plugin DPU version
- DOCA UROM App – user UROM host application
- DOCA UROM Worker – the offload functionality component that executes the offloading logic
- DOCA UROM Daemon – is responsible for resource discovery, coordination between the host and DPU, managing the workers on BlueField



5.4.6.4 API

More information is available on DOCA UROM API in the DOCA API References.

The pkg-config (`*.pc` file) for the UROM library is `doca-urom`.

The following sections provide additional details about the library API.

5.4.6.4.1 DOCA_UROM_SERVICE_FILE

This environment variable sets the path to the UROM service file. When creating the UROM service object (see `doca_urom_service_create`), UROM performs a look-up using this file, the hostname where an application is running, and the PCIe address of the associated DOCA device to identify the network address, and network devices associated with the UROM service.

This file contains one entry per line describing the location of each UROM service that may be used by UROM. The format of each line must be as follows:

```
<app_hostname> <service_type> <dev_hostname> <dev_pci_addr> <net,devs>
```

Example:

```
app_host1 dpu dpu_host1 03:00.0 dev1:1,dev2:1
```

Fields are described in the following table:

Field	Description
`app_hostname`	Network hostname (or IP address) for the node that this line applies to
`service_type`	The UROM service type. Valid type is `dpu` (used for all DOCA devices).
`dev_hostname`	Network hostname (or IP address) for the associated DOCA device
`dev_pci_addr`	PCIe address of the associated DOCA device. This must match the PCIe address provided by DOCA.
`net,devs`	Comma-separated list of network devices shared between the host and DOCA device

5.4.6.4.2 doca_urom_service

An opaque structure that represents a DOCA UROM service.

```
struct doca_urom_service;
```

5.4.6.4.3 doca_urom_service_plugin_info

DOCA UROM plugin info structure. UROM generates this structure for each plugin on the local DPU where the UROM service is running and the service returns an array of available plugins to the host application to pick which plugins to use.

```
struct doca_urom_service_plugin_info {
    uint64_t id;
    uint64_t version;
    char plugin_name[DOCA_UROM_PLUGIN_NAME_MAX_LEN];
};
```

- `id` – Unique ID to send commands to the plugin, UROM generates this ID
- `version` – Plugin DPU version to verify that the plugin host interface has the same version
- `plugin_name` – The `.so` plugin file name without "`.so`". The name is used to find the desired plugin.

5.4.6.4.4 doca_urom_service_get_workers_by_gid_task

An opaque structure representing a DOCA service gets workers by group ID task.

```
struct doca_urom_service_get_workers_by_gid_task;
```

5.4.6.4.5 doca_urom_service_create

Before performing any UROM service operation (spawn worker, destroy worker, etc.), it is essential to create a `doca_urom_service` object. A service object is created in state `DOCA_CTX_STATE_IDLE`. After creation, the user may configure the service using setter methods (e.g., `doca_urom_service_set_dev()`).

Before use, a service object must be transitioned to state `DOCA_CTX_STATE_RUNNING` using the `doca_ctx_start()` interface. A typical invocation looks like `doca_ctx_start(doca_urom_service_as_ctx(service_ctx))`.

```
doca_error_t doca_urom_service_create(struct doca_urom_service **service_ctx);
```

- `service_ctx [in/out]` – `doca_urom_service` object to be created
- Returns – `DOCA_SUCCESS` on success, error code otherwise

> Multiple application processes could create different service objects that represent/connect to the same worker on the DPU.

5.4.6.4.6 doca_urom_service_destroy

Destroy a `doca_urom_service` object.

```
doca_error_t doca_urom_service_destroy(struct doca_urom_service *service_ctx);
```

- `service_ctx[in]` – `doca_urom_service` object to be destroyed. It is created by `doca_urom_service_create()`.
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.7 doca_urom_service_set_max_comm_msg_size

Set the maximum size for a message in the UROM communication channel. The default message size is 4096B.

> It is important to ensure that the combined size of the plugins' commands and notifications and the UROM structure's size do not exceed this maximum size.

Once the service state is running, users cannot update the maximum size for the message.

```
doca_error_t doca_urom_service_set_max_comm_msg_size(struct doca_urom_service *service_ctx, size_t msg_size);
```

- `service_ctx[in]` – a pointer to `doca_urom_service` object to set new message size
- `msg_size[in]` – new message size to set
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.8 doca_urom_service_as_ctx

Convert a `doca_urom_service` object into a DOCA object.

```
struct doca_ctx *doca_urom_service_as_ctx(struct doca_urom_service *service_ctx);
```

- `service_ctx[in]` – a pointer to `doca_urom_service` object
- Returns – a pointer to the `doca_ctx` object on success, `NULL` otherwise

5.4.6.4.9 doca_urom_service_get_plugins_list

Retrieve the list of supported plugins on the UROM service.

```
doca_error_t doca_urom_service_get_plugins_list(struct doca_urom_service *service_ctx, const struct
doca_urom_service_plugin_info **plugins, size_t *plugins_count);
```

- `service_ctx[in]` – a pointer to `doca_urom_service` object
- `plugins[out]` – an array of pointers to `doca_urom_service_plugin_info` object
- `plugins_count[out]` – number of plugins
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.10 doca_urom_service_get_cpuset

Get the allowed CPU set for the UROM service on BlueField, which can be used when spawning workers to set processor affinity.

```
doca_error_t doca_urom_service_get_cpuset(struct doca_urom_service *service_ctx, doca_cpu_set_t *cpuset);
```

- `service_ctx[in]` – a pointer to `doca_urom_service` object
- `cpuset[out]` – set of allowed CPUs
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.11 doca_urom_service_get_workers_by_gid_task_allocate_init

Allocate a get-workers-by-GID service task and set task attributes.

```
doca_error_t doca_urom_service_get_workers_by_gid_task_allocate_init(struct doca_urom_service *service_ctx,
                                                                     uint32_t gid,
doca_urom_service_get_workers_by_gid_task_completion_cb_t cb,
                                                                     struct
doca_urom_service_get_workers_by_gid_task **task);
```

- `service_ctx[in]` – a pointer to `doca_urom_service` object
- `gid[in]` – group ID to set
- `cb[in]` – user task completion callback
- `task[out]` – a new get-workers-by-GID service task
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.12 doca_urom_service_get_workers_by_gid_task_release

Release a get-workers-by-GID service task and task resources.

```
doca_error_t doca_urom_service_get_workers_by_gid_task_release(struct doca_urom_service_get_workers_by_gid_task
*task);
```

- `task[in]` – service task to release
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.13 doca_urom_service_get_workers_by_gid_task_as_task

Convert a `doca_urom_service_get_workers_by_gid_task` object into a DOCA task object.

After creating a service task and configuring it using setter methods (e.g., `doca_urom_service_get_workers_by_gid_task_set_gid()`) or as part of task allocation, the user should submit the task by calling `doca_task_submit`.

A typical invocation looks like `doca_task_submit(doca_urom_service_get_workers_by_gid_task_as_task(task))`.

```
struct doca_task *doca_urom_service_get_workers_by_gid_task_as_task(struct
doca_urom_service_get_workers_by_gid_task *task);
```

- `task[in]` – get-workers-by-GID service task
- Returns – a pointer to the `doca_task` object on success, `NULL` otherwise

5.4.6.4.14 doca_urom_service_get_workers_by_gid_task_get_workers_count

Get the number of workers returned for the requested GID.

```
size_t doca_urom_service_get_workers_by_gid_task_get_workers_count(struct doca_urom_service_get_workers_by_gid_task
*task);
```

- `task[in]` – get-workers-by-GID service task
- Returns – workers ID's array size

5.4.6.4.15 doca_urom_service_get_workers_by_gid_task_get_worker_ids

Get service get workers task IDs array.

```
const uint64_t *doca_urom_service_get_workers_by_gid_task_get_worker_ids(struct
doca_urom_service_get_workers_by_gid_task *task);
```

- `task[in]` – get-workers-by-GID service task
- Returns – workers ID's array, `NULL` otherwise

5.4.6.4.16 doca_urom_worker

An opaque structure representing a DOCA UROM worker context.

```
struct doca_urom_worker;
```

5.4.6.4.17 doca_urom_worker_cmd_task

An opaque structure representing a DOCA UROM worker command task context.

```
struct doca_urom_worker_cmd_task;
```

5.4.6.4.18 doca_urom_worker_cmd_task_completion_cb_t

A worker command task completion callback type. It is called once the worker task is completed.

```
typedef void (*doca_urom_worker_cmd_task_completion_cb_t)(struct doca_urom_worker_cmd_task *task,
                                                          union doca_data task_user_data,
                                                          union doca_data ctx_user_data);
```

- `task[in]` – a pointer to worker command task

- `task_user_data[in]` – user task data
- `ctx_user_data[in]` – user worker context data

5.4.6.4.19 doca_urom_worker_create

This method creates a UROM worker context.

A worker is created in a `DOCA_CTX_STATE_IDLE` state. After creation, a user may configure the worker using setter methods (e.g., `doca_urom_worker_set_service()`). Before use, a worker must be transitioned to state `DOCA_CTX_STATE_RUNNING` using the `doca_ctx_start()` interface. A typical invocation looks like `doca_ctx_start(doca_urom_worker_as_ctx(worker_ctx))`.

```
doca_error_t doca_urom_worker_create(struct doca_urom_worker **worker_ctx);
```

- `worker_ctx [in/out]` – `doca_urom_worker` object to be created
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.20 doca_urom_worker_destroy

Destroys a UROM worker context.

```
doca_error_t doca_urom_worker_destroy(struct doca_urom_worker *worker_ctx);
```

- `worker_ctx [in]` – `doca_urom_worker` object to be destroyed. It is created by `doca_urom_worker_create()`.
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.21 doca_urom_worker_set_service

Attaches a UROM service to the worker context. The worker is launched on the DOCA device managed by the provided service context.

```
doca_error_t doca_urom_worker_set_service(struct doca_urom_worker *worker_ctx, struct doca_urom_service
*service_ctx);
```

- `service_ctx [in]` – service context to set
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.22 doca_urom_worker_set_id

This method sets the worker context ID to be used to identify the worker. Worker IDs enable an application to establish multiple connections to the same worker process running on a DOCA device.

Worker ID must be unique to a UROM service.

- If `DOCA_UROM_WORKER_ID_ANY` is specified, the service assigns a unique ID for the newly created worker.
- If a specific ID is used, the service looks for an existing worker with matching ID. If one exists, the service establishes a new connection to the existing worker. If a matching worker does not exist, a new worker is created with the specified worker ID.

```
doca_error_t doca_urom_worker_set_id(struct doca_urom_worker *worker_ctx, uint64_t worker_id);
```

- `worker_ctx [in]` – `doca_urom_worker` object
- `worker_id [in]` – worker ID
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.23 doca_urom_worker_set_gid

Set worker group ID. This ID must be set before starting the worker context.

Through service get workers by GID task, the application can have the list of workers' IDs which are running on DOCA device and that belong to the same group ID.

```
doca_error_t doca_urom_worker_set_gid(struct doca_urom_worker *worker_ctx, uint32_t gid);
```

- `worker_ctx [in]` – `doca_urom_worker` object
- `gid [in]` – worker group ID
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.24 doca_urom_worker_set_plugins

Adds a plugin mask for the supported plugins by the UROM worker on the DPU. The application can use up to 62 plugins.

```
doca_error_t doca_urom_worker_set_plugins(struct doca_urom_worker *worker_ctx, uint64_t plugins);
```

- `worker_ctx[in]` – `doca_urom_worker` object
- `plugins[in]` – an ORing set of worker plugin IDs

- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.25 doca_urom_worker_set_env

Set worker environment variables when spawning worker on DPU side by DOCA UROM service. They must be set before starting the worker context.

> This call fails if the worker already spawned on the DPU.

```
doca_error_t doca_urom_worker_set_env(struct doca_urom_worker *worker_ctx, char *const env[], size_t count);
```

- `worker_ctx [in]` – `doca_urom_worker` object
- `env [in]` – an array of environment variables
- `count [in]` – array size
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.26 doca_urom_worker_as_ctx

Convert a `doca_urom_worker` object into a DOCA object.

```
struct doca_ctx *doca_urom_worker_as_ctx(struct doca_urom_worker *worker_ctx);
```

- `worker_ctx[in]` – a pointer to `doca_urom_worker` object
- Returns – a pointer to the `doca_ctx` object on success, `NULL` otherwise

5.4.6.4.27 doca_urom_worker_cmd_task_allocate_init

Allocate worker command task and set task attributes.

```
doca_error_t doca_urom_worker_cmd_task_allocate_init(struct doca_urom_worker *worker_ctx, uint64_t plugin, struct
doca_urom_worker_cmd_task **task);
```

- `worker_ctx [in]` – a pointer to `doca_urom_worker` object
- `plugin [in]` – task plugin ID
- `task [out]` – set worker command new task
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.28 doca_urom_worker_cmd_task_release

Release worker command task.

```
doca_error_t doca_urom_worker_cmd_task_release(struct doca_urom_worker_cmd_task *task);
```

- `task[in]` – worker task to release
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.29 doca_urom_worker_cmd_task_set_plugin

Set worker command task plugin ID. The plugin ID is created by the UROM service and the plugin host interface should hold it to create UROM worker command tasks.

```
void doca_urom_worker_cmd_task_set_plugin(struct doca_urom_worker_cmd_task *task, uint64_t plugin);
```

- `task [in]` – worker task
- `plugin [in]` – task plugin to set

5.4.6.4.30 doca_urom_worker_cmd_task_set_cb

Set worker command task completion callback.

```
void doca_urom_worker_cmd_task_set_cb(struct doca_urom_worker_cmd_task *task,
doca_urom_worker_cmd_task_completion_cb_t cb);
```

- `task[in]` – worker task
- `plugin[in]` – task callback to set

5.4.6.4.31 doca_urom_worker_cmd_task_get_payload

Get worker command task payload. The plugin interface populates this buffer by plugin command structure. The payload size is the maximum message size in the DOCA UROM communication channel (the user can configure the size by calling `doca_urom_service_set_max_comm_msg_size()`). To update the payload buffer, the user should call `doca_buf_set_data()`.

```
struct doca_buf *doca_urom_worker_cmd_task_get_payload(struct doca_urom_worker_cmd_task *task);
```

- `task [in]` – worker task
- Returns – a `doca_buf` that represents the task's payload

5.4.6.4.32 doca_urom_worker_cmd_task_get_response

Get worker command task response. To get the response's buffer, the user should call `doca_buf_get_data()`.

```
struct doca_buf *doca_urom_worker_cmd_task_get_response(struct doca_urom_worker_cmd_task *task);
```

- `task [in]` – worker task
- Returns – a `doca_buf` that represents the task's response

5.4.6.4.33 doca_urom_worker_cmd_task_get_user_data

Get worker command user data to populate. The data refers to the reserved data inside the task that the user can get when calling the completion callback. The maximum data size is 32 bytes.

```
void *doca_urom_worker_cmd_task_get_user_data(struct doca_urom_worker_cmd_task *task);
```

- `task [in]` – worker task
- Returns – a pointer to user data memory

5.4.6.4.34 doca_urom_worker_cmd_task_as_task

Convert a `doca_urom_worker_cmd_task` object into a DOCA task object.

After creating a worker command task and configuring it using setter methods (e.g., `doca_urom_worker_cmd_task_set_plugin()`) or as part of task allocation, the user should submit the task by calling `doca_task_submit`.

A typical invocation looks like `doca_task_submit(doca_urom_worker_cmd_task_as_task(task))`.

```
struct doca_task *doca_urom_worker_cmd_task_as_task(struct doca_urom_worker_cmd_task *task);
```

- `task[in]` – worker command task
- Returns – a pointer to the `doca_task` object on success, `NULL` otherwise

5.4.6.4.35 doca_urom_domain

An opaque structure representing a DOCA UROM domain context.

```
struct doca_urom_domain;
```

5.4.6.4.36 doca_urom_domain_allgather_cb_t

A callback for a non-blocking all-gather operation.

```
typedef doca_error_t (*doca_urom_domain_allgather_cb_t)(void *sbuf, void *rbuf, size_t msglen, void *coll_info,
void **req);
```

- `sbuf [in]` – local buffer to send to other processes
- `rbuf [in]` – global buffer to include other process's source buffer
- `msglen [in]` – source buffer length
- `coll_info [in]` – collection info
- `req [in]` – allgather request data
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.37 doca_urom_domain_req_test_cb_t

A callback to test the status of a non-blocking allgather request.

```
typedef doca_error_t (*doca_urom_domain_req_test_cb_t)(void *req);
```

- `req [in]` – allgather request data to check status
- Returns – `DOCA_SUCCESS` on success, `DOCA_ERROR_IN_PROGRESS` otherwise

5.4.6.4.38 doca_urom_domain_req_free_cb_t

A callback to free a non-blocking allgather request.

```
typedef doca_error_t (*doca_urom_domain_req_free_cb_t)(void *req);
```

- `req [in]` – allgather request data to release.
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.39 doca_urom_domain_oob_coll

Out-of-band communication descriptor for domain creation.

```
struct doca_urom_domain_oob_coll {
    doca_urom_domain_allgather_cb_t allgather;
    doca_urom_domain_req_test_cb_t req_test;
    doca_urom_domain_req_free_cb_t req_free;
    void *coll_info;
    uint32_t n_oob_indexes;
    uint32_t oob_index;
};
```

- `allgather` – non-blocking allgather callback

- `req_test` – request test callback
- `req_free` – request free callback
- `coll_info` – context or metadata required by the OOB collective
- `n_oob_indexes` – number of endpoints participating in the OOB operation (e.g., number of client processes representing domain workers)
- `oob_index` – an integer value that represents the position of the calling processes in the given OOB operation. The data specified by `src_buf` is placed at the offset "`oob_index`*size" in the `recv_buf`.

  ⚠ `oob_index` must be unique at every calling process and should be in the range [0: `n_oob_indexes`).

5.4.6.4.40 doca_urom_domain_create

Creates a UROM domain context. A domain is created in state `DOCA_CTX_STATE_IDLE`. After creation, a user may configure the domain using setter methods (e.g., `doca_urom_domain_set_workers()`). Before use, a domain must be transitioned to state `DOCA_CTX_STATE_RUNNING` using the `doca_ctx_start()` interface. A typical invocation looks like `doca_ctx_start(doca_urom_domain_as_ctx(worker_ctx))`.

```
doca_error_t doca_urom_domain_create(struct doca_urom_domain **domain_ctx);
```

- `domain_ctx [in/out]` – `doca_urom_domain` object to be created
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.41 doca_urom_domain_destroy

Destroys a UROM domain context.

```
doca_error_t doca_urom_domain_destroy(struct doca_urom_domain *domain_ctx);
```

- `domain_ctx [in]` – `doca_urom_domain` object to be destroyed; it is created by `doca_urom_domain_create()`
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.42 doca_urom_domain_set_workers

Sets the list of workers in the domain.

```
doca_error_t doca_urom_domain_set_workers(struct doca_urom_domain *domain_ctx, uint64_t *domain_worker_ids, struct
doca_urom_worker **workers, size_t workers_cnt);
```

- `domain_ctx [in]` – `doca_urom_domain` object
- `domain_worker_ids [in]` – list of domain worker IDs
- `workers [in]` – an array of UROM worker contexts that should be part of the domain
- `workers_cnt [in]` – the number of workers in the given array
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.43 doca_urom_domain_add_buffer

Attaches local buffer attributes to the domain. It should be called after calling `doca_urom_domain_set_buffers_count()`.

The local buffer will be shared with all workers belonging to the domain.

```
doca_error_t doca_urom_domain_add_buffer(struct doca_urom_domain *domain_ctx, void *buffer, size_t buf_len, void
 *memh, size_t memh_len, void *mkey, size_t mkey_len);
```

- `domain_ctx [in]` – `doca_urom_domain` object
- `buffer [in]` – buffer ready for remote access which is given to the domain
- `buf_len [in]` – buffer length
- `memh [in]` – memory handle for the exported buffer. (should be packed)
- `memh_len [in]` – memory handle size
- `mkey [in]` – memory key for the exported buffer. (should be packed)
- `mkey_len [in]` – memory key size
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.44 doca_urom_domain_set_oob

Sets OOB communication info to be used for domain initialization.

```
doca_error_t doca_urom_domain_set_oob(struct doca_urom_domain *domain_ctx, struct doca_urom_domain_oob_coll *oob);
```

- `domain_ctx [in]` – `doca_urom_domain` object
- `oob [in]` – OOB communication info to set
- Returns – `DOCA_SUCCESS` on success, error code otherwise

5.4.6.4.45 doca_urom_domain_as_ctx

Convert a `doca_urom_domain` object into a DOCA object.

```
struct doca_ctx *doca_urom_domain_as_ctx(struct doca_urom_domain *domain_ctx);
```

- `domain_ctx[in]` – a pointer to `doca_urom_domain` object
- Returns – a pointer to the `doca_ctx` object on success, `NULL` otherwise

5.4.6.5 Execution Model

DOCA UROM uses the DOCA Core Progress Engine as an execution model for service and worker contexts and tasks progress. For more details about it please refer to this guide.

5.4.6.6 UROM Building Blocks

This section explains the general concepts behind the fundamental building blocks to use when creating a DOCA UROM application and offloading functionality.

5.4.6.6.1 Program Flow

5.4.6.6.1.1 DPU

Launching DOCA UROM Service

DOCA UROM service should be run before running the application on the host to offload commands to BlueField. For more information, refer to the DOCA UROM Service Guide.

5.4.6.6.1.2 Host

Initializing UROM Service Context

1. Create service context: Establish a service context within the control plane alongside the progress engine.
2. Set service context attributes: Specific attributes of the service context are configured. The required attribute is `doca_dev`.
3. Start the service context: The service context is initiated by invoking the `doca_ctx_start` function.
    a. Discover BlueField availability: The UROM library identifies the available BlueField device.

b. Connect to UROM service: The library establishes a connection to the UROM service. The connection process is synchronized, meaning that the host process and the BlueField service process are blocked until the connection is established.
c. Perform lookup using UROM service file: A lookup operation is executed using the UROM service file. The path to this file should be specified in the `DOCA_UROM_SERVICE_FILE` environment variable. More information can be found in `doca_urom.h`.

4. Switch context state to `DOCA_CTX_STATE_RUNNING`: The context state transitions to `DOCA_CTX_STATE_RUNNING` at this point.
5. Service context waits for worker bootstrap requests: The service context is now in a state where it awaits and handles worker bootstrap requests.

```
/* Create DOCA UROM service instance */
doca_urom_service_create(&service);

/* Connect service context to DOCA progress engine */
doca_pe_connect_ctx(pe, doca_urom_service_as_ctx(service));

/* Set service attributes */
doca_urom_service_set_max_workers(service, nb_workers)
doca_urom_service_set_dev(service, dev);

/* Start service context */
doca_ctx_start(doca_urom_service_as_ctx(service));

/* Handling workers bootstrap requests */
do {
    doca_pe_progress(pe);
} while (!are_all_workers_started);
```

Picking UROM Worker Offload Functionality

Once the service context state is running, the application can call `doca_urom_service_get_plugins_list()` to get the available plugins on the local BlueField device where the UROM service is running.

The UROM service generates an identifier for each plugin and the application is responsible for forwarding this ID to the host plugin interface for sending commands and receiving notifications by calling `urom_<plugin_name>_init(<plugin_id>, <plugin_version>)`.

```
const char *plugin_name = "worker_rdmo";
struct doca_urom_service *service;
const struct doca_urom_service_plugin_info *plugins, *rdmo_info;

/* Create and Start UROM service context. */
..

/* Get worker plugins list. */
doca_urom_service_get_plugins_list(*service, &plugins, &plugins_count);

/* Check if RDMO plugin exists. */
for (i = 0; i < plugins_count; i++) {
        if (strcmp(plugin_name, plugins[i].plugin_name) == 0) {
            rdmo_info = &plugins[i];
            break;
        }
}

/* Attach RDMO plugin ID and DPU plugin version for compatibility check */
urom_rdmo_init(rdmo_info->id, rdmo_info->version);
```

Initializing UROM Worker Context

1. Create a service context and connect the worker context to DOCA Progress Engine (PE).
2. Set worker context attributes (in the example below worker plugin is RDMO).
3. Start worker context, submitting internally spawns worker requests on the service context.
4. Worker context state changes to `DOCA_CTX_STATE_STARTING` (this process is asynchronous).
5. Wait until the worker context state changes to `DOCA_CTX_STATE_RUNNING`:
    a. When calling `doca_pe_progress`, check for a response from the service context that the spawning worker on BlueField is done.
    b. If the worker is spawned on BlueField, connect to it and change the status to running.

```
const struct doca_urom_service_plugin_info *rdmo_info;

/* Create DOCA UROM worker instance */
doca_urom_worker_create(&worker);

/* Connect worker context to DOCA progress engine */
doca_pe_connect_ctx(pe, doca_urom_worker_as_ctx(worker));

/* Set worker attributes */
doca_urom_worker_set_service(worker, service);
doca_urom_worker_set_id(worker, worker_id);
doca_urom_worker_set_max_inflight_tasks(worker, nb_tasks);
doca_urom_worker_set_plugins(worker, rdmo_info->id);
doca_urom_worker_set_cpuset(worker, cpuset);

/* Start UROM worker context */
doca_ctx_start(doca_urom_worker_as_ctx(worker));

/* Progress until worker state changes to running or error happened */
do {
    doca_pe_progress(pe);
    result = doca_ctx_get_state(doca_urom_worker_as_ctx(worker), &state);
} while (state == DOCA_CTX_STATE_STARTING);
```

Offloading Plugin Task

Once the worker context state is `DOCA_CTX_STATE_RUNNING`, the worker is ready to execute offload tasks. The example below is for offloading an RDMO command.

1. Prepare RDMO task arguments (e.g., completion callback).
2. Call the task function from the plugin host interface.
3. Poll for completion by calling `doca_pe_progress`.
4. Get completion notification through the user callback.

```
    int ret;
    struct doca_urom_worker *worker;
    struct rdmo_result res = {0};
    union doca_data cookie = {0};
    size_t server_worker_addr_len;
    ucp_address_t *server_worker_addr;

    cookie.ptr = &res;
    res.result = DOCA_SUCCESS;

    ucp_worker_create(*ucp_context, &worker_params, server_ucp_worker);
    ucp_worker_get_address(*server_ucp_worker, &server_worker_addr, &server_worker_addr_len);

    /* Create and submit RDMO client init task */
    urom_rdmo_task_client_init(worker, cookie, 0, server_worker_addr, server_worker_addr_len,
urom_rdmo_client_init_finished);

    /* Wait for completion */
    do {
        ret = doca_pe_progress(pe);
        ucp_worker_progress(*server_ucp_worker);
    } while (ret == 0 && res.result == DOCA_SUCCESS);
```

```
    /* Check task result */
    if (res.result != DOCA_SUCCESS)
        DOCA_LOG_ERR("Client init task finished with error");
```

Initializing UROM Domain Context

1. Create a domain context on the control plane PE.
2. Set domain context attributes.
3. Start the domain context by calling `doca_ctx_start`.
    a. Exchange memory descriptors between all workers.
4. Wait until the domain context state is running.

```
/* Create DOCA UROM domain instance */
doca_urom_domain_create(&domain);

/* Connect domain context to DOCA progress engine */
doca_pe_connect_ctx(pe, doca_urom_domain_as_ctx(domain));;

/* Set domain attributes */
doca_urom_domain_set_oob(domain, oob);
doca_urom_domain_set_workers(domain, worker_ids, workers, nb_workers);
doca_urom_domain_set_buffers_count(domain, nb_buffers);
for each buffer:
    doca_urom_domain_add_buffer(domain);

/* Start domain context */
doca_ctx_start(doca_urom_domain_as_ctx(domain));

/* Loop till domain state changes to running */
do {
    doca_pe_progress(pe);
    result = doca_ctx_get_state(doca_urom_domain_as_ctx(domain), &state);
} while (state == DOCA_CTX_STATE_STARTING && result == DOCA_SUCCESS);
```

Destroying UROM Domain Context

1. Request the domain context to stop by calling `doca_ctx_stop`.
2. Clean up resources by destroying the domain context.

```
/* Request domain context stop */
doca_ctx_stop(doca_urom_domain_as_ctx(domain));

/* Destroy domain context */
doca_urom_domain_destroy(domain);
```

Destroying UROM Worker Context

1. Request the worker context stop by calling `doca_ctx_stop` and posting the destroy command on the service context.
2. Wait until completion for the destroy command is received.
    a. Change worker state to idle.
3. Clean up resources.

```
/* Stop worker context */
doca_ctx_stop(doca_urom_worker_as_ctx(worker));

/* Progress till receiving a completion */
do {
    doca_pe_progress(pe);
    doca_ctx_get_state(doca_urom_worker_as_ctx(worker), &state);
} while (state != DOCA_CTX_STATE_IDLE);

/* Destroy worker context */
doca_urom_worker_destroy(worker);
```

Destroying UROM Service Context

1. Wait for the completion of the UROM worker context commands.
2. Once all UROM workers have been successfully destroyed, initiate service context stop by invoking `doca_ctx_stop`.
3. Disconnect from the UROM service.
4. Perform resource cleanup.

```
/* Handling workers teardown requests*/
do {
    doca_pe_progress(pe);
} while (!are_all_workers_exited);

/* Stop service context */
doca_ctx_stop(doca_urom_service_as_ctx(service));

/* Destroy service context */
doca_urom_service_destroy(service);
```

5.4.6.6.2 Plugin Development

5.4.6.6.2.1 Developing Offload Plugin on DPU

1. Implement `struct urom_plugin_iface` methods.
    a. The `open()` method initializes the plugin connection state and may create an endpoint to perform communication with other processes/workers.

```
static doca_error_t urom_worker_rdmo_open(struct urom_worker_ctx *ctx)
{
    ucp_context_h ucp_context;
    ucp_worker_h ucp_worker;
    struct urom_worker_rdmo *rdmo_worker;

    rdmo_worker = calloc(1, sizeof(*rdmo_worker));
    if (rdmo_worker == NULL)
        return DOCA_ERROR_NO_MEMORY;

    ctx->plugin_ctx = rdmo_worker;

    /* UCX transport layer initialization */
    .
    .
    .

    /* Create UCX worker Endpoint */
    ucp_worker_create(ucp_context, &worker_params, &ucp_worker);
    ucp_worker_get_address(ucp_worker, &rdmo_worker->ucp_data.worker_address, &rdmo_worker-
>ucp_data.ucp_addrlen);

    /* Resources  initialization */
    rdmo_worker->clients = kh_init(client);
    rdmo_worker->eps = kh_init(ep);

    /* Init completions list, UROM worker checks completed requests by calling progress() method */
    ucs_list_head_init(&rdmo_worker->completed_reqs);

    return DOCA_SUCCESS;
}
```

    b. The `addr()` method returns the address of the plugin endpoint generated during `open()` if it exists (e.g., UCX endpoint to communicate with other UROM workers).
    c. The `worker_cmd()` method is used to parse and start work on incoming commands to the plugin.

```
static doca_error_t urom_worker_rdmo_worker_cmd(struct urom_worker_ctx *ctx, ucs_list_link_t
*cmd_list)
{
    struct urom_worker_rdmo_cmd *rdmo_cmd;
    struct urom_worker_cmd_desc *cmd_desc;
```

```
    struct urom_worker_rdmo *rdmo_worker = (struct urom_worker_rdmo *)ctx->plugin_ctx;

    while (!ucs_list_is_empty(cmd_list)) {
        /* Get new RDMO command from the list */
        cmd_desc = ucs_list_extract_head(cmd_list, struct urom_worker_cmd_desc, entry);

        /* Unpack and deserialize RDMO command */
        urom_worker_rdmo_cmd_unpack(&cmd_desc->worker_cmd, cmd_desc->worker_cmd.len, &cmd);

        rdmo_cmd = (struct urom_worker_rdmo_cmd *)cmd->plugin_cmd;
        /* Handle command according to it's type */
        switch (rdmo_cmd->type) {
        case UROM_WORKER_CMD_RDMO_CLIENT_INIT:
            /* Handle RDMO client init command */
            status = urom_worker_rdmo_client_init_cmd(rdmo_worker, cmd_desc);
            break;
        case UROM_WORKER_CMD_RDMO_RQ_CREATE:
            /* Handle RDMO RQ create command */
            status = urom_worker_rdmo_rq_create_cmd(rdmo_worker, cmd_desc);
            break;
         .
         .
         .
        default:
            DOCA_LOG_INFO("Invalid RDMO command type: %lu", rdmo_cmd->type);
            status = DOCA_ERROR_INVALID_VALUE;
            break;
        }
        free(cmd_desc);
        if (status != DOCA_SUCCESS)
            return status;
    }
    return status;
}
```

d. The `progress()` method is used to give CPU time to the plugin code to advance asynchronous tasks.

```
static doca_error_t urom_worker_rdmo_progress(struct urom_worker_ctx *ctx, ucs_list_link_t
*notif_list)
{
    struct urom_worker_notif_desc *nd;
    struct urom_worker_rdmo *rdmo_worker = (struct urom_worker_rdmo *)ctx->plugin_ctx;

    /* RDMO UCP worker progress */
    ucp_worker_progress(rdmo_worker->ucp_data.ucp_worker);

    /* Check if completion list is empty */
    if (ucs_list_is_empty(&rdmo_worker->completed_reqs))
        return DOCA_ERROR_EMPTY;

    /* Pop completed commands from the list */
    while (!ucs_list_is_empty(&rdmo_worker->completed_reqs)) {
        nd = ucs_list_extract_head(&rdmo_worker->completed_reqs, struct urom_worker_notif_desc,
entry);
        ucs_list_add_tail(notif_list, &nd->entry);
    }
    return DOCA_SUCCESS;
}
```

e. The `notif_pack()` method is used to serialize notifications before they are sent back to the host.

2. Implement and expose the following symbols:
    a. `doca_error_t urom_plugin_get_version(uint64_t *version);`

    Returns a compile-time constant value stored within the `.so` file and is used to verify that the host and DPU plugin versions are compatible.

    b. `doca_error_t urom_plugin_get_iface(struct urom_plugin_iface *iface);`

    Get the `urom_plugin_iface` struct with methods implemented by the plugin.
3. Compile the user plugin as an `.so` file and place it where the UROM service can access it. For more details, refer to section "Plugin Discovery and Reporting" under the NVIDIA DOCA UROM Service Guide.

5.4.6.6.2.2 Creating Plugin Host Task

1. Allocate and init worker command task.
2. Populate payload buffer by task command.
3. Pack and serialize the command.
4. Set user data.
5. Submit the task.

```
doca_error_t urom_rdmo_task_client_init(struct doca_urom_worker *worker_ctx, union doca_data cookie,
uint32_t id, void *addr, uint64_t addr_len, urom_rdmo_client_init_finished cb)
{
    doca_error_t result;
    size_t pack_len = 0;
    struct doca_buf *payload;
    struct doca_urom_worker_cmd_task *task;
    struct doca_rdmo_task_data *task_data;
    struct urom_worker_rdmo_cmd *rdmo_cmd;

    /* Allocate task */
    doca_urom_worker_cmd_task_allocate_init(worker_ctx, rdmo_id, &task);

    /* Get payload buffer */
    payload = doca_urom_worker_cmd_task_get_payload(task);
    doca_buf_get_data(payload, (void **)&rdmo_cmd);
    doca_buf_get_data_len(payload, &pack_len);

    /* Populate commands attributes */
    rdmo_cmd->type = UROM_WORKER_CMD_RDMO_CLIENT_INIT;
    rdmo_cmd->client_init.id = id;
    rdmo_cmd->client_init.addr = addr;
    rdmo_cmd->client_init.addr_len = addr_len;

    /* Pack and serialize the command */
    urom_worker_rdmo_cmd_pack(rdmo_cmd, &pack_len, (void *)rdmo_cmd);

    /* Update payload data size */
    doca_buf_set_data(payload, rdmo_cmd, pack_len);

    /* Set user data */
    task_data = (struct doca_rdmo_task_data *)doca_urom_worker_cmd_task_get_user_data(task);
    task_data->client_init_cb = cb;
    task_data->cookie = cookie;

    /* Set task plugin callback */
    doca_urom_worker_cmd_task_set_cb(task, urom_rdmo_client_init_completed);

    /* Submit task */
    doca_task_submit(doca_urom_worker_cmd_task_as_task(task));

    return DOCA_SUCCESS;
}
```

5.4.6.7 DOCA UROM Samples

This section provides DOCA UROM library sample implementations on top of BlueField.

The samples illustrate how to use the DOCA UROM API to do the following:

- Define and create a UROM plugin host and DPU versions for offloading HPC/AI tasks
- Build host applications that use the plugin to execute jobs on BlueField by the DOCA UROM service and workers

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement. These samples are also available on GitHub.

5.4.6.7.1 Sample Prerequisite

Sample	Type	Prerequisite
Sandbox	Plugin	A plugin which offloads the UCX tagged send/receive API
Graph	Plugin	The plugin uses UCX data structures and UCX endpoint
UROM Ping Pong	Program	The sample uses the Open MPI package as a launcher framework to launch two processes in parallel

5.4.6.7.2 Running the Sample

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_urom/<sample_name>
meson /tmp/build
ninja -C /tmp/build
```

   The binary `doca_<sample_name>` is created under `/tmp/build/`.

3. UROM Sample arguments:

Sample	Argument	Description
UROM multi-workers bootstrap	`-d, --device <IB device name>`	IB device name
UROM Ping Pong	`-d, --device <IB device name>`	IB device name
	`-m, --message`	Specify ping pong message

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name> -h
```

5.4.6.7.3 UROM Plugin Samples

DOCA UROM plugin samples have two components. The first one is the host component which is linked with UROM host programs. The second is the DPU component which is

compiled as an `.so` file and is loaded at runtime by the DOCA UROM service (daemon, workers).

To build a given plugin:

```
cd /opt/mellanox/doca/samples/doca_urom/plugins/worker_<plugin_name>
meson /tmp/build
ninja -C /tmp/build
```

The binary `worker_<sample_name>.so` file is created under `/tmp/build/`.

5.4.6.7.3.1 Graph

This plugin provides a simple example for creating a UROM plugin interface. It exposes only a single command loopback, sending a specific value in the command, and expects to receive the same value in the notification from UROM worker.

References:

- `/opt/mellanox/doca/samples/doca_urom/plugins/worker_graph/meson.build`
- `/opt/mellanox/doca/samples/doca_urom/plugins/worker_graph/urom_graph.h`
- `/opt/mellanox/doca/samples/doca_urom/plugins/worker_graph/worker_graph.c`
- `/opt/mellanox/doca/samples/doca_urom/plugins/worker_graph/worker_graph.h`

5.4.6.7.3.2 Sandbox

This plugin provides a set of commands for using the offloaded ping pong communication operation.

References:

- `/opt/mellanox/doca/samples/doca_urom/plugins/worker_sandbox/meson.build`
- `/opt/mellanox/doca/samples/doca_urom/plugins/worker_sandbox/urom_sandbox.h`
- `/opt/mellanox/doca/samples/doca_urom/plugins/worker_sandbox/worker_sandbox.c`
- `/opt/mellanox/doca/samples/doca_urom/plugins/worker_sandbox/worker_sandbox.h`

5.4.6.7.4 UROM Program Samples

DOCA UROM program samples can run only on the host side and require at least one DOCA UROM service instance to be running on BlueField.

The environment variable should be set `DOCA_UROM_SERVICE_FILE` to the path to the UROM service file.

5.4.6.7.4.1 UROM Multi-worker Bootstrap

This sample illustrates how to properly initialize DOCA UROM interfaces and use the API to spawn multiple workers on the same application process.

The sample initiates four threads as UROM workers to execute concurrently, alongside the main thread operating as a UROM service. It divides the workers into two groups based on their IDs, with odd-numbered workers in one group and even-numbered workers in the other.

Each worker executes the data loopback command by using the Graph plugin, sends a specific value, and expects to receive the same value in the notification.

The sample logic includes:

1. Opening DOCA IB device.
2. Initializing needed DOCA core structures.
3. Creating and starting UROM service context.
4. Initiating the Graph plugin host interface by attaching the generated plugin ID.
5. Launching 4 threads and for each of them:
    a. Creating and starting UROM worker context.
    b. Once the worker context switches to running, sending the loopback graph command to wait until receiving a notification.
    c. Verifying the received data.
    d. Waiting until an interrupt signal is received.
6. The main thread checking for pending jobs of spawning workers (4 jobs, one per thread).
7. Waiting until an interrupt signal is received.
8. The main thread checking for pending jobs of destroying workers (4 jobs, one per thread) for exiting.
9. Cleaning up and exiting.

5.4.6.7.4.2 UROM Ping Pong

This sample illustrates how to properly initialize the DOCA UROM interfaces and use its API to create two different workers and run ping pong between them by using Sandbox plugin-based UCX.

The sample is using Open MPI to launch two different processes, one process as server and the second one as client, the flow is decided according to process rank.

The sample logic per process includes:

1. Initializing MPI.
2. Opening DOCA IB device.
3. Creating and starting UROM service context.
4. Initiating the Sandbox plugin host interface by attaching the generated plugin id.
5. Creating and starting UROM worker context.
6. Creating and starting domain context.
7. Through domain context, the sample processes exchange the worker's details to communicate between them on the BlueField side for ping pong flow.
8. Starting ping pong flow between the processes, each process offloading the commands to its worker on the BlueField side.
9. Verifying that ping pong is finished successfully.
10. Destroying the domain context.
11. Destroying the worker context.
12. Destroying the service context.

5.4.7 DOCA RDMA

This guide provides an overview and configuration instructions for the DOCA RDMA API.

5.4.7.1 Introduction

> The quality status of DOCA libraries is listed here.

DOCA RDMA (Remote Direct Memory Access) enables applications to directly access the memory of remote machines without involving their CPUs or operating systems. By avoiding CPU interruptions, RDMA significantly reduces context switching for I/O operations, yielding:

- Lower latency
- Higher bandwidth
- Improved application performance

The DOCA RDMA library offers an API to execute a variety of RDMA operations, providing software developers with the tools to optimize their applications using high-performance memory access.

> In production environments, ensure RDMA operations are performed over a secure channel. Due to the direct memory access nature of RDMA, unauthorized access can pose significant security risks. Implement appropriate security measures to protect your application and network.

5.4.7.2 Prerequisites

This library follows the architecture of a DOCA Core Context, it is recommended read the following sections before proceeding:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

5.4.7.3 Changes From Previous Release

N/A

5.4.7.4 Environment

DOCA RDMA-based applications can run either on the host machine or on the NVIDIA® BlueField® networking platform (DPU or SuperNIC).

5.4.7.5 Architecture

DOCA RDMA is a DOCA Context as defined by DOCA Core. See NVIDIA DOCA Core Context for more information.

DOCA RDMA consists of two connected sides, passing data between one another. This includes the option for one side to access the remote side's memory if the granted permissions allow it.

The connection between the two sides can either be based on InfiniBand (IB) or based on Ethernet using RoCE.

DOCA RDMA leverages the Core architecture to expose asynchronous tasks/events that are offloaded to hardware.

The supported operations that may be executed between the two sides, using DOCA RDMA, are:

- Receive
- Send
- Send with immediate
- Write
- Write with immediate
- Read
- Atomic compare and swap
- Atomic fetch and add
- Get remote DOCA Sync Event
- Set remote DOCA Sync Event
- Add remote DOCA Sync Event

5.4.7.5.1 Objects

5.4.7.5.1.1 Device

The RDMA library requires a DOCA device to operate. This device is used to utilize the connection between the peers in RDMA, access memory, and perform the different operations.

⚠ The device must stay valid until the RDMA instance is destroyed.

5.4.7.5.1.2 Memory Map

Executing any DOCA RDMA operation in which data is passed between the peers requires creating a memory map (mmap) on each side.

- The mmap's permissions must include the relevant RDMA permission, according to the required RDMA operations. Tasks fail in case of insufficient permissions.

  > Refer to section "Permissions" for more information.

- To allow the peer to execute RDMA operations, the mmap must be exported, using `doca_mmap_export_rdma()`, and passed to the peer (i.e., the side requesting the RDMA operation) where the remote mmap is created and used to access the memory.

5.4.7.5.1.3 Buffer Inventory and Buffers

Executing any DOCA RDMA operation, in which data is passed between the peers, requires using buffers, and thus requires a buffer inventory as well.

Each operation calls for a different set-up for the buffers in use, this is explicitly explained in the "Tasks" section.

5.4.7.6 Configuration Phase

To start using the library you need to first go through a configuration phase as described in DOCA Core Context Configuration Phase

This section describes how to configure and start the context, to allow execution of tasks and retrieval of events.

5.4.7.6.1 Configurations

The context can be configured to match the application use case.

5.4.7.6.1.1 Mandatory Configurations

These configurations are mandatory and must be set by the application before attempting to start the context:

Task Configurations

At least one task/event type must be configured. See configuration of Tasks and/or Events.

Permissions

Different tasks require different permission to be set for both the RDMA and the mmap in use.

The following table summarizes the necessary RDMA and mmap permissions for each RDMA operation:

DOCA RDMA task Types	Minimal Permissions				Should Export MMAP? [1]
	The Side Submitting the Task		The Peer		
	RDMA	MMAP	RDMA	MMAP	
Read Get Remote Sync Event	–	Local read write	RDMA read	Local read write | RDMA read	Yes
Write Write with Immediate Set Remote Sync Event	–	Local read write	RDMA write	Local read write | RDMA write	Yes
Atomic Compare and Swap Atomic Fetch and Add Add Remote Sync Event	–	Local read write	RDMA atomic	Local read write | RDMA atomic	Yes
Send Send with Immediate	–	Local read write	–	Local read write	No
Receive	Depending on the received task	Local read write	Not relevant		

1. Refers to the peer. A side that only submits tasks is never required to export an mmap.

5.4.7.6.1.2 Optional Configurations

If these configurations are not set, a default value is used.

Users may edit the default properties of the RDMA instance using the `doca_rdma_set_<property>()`. The user may also query the default/set properties using `doca_rdma_cap_get_<property>(struct doca_rdma *, …)` functions.

> The number of tasks that can be submitted in bulk is dependent on the properties `max_send_buf_list_len` and `send_queue_size`.

Refer to section "Library Capability" for querying valid property values when configuring the library context.

While it is possible to select "dynamically connected" (DC) as transport type using `doca_rdma_set_transport_type()`, current support for this transport type is in alpha level only.

5.4.7.6.2 Device Support

DOCA RDMA requires a device to operate. For picking a device, see DOCA Core Device Discovery.

As device capabilities may change in the future, it is recommended to query each `doca_devinfo` for its capabilities relevant to RDMA operations, using `doca_rdma_cap_*(struct doca_devinfo *, …)` functions, and check whether the device is suitable for the required RDMA task types, using `doca_rdma_task_<task_type>_is_supported()`.

BlueField-2 and higher devices are supported:

- On the host, any `doca_dev` is supported
- On the BlueField Platform, applications must provide the library with SFs as a `doca_dev`. See OpenvSwitch Acceleration - OVS in DOCA and BlueField DPU Scalable Function to see how to create SFs and connect them to the appropriate ports.

  An exception to this is when running RDMA on the DPA datapath, which currently only supports PFs.

5.4.7.6.3 Buffer Support

The DOCA RDMA library utilizes different buffer types, depending on the task and the buffer's purpose:

- Local mmap buffer
- Mmap from RDMA export buffer
- Mmap from PCIe export buffers

  This type of buffer can be used in an equivalent manner to local mmap buffers.

- Linked list buffer

For task-specific information, refer to section "Tasks".

5.4.7.6.4 Multiple Connections

Multiple parallel connections can be established between peers, enabling an RDMA instance to simultaneously connect to different peers. A unique connection object is provided as to identify and use each established connection.

The maximum number of connection supported by a RDMA instance may be configured using `doca_rdma_set_max_num_connections()`.

To terminate a connection, the connection object must be provided as input to `doca_rdma_connection_disconnect()`.

> ⚠ All established connections are automatically terminated when the context is stopped

> ⚠ All connection methods allow multiple connections. However, the specifics way for providing the connection object depends on the connection methods. See section "Establishing RDMA Connections" for more information

5.4.7.6.5 Establishing RDMA Connections

To establish the communication between the peers and allow the execution of different DOCA RDMA tasks, the RDMA instances must be connected.

> ⚠ This should be executed after `doca_ctx_start()` is called.

> ℹ Refer to section "State Machine" for more information.

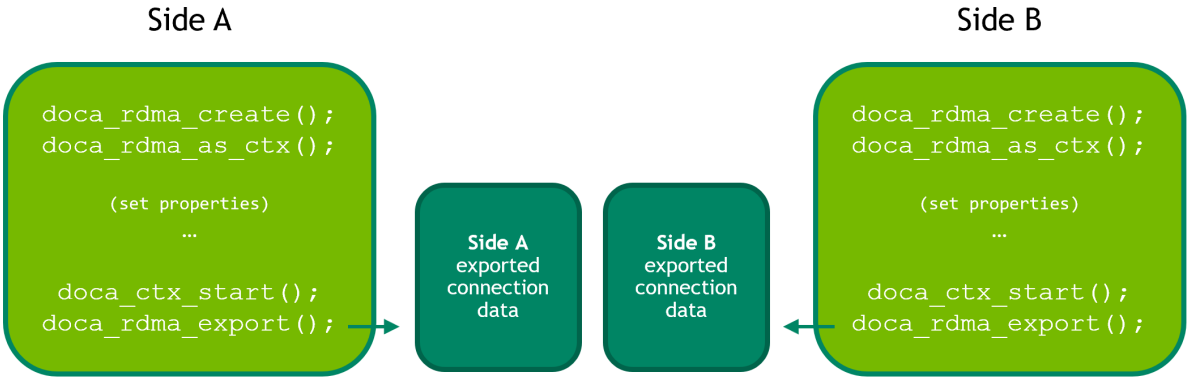
There are three methods for establishing RDMA connections as detailed in the following subsections.

5.4.7.6.5.1 Exporting and Connecting RDMA

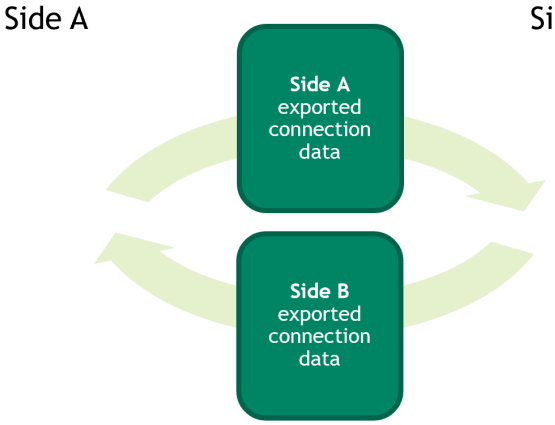
Connecting the RDMA instances can be done by exporting each RDMA instance to the remote side to a blob by using `doca_rdma_export()`, transferring the blob to the opposite side, out-of-band (OOB), and providing it as input to the `doca_rdma_connect()` function on that side.

All in all, the configuration flow should be as presented in the following image:

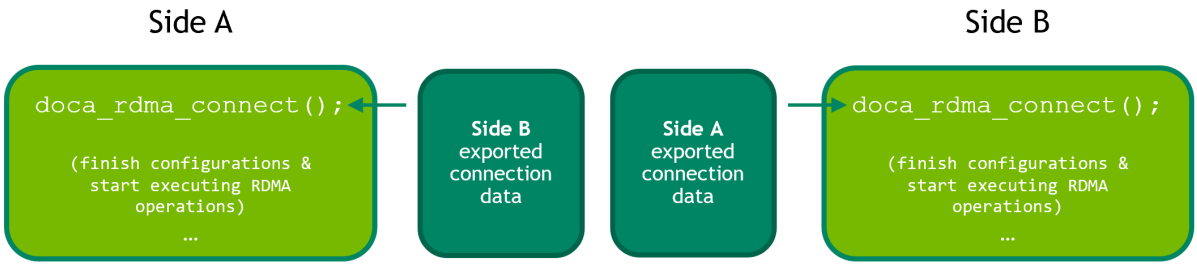
Step 1: Initiate the RDMA instance, and when ready, export it



Step 2: Transfer the exported connection data out-of-band



Step 3: Connect the two RDMA instances



The exported data contains sensitive information. Make sure to pass this data through a secure channel!

The doca_rdma_export() returns a unique connection object identifying this connection. This object must be provided as input to doca_rdma_connect() (to perform a connection) or to doca_rdma_connection_disconnect() (to perform a disconnection), and to all task allocations exchanged over this connection.

An RDMA instance can perform an asymmetric disconnection process using doca_rdma_connection_disconnect().

The RDMA instance which did not initiate the disconnection process will not receive a notification.

5.4.7.6.5.2 Connecting Using RDMA CM Connection Flow

The RDMA CM (communication manager) flow uses the server/client scheme where one of the RDMA instances acts as a server for the second RDMA instance (client). The process for both RDMA instances is non-blocking, event driven, and governed by the progress engine (PE). The connection process is reported to both instances by callbacks which should be set with doca_rdma_set_connection_state_callbacks().

There are four state callbacks:

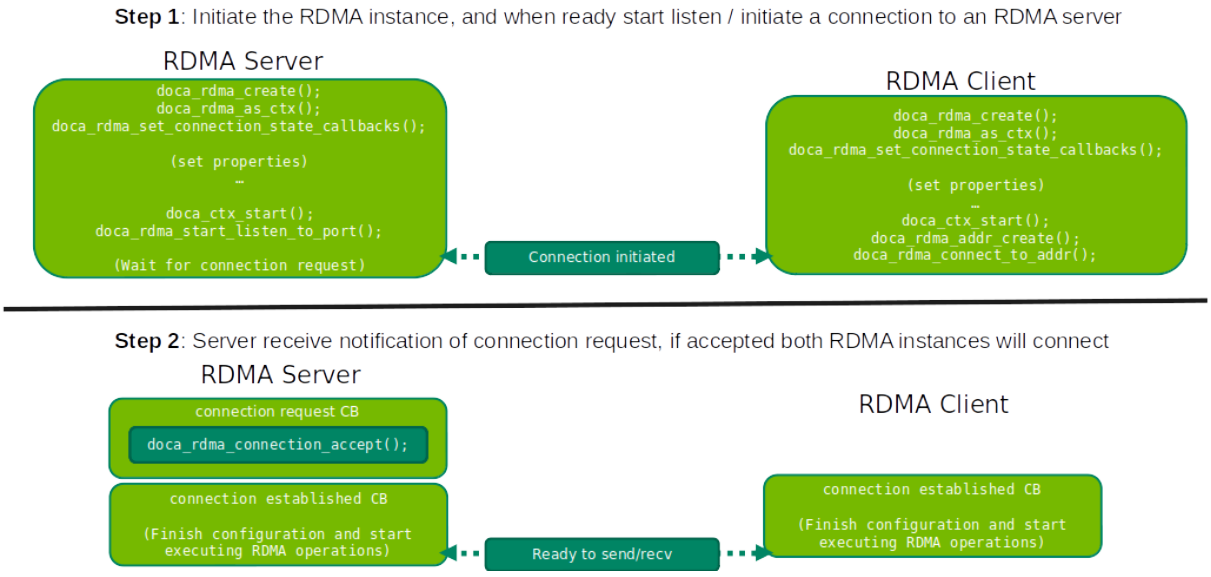
- Connection request callback – This function is called by doca_pe_progress() when a connection request is received by an RDMA instance acting as server
- Connection established callback – This function is called by doca_pe_progress() when a connection is successfully established between server/client RDMA instances
- Connection failure callback – This function is called by doca_pe_progress() when a connection fails to be established between server/client RDMA instances
- Connection disconnection callback – This function is called by doca_pe_progress() when a connection disconnects either server/client RDMA instances

A typical connection flow would be as follows:

1. Prior to initiating a connection, the RDMA instance acting as server (i.e., RDMA server) must start active listening for a connection from a remote RDMA peer (using RDMA CM) to a specific port using doca_rdma_start_listen_to_port(). An RDMA server can stop listening for a connection from a remote RDMA peer (using RDMA CM) by using doca_rdma_stop_listen_to_port().
2. The RDMA CM instance acting as client (i.e., RDMA client) can now perform an RDMA connection to the RDMA server. As first step it must create an address object by using doca_rdma_addr_create(). The parameters to this function

correspond to the RDMA server details required to perform a connection. This object can be destroyed by using `doca_rdma_addr_destroy()`, and retrieve it from a connection with `doca_rdma_connection_get_addr()`.

3. The RDMA client can set the connection user data to include in each connection using `doca_rdma_connection_set_user_data()`, and retrieve it from a connection using `doca_rdma_connection_get_user_data()`.
4. The RDMA client can now perform a connection to the RDMA server using `doca_rdma_connect_to_addr()`. Depending on the network topology and configuration, the connection can be established with IPv4, IPv6, or GID.
5. The RDMA server receives a notification with a connection request through the previously set connection request callback function. The RDMA server can decide to accept the connection with `doca_rdma_connection_accept()` or reject the connection with `doca_rdma_connection_reject()`.
    - If the RDMA server rejects the connection or the connection cannot be successfully established, the RDMA server and RDMA client receive a notification through the connection failure callback function.
    - If the RDMA server accepts the connection and the connection can be successfully established, the RDMA server and RDMA client receive a notification through the connection established callback function.
6. After the RDMA operation is complete, either side can perform the disconnection process using `doca_rdma_connection_disconnect()`. The RDMA instance that did not initiate the disconnection process receives a notification through the disconnection callback function.



⚠ The connection process involves resolving the RDMA server connection address. This process is limited by the `connection_request_timeout` property which can be set using `doca_rdma_set_connection_request_timeout()` and retrieved using `doca_rdma_get_connection_request_timeout()`.

⚠ The RDMA server "connection request" callback and the RDMA client "connection established" callback functions provide a connection object unique to the connection. This object must be provided as input to `doca_rdma_connection_accept()`, `doca_rdma_connection_reject()`, and/or `doca_rdma_connection_disconnect()` as well as to all task allocations exchanged over this connection. The same procedure is followed for each separate connection in order to have a unique connection object per connection.

⚠ If a connection fails to be established between server/client RDMA instances, the connection object is valid only in the connection failure callback, and is implicitly destroyed immediately after return.

⚠ The `doca_rdma_connection_accept()` method accepts private data as an input parameter that gets transparently passed to the remote side as part of the communication request.

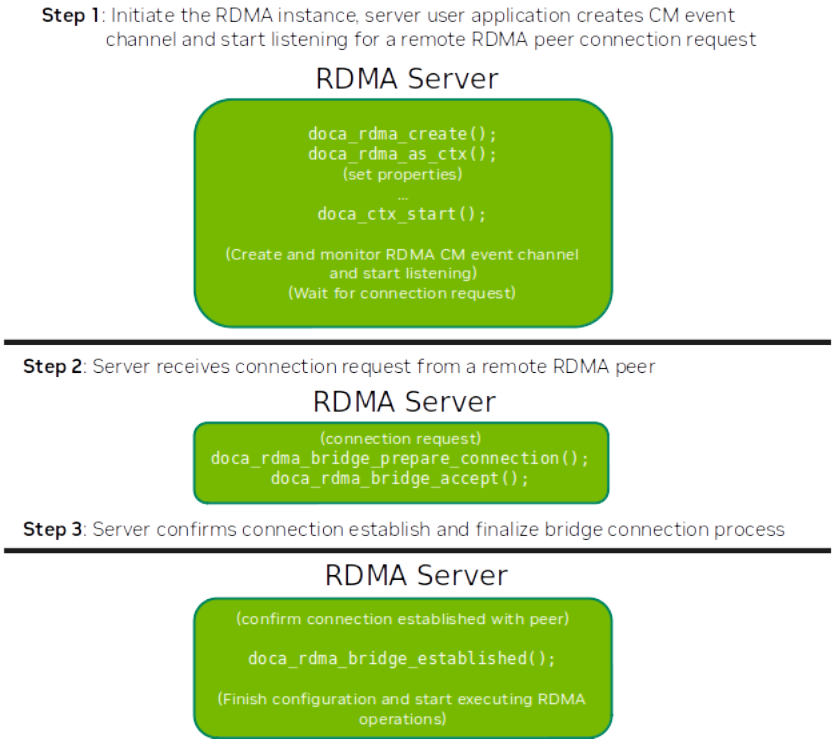
5.4.7.6.5.3 Using Bridge Functions to Accept CM Connection

DOCA RDMA offers connection functionality for user RDMA CM applications acting as a server that maintains a CM event channel and performs the listen process itself (i.e., not using DOCA RDMA connection flow functions).

The functionality must be executed as follows:

1. Server user application, using RDMA CM, must create an RDMA CM event channel, start active listening for a connection from a remote RDMA peer, and monitor the created CM event channel. These functions are performed without the use of the DOCA RDMA connection flow functions explained in section "Connecting Using RDMA CM Connection Flow".
2. Once the server user application received a connection request from a remote RDMA peer acting as client (using RDMA CM), it can call `doca_rdma_bridge_prepare_connection()`. This method acts as a bridge to prepare and perform the doca connection to a connection request, from an application that performs the listen process by itself. The previously explained `doca_rdma_connection_accept()` cannot be used for this connection step as the user application needs to provide the RDMA CM id to prepare the connection.

3. Once the connection is ready, the server can call `doca_rdma_bridge_accept()`. This method acts as a bridge to accept a connection request from an application that performs the listen process by itself.
4. After the server side calls `doca_rdma_bridge_accept()` and confirms the client connection is successfully established, it should call `doca_rdma_bridge_established()` to finish the connection process from the server side. Only after a connection is established can DOCA RDMA tasks be allocated and submitted.



The `doca_rdma_bridge_prepare_connection()` method returns a unique connection object that identifies the connection. This object must be provided as input to `doca_rdma_bridge_accept()` and `doca_rdma_bridge_established()` to finish the connection process from the server side as well as to all task allocations exchanged over this connection. The same procedure is required for each separate connection so as to have a unique connection object per connection.

The `doca_rdma_bridge_accept()` method accepts private data as input parameter that is transparently passed to the remote side as part of the communication request.

5.4.7.7 Execution Phase

This section describes execution on CPU using DOCA Core PE. For additional execution environments refer to section "Alternative Datapath Options".

5.4.7.7.1 Tasks

DOCA RDMA exposes asynchronous tasks that leverage the DPU hardware according to the DOCA Core architecture. See DOCA Core Task.

> ⚠ Most DOCA RDMA operations are not atomic and therefore it is imperative that the application handle synchronization appropriately. Moreover, successful completion of a write task, with or without immediate, does not guarantee data has been fully written to the remote address.

> ⚠ All buffers used in DOCA RDMA tasks must remain valid until the task result is retrieved.

5.4.7.7.1.1 Receive Task

This task should be submitted prior to an expected submission of a send/send with immediate/write with immediate task on the remote side.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_receive_set_conf`	`doca_rdma_cap_task_receive_is_supported`
Number of tasks	`doca_rdma_task_receive_set_conf`	–
Destination buffer list length	`doca_rdma_task_receive_set_dst_buf_list_len`	`doca_rdma_cap_task_receive_get_max_dst_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Destination buffer	Buffer pointing to a local memory address. The data is written to the buffer upon successful completion of the task.	• Linked list buffers are supported • The given destination buffer/list of buffers (given in `dst_buf`) must have a total length sufficient for the expected message size or the task would fail • The destination buffer is not mandatory and may be NULL when the requested DOCA RDMA task on the remote side is "write with immediate" or when the remote side is sending an empty message, with or without immediate (these tasks are presented later on in the "Tasks" section) • For the DOCA RDMA receive task, the length of each buffer is considered as the length from the end of the data section until the end of the buffer, as this is the available memory that can be written to in each buffer. The data length is increased in each buffer if data is written to it once the task is successfully completed.

Task Output

Common output as described in DOCA Core Task.

Name	Description	Notes
Result length	The length of data received by the task	Valid only on successful completion of the task
Result opcode	The opcode of the operation executed by the peer and received by the task	Valid only after task completion, irrespective of success
Result immediate data	The immediate data received by the task	• Valid only on successful completion of the task • Valid only when an immediate value was received (i.e. when the result opcode is `DOCA_RDMA_OPCODE_RECV_SEND_WITH_IMM` or `DOCA_RDMA_OPCODE_RECV_WRITE_WITH_IMM`) – may be retrieved using `doca_rdma_task_receive_get_result_opcode()`)
RDMA connection	The RDMA connection used by the task	Valid only on successful completion callback of the task

Task Completion Success

After the task completes successfully, the following happens:

- The received data is copied to the tail segment extending the original data segment
- The data length is increased by the received data length

Task Completion Failure

If the task fails midway:

- If a fatal error occurs, the context is stopped, and the task should be freed by the user

- If a non-fatal error occurs, the task status is updated. Some buffers may be updated and some may remain unchanged.

Task Limitations

- The operation is not atomic and therefore it is imperative that the application handle synchronization appropriately
- The destination buffer must remain valid until task is completed
- The total length of the message must not exceed the `max_message_size` device capability
- The buffer list length must not exceed the `dst_buf_list_len` property of the DOCA RDMA receive task
- Other limitations are described in DOCA Core Task

5.4.7.7.1.2 Send Task

This task should be submitted to transfer a message to the remote side, and while the remote side is expecting a message and had submitted a receive task beforehand.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_send_set_conf`	`doca_rdma_cap_task_send_is_supported`
Number of tasks	`doca_rdma_task_send_set_conf`	–
Source buffer list length	`doca_rdma_set_max_send_buf_list_len` [2]	`doca_rdma_cap_get_max_send_buf_list_len`

2. This configuration affects other tasks as well.

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to a local memory address and holds the data to be sent to the remote peer	• Linked list buffers are supported • The total length of the given source buffer/list of buffers (in `src_buf`) may not exceed the expected message size on the remote side or the task fails • The source buffer is not mandatory and may be NULL when wishing to send an empty message • For the DOCA RDMA send task, the length of each buffer is considered as its data length
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- On successful completion of the task, the data in the source buffer will be sent to the remote side.
- It doesn't indicate that the data is received by the remote side.

Task Completion Failure

If the task fails midway:

- If a fatal error occurs, the context is stopped, and the task should be freed by the user
- If a non-fatal error occurs, the task status is updated

Task Limitations

- The operation is not atomic. Therefore, it is imperative for the application to handle synchronization appropriately.
- The source buffer must remain valid until the task completes
- The total length of the message must not exceed the `max_message_size` device capability
- The buffer list length must not exceed the `max_send_buf_list_len` property of the DOCA RDMA instance
- Other limitations are described in DOCA Core Task

5.4.7.7.1.3 Send With Immediate Task

This task should be submitted to transfer a message to the remote side with immediate data (a 32-bit value sent to the remote side, out-of-band), and while the remote side is expecting a message and had submitted a receive task beforehand.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_send_imm_set_conf`	`doca_rdma_cap_task_send_imm_is_supported`
Number of tasks	`doca_rdma_task_send_imm_set_conf`	–
Source buffer list length	`doca_rdma_set_max_send_buf_list_len` [3]	`doca_rdma_cap_get_max_send_buf_list_len`

3. This configuration affects other tasks as well.

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to a local memory address and holding the data to be sent to the remote peer	• Linked list buffers are supported. • The total length of the given source buffer/list of buffers (in `src_buf`) may not exceed the expected message size on the remote side or the task fails. • The source buffer is not mandatory and may be NULL when wishing to send an empty message (may be relevant when wishing to keep a connection alive) • For the DOCA RDMA send task, the length of each buffer is considered as its data length
Immediate data	32-bit value sent to the remote side, out-of-band	• The `immediate_data` field should be in Big-Endian format. This value is received by the remote side only once a receive task is completed successfully.
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The data in the source buffer is sent to the remote side
- It does not indicate that the data is received by the remote side

Task Completion Failure

If the task fails midway:

- If a fatal error occurs, the context is stopped, and the task should be freed by the user
- If a non-fatal error occurs, the task status is updated

Task Limitations

- The operation is not atomic. Therefore, it is imperative for the application to handle synchronization appropriately.
- The source buffer must remain valid until the task completes
- The total length of the message must not exceed the `max_message_size` device capability
- The buffer list length must not exceed the `max_send_buf_list_len` property of the DOCA RDMA instance
- Other limitations are described in DOCA Core Task

5.4.7.7.1.4 Read Task

This task should be submitted when wishing to read data from remote memory (i.e., the memory on the remote side of the connection).

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_read_set_conf`	`doca_rdma_cap_task_read_is_supported`
Number of tasks	`doca_rdma_task_read_set_conf`	–
Destination buffer list length	`doca_rdma_set_max_send_buf_list_len` [4]	`doca_rdma_cap_get_max_send_buf_list_len`

4. This configuration affects other tasks as well.

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Points to a remote memory address and holds the data to be read	• Linked list buffers are not supported • The source buffer (`src_buf`) is not mandatory and may be NULL when wishing to read zero bytes (may be relevant when wishing to keep a connection alive) • The data is read only from the data section of the source buffer • The length of the source buffer is considered its data length. The length of data read from the source buffer depends on its data length yet cannot exceed the total length of the given destination buffer/list of buffers. That is, the actual length read depends on the minimal length between the source and destination.
Destination buffer	Points to a local memory address. The data is written to the buffer upon successful completion of the task	• Linked list buffers are supported • The length of each destination buffer is considered as the length from the end of the data section until the end of the buffer, as this is the available memory that can be written to in each buffer • May be NULL if the source buffer has been set to NULL
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Name	Description	Notes
Result length	The length of data read by the task	Valid only on successful completion of the task

Task Completion Success

After the task completes successfully, the following happens:

- The read data is appended after the data section in the destination buffer, as it was prior to the task submission
- The data length is increased by the read data length

Task Completion Failure

If the task fails midway:

- If a fatal error occurs, the context is stopped, and the task should be freed by the user
- If a non-fatal error occurs, the task status is updated. Some destination buffers may be updated, and some may remain unchanged.

Task Limitations

- The operation is not atomic. Therefore, it is imperative for the application to handle synchronization appropriately.
- The task buffers must remain valid until task is completed
- The given source buffer length must not exceed the `max_message_size` device capability
- The destination buffer list length must not exceed the `max_send_buf_list_len` property of the DOCA RDMA instance
- Other limitations are described in DOCA Core Task

5.4.7.7.1.5 Write Task

This task should be submitted when wishing to write data to remote memory (i.e., the memory on the remote side of the connection).

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_write_set_conf`	`doca_rdma_cap_task_write_is_supported`
Number of tasks	`doca_rdma_task_write_set_conf`	–
Source buffer list length	`doca_rdma_set_max_send_buf_list_len` [5]	`doca_rdma_cap_get_max_send_buf_list_len`

5. This configuration affects other tasks as well.

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to a local memory address and holding the data to be written to the remote peer.	• Linked list buffers are supported • The source buffer should point to a local memory address from which the data should be read. The data is read only from the data section of the source buffer. • The source buffer (`src_buf`) is not mandatory and may be NULL when wishing to write zero bytes (may be relevant when wishing to keep a connection alive) • The length of the buffer is considered as its data length
Destination buffer	Points to a remote memory address. The data is written to the buffer upon successful completion of the task.	• Linked list buffers are not supported • The destination buffer (`dst_buf`) should point to a remote memory address • The length of the buffer is considered as its data length • The length of the destination buffer is considered as the length from the end of the data section until the end of the buffer, as this is the available memory that can be written to • The length of data written to the destination buffer depends on the total length of the given source buffer/list of buffers • May be NULL if the source buffer was set to NULL
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The written data is appended after the data section in the destination buffer, as it was prior to the task submission.
- The data length is increased by the written data length

Task Completion Failure

If the task fails midway:

- If a fatal error occurs, the context is stopped, and the task should be freed by the user
- If a non-fatal error occurs, the task status is updated. Some destination buffers may be updated, and some may remain unchanged.

Task Limitations

- The operation is not atomic. Therefore, it is imperative for the application to handle synchronization appropriately.
- The task buffers must remain valid until task is completed

- The total length of the given source buffer/list of buffers must be not exceed the `max_message_size` device capability
- The source buffer list length must not exceed the `max_send_buf_list_len` property of the DOCA RDMA instance
- Other limitations are described in DOCA Core Task

5.4.7.7.1.6 Write With Immediate Task

This task should be submitted when wishing to write data to remote memory (i.e., the memory on the remote side of the connection).

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_write_imm_set_conf`	`doca_rdma_cap_task_write_imm_is_supported`
Number of tasks	`doca_rdma_task_write_imm_set_conf`	-
Source buffer list length	`doca_rdma_set_max_send_buf_list_len` [6]	`doca_rdma_cap_get_max_send_buf_list_len`

6. This configuration affects other tasks as well.

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to a local memory address and holding the data to be written to the remote peer	• Linked list buffers are supported • The source buffer should point to a local memory address from which the data should be read. The data is read only from the data section of the source buffer. • The source buffer (`src_buf`) is not mandatory and may be NULL when wishing to write zero bytes • The length of the buffer is considered as its data length
Destination buffer	Points to a remote memory address. The data is written to the buffer upon successful completion of the task.	• Linked list buffers are not supported • The destination buffer (`dst_buf`) should point to a remote memory address • The length of the buffer is considered as its data length • The length of the destination buffer is considered as the length from the end of the data section until the end of the buffer, as this is the available memory that can be written to • The length of data written to the destination buffer depends on the total length of the given source buffer/list of buffers • May be NULL if the source buffer was set to NULL

Name	Description	Notes
Immediate data	32-bit value sent to the remote side, out-of-band	• Should be in a Big-Endian format • Value is received by the remote side only once a receive task completes successfully
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

A write with immediate task succeeds only if the remote side is expecting the immediate and had submitted a receive task beforehand.

After the task completes successfully, the following happens:

- The written data is appended after the data section in the destination buffer, as it was prior to the task submission
- The data length is increased by the written data length.

Task Completion Failure

If the task fails midway:

- If a fatal error occurs, the context is stopped, and the task should be freed by the user
- If a non-fatal error occurs, the task status is updated. Some destination buffers may be updated, and some may remain unchanged.

Task Limitations

- The operation is not atomic. Therefore, it is imperative for the application to handle synchronization appropriately.
- The tasks buffers must remain valid until task is completed
- The total length of the given source buffer/list of buffers must be not exceed the `max_message_size` device capability
- The source buffer list length must not exceed the `max_send_buf_list_len` property of the DOCA RDMA instance
- Other limitations are described in DOCA Core Task

5.4.7.7.1.7 Atomic Compare and Swap Task

This task should be submitted when wishing to execute an 8-byte atomic read-modify-write operation on the remote memory (i.e., the memory on the remote side of the connection), in which the remote value is retrieved and updated if it is equal to a given value.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_atomic_cmp_swp_set_conf`	`doca_rdma_cap_task_atomic_cmp_swp_is_supported`
Number of tasks	`doca_rdma_task_atomic_cmp_swp_set_conf`	-

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Destination buffer	Buffer pointing to a remote memory address	• Linked list buffers are not supported • The destination buffer's data section must begin in a memory address aligned to 8-bytes • Only the first 8-bytes following the data address are considered for atomic operations
Compare data	64-bit value to be compared with the value in the destination buffer	
Swap data	64-bit value to be swapped with the value in the destination buffer	• The value in the destination buffer is only swapped if the compared data value is equal to the value in the destination buffer. Otherwise, the destination buffer remains unchanged.
Result buffer	Buffer pointing to a local memory address. The original value of the destination buffer (before executing the atomic operation) is written to the buffer upon success.	• Linked list buffers are not supported • The result is written to the first 8-bytes following the data address
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- If the compared values are equal, the value in the destination is swapped with the 64-bit value in the task's swap data field (`swap_data`)
- If the compared values are not equal, the value in the destination value remains unchanged
- The original value of the destination buffer (before executing the atomic operation) is written to the result buffer

Task Completion Failure

If the task fails midway:

- The context is stopped, and the task should be freed by the user

Task Limitations

- Task buffers must remain valid until task is completed
- Other limitations are described in DOCA Core Task

5.4.7.7.1.8 Atomic Fetch and Add Task

This task should be submitted when wishing to execute an 8-byte atomic read-modify-write operation on the remote memory (i.e., the memory on the remote side of the connection), in which the remote value is retrieved and increased by a given value.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_atomic_fetch_add_set_conf`	`doca_rdma_cap_task_atomic_fetch_add_is_supported`
Number of tasks	`doca_rdma_task_atomic_fetch_add_set_conf`	–

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Destination buffer	Buffer that points to a remote memory address	• Linked list buffers are not supported • The destination buffer's data section must begin in a memory address aligned to 8-bytes • Only the first 8-bytes following the data address are considered for atomic operations
Add data	64-bit value to be added to the value in the destination buffer	
Result buffer	Buffer pointing to a local memory address. The original value of the destination buffer (before executing the atomic operation) is written to the buffer upon success.	• Linked list buffers are not supported • The result is written to the first 8-bytes following the data address
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The value in the destination is increased by the 64-bit value in the task's add data field
- The original value of the destination buffer (before executing the atomic operation) is written to the result buffer

Task Completion Failure

If the task fails midway:

- The context is stopped, and the task should be freed by the user

Task Limitations

- Task buffers must remain valid until task is completed
- Other limitations are described in DOCA Core Task

5.4.7.7.1.9 Get Remote Sync Event Task

This task should be submitted when wishing to get the value of a remote sync event.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_remote_net_sync_event_get_set_conf`	`doca_rdma_cap_task_remote_net_sync_event_get_is_supported`
Number of tasks	`doca_rdma_task_remote_net_sync_event_get_set_conf`	–
Destination buffer list length	`doca_rdma_set_max_send_buf_list_len` [7]	`doca_rdma_cap_get_max_send_buf_list_len`

7. This configuration affects other tasks as well.

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Sync Event	The remote DOCA Sync Event to get its value	
Destination buffer	Points to a local memory address. The Sync Event value is written to the buffer upon successful completion of the task.	• Linked list buffers are supported • The length of the each buffer is considered as the length from the end of the data section until the end of the buffer, as this is the available memory that can be written to in each buffer

Name	Description	Notes
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Name	Description	Notes
Result length	The length of data received by the task	Valid only on successful completion of the task

Task Completion Success

After the task completes successfully, the following happens:

- The remote Sync Event value is appended after the data section in the destination buffer, as it was prior to the task submission
- The data length is increased by the retrieved data length

Task Completion Failure

If the task fails midway:

- If a fatal error occurs, the context is stopped, and the task should be freed by the user
- If a non-fatal error occurs, the task status is updated. Some destination buffers may be updated, and some may remain unchanged.

Task Limitations

- The operation is not atomic. Therefore, it is imperative for the application to handle synchronization appropriately.
- The destination buffer must remain valid until the task is completed
- The destination buffer list length must not exceed the `max_send_buf_list_len` property of the DOCA RDMA instance
- Other limitations are described in DOCA Core Task

5.4.7.7.1.10 Set Remote Sync Event Task

This task should be submitted when wishing to set a remote sync event to a given value.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_remote_net_sync_event_notify_set_set_conf`	`doca_rdma_cap_task_remote_net_sync_event_notify_set_is_supported`

Description	API to Set the Configuration	API to Query Support
Number of tasks	`doca_rdma_task_remote_net_sync_event_notify_set_set_conf`	-
Source buffer list length	`doca_rdma_set_max_send_buf_list_len` [8]	`doca_rdma_cap_get_max_send_buf_list_len`

8. This configuration affects other tasks as well.

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Points to a local memory address from which the Sync Event should be retrieved	• Linked list buffers are supported • The data is retrieved only from the buffer data section, until 8-bytes • The length of the source buffer is considered its data length. The length of data retrieved from the source buffer will not exceed the Sync Event value length (8-bytes). Thus, the actual length retrieved depends on the minimal length between the source buffer and Sync Event value length.
Sync Event	The remote DOCA Sync Event to set its value	
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The remote sync event value is set to the data in the source buffer

Task Completion Failure

If the task fails midway:

- If a fatal error occurs, the context is stopped, and the task should be freed by the user
- If a non-fatal error occurs, the task status is updated, and the Sync Event value is undefined

Task Limitations

- The operation is not atomic. Therefore, it is imperative for the application to handle synchronization appropriately.
- The source buffer must remain valid until the task completes
- The source buffer list length must not exceed the `max_send_buf_list_len` property of the DOCA RDMA instance
- Other limitations are described in DOCA Core Task

5.4.7.7.1.11 Add Remote Sync Event Task

This task should be submitted when wishing to atomically increase a remote sync event by a given value.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_rdma_task_remote_net_sync_event_notify_add_set_conf`	`doca_rdma_cap_task_remote_net_sync_event_notify_add_is_supported`
Number of tasks	`doca_rdma_task_remote_net_sync_event_notify_add_set_conf`	–

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Sync event	A remote Sync Event	
Add data	64-bit value that is added to the Sync Event value	
Result buffer	Buffer pointing to a local memory address. The original Sync Event value of the destination buffer (before executing the atomic operation) is written to the buffer upon success.	• Linked list buffers are not supported • The result is written to the first 8-bytes following the data address
RDMA connection	The RDMA connection to use on the task	Connection object provided in the connection establishment process as described in the "Establishing RDMA Connections" section

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The value of the remote sync event is increased by the 64-bit value in the task's add data field

- The original value of the remote sync event (before executing the operation) is written to the result buffer

Task Completion Failure

If the task fails midway:

- The context is stopped, and the task should be freed by the user

Task Limitations

- Result buffer must remain valid until task is completed
- Other limitations are described in DOCA Core Task

5.4.7.7.2 Events

DOCA RDMA exposes asynchronous events to notify about changes that happen unexpectedly, according to DOCA Core architecture.

The only event DOCA RDMA exposes is common events as described in DOCA Core Event.

5.4.7.8 State Machine

The DOCA RDMA library follows the Context state machine as described in DOCA Core Context State Machine.

The following section describes how to move states and what is allowed in each state.

5.4.7.8.1 Idle

In this state, it is expected that application either:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to section "Configurations"
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
N/A	Create the context
Running	Call stop after making sure all tasks have been freed

Previous State	Transition Action
Stopping	Call progress until all tasks are completed and freed

5.4.7.8.2 Starting

This state cannot be reached.

5.4.7.8.3 Running

In this state, it is expected that application:

1. Connects the RDMA instances on both peers. Refer to section "Establishing RDMA Connections" for more information.
2. Performs an RDMA instance disconnection process. Refer to section "Establishing RDMA Connections" for more information.
3. Performs a new connection of the RDMA instances on both peers after an RDMA instance disconnection process. Refer to section "Establishing RDMA Connections" for more information.
4. Accepts and indicates an established RDMA connection if the listening and CM channel monitoring was done by the user application. Refer to section "Connecting Using RDMA CM Connection Flow" for more information.
5. Allocates and submits tasks.
6. Calls progress to complete tasks and/or receive events.

Allowed operations:

- Performing a connection between 2 peers
- Allocating previously configured task
- Submitting an allocated task
- Calling stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

5.4.7.8.4 Stopping

In this state, it is expected that application:

1. Calls progress to complete all inflight tasks (tasks complete with failure)
2. Frees any completed tasks

3. Performs an RDMA instance disconnection process. Refer to section "Establishing RDMA Connections" for more information

Allowed operations:

- Call progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without freeing all tasks

5.4.7.9 Alternative Datapath Options

DOCA RDMA allows data path to be run on DPA or GPU.

5.4.7.9.1 DPA Datapath

DOCA offers the DOCA DPA library which provides a programming model for offloading communication-centric user code to run on the DPA processor on the BlueField DPU. For additional information on the DOCA DPA library.

The user can choose to run an RDMA operation on the DPA datapath by configuring the DOCA RDMA context used by the application in the following manner:

1. Obtain DOCA CTX by calling `doca_rdma_as_ctx()`.
2. Set the datapath of the context to DPA by calling `doca_ctx_set_datapath_on_dpa()`. For additional information, refer to DOCA Core Alternative Data Path.
3. Finish context configuration and start the context by calling `doca_ctx_start()`. For additional information, refer to DOCA Context.

After configuring the datapath, the user can obtain a DPA handle for the DOCA RDMA context by calling `doca_rdma_get_dpa_handle()`.

The DPA handle can be used by the DOCA DPA library for datapath operations. For additional information, refer to DOCA DPA Communication Model.

5.4.7.9.2 GPU Datapath

DOCA offers the DOCA GPUNetIO library which provides a programming model for offloading the orchestration of the communication to a GPU CUDA kernel. For additional information on the DOCA GPUNetIO library.

The user can choose to run an RDMA operation on the GPU datapath by configuring the DOCA RDMA context used by the application in the following manner:

1. Obtain DOCA CTX by calling `doca_rdma_as_ctx()`.
2. Set the datapath of the context to GPU by calling `doca_ctx_set_datapath_on_gpu()`. For additional information, refer to DOCA Core Alternative Data Path.
3. Finish context configuration and start the context by calling `doca_ctx_start()`. For additional information, refer to DOCA Core Context.

After configuring the datapath, the user can obtain a GPU handle for the DOCA RDMA context by calling `doca_rdma_get_gpu_handle()`.

The GPU handle must be passed to a GPU CUDA kernel so the DOCA GPUNetIO CUDA device functions can execute datapath operations. For additional information, refer to DOCA GPUNetIO device functions.

5.4.7.10 DOCA RDMA Samples

These samples illustrate how to use the DOCA RDMA API to execute DOCA RDMA operations.

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.7.10.1 Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

   ```
   cd /opt/mellanox/doca/samples/doca_rdma/<sample_name>
   meson /tmp/build
   ninja -C /tmp/build
   ```

   > The binary `doca_<sample_name>` is created under `/tmp/build/`.

3. Sample usage:

- Common arguments

Argument	Description
`-d`, `--device`	IB device name (optional). If not provided, a random IB device is assigned.
`-ld`, `--local-descriptor-path`	Local descriptor file path that includes the local connection information to be copied to the remote program
`-re`, `--remote-descriptor-path`	Remote descriptor file path that includes the remote connection information to be copied from the remote program
`-m`, `--mmap-descriptor-path`	Remote descriptor file path that includes the remote mmap connection information to be copied from the remote program
`-g`, `--gid-index`	GID index for DOCA RDMA (optional)
`-tt`, `---transport-type`	Transport type for DOCA RDMA (RC or DC; optional); only useful for single out-of-band RDMA connection currently
`-cm`, `--use-rdma-cm`	Whether to use RDMA CM or OOB to setup connection
`-lp`, `--listen-port`	Server listen port number
`-sa`, `--server-addr`	RDMA CM server device address
`-sat`, `--server-addr-type`	RDMA CM server device address type: IPv4, IPv6, or GID

- Sample-specific arguments

Sample	Argument	Description
RDMA Read Responder	`-r`, `--read-string`	String to read (optional). If not provided, "Hi DOCA RDMA!" is defined.
RDMA Send RDMA Send Immediate RDMA Multi-conn Send	`-s`, `--send-string`	
RDMA Write Requester RDMA Write Immediate Requester	`-w`, `--write-string`	
RDMA Multi-conn Send RDMA Multi-conn Receive	`-nc`, `--num-connections`	Number of connections for DOCA RDMA (optional); max connections number must be ≤8 in this sample

4. For additional information per sample, use the `-h` option:

```
/tmp/build/<sample_name> -h
```

5.4.7.10.2 Configuring Scalable Functions for DOCA RDMA Samples

When running DOCA RDMA samples on DPU-DPU setups with multiple SFs configured for a port, ensure the SF attribute `trust` is set to `off`.

By default, two SFs are present after logging into a DPU:

- `en3f0pf0sf0` corresponds to port `p0`.
- `en3f1pf1sf0` corresponds to port `p1`.

Steps:

1. Run the following command on both DPUs:

```
/opt/mellanox/iproute2/sbin/mlxdevm port add pci/0000:03:00.0 flavour pcisf pfnum 0 sfnum 1 controller 0
```

2. Find the SF index:

```
/opt/mellanox/iproute2/sbin/mlxdevm port show -jp
```

3. Set the SF attribute `trust` to `off`:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/SF-INDEX trust off
```

4. Configure the SF:
    - Set the hardware address:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/SF-INDEX hw_addr MAC-ADDR-USER-SPECIFIED
```

    - Activate the SF:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/SF-INDEX state active
```

5. Find SF-NEXT-SEQ:

```
devlink dev show
```

6. Unbind and bind the SF:

```
echo mlx5_core.sf.SF-NEXT-SEQ > /sys/bus/auxiliary/drivers/mlx5_core.sf_cfg/unbind
echo mlx5_core.sf.SF-NEXT-SEQ > /sys/bus/auxiliary/drivers/mlx5_core.sf/bind
```

7. Verify the SF status:

```
/opt/mellanox/iproute2/sbin/mlxdevm port show -jp
```

8. Add the new SF's representor to `ovs-vswitch`.
9. Assign a new IP address to the SF.

10. Run the DOCA RDMA samples using the new SF on port `p0`.

5.4.7.10.3 Samples

> These samples are also available on GitHub.

Each sample presents a connection between two peers, transferring data from one to another, using a different RDMA operation in each sample. For more information on the available RDMA operations, refer to section "Tasks".

Each sample is comprised of two executables, each running on a peer.

The samples can run on either DPU or host, as long as the chosen peers have a connection between them.

> Prior to running the samples, ensure that the chosen devices, selected by the device name and the GID index, are set correctly and have a connection between one another. In each sample, it is the user's responsibility to copy the descriptors between the peers.

Most of the samples follow the following main basic steps:

1. Allocating resources:
    a. Locating and opening a device. The chosen device is one that supports the tasks relevant for the sample. If the sample requires no task, any device may be chosen.
    b. Creating a local MMAP and configuring it (including setting the MMAP memory range and relevant permissions)
    c. Creating a DOCA PE
    d. Creating an RDMA instance and configuring it (including setting the relevant permissions)
    e. Connecting the RDMA context to the PE
2. Sample-specific configurations:
    a. Configuring the tasks relevant to the sample, if any. Including:
        i. Setting the number of tasks for each task type.
        ii. Setting callback functions for each task type, with the following logic:
            1. Successful completion callback:
                a. Verifying the data received from the remote, if any, is valid.
                b. Printing the transferred data.
                c. Freeing the task and task-specific resources (such as source/destination buffers).
                d. If an error occurs in steps a. and b., update the error that was encountered.

> ⚠ If the context is not in an idle state, only the first error in the flow is saved.

e. Decreasing the number of remaining tasks and stopping the context once it reaches 0.

2. Failed completion callback:
   a. Update the error that was encountered.

> ⚠ If the context is not in an idle state, only the first error in the flow is saved.

   b. Freeing the task and task-specific resources (such as source/destination buffers).
   c. Decreasing the number of remaining tasks and stopping the context once it reaches 0.

b. Setting a state change callback function, with the following logic:

- Once the context moves to Starting state (can only be reached from Idle), export and connect the RDMA and, in some samples, export the local mmap or the sync event.

> ⚠ During this step, the user is responsible for copying the descriptors between the two peers.

> ⚠ The descriptors are to be read and used only by the peer, using the relevant DOCA functions (the descriptors contain encoded data).

- Once the context moves to Running state (can only be reached from Starting state in RDMA samples):
  - In some samples, only print a log and wait for the peer, or synchronize events
  - In other samples, prepare and submit a task:
    a. If needed, create an mmap from the received exported mmap descriptor, passed from the peer.
    b. Request the required buffers from the buffer inventory.
    c. Allocate and initiate the required task, together with setting the number of remaining tasks parameter as the task's user data.
    d. Submit the task.
- Once the context moves to Stopping state, print a relevant log.
- Once the context moves to Idle state:
  1. Print a relevant log.

2. Send update that the main loop may be stopped.

3. Setting the program's resources as the context user data to be used in callbacks.
4. Creating a buffer inventory and starting it.
5. Starting the context.

> After starting the context, the state change callback function is called by the PE which executes the relevant steps.

> In a successful run, each section is executed in the order they are presented in section 2.b.

6. Progressing the PE until the context returns to Idle state and the main loop may be stooped, either because of a run in which all tasks have been completed, or due to a fatal error.
7. Cleaning up the resources.

5.4.7.10.3.1 RDMA Read

RDMA Read Requester

This sample illustrates how to read from a remote peer (the responder) using DOCA RDMA.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A read task is configured for this sample.
3. In this sample, data is read from the peer, verified to be valid, and printed in the successful task completion callback.
4. The local mmap is not exported as the peer does not intend to access it.
5. To read from the peer, a remote mmap is created from the peer's exported mmap.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_read_requester/rdma_read_requester_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_read_requester/rdma_read_requester_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_read_requester/meson.build`

RDMA Read Responder

This sample illustrates how to set up a remote peer for a DOCA RDMA read request.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for both the local mmap and the RDMA instance in this sample allow for RDMA read.
2. No tasks are configured for this sample, and thus no tasks are prepared and submitted, nor are there task completion callbacks.
3. The local mmap is exported to the remote memory to allow it to be used by the peer for RDMA read.
4. No remote mmap is created as there is no intention to access the remote memory in this sample.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_read_responder/rdma_read_responder_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_read_responder/rdma_read_responder_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_read_responder/meson.build`

5.4.7.10.3.2 RDMA Write

RDMA Write Requester

This sample illustrates how to write to a remote peer (the responder) using DOCA RDMA.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A write task is configured for this sample.
3. In this sample, data is written to the peer and printed in the successful task completion callback.
4. The local mmap is not exported as the peer does not intend to access it.
5. To write to the peer, a remote mmap is created from the peer's exported mmap.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_requester/rdma_write_requester_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_requester/rdma_write_requester_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_requester/meson.build`

RDMA Write Responder

This sample illustrates how to set up a remote peer for a DOCA RDMA write request.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for both the local mmap and the RDMA instance in this sample allow for RDMA write.
2. No tasks are configured for this sample, and thus no tasks are prepared and submitted, nor are there task completion callbacks. In this sample, the data written to the memory of the responder is printed once the context state is changed to Running, using the state change callback. This is done only after receiving input from the user, indicating that the requester had finished writing.
3. The local mmap is exported to the remote memory to allow it to be used by the peer for RDMA write.
4. No remote mmap is created as there is no intention to access the remote memory in this sample.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_responder/rdma_write_responder_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_responder/rdma_write_responder_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_responder/meson.build`

5.4.7.10.3.3 RDMA Write Immediate

RDMA Write Immediate Requester

This sample illustrates how to write to a remote peer (the responder) using DOCA RDMA along with a 32-bit immediate value which is sent OOB.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A write with immediate task is configured for this sample.
3. In this sample, data is written to the peer and printed in the successful task completion callback.
4. The local mmap is not exported as the peer does not intend to access it.
5. To write to the peer, a remote mmap is created from the peer's exported mmap.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_immediate_requester/rdma_write_immediate_requester_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_immediate_requester/rdma_write_immediate_requester_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_immediate_requester/meson.build`

RDMA Write Immediate Responder

This sample illustrates how the set up a remote peer for a DOCA RDMA write request whilst receiving a 32-bit immediate value from the peer's OOB.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for both the local mmap and the RDMA instance in this sample allow for RDMA write.
2. A receive task is configured for this sample to retrieve the immediate value. Failing to submit a receive task prior to the write with immediate task results in a fatal failure.
3. In this sample, the successful task completion callback also includes:
    a. Checking the result opcode, to verify that the receive task has completed after receiving a write with immediate request.
    b. Verifying the data written to the memory of the responder is valid and printing it, along with the immediate data received.
4. The local mmap is exported to the remote memory, to allow it to be used by the peer for RDMA write.
5. No remote mmap is created as there is no intention to access the remote memory in this sample.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_immediate_responder/rdma_write_immediate_responder_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_immediate_responder/rdma_write_immediate_responder_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_write_immediate_responder/meson.build`

5.4.7.10.3.4 RDMA Send and Receive

RDMA Send

This sample illustrates how to send a message to a remote peer using DOCA RDMA.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A send task is configured for this sample.
3. In this sample, the data sent is printed during the task preparation, not in the successful task completion callback.
4. The local mmap is not exported as the peer does not intend to access it.
5. No remote mmap is created as there is no intention to access the remote memory in this sample.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_send/rdma_send_sample.c`

- `/opt/mellanox/doca/samples/doca_rdma/rdma_send/meson.build`

RDMA Receive

This sample illustrates how the remote peer can receive a message sent by the peer (the sender).

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A receive task is configured for this sample to retrieve the sent data. Failing to submit a receive task prior to the send task results in a fatal failure.
3. In this sample, data is received from the peer verified to be valid and printed in the successful task completion callback.
4. The local mmap is not exported as the peer does not intend to access it.
5. No remote mmap is created as there is no intention to access the remote memory in this sample.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_receive/rdma_receive_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_receive/rdma_receive_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_receive/meson.build`

5.4.7.10.3.5 RDMA Send and Receive with Immediate

RDMA Send with Immediate

This sample illustrates how to send a message to a remote peer using DOCA RDMA along with a 32-bit immediate value which is sent OOB.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A send with immediate task is configured for this sample.
3. In this sample, the data sent is printed during the task preparation, not in the successful task completion callback.
4. The local mmap is not exported as the peer does not intend to access it.
5. No remote mmap is created as there is no intention to access the remote memory in this sample.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_send_immediate/rdma_send_immediate_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_send_immediate/rdma_send_immediate_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_send_immediate/meson.build`

RDMA Receive with Immediate

This sample illustrates how the remote peer can receive a message sent by the peer (the sender) while also receiving a 32-bit immediate value from the peer's OOB.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A receive task is configured for this sample to retrieve the sent data and the immediate value. Failing to submit a receive task prior to the send with immediate task results in a fatal failure.
3. In this sample, the successful task completion callback also includes:
    a. Checking the result opcode, to verify that the receive task has completed after receiving a sent message with an immediate.
    b. Verifying the data received from the peer is valid and printing it along with the immediate data received.
4. In this sample, data is received from the peer verified to be valid and printed in the successful task completion callback.
5. The local mmap is not exported as the peer does not intend to access it.
6. No remote mmap is created as there is no intention to access the remote memory in this sample.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_receive_immediate/rdma_receive_immediate_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_receive_immediate/rdma_receive_immediate_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_receive_immediate/meson.build`

5.4.7.10.3.6 RDMA Remote Sync Event

This sample illustrates how to synchronize between local sync event and a remote sync event DOCA RDMA.

RDMA Remote Sync Event Requester

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.

2. A "remote net sync event notify set" task is configured for this sample.
    - For this task, the successful task completion callback has the following logic:
        i. Printing an info log saying the task was successfully completed and a specific successful completion log for the task.
        ii. Decreasing the number of remaining tasks. Once 0 is reached:
            1. Freeing the task and task-specific resources.
            2. Stopping the context.
    - For this task, the failed task completion callback stops the context even when the number of remaining tasks is different than 0 (since the synchronization between the peers would fail).
3. A "remote net sync event get" task is configured for this sample.
    - For this task, the successful task completion callback also includes:
        i. Resubmitting the task, until a value greater than or equal to the expected value is retrieved.
        ii. Once such value is retrieved, submitting a "remote net sync event notify set" task to signal sample completion, including:
            1. Updating the successful completion message accordingly.
            2. Increasing the number of submitted tasks.
            3. If an error was encountered, and the "remote net sync event notify set" task was not submitted, the task and task resources are freed.
    - For this task, the failed task completion callback also includes freeing the "remote net sync event notify set" task and task resources.
4. The local mmap is not exported as the peer does not intend to access it.
5. No remote mmap is created as there is no intention to access the remote memory in this sample.
6. To synchronize events with the peer, a sync event remote net is created from the peer's exported sync event.
7. Both tasks are prepared and submitted in the state change callback, once the context moves from starting to running.
8. The user data of the "remote net sync event get" task points to the "remote net sync event notify set" task.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_sync_event_requester/rdma_sync_event_requester_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_sync_event_requester/rdma_sync_event_requester_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_sync_event_requester/meson.build`

RDMA Remote Sync Event Responder

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. This sample includes creating a local sync event and exporting it to the remote memory to allow the peer to create a remote handle.
3. No tasks are configured for this sample, and thus no tasks are prepared and submitted, nor are there task completion callbacks. In this sample, the following steps are executed once the context moves from starting to running, using the state change callback:
    a. Waiting for the sync event to be signaled from the remote side.
    b. Notifying the sync event from the local side.
    c. Waiting for completion notification from the remote side.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_sync_event_responder/rdma_sync_event_responder_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_sync_event_responder/rdma_sync_event_responder_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_sync_event_responder/meson.build`

5.4.7.10.3.7 RDMA Multi-connections Send and Receive

The following samples illustrates how to multiple connections can be performed to demonstrate an exchange of messages between peers.

Please note, using DOCA RDMA CM flow (see section "Connecting Using RDMA CM Connection Flow"):

1. One sample would act as Server while the other would act as a client
2. Multiple instances of the sample acting as client need to be independently executed to simulate each client peer to reach the amount of desired RDMA connections.

RDMA Multi-conn Send

This sample shows how multiple connections can be established and demonstrates:

- How multiple peers (clients) can send a message to a remote single peer (server) using DOCA RDMA CM flow (see section "Connecting Using RDMA CM Connection Flow").
- How a single peer (server) can send a message to multiple remote peers (clients) using DOCA RDMA CM flow (see section "Connecting Using RDMA CM Connection Flow").

- How multiple remote peers can send a message to their connected peers using the DOCA RDMA exporting and connection flow (see section "Exporting and Connecting RDMA").

> ⚠ In DOCA RDMA CM flow multiple instances of this sample need to be independently executed to simulate each client peer to reach the amount of desired RDMA connections.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A send task is configured for this sample.
3. In this sample, the data sent is printed during the task preparation, not in the successful task completion callback.
4. The local mmap is not exported as the peer does not intend to access it.
5. No remote mmap is created as there is no intention to access the remote memory in this sample.
6. The number of connections option can be set to
    a. the number of remote peers expected by the single peer (server sender) when using DOCA RDMA CM flow (see section "Connecting Using RDMA CM Connection Flow").
    b. the number of peers to connect to its remote peers using the DOCA RDMA exporting and connection flow (see section "Exporting and Connecting RDMA").

> ⚠ In DOCA RDMA CM flow, the number of connections cannot be used to simulate each client peer.

Reference:

- `/opt/mellanox/doca/samples/doca_rdma/rdma_multi_conn_send/rdma_multi_conn_send_sample.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_multi_conn_send/rdma_multi_conn_send_main.c`
- `/opt/mellanox/doca/samples/doca_rdma/rdma_multi_conn_send/meson.build`

RDMA Multi-conn Receive

This sample shows how multiple connections can be performed and demonstrates:

- How multiple remote peers (clients) can receive a message sent by one single peer (the sender server) using DOCA RDMA CM flow (see section "Connecting Using RDMA CM Connection Flow").

- How a single remote peer (server) can receive a message from multiple peers (the sender clients) using DOCA RDMA CM flow (see section "Connecting Using RDMA CM Connection Flow").
- How multiple remote peers can receive a message sent by their connected peers using the DOCA RDMA exporting and connection flow (see section "Exporting and Connecting RDMA").

> ⚠ In DOCA RDMA CM flow multiple instances of this sample need to be independently executed to simulate each client peer to reach the amount of desired RDMA connections.

The sample logic is as presented in the General Sample Steps, with attention to the following:

1. The permissions for the local mmap in this sample are set to local read and write.
2. A receive task is configured for this sample to retrieve the sent data.

   > ⚠ Failing to submit a receive task prior to the send task results in a fatal failure.

3. In this sample, data is received from the peer verified to be valid and printed in the successful task completion callback.
4. The local mmap is not exported as the peer does not intend to access it.
5. No remote mmap is created as there is no intention to access the remote memory in this sample.
6. The number of connections can be set to:
   a. The number of peers expected by the single remote peer (server) when using DOCA RDMA CM flow (see section "Connecting Using RDMA CM Connection Flow").
   b. The number of remote peers connected to their sender peers using the DOCA RDMA exporting and connection flow (see section "Exporting and Connecting RDMA").

> ⚠ In DOCA RDMA CM flow the number of connections cannot be used to simulate each client peer.

5.4.8 DOCA RDMA Verbs

This guide provides an overview and configuration instructions for the DOCA Verbs API.

5.4.8.1 Introduction

DOCA RDMA Verbs is a Verbs-like API that exposes the low-level features of Remote Direct Memory Access (RDMA). By enabling direct access to remote machine memory without CPU interruptions, DOCA RDMA Verbs reduces context switching for I/O operations, resulting in lower latency and higher bandwidth compared to traditional network communication methods.

> DOCA RDMA Verbs supports both InfiniBand and Ethernet using RoCE.

Key features:

- Vendor Agnostic: Supports multiple RDMA protocols.
- Verbs Compatibility: Built on established Verbs interfaces for easy migration from existing Verbs-based applications.
- Low-Level Control: Provides direct access to hardware capabilities for optimal performance tuning.
- Generic Design: Offers a unified API interface for various RDMA protocols.

DOCA RDMA Verbs operates on Verbs objects and is designed to ensure compatibility while extending capabilities for new RDMA protocols and hardware features. The library includes both native DOCA Verbs APIs and bridge APIs for seamless integration with existing IB Verbs applications.

For detailed API documentation and implementation, refer to the `doca_verbs.h` and `doca_verbs_bridge.h` header files.

5.4.8.2 Prerequisites

This library follows the architecture of DOCA Core and Verbs, it is recommended to read the following sections before proceeding:

- DOCA Core Device
- Libibverbs external guides

5.4.8.3 Environment

DOCA RDMA Verbs-based applications can run on either the host machine or the NVIDIA® BlueField® networking platform (DPU or SuperNIC).

5.4.8.4 Architecture

The DOCA Verbs API is centered around Verbs objects, designed to utilize the RDMA NIC's capabilities for high-performance data transfer. Each object plays a specific role in enabling and managing RDMA operations.

The API is categorized into two main function types:

- Control Path APIs: For initializing and configuring RDMA resources based on user requirements.
- Data Path APIs: For performing RDMA operations like sending, receiving, reading, and writing data. These functions are bridge functions relying on IB Verbs structures (e.g., `ibv_send_wr`, `ibv_wc`).

5.4.8.4.1 Objects

5.4.8.4.1.1 DOCA RDMA Verbs Device Attributes

> For DOCA Device documentation, read DOCA Core Device.

A DOCA Device represents a hardware device that supports RDMA operations through the DOCA RDMA Verbs library, serving as the foundation for creating Verbs contexts, protection domains, and other necessary resources.

DOCA RDMA Verbs Device Attributes provide detailed information about the device's capabilities and limitations, including:

- Maximum number of supported Queue Pairs (QPs), Completion Queues (CQs), Memory Regions (MRs), Protection Domains (PDs), Address Handles (AHs), and Shared Receive Queues (SRQs)
- Support for different QP types (RC, UC)
- Support for atomic operations
- Support for specialized data paths like DPA or GPU acceleration

These attributes are typically queried during application initialization to validate resource requirements against hardware capabilities.

The `doca_verbs_query_device` function is used to retrieve device attributes:

```
doca_error_t doca_verbs_query_device(struct doca_verbs_context *context, struct doca_verbs_device_attr
**verbs_device_attr)
```

5.4.8.4.1.2 DOCA RDMA Verbs Context

A DOCA RDMA Verbs Context represents a logical connection to an RDMA device, providing access to the RDMA NIC and serving as the root for other Verbs-related objects. It enables centralized cleanup and resource management for objects created under the Verbs library.

DOCA RDMA Verbs context can be created or imported (more information on IB Verbs Bridge section):

- Create context from `devinfo` or `ibv_device`:

  ```
  doca_error_t doca_verbs_context_create(struct doca_devinfo *devinfo, uint32_t flags, struct
  doca_verbs_context **verbs_context)
  doca_error_t doca_verbs_bridge_verbs_context_create(struct ibv_device *ibv_dev, uint32_t flags, struct
  doca_verbs_context **verbs_context)
  ```

  DOCA manages the resources and is independent of the IBV resources.
- The context can also be imported from an already existing IB Verbs context using the RDMA bridge:

  ```
  doca_error_t doca_verbs_bridge_verbs_context_import(struct ibv_context *ibv_ctx, uint32_t flags, struct
  doca_verbs_context **verbs_context)
  ```

  The user is responsible for cleanup operations, as the library does not manage the lifecycle of imported contexts.

  > ⚠ When importing using the bridge method, the IB context must remain open until the Verbs context is closed.

5.4.8.4.1.3 DOCA RDMA Verbs Protection Domain (PD)

A DOCA RDMA Verbs Protection Domain (PD) defines a logical security boundary within an RDMA device. It acts as a *sandbox* for grouping RDMA resources and ensures hardware-enforced isolation between applications or components sharing the same RDMA device.

The PD guarantees that all RDMA objects created within the same domain can trust and safely interact with each other, while any access from outside the domain is explicitly prohibited. This isolation creates a secure environment for RDMA operations.

Key features:

- Memory Access Control: Restricts RDMA operations to authorized memory regions.
- Hardware-Enforced Security: Utilizes hardware mechanisms to prevent unauthorized access.

- Application Isolation: Enforces separation between different applications using the same RDMA device.
- Safe Resource Grouping: Organizes related RDMA resources (e.g., memory regions, queue pairs) within a trusted context.

Interoperability with IB Verbs

- You can import an existing `ibv_pd` instance into DOCA RDMA Verbs using:

```
doca_error_t doca_verbs_bridge_verbs_pd_import(struct ibv_pd *pd, struct doca_verbs_pd **verbs_pd)
```

- For use cases such as registering memory with `ibv_reg_mr()`, retrieve the underlying IB Verbs PD:

```
struct ibv_pd *doca_verbs_bridge_verbs_pd_get_ibv_pd(const struct doca_verbs_pd *verbs_pd)
```

PD Creation and Usage

- Create a DOCA RDMA Verbs PD

```
doca_error_t doca_verbs_pd_create(struct doca_verbs_context *verbs_context, struct doca_verbs_pd
**verbs_pd);
```

- When initializing a queue pair (QP), associate it with the PD:

```
doca_error_t doca_verbs_qp_init_attr_set_pd(struct doca_verbs_qp_init_attr *verbs_qp_init_attr, struct
doca_verbs_pd *pd);
```

5.4.8.4.1.4 Memory Region (MR)

A Memory Region (MR) is a block of memory registered with the RDMA NIC to enable direct memory access through RDMA operations. Registering a memory region allows the NIC to perform zero-copy data transfers while enforcing access permissions and hardware-level protections.

Access Permissions

When registering an MR, the following access permissions can be enabled:

- Local Write – Allows local RDMA operations to write to the memory.
- Remote Read – Allows remote RDMA peers to read from the memory.
- Remote Write – Allows remote RDMA peers to write to the memory.
- Atomic Operations – Enables support for remote atomic operations (e.g., compare-and-swap, fetch-and-add).

Memory Keys

Each MR is associated with two keys used to authorize RDMA access:

- Local Key (lkey) – Used by the local RDMA NIC for internal access to the memory.

- Remote Key (rkey) – Shared with remote peers to grant them access, based on the permissions set during registration.

Registration

Memory regions are registered using the `ibv_reg_mr()` function from the RDMA Core API. This call:

- Allocates the necessary hardware resources for the memory region.
- Returns the local and remote keys (lkey and rkey).
- Enforces the specified access permissions for RDMA operations.

5.4.8.4.1.5 DOCA RDMA Verbs Queue Pair

A DOCA RDMA Verbs Queue Pair (QP) represents a connection between two RDMA-capable nodes. Each QP consists of a Send Queue and a Receive Queue, which process Work Requests (WRs) for RDMA operations.

QP Types

- RC (Reliable Connection) – Guarantees reliable, ordered delivery of messages.
- UC (Unreliable Connection) – Provides best-effort delivery without guaranteed ordering or reliability.

QP Initialization

Before creating a QP, users must first configure the desired attributes using a `doca_verbs_qp_init_attr` object. This object specifies:

- Send and receive queue sizes
- Associated Completion Queues (CQs)
- Protection Domain (PD)
- Optional data-path configuration

The configured initialization object is then used to instantiate the QP.

```
doca_error_t doca_verbs_qp_init_attr_create(struct doca_verbs_qp_init_attr **verbs_qp_init_attr);
doca_error_t doca_verbs_qp_create(struct doca_verbs_context *verbs_context,
                                  struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
                                  struct doca_verbs_qp **verbs_qp);
```

QP Modification

After creation, QPs may require state transitions or updates to their configuration. This is done using a `doca_verbs_qp_attr` object.

Common use cases include transitioning a QP from INIT → RTR (Ready to Receive) → RTS (Ready to Send) or updating addressing and connection parameters.

```
doca_error_t doca_verbs_qp_attr_create(struct doca_verbs_qp_attr **verbs_qp_attr);
doca_error_t doca_verbs_qp_modify(struct doca_verbs_qp *verbs_qp,
                                  struct doca_verbs_qp_attr *verbs_qp_attr,
```

```
                                int attr_mask);
```

QP Query

To inspect the current configuration or state of an existing QP, use the `doca_verbs_qp_query()` function. This retrieves attributes and initialization parameters according to the specified mask.

```
doca_error_t doca_verbs_qp_query(struct doca_verbs_qp *verbs_qp,
                                 struct doca_verbs_qp_attr *verbs_qp_attr,
                                 struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
                                 int *attr_mask);
```

External Data Path Mode

DOCA RDMA Verbs supports an external data path mode, allowing the data path to be implemented by the user or a third-party library (e.g., `doca_dpa` or `doca_gpunetio`). To enable this mode:

```
doca_error_t doca_verbs_qp_init_attr_set_external_datapath_en(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    uint8_t external_datapath_en);
```

Refer to the Bridge Execution Phase and Alternative Data Path Options sections for more details on integrating external data-path logic.

5.4.8.4.1.6 DOCA RDMA Verbs Completion Queue

A DOCA RDMA Verbs Completion Queue (CQ) is a data structure that collects notifications for completed RDMA operations. CQs are essential for tracking the status of Send and Receive Work Requests (WRs) submitted to a Queue Pair (QP).

Associating CQs with a QP

During QP initialization, the application must specify the CQs for send and receive operations:

```
doca_error_t doca_verbs_qp_init_attr_set_send_cq(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_verbs_cq *send_cq);

doca_error_t doca_verbs_qp_init_attr_set_receive_cq(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_verbs_cq *receive_cq);
```

CQ Initialization

A `doca_verbs_cq_attr` object defines the configuration for the CQ, including:

- Queue size
- Entry size
- Completion channel binding
- Data-path mode settings

To create and configure a CQ:

```
doca_error_t doca_verbs_cq_attr_create(struct doca_verbs_cq_attr **verbs_cq_attr);
doca_error_t doca_verbs_cq_create(struct doca_verbs_context *verbs_context,
                                  struct doca_verbs_cq_attr *verbs_cq_attr,
                                  struct doca_verbs_cq **verbs_cq);
```

External Data Path Mode

DOCA RDMA Verbs supports an external data path mode for advanced integration with external processing frameworks (e.g., `doca_dpa`, `doca_gpunetio`). In this mode, CQ data management and notification handling are offloaded outside of DOCA RDMA Verbs.

To enable this mode:

```
doca_error_t doca_verbs_cq_attr_set_external_datapath_en(
    struct doca_verbs_cq_attr *cq_attr,
    uint8_t external_datapath_en);
```

Refer to the Bridge Execution Phase and Alternative Data Path Options sections for more details.

5.4.8.4.1.7 DOCA RDMA Verbs Address Handle Attribute

A DOCA RDMA Verbs Address Handle Attribute (AH) is a data structure that encapsulates the addressing information required to establish communication with remote Queue Pairs (QPs). It is typically used during QP state transitions—such as INIT → RTR (Ready to Receive)—to define the destination addressing parameters.

Key Attributes

The AH structure may include the following fields depending on the address type and transport:

- Address Type – Specifies the type of addressing:
  - IPv4
  - IPv6
  - InfiniBand (with or without GRH)
- GID (Global Identifier) – Used for global routing in RoCE or IB with GRH.
- LID (Local Identifier) – Used for local routing in InfiniBand.
- Hop Limit – Specifies the maximum number of network hops (TTL equivalent).
- Service Level (SL) – Indicates QoS priority level on the fabric.
- Traffic Class – Classifies packets for differentiated services in IP-based networks.

Creating and Associating AH Attributes

To define an address handle and attach it to a QP modification request:

```
doca_error_t doca_verbs_ah_attr_create(
    struct doca_verbs_context *verbs_context,
    struct doca_verbs_ah_attr **verbs_ah);

doca_error_t doca_verbs_qp_attr_set_ah_attr(
    struct doca_verbs_qp_attr *verbs_qp_attr,
    struct doca_verbs_ah_attr *ah_attr);
```

The configured AH attribute can then be used during QP state transitions, particularly in INIT2RTR operations, to ensure proper remote addressing.

5.4.8.4.1.8 DOCA RDMA Verbs Completion Channel

A DOCA RDMA Verbs Completion Channel (CC) is a mechanism for managing asynchronous completion events from one or more associated Completion Queues (CQs). Completion channels enable efficient event-driven processing, reducing the need for continuous polling.

Creation and Association

To create a completion channel and associate it with a CQ:

```
doca_error_t doca_verbs_comp_channel_create(
    struct doca_verbs_context *verbs_context,
    struct doca_verbs_comp_channel **verbs_comp_channel);

doca_error_t doca_verbs_cq_attr_set_comp_channel(
    struct doca_verbs_cq_attr *cq_attr,
    struct doca_verbs_comp_channel *comp_channel);
```

Receiving and Acknowledging Events

To retrieve the next event (i.e., notification of completed work) from the completion channel:

```
doca_error_t doca_verbs_get_cq_event(
    struct doca_verbs_comp_channel *verbs_comp_channel,
    struct doca_verbs_cq **verbs_cq,
    void **cq_context);
```

Each event retrieved using `doca_verbs_get_cq_event()` must be acknowledged using:

```
void doca_verbs_ack_cq_events(struct doca_verbs_cq *verbs_cq, unsigned int nevents);
```

Integration with Epoll

The completion channel can be integrated into a standard event loop using `epoll` for scalable I/O multiplexing. To retrieve the file descriptor:

```
doca_event_handle_t doca_verbs_comp_channel_get_handle(
    struct doca_verbs_comp_channel *verbs_comp_channel);
```

This handle can be registered with `epoll` to receive readiness notifications, enabling synchronization across multiple RDMA and non-RDMA events.

5.4.8.4.1.9 DOCA RDMA Verbs Shared Received Queue (SRQ)

A Shared Receive Queue (SRQ) allows multiple RDMA Queue Pairs (QPs) to pull receive buffers from a common pool. Instead of maintaining separate receive queues per QP, the SRQ model supports scalable, efficient buffer sharing—especially useful in high-connection-count scenarios.

When work requests (WRs) are posted to the SRQ, any associated QP can consume them upon receiving data. Receive completions are still reported via the Completion Queue (CQ) attached to the individual QP, not the SRQ.

Advantages of SRQ-Based Design

- Scalable Design – Reduces the overhead of managing thousands of per-QP receive queues.
- Efficient Buffer Utilization – Ideal for servers with many clients where only a subset are active simultaneously.
- Lower Memory Footprint – A shared buffer pool minimizes overall memory usage.
- Simplified Buffer Management – Centralized posting reduces CPU and management complexity.

SRQ Types

- Linked List SRQ
  - Receive Work Queue (WQ) is organized as a linked list.
  - Supports out-of-order (OOO) processing across different QPs.
  - Supported by DOCA RDMA Verbs data path.
- Contiguous SRQ
  - Receive WQ is managed like a regular per-QP Receive Queue (RQ).
  - Supported only in external data-path mode (e.g., via `doca_dpa`, `doca_gpunetio`).

Associating SRQ with a QP

During QP initialization, an SRQ can be linked to a QP to enable shared receive functionality:

```
doca_error_t doca_verbs_qp_init_attr_set_srq(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_verbs_srq *srq);
```

SRQ Initialization

An `srq_init_attr` object is used to configure SRQ creation parameters, including:

- Queue size
- Maximum scatter/gather elements per WR
- SRQ type (linked list or contiguous)
- Data-path configuration

To create and configure an SRQ:

```
doca_error_t doca_verbs_srq_init_attr_create(
    struct doca_verbs_srq_init_attr **verbs_srq_init_attr);

doca_error_t doca_verbs_srq_create(
    struct doca_verbs_context *verbs_context,
    struct doca_verbs_srq_init_attr *verbs_srq_init_attr,
    struct doca_verbs_srq **verbs_srq);
```

Query SRQ Attributes:

Use `srq_query()` to retrieve the current configuration and parameters of an SRQ:

```
doca_error_t doca_verbs_srq_query(
    struct doca_verbs_srq *verbs_srq,
    struct doca_verbs_srq_init_attr *verbs_srq_init_attr);
```

External Data Path Mode

To offload the SRQ data path to an external engine (e.g., `doca_dpa`, `doca_gpunetio`), enable external data-path mode:

```
doca_error_t doca_verbs_srq_init_attr_set_external_datapath_en(
    struct doca_verbs_srq_init_attr *verbs_srq_init_attr,
    uint8_t external_datapath_en);
```

Refer to the Alternative Data Path Options section for further details.

5.4.8.4.1.10 DOCA RDMA Verbs Asynchronous Events

DOCA RDMA Verbs asynchronous events (async events) are non-blocking notifications that inform the application of significant hardware events or error conditions that occur during RDMA operations. These events are essential for detecting issues such as QP errors, memory registration failures, or transport problems.

Async events enable proactive error handling and health monitoring of RDMA resources without interrupting the primary application flow.

Retrieving and Acknowledging Events

To receive the next asynchronous event:

```
doca_error_t doca_verbs_get_async_event(
    struct doca_verbs_context *verbs_context,
    struct doca_verbs_async_event *async_event);
```

Each retrieved event must be acknowledged using the following function to release internal resources and prevent leaks:

```
void doca_verbs_ack_async_event(struct doca_verbs_async_event *async_event);
```

Event Handling Best Practices

- Applications should use the event handle obtained from the DOCA RDMA Verbs context to integrate async event monitoring into their event loop (e.g., using `epoll`).
- Async events should be processed promptly to avoid overflows in the internal event queue.
- Acknowledgment is mandatory for each event to ensure proper resource cleanup.

5.4.8.4.1.11 DOCA RDMA Verbs External Resources

DOCA RDMA Verbs supports both DOCA-managed and user-managed (external) modes for managing the low-level hardware resources used in RDMA operations. These include memory regions for work queues, user access regions (UARs), and doorbell registers.

For background on memory management concepts, refer to the DOCA Core Memory Subsystem documentation.

Key External Resources

- External UAR (User Access Region) – A memory-mapped region that provides direct access to hardware doorbell registers. UARs are used to signal the RDMA device when new work requests or completions are ready.
- External UMEM (User Memory) – Represents the physical memory region backing the Work Queue (WQ) structures, which hold posted Send and Receive Work Requests (WRs).
- External DBR UMEM (Doorbell Register UMEM) – A dedicated memory region used for doorbell registers that notify the hardware of new entries in the work queues.

Usage Modes

Mode	Description
DOCA-managed (default)	DOCA internally allocates and manages all UAR, UMEM, and DBR UMEM resources. The application is abstracted from memory alignment, sizing, and cleanup.
External mode	The application provides and manages its own UAR, UMEM, and DBR UMEM resources. This offers greater flexibility but requires a deep understanding of hardware constraints and careful memory management. External mode responsibilities: • Manual memory allocation with correct alignment and sizing • Lifetime management and cleanup of resources • Compliance with device and queue layout requirements

Setting External Resources

To configure external resource pointers during QP initialization:

```
doca_error_t doca_verbs_qp_init_attr_set_external_umem(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_umem *external_umem,
    uint64_t external_umem_offset);

doca_error_t doca_verbs_qp_init_attr_set_external_dbr_umem(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_umem *external_dbr_umem,
    uint64_t external_dbr_umem_offset);

doca_error_t doca_verbs_qp_init_attr_set_external_uar(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_uar *external_uar);
```

5.4.8.4.2 IB Verbs Bridge

DOCA RDMA Verbs provides a bridge between the traditional InfiniBand Verbs (IB Verbs) interface and DOCA abstractions, enabling a layered and interoperable architecture for RDMA operations. This bridge allows applications to integrate DOCA's enhanced features while preserving compatibility with the low-level IB Verbs API.

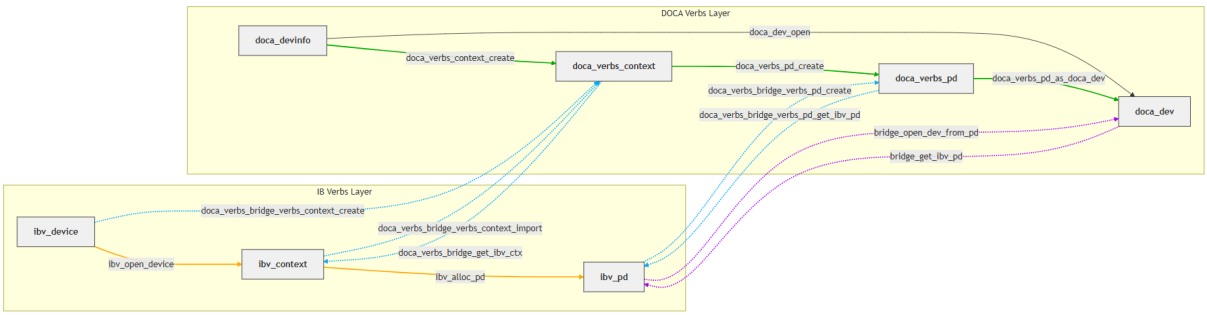
5.4.8.4.2.1 Bridge Configuration Phase

This dual-layer architecture allows applications to mix and match DOCA Verbs APIs and IB Verbs APIs based on their requirements. Developers can, for example, manage resources using DOCA abstractions while executing operations using native IB Verbs data structures.

- The `doca_rdma_verbs_context` is created using `doca_devinfo` and provides the entry point to the DOCA RDMA Verbs layer.
- The underlying `ibv_context` is created from an `ibv_device` using the standard IB Verbs API.
- The bridge components span across several API libraries: `doca_dev`, `doca_verbs`, `doca_verbs_bridge`, `doca_rdma_bridge`, and `libibverbs`.

> The recommended sequence is to first create the DOCA RDMA Verbs context, and then retrieve the DOCA device handle from it—not the other way around.

The following diagram illustrates the relationships between components (not included here, but referenced):



5.4.8.4.2.2 Bridge Execution Phase

The bridge also supports execution-time interoperability. Applications can use IB Verbs work requests (`ibv_send_wr`, `ibv_recv_wr`) and completions (`ibv_wc`) with DOCA-managed QPs and CQs.

Posting Work Requests

Use IB Verbs WRs with DOCA RDMA Verbs QPs to submit send or receive operations:

```
int doca_verbs_bridge_post_send(
    struct doca_verbs_qp *verbs_qp,
    struct ibv_send_wr *wr,
    struct ibv_send_wr **bad_wr);

int doca_verbs_bridge_post_recv(
    struct doca_verbs_qp *verbs_qp,
    struct ibv_recv_wr *wr,
    struct ibv_recv_wr **bad_wr);
```

Polling Completions

Poll a DOCA RDMA Verbs CQ for completions and retrieve results as an array of `ibv_wc` entries:

```
int doca_verbs_bridge_poll_cq(
    struct doca_verbs_cq *verbs_cq,
    int num_entries,
    struct ibv_wc *ibv_wc);
```

This enables applications to maintain compatibility with existing RDMA workflows while benefiting from DOCA's abstraction, resource management, and hardware integration.

5.4.8.5 Alternative Data Path Options

5.4.8.5.1 DPA Data Path

The DPA Data Path enables offloading RDMA operations from the host CPU to the device (e.g., BlueField DPU), allowing RDMA work to be initiated and completed entirely in the data plane. This mode is especially useful for accelerating networking applications by reducing host CPU involvement.

5.4.8.5.1.1 Configuration Phase

The DPA data path enables execution of RDMA operations directly on the device, bypassing the host CPU. This offload model improves performance and scalability for data-centric applications.

Key differences from host-side (CPU) configuration:

- External data path must be explicitly enabled.
- All RDMA operations, including buffer allocation and queue management, are performed on the device.
- RDMA queues are created to operate entirely within the DPA context.

To create a `doca_verbs_qp` in DPA mode, use one of the following approaches:

- Set DPA context in QP initialization attributes:

```
doca_error_t doca_verbs_qp_init_attr_set_dpa(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_dpa *dpa_ctx);
```

In this mode, external UMEM (for WQ and DBR), external UAR, and PD are created or retrieved internally using the provided DPA context. This is the *simplified* configuration mode, where DOCA manages all required resources.

- Set external UMEM/UAR manually using the standard external resource APIs: In this *advanced* configuration mode, the application allocates external UMEM regions for WQ and DBR, and provides its own UAR. This offers maximum control over memory layout, alignment, and resource lifecycle.
- Use a DPA completion context instead of a traditional Verbs CQ:

```
doca_error_t doca_verbs_qp_init_attr_set_send_dpa_completion(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_dpa_completion *send_dpa_completion);
```

To use the QP from within the DPA kernel, retrieve the DPA QP handle using:

```
doca_error_t doca_verbs_qp_get_dpa_handle(
    struct doca_verbs_qp *verbs_qp,
    struct doca_dpa *dpa_ctx,
    doca_dpa_dev_verbs_qp_t *dpa_qp_handle);
```

The returned `dpa_qp_handle` can then be used to post send and receive work requests from DPA-side execution flows.

5.4.8.5.1.2 Execution Phase

Refer to section "DOCA DPA Verbs" for information.

5.4.8.5.2 GPU Data Path

The GPU data path enables RDMA operations to be initiated and completed directly on the GPU, bypassing the host CPU entirely. This mode is essential for accelerating GPU-to-GPU and GPU-to-network communication in high-performance computing and AI workloads.

5.4.8.5.2.1 Configuration Phase

Main differences from host-side (CPU) configuration:

- External data path must be explicitly enabled.
- All RDMA operations, including buffer management, are performed on the device side.
- The application must explicitly allocate GPU memory and bind it to DOCA RDMA Verbs structures.

To create a `doca_verbs_qp` for GPU use:

- Allocate a GPU buffer and use it to create a UMEM object, then assign it to the QP as external UMEM:

```
doca_error_t doca_verbs_qp_init_attr_set_external_umem(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_umem *external_umem,
    uint64_t external_umem_offset);
```

- Allocate another GPU buffer and use it to set an external UAR:

```
doca_error_t doca_verbs_qp_init_attr_set_external_uar(
    struct doca_verbs_qp_init_attr *verbs_qp_init_attr,
    struct doca_uar *external_uar);
```

To create a `doca_verbs_cq` for GPU use:

- Allocate a GPU buffer, wrap it as a UMEM object, and assign it as the external UMEM for the CQ:

```
doca_error_t doca_verbs_cq_attr_set_external_umem(
    struct doca_verbs_cq_attr *cq_attr,
    struct doca_umem *external_umem,
    uint64_t external_umem_offset);
```

- Enable CQ overrun mode, as it is required by most GPU-side data path operations:

```
doca_error_t doca_verbs_cq_attr_set_cq_overrun(
    struct doca_verbs_cq_attr *cq_attr,
    uint8_t overrun);
```

To use the QP on the GPU side, export a handle using DOCA GPUNetIO:

```
doca_error_t doca_gpu_verbs_export_qp(
    struct doca_gpu *gpu_dev,
    struct doca_dev *dev,
    struct doca_verbs_qp *qp,
    enum doca_gpu_dev_verbs_nic_handler nic_handler,
    void *gpu_qp_umem_dev_ptr,
    struct doca_verbs_cq *cq_sq,
    struct doca_verbs_cq *cq_rq,
    struct doca_gpu_verbs_qp **qp_out);
```

The exported `doca_gpu_verbs_qp` handle enables GPU kernels to post send and receive work requests directly from device code, facilitating low-latency, high-throughput RDMA operations within GPU execution contexts.

5.4.8.5.2.2 Execution Phase

Refer to section "GPU Functions – Verbs" for information.

5.4.8.6 Samples

5.4.8.6.1 Verbs Server Client

The `doca_verbs_server_client` sample demonstrates how to perform RDMA verbs operations using DOCA RDMA Verbs for a server-client mechanism. The sample queries the device port and executes the data path according to the link layer configuration (IB or RoCE).

Sample logic:

1. Resource setup:
    a. Creating `verbs_ctx` from device name given as an argument.
    b. Creating `verbs_pd` from `verbs_ctx`.
    c. Creating and setting `cq_attr` to create `verbs_cq`.
    d. Creating `verbs_ah` and setting attributes.
    e. Creating and setting `qp_init_attr` to create `verbs_qp`.
    f. Allocating local memory to execute the RDMA operations using `verbs_pd` and `ibv_reg_mr`.
2. Establishing connection between server and client using TCP socket.
3. Exchanging RDMA parameters: Server and client exchange local buffer addresses, MKEYs, QP numbers and GID/LID addresses
4. QP connection: Setting QP attributes, Modify QP states – RST →INIT → RTR → RTS
5. Data Path Execution: Performing RDMA operations according to user flags:
    a. Send/receive operation –
        - Client side – post send WR (opcode `IBV_WR_RDMA_SEND`), poll CQ completion
        - Server side – post receive WR, poll CQ completion, read the message from the client via local buffer
    b. Write operation –
        - Client side – post send WR (opcode `IBV_WR_RDMA_WRITE` and remote address), poll CQ completion
        - Server side – poll the local buffer and wait for the expected message
    c. Read operation –
        - Client side – post send WR (opcode `IBV_WR_RDMA_READ` and remote address), poll CQ completion
        - Server side – no action needed
6. Syncing completions of local and remote peer via socket message.
7. Verifying completions or received messages.
8. Cleanup: Destroying QP, AH, CQ, PD, Verbs Context, close device, TCP connection and free memory buffers.

Sample usage:

```
Usage: doca_verbs_server_client [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>

Program Flags:
  -c, --client <Sample is client, requires server OOB IP> Sample is client, requires server OOB IP
  -d, --device <IB device name>     IB device name
  -gid, --gid-index                 GID index for DOCA RDMA. Default value 0
  -ro, --rdma-oper-type             RDMA operation type: Send, Write, Read. Default type Send
  -s, --buffer-size                 Buffer size. Default value 64
```

```
-qt, --qp-type                  QP Type: RC. Default type RC
-n, --iters                     Number of iterations. Default value 1
-b, --send-burst                Send all messages at once in a burst
```

Reference:

- `/opt/mellanox/doca/samples/doca_verbs/verbs_server_client/verbs_server_client_sample.c`
- `/opt/mellanox/doca/samples/doca_verbs/verbs_server_client/verbs_server_client_main.c`
- `/opt/mellanox/doca/samples/doca_verbs/verbs_server_client/meson.build`

5.4.8.6.2 Verbs Wait CQ WR

This sample illustrates how to use the `wait_cq_pi` work request to chain messages and force order of execution.

Sample logic:

1. Locating DOCA device.
2. Initializing required DOCA Core structures.
3. Creating two pairs of QPs, each pair connected between them (QP1, QP2, QP3 and QP4 where QP1 is connected to QP2, QP3 is connected to QP4).
4. Creating three buffers and populate the first with data.
5. The send flows:
    a. QP1 sends data from the first buffer to QP2, which receives the data in the second buffer.
    b. QP3 sends the data from the second buffer to QP4, which receives the data in the third buffer.

    > ⚠ For the data to arrive properly in the third buffer, the send operation on QP3 must be done only after the send operation on QP1 finishes successfully.

6. Posting recv WRs on QP2 and QP4 to prepare for receiving the data.
7. Posting a `wait_cq_pi` WR on QP3 to wait with the send execution until QP1 finishes sending its data.
8. Posting the send WR on QP3 which is only executed after the `wait_cq_pi` WR finishes waiting.
9. Posting the send WR on QP1 to start the data transfer.
10. Waiting for all WRs to complete.
11. Assuring the data on the third buffer is identical to the data on the first, indicating the WRs were executed in the correct order.

Sample usage:

```
Usage: wait_cq_wr [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>

Program Flags:
  -d, --device-name                 IBV device name to be used.
  -gi, --gid-index                  GID index to use, deafult: 0.
  --ipv6                            Use IPv6 instead of IPv4
```

5.4.9 DOCA Ethernet

This guide provides an overview and configuration instructions for the DOCA ETH API.

5.4.9.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

The DOCA ETH library provides a high-performance interface for transmitting and receiving Ethernet packets on NVIDIA network adapters. It allows developers to build efficient network applications by leveraging hardware acceleration and flexible queue management.

The library consists of two main components:

- DOCA ETH RXQ (Receive Queue) Manages the reception of incoming Ethernet packets. It supports multiple queue types (regular, cyclic, and managed memory pool) optimized for different use cases and performance requirements.
- DOCA ETH TXQ (Transmit Queue) Manages the transmission of outgoing Ethernet packets. It supports hardware offloads, including checksum calculation and Large Send Offload (LSO).

The library always handles the control path (configuration, queue management) on the host or DPU's CPU. The data path (the actual packet processing), however, can be managed either on the CPU using the DOCA ETH library or on the GPU using the DOCA GPUNetIO library.

5.4.9.2 Prerequisites

This library follows the architecture of a DOCA Core Context. It is recommended to read the following sections:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem
- DOCA Flow Programming Guide
- BlueField DPU Scalable Function (for using SF on DPU)
- DOCA GPUNetIO (for GPU datapath)

5.4.9.3 Changes From Previous Releases

5.4.9.3.1 Changes in 3.2.0

The following subsection(s) detail the `doca_eth` library updates in version 3.2.0.

5.4.9.3.1.1 Added

ETH RXQ

- `doca_error_t doca_eth_rxq_get_hw_queue_num(struct doca_eth_rxq *eth_rxq, uint32_t *hw_queue_num)`

ETH TXQ

- `doca_error_t doca_eth_txq_get_hw_queue_num(struct doca_eth_txq *eth_txq, uint32_t *hw_queue_num)`

5.4.9.4 Environment

DOCA ETH-based applications can run on either the Linux host or the NVIDIA® BlueField® DPU.

Before running an application, please ensure the following requirements are met:

- Root privileges – Applications must be run with root privileges.
- Packet steering – DOCA Flow is required to ensure packets are steered correctly to the ETH queues. Refer to the DOCA Flow documentation and the DOCA ETH samples for implementation examples.

- Timestamping – Applications that need to retrieve timestamps in the ETH RXQ must enable the device's real-time clock. This is done using `mlxconfig`:

```
mlxconfig -d <device_id> s REAL_TIME_CLOCK_ENABLE=1
```

5.4.9.5 Architecture

DOCA ETH is comprised of two parts: DOCA ETH RXQ and DOCA ETH TXQ.

5.4.9.5.1 DOCA ETH RXQ

5.4.9.5.1.1 Operating Modes

DOCA ETH RXQ can operate in the three modes, each exposing a slightly different control/datapath.

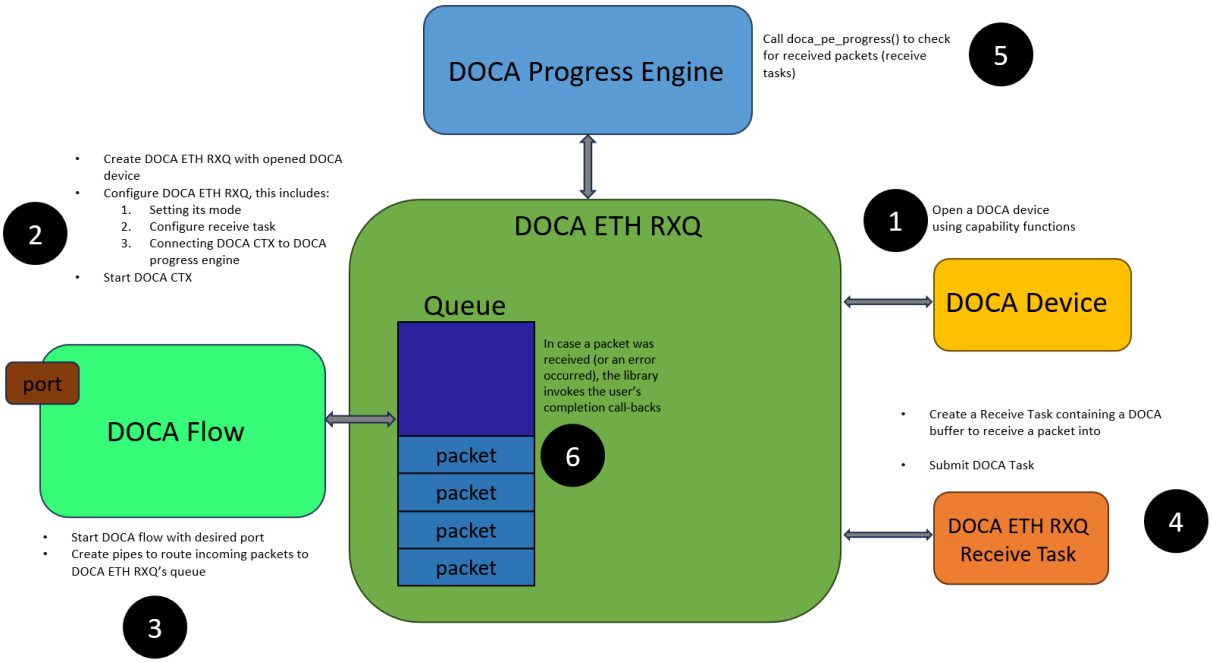
Regular Receive

> This mode is supported only for CPU datapath.

In this mode, the received packet buffers are managed by the user. To receive a packet, the user should submit a receive task containing a `doca_buf` to write the packet into.

The application uses this mode if it wants to:

- Run on CPU
- Manage the memory of received packet and the packet's exact place in memory
- Forward the received packets to other DOCA libraries



Cyclic Receive

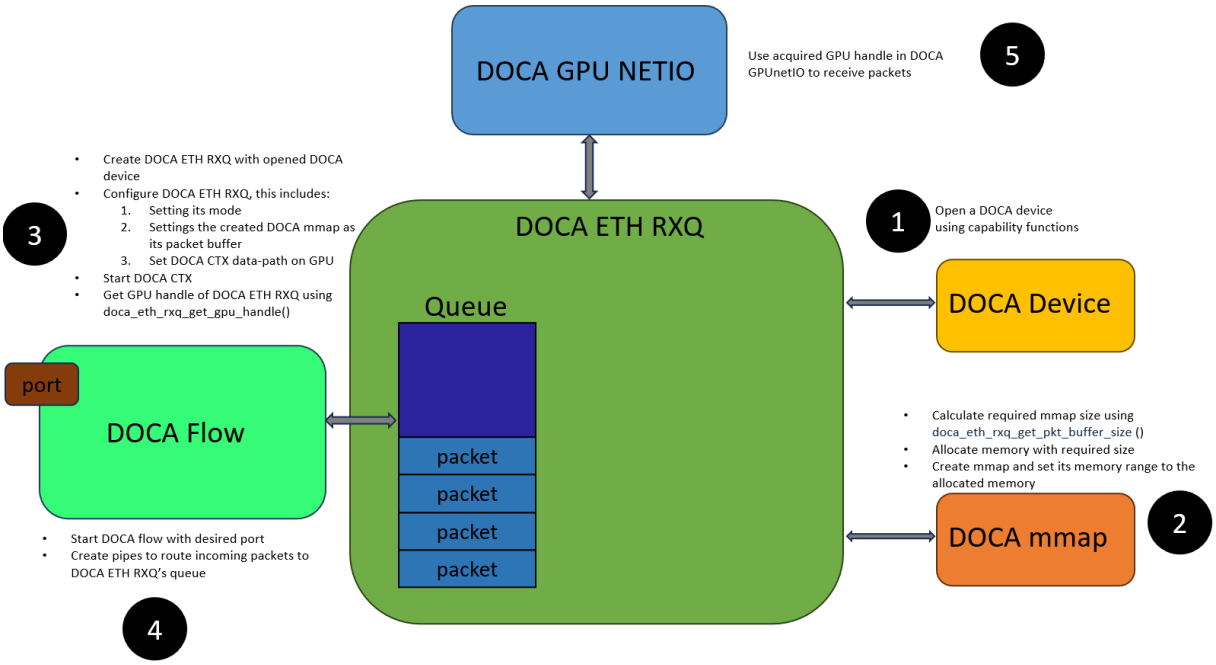
> This mode is supported only for GPU datapath.

In this mode, the library scatters packets to the packet buffer (supplied by the user as `doca_mmap`) in a cyclic manner. Packets acquired by the user may be overwritten by the library if not processed fast enough by the application.

In this mode, the user must provide DOCA ETH RXQ with a packet buffer to be managed by the library (see `doca_eth_rxq_set_pkt_buf()`). The buffer should be large enough to avoid packet loss (see `doca_eth_rxq_estimate_packet_buf_size()`).

The application uses this mode if:

- It wants to run on GPU
- It has a deterministic packet processing time, where a packet is guaranteed to be processed before the library overwrites it with a new packet
- It wants best performance



Managed Memory Pool Receive

> This mode is supported only for CPU datapath.

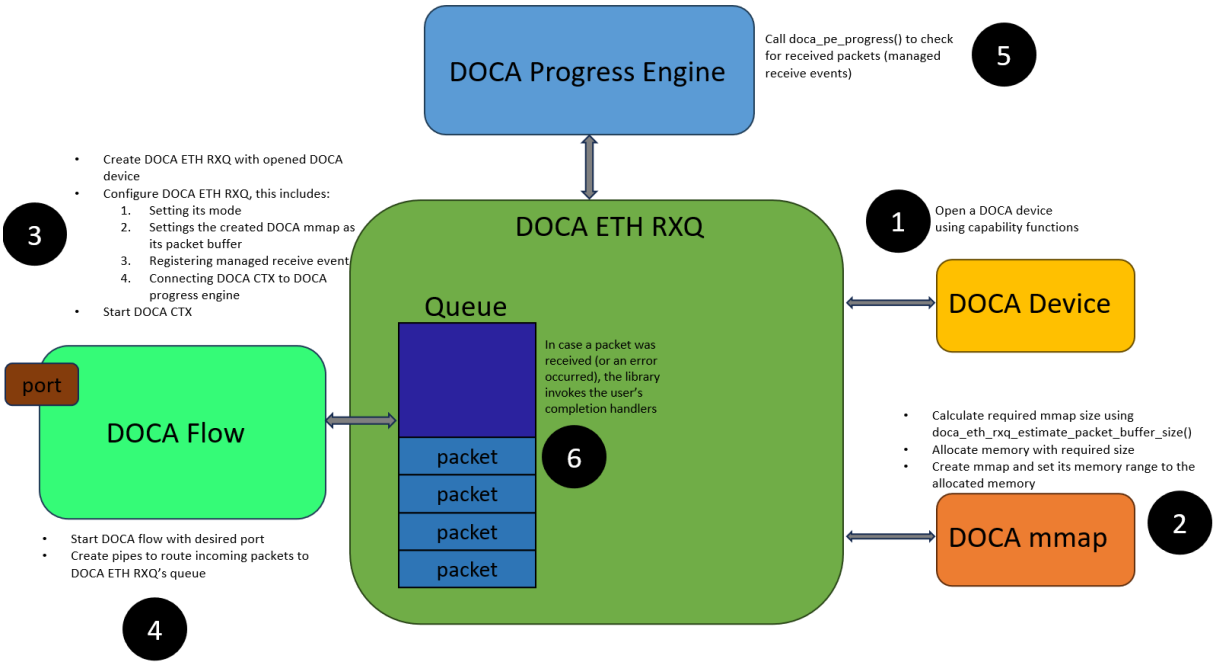
In this mode, the library uses various optimizations to manage the packet buffers. Packets acquired by the user cannot be overwritten by the library unless explicitly freed by the application. Thus, if the application does not release the packet buffers fast enough, the library would run out of memory and packets would start dropping.

Unlike Cyclic Receive mode, the user can pass the packet to other libraries in DOCA with the guarantee that the packet is not overwritten while being processed by those libraries.

In this mode, the user must provide DOCA ETH RXQ with a packet buffer to be managed by the library (see `doca_eth_rxq_set_pkt_buf()`). The buffer should be large enough to avoid packet loss (see `doca_eth_rxq_estimate_packet_buf_size()`).

The application uses this mode if:

- It wants to run on CPU
- It has a deterministic packet processing time, where a packet is guaranteed to be processed before the library runs out of memory and packets start dropping
- It wants to forward the received packets to other DOCA libraries
- It wants best performance



5.4.9.5.1.2 Receive Offloads

The DOCA ETH RXQ supports several hardware offloads:

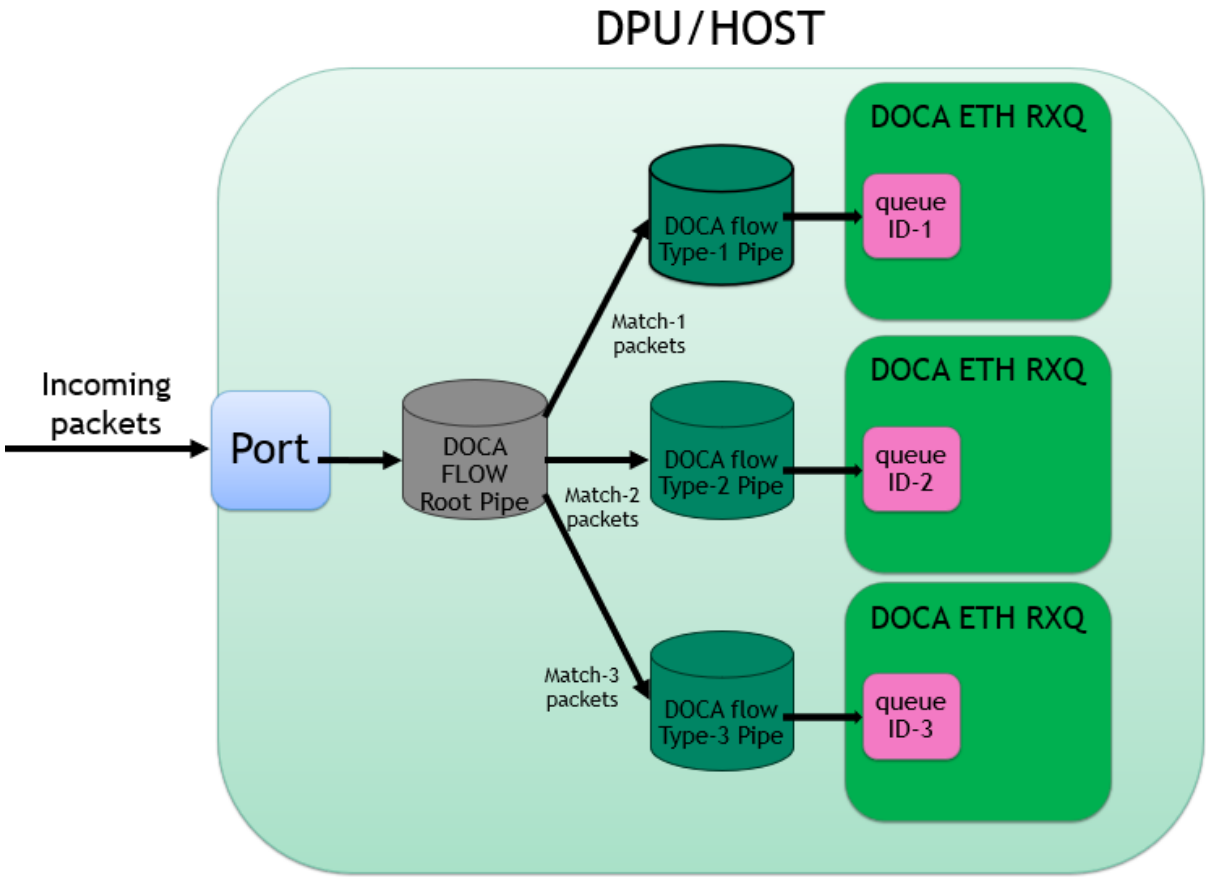
- Metadata – Supports retrieving the metadata value collected during packet flow table processing. (See `doca_eth_rxq_set_metadata_num()`).
- Flow Tag – Supports retrieving the flow tag value that was set by software (e.g., DOCA Flow) when the flow entry was created.
  (See `doca_eth_rxq_set_flow_tag()`).
- RX Hash – Supports retrieving the calculated RX hash value of the packet.
  (See `doca_eth_rxq_set_rx_hash()`).
- Packet Headroom/Tailroom – For RXQ in managed memory pool mode only, supports reserving user-requested space in the `doca_buf` headroom (via `doca_eth_rxq_set_packet_headroom()`) and tailroom (via `doca_eth_rxq_set_packet_tailroom()`).
- Packet Timestamp – Supports retrieving the timestamp (time since epoch, in nanoseconds) of when the packet was received.
  (See `doca_eth_rxq_set_timestamp()`).

5.4.9.5.1.3 Working with DOCA Flow

To route incoming packets to the desired DOCA ETH RXQ, applications need to use DOCA Flow. Applications need to do the following:

- Create and start DOCA Flow on the appropriate port (device)
- Create pipes to route packets into

- Apply unique queue ID of the queue (inside DOCA ETH RXQ) using `doca_eth_rxq_apply_queue_id()`
- Add an entry to a pipe which routes packets into the RX queue (using the queue ID we applied)



For more details see DOCA ETH RXQ samples and DOCA Flow.

5.4.9.5.2 DOCA ETH TXQ

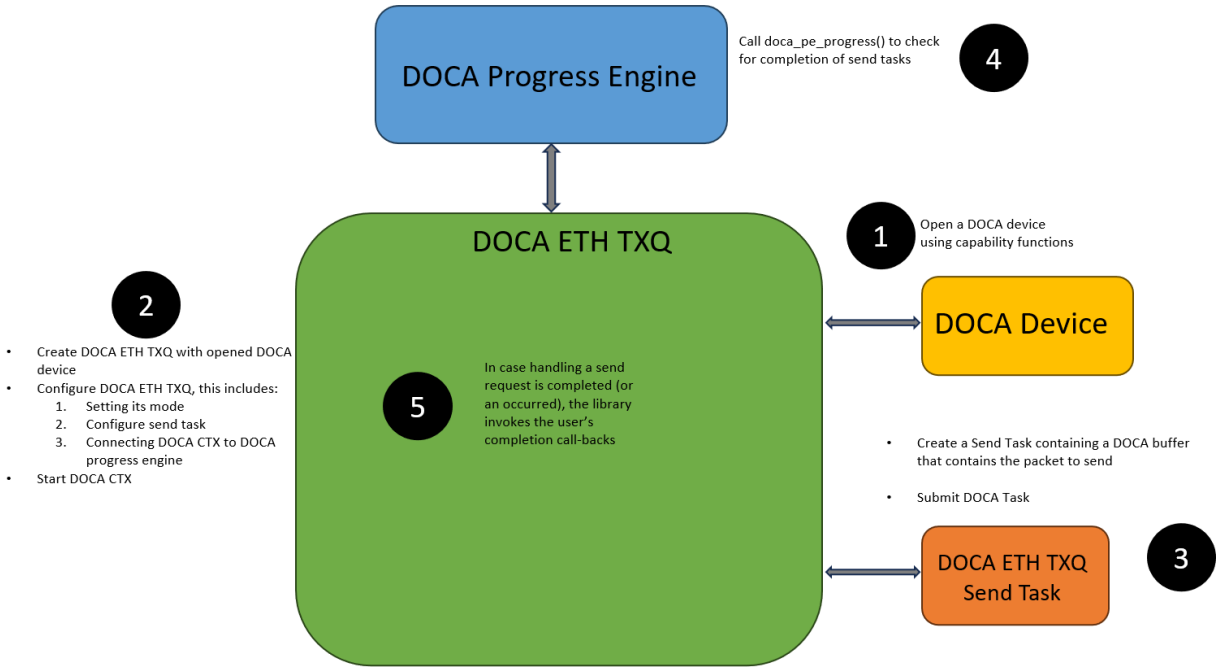
5.4.9.5.2.1 Operating Modes

DOCA ETH TXQ can only operate in one mode.

Regular Send

For the CPU datapath, the user should submit a send task containing a `doca_buf` of the packet to send.

For information regarding the datapath on the GPU, see DOCA GPUNetIO.



5.4.9.5.2.2 Transmit Offloads

The DOCA ETH TXQ supports several hardware offloads:

- Large segment offloading (LSO) – The hardware can segment large TCP messages (over IPv4 or IPv6) into multiple valid TCP segments. The application provides a header template, which the hardware automatically replicates and updates (e.g., sequence numbers) for each generated segment (see LSO Send Task).
- L3/L4 checksum offloading – The hardware supports the calculation of L3 (IP) and L4 (TCP/UDP) checksums for outgoing packets (IPv4 and IPv6).
  - In tunneling scenarios, the hardware calculates the checksum for the outer header.
  - The hardware performs the calculation directly, ignoring any value already present in the packet's checksum field1s (see `doca_eth_txq_set_l3_chksum_offload()` and `doca_eth_txq_set_l4_chksum_offload()`).
- Metadata – Supports attaching a metadata value to the packet, which is then carried into the transmit flow table processing (see `doca_eth_txq_set_metadata_num()`).

5.4.9.6 Configurations Phase

To start using the library, the user must first first go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context to allow execution of tasks and retrieval of events.

> ⚠ DOCA ETH in GPU datapath does not need to be associated with a DOCA PE (since the datapath is not on the CPU).

5.4.9.6.1 Configurations

The context can be configured to match the application use case.

To find if a configuration is supported or the min/max value for it, refer to Device Support.

> ⚠ For specific APIs related to GPU or CPU data-path configuration, refer to the main DOCA API documentation.

5.4.9.6.2 Mandatory Configurations

These configurations are mandatory and must be set by the application before attempting to start the context.

5.4.9.6.2.1 DOCA ETH RXQ

- At least one task/event/event_batch type must be configured. Refer to Tasks/Events/Event Batch for more information.
- Max packet size (the maximum size of packet that can be received) must be provided at creation time of the DOCA ETH RXQ context (see `max_packet_size` in `doca_eth_rxq_create()`).
- Max burst size (the maximum number of packets that the library can handle at the same time) must be provided at creation time of the DOCA ETH RXQ context (see `max_burst_size` in `doca_eth_rxq_create()`).
- A device with appropriate support must be provided upon creation (see `dev` in `doca_eth_rxq_create()`).
- When in Cyclic Receive or Managed Memory Pool Receive modes, a `doca_mmap` must be provided in-order write the received packets into (see `doca_eth_rxq_set_pkt_buf()`).
- In case of a GPU datapath, A DOCA GPU sub-device must be provided using `doca_ctx_set_datapath_on_gpu()`

5.4.9.6.2.2 DOCA ETH TXQ

- At least one `task` / `task_batch` type must be configured. Refer to Tasks/Task Batch for more information.
- Max burst size (the maximum number of packets that the library can handle at the same time) must be provided at creation time of the DOCA ETH TXQ context (see `max_burst_size` in `doca_eth_txq_create()`).
- A device with appropriate support must be provided on creation (see `dev` in `doca_eth_txq_create()`).
- In case of a GPU datapath, a DOCA GPU sub-device must be provided using `doca_ctx_set_datapath_on_gpu()`

5.4.9.6.3 Optional Configurations

The following configurations are optional. If they are not set, a default value is used.

5.4.9.6.3.1 DOCA ETH RXQ

Setting	API Function	Default Value	Affected Operations
RXQ Mode	`doca_eth_rxq_set_type()`	`Regular Receive`	N/A
Max. Receive Buffer List Length	`doca_eth_rxq_set_max_recv_buf_list_len()`	`1`	Receive Task
Metadata Retrieval	`doca_eth_rxq_set_metadata_num()`	`0` (Disabled)	Receive Task / Managed Receive Event / Managed Receive Event Batch
Flow Tag Retrieval	`doca_eth_rxq_set_flow_tag()`	Disabled	Receive Task / Managed Receive Event / Managed Receive Event Batch
RX Hash Retrieval	`doca_eth_rxq_set_rx_hash()`	Disabled	Receive Task / Managed Receive Event / Managed Receive Event Batch
Packet Headroom	`doca_eth_rxq_set_packet_headroom()`	`0` (Disabled)	Managed Receive Event / Managed Receive Event Batch
Packet Tailroom	`doca_eth_rxq_set_packet_tailroom()`	`0` (Disabled)	Managed Receive Event / Managed Receive Event Batch
* Timestamp Retrieval	`doca_eth_rxq_set_timestamp()`	Disabled	Receive Task / Managed Receive Event / Managed Receive Event Batch

5.4.9.6.3.2 DOCA ETH TXQ

Setting	API Function	Default Value	Affected Operations
TXQ Mode	`doca_eth_txq_set_type()`	`Regular Send`	N/A
Max. Send Buffer List Length	`doca_eth_txq_set_max_send_buf_list_len()`	`1S`	Send Task / Send Task Batch / LSO Send Task / LSO Send Task Batch
L3 Checksum Offload	`doca_eth_txq_set_l3_chksum_offload()`	Disabled	Send Task / Send Task Batch / LSO Send Task / LSO Send Task Batch
L4 Checksum Offload	`doca_eth_txq_set_l4_chksum_offload()`	Disabled	Send Task / Send Task Batch / LSO Send Task / LSO Send Task Batch
LSO Default MSS	`doca_eth_txq_set_mss()`	`1500`	LSO Send Task / LSO Send Task Batch
LSO Max Header Size	`doca_eth_txq_set_max_lso_header_size()`	`74`	LSO Send Task / LSO Send Task Batch
Metadata Attachment	`doca_eth_txq_set_metadata_num()`	`0` (Disabled)	Send Task / Send Task Batch / LSO Send Task / LSO Send Task Batch

5.4.9.6.4 Device Support

DOCA ETH requires a device to operate. For picking a device, see DOCA Core Device Discovery.

To check if a device supports a specific mode, use the type capabilities functions (see `doca_eth_rxq_cap_is_type_supported()` and `doca_eth_txq_cap_is_type_supported()`).

Devices can allow the following capabilities:

- The maximum burst size
- The maximum buffer chain list (only for Regular Receive/Regular Send modes)
- The maximum packet size (only for DOCA ETH RXQ)
- L3/L4 checksum offloading capability (only for DOCA ETH TXQ)
- Maximum LSO message/header size (only for DOCA ETH TXQ)
- Wait-on-time offloading capability (only for DOCA ETH TXQ in GPU datapath)
- Max metadata number capability (only for CPU datapath)

5.4.9.6.5 Buffer Support

DOCA ETH support buffers (`doca_mmap` or `doca_buf`) with the following features:

Buffer Type	Send Task	LSO Send Task	Receive Task	Managed Receive Event
Local mmap buffer	Yes	Yes	Yes	Yes
Mmap from PCIe export buffer	Yes	Yes	Yes	Yes
Mmap from RDMA export buffer	No	No	No	No
Linked list buffer	Yes	Yes	Yes	No

For buffer support in the case of GPU datapath, see DOCA GPUNetIO Programming Guide.

5.4.9.7 Execution Phase

This section describes execution on CPU (unless stated otherwise) using DOCA Core Progress Engine.

> For information regarding GPU datapath, see DOCA GPUNetIO.

5.4.9.7.1 Tasks

DOCA ETH exposes asynchronous tasks that leverage the DPU hardware according to the DOCA Core architecture. See DOCA Core Task.

5.4.9.7.1.1 DOCA ETH RXQ

Receive Task

This task allows receiving packets from a `doca_dev`.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	calling `doca_eth_rxq_task_recv_set_conf()`	`doca_eth_rxq_cap_is_type_supported()` checking support for Regular Receive mode
Number of tasks	`task_recv_num` in `doca_eth_rxq_task_recv_set_conf()`	–

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Packet buffer	Buffer pointing to the memory where received packet are to be written	The received packet is written to the tail segment extending the data segment

Task Output

Common output as described in DOCA Core Task.

Additionally:

Name	Description	Notes
L3 checksum result	Value indicating whether the L3 checksum of the received packet is valid or not	Can be queried using `doca_eth_rxq_task_recv_get_l3_ok()`
L4 checksum result	Value indicating whether the L4 checksum of the received packet is valid or not	Can be queried using `doca_eth_rxq_task_recv_get_l4_ok()`
Metadata array	Array containing metadata values associated with the packet	Can be queried using `doca_eth_rxq_task_recv_get_metadata_array()`
Flow tag	Flow tag value associated with the packet	Can be queried using `doca_eth_rxq_task_recv_get_flow_tag()`
RX hash	RX hash value associated with the packet	Can be queried using `doca_eth_rxq_task_recv_get_rx_hash()`
Timestamp	Timestamp ([ns] since epoch) associated with the packet	Can be queried using `doca_eth_rxq_task_recv_get_timestamp()`

Task Completion Success

After the task is completed successfully the following will happen:

- The received packet is written to the packet buffer
- The packet buffer data segment is extended to include the received packet

Task Completion Failure

If the task fails midway:

- The context enters stopping state
- The packet buffer `doca_buf` object is not modified
- The packet buffer contents may be modified

Task Limitations

All limitations described in DOCA Core Task

Additionally:

- The operation is not atomic.
- Once the task has been submitted, then the packet buffer should not be read/written to.

5.4.9.7.1.2 DOCA ETH TXQ

Send Task

This task allows sending packets from a `doca_dev`.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	calling `doca_eth_txq_task_send_set_conf()`	`doca_eth_txq_cap_is_type_supported()` checking support for Regular Send mode
Number of tasks	`task_send_num` in `doca_eth_txq_task_send_set_conf()` ⚠ The number of tasks can be expanded using `doca_eth_txq_task_send_num_expand()`.	–

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Packet buffer	Buffer pointing to the packet to send	The sent packet is the memory in the data segment
Metadata values	Metadata array containing metadata values to attach with packet	Array length is the `metadata_num` in `doca_eth_txq_set_metadata_num()`
Offload flags	Offload flags to associate with specific packet (if users want to override default values)	Offload flags is a bit mask of values in `enum doca_eth_txq_ol_flags`

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

The task finishing successfully does not guarantee that the packet has been transmitted onto the wire. It only signifies that the packet has successfully entered the device's TX hardware and that the packet buffer `doca_buf` is no longer in the library's ownership and it can be reused by the application.

Task Completion Failure

If the task fails midway:

- The context enters stopping state
- The packet buffer `doca_buf` object is not modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the packet buffer should not be written to
- Other limitations are described in DOCA Core Task

LSO Send Task

This task allows sending "large" packets (larger than MTU) from a `doca_dev` (hardware splits the packet into several packets smaller than the MTU and sends them).

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	calling `doca_eth_txq_task_lso_send_set_conf()`	`doca_eth_txq_cap_is_type_supported()` checking support for Regular Send mode
Number of tasks	`task_lso_send_num` in `doca_eth_txq_task_lso_send_set_conf()` ⚠ The number of tasks can be expanded using `doca_eth_txq_task_lso_send_num_expand()`.	–

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Packet payload buffer	Buffer that points to the "large" packet's payload (does not include headers) to send	The sent packet is the memory in the data segment
Packet headers buffer	Gather list that when combined includes the "large" packet's headers to send	See `struct doca_gather_list`
Metadata values	Metadata array containing metadata values to attach with packet	Array length is the `metadata_num` in `doca_eth_txq_set_metadata_num()`
Offload flags	Offload flags to associate with specific packet (if users want to override default values)	Offload flags is a bit mask of values in `enum doca_eth_txq_ol_flags`
MSS	MSS to associate with LSO packet (if users want to override default values)	–

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

The task finishing successfully does not guarantee that the packet has been transmitted onto the wire. It only means that the packet has successfully entered the device's TX hardware and that the packet payload buffer and the packet headers buffer is no longer in the library's ownership and it can be reused by the application.

Task Completion Failure

If the task fails midway:

- The context enters stopping state
- The packet payload buffer `doca_buf` object and the packet header buffer `doca_gather_list` are not modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the packet payload buffer and the packet headers buffer should not be written to
- Other limitations are described in DOCA Core Task

5.4.9.7.2 Events

DOCA ETH exposes asynchronous events to notify about changes that happen asynchronously, according to the DOCA Core architecture. See DOCA Core Event.

In addition to common events as described in DOCA Core Event, DOCA ETH exposes an extra events:

5.4.9.7.2.1 DOCA ETH RXQ

Managed Receive Event

This event allows receiving packets from a `doca_dev` (without requiring the application to manage the memory the packets are written to).

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_eth_rxq_event_managed_recv_register()`	`doca_eth_rxq_cap_is_type_supported()` checking support for Managed Memory Pool Receive mode

Event Trigger Condition

The event is triggered every time a packet is received.

Event Success Handler

The success callback (provided in the event registration) is invoked and the user is expected to perform the following:

- Use the `pkt` parameter to process the received packet
- Use `event_user_data` to get the application context
- Query L3/L4 checksum results of the packet
- Query metadata array of metadata values associated with the packet
- Query flow tag value associated with the packet
- Query RX hash value associated with the packet
- Query packet timestamp associated with the packet
- Free the `pkt` (`doca_buf` object) and return it to the library

> ⚠ Not freeing the `pkt` may cause scenario where packets are lost.

Event Failure Handler

The failure callback (provided in the event registration) is invoked, and the following happens:

- The context enters stopping state
- The `pkt` parameter becomes NULL
- The `event_user_data` parameter contains the value provided by the application when registering the event

5.4.9.7.2.2 DOCA ETH TXQ

Error Send Packet

This event is relevant when running DOCA ETH on GPU datapath (see DOCA GPUNetIO). It allows detecting failure in sending packets.

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_eth_txq_gpu_event_error_send_packet_register()`	Always supported

Event Trigger Condition

The event is triggered when sending a packet fails.

Event Handler

The callback (provided in the event registration) is invoked and the user can:

- Get the position (index) of the packet that TXQ failed to send

Notify Send Packet

This event is relevant when running DOCA ETH on GPU datapath (see DOCA GPUNetIO). It notifies user every time a packet is sent successfully.

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_eth_txq_gpu_event_notify_send_packet_register()`	Always supported

Event Trigger Condition

The event is triggered when sending a packet fails.

Event Handler

The callback (provided in the event registration) is invoked and the user can:

- Get the position (index) of the packet was sent
- Timestamp of sending the packet

5.4.9.7.3 Task Batch

DOCA ETH exposes asynchronous task batches that leverage the BlueField Platform hardware according to the DOCA Core architecture.

5.4.9.7.3.1 DOCA ETH RXQ

There are currently no task batches in ETH RXQ.

5.4.9.7.3.2 DOCA ETH TXQ

Send Task Batch

This is an extended task batch for Send Task which allows batched sending of packets from a `doca_dev`.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task batch	calling `doca_eth_txq_task_batch_send_set_conf()`	`doca_eth_txq_cap_is_type_supported()` checking support for Regular Send mode

Description	API to Set the Configuration	API to Query Support
Number of task batches	`num_task_batches` in `doca_eth_txq_task_batch_send_set_conf()` Number of task batches can be expanded using `doca_eth_txq_task_batch_send_num_expand()`.	–
Max number of tasks per task batch	`max_tasks_number` in `doca_eth_txq_task_batch_send_set_conf()`	–

Task Input

Name	Description	Notes
Tasks number	Number of send tasks "behind" the task batch	This number equals the number of packets to send
Batch user data	User data associated for the task batch	–
Packets array	Pointer to an array of buffers pointing at the packets to send per task	The sent packet is the memory in the data segment of each buffer
User data array	Pointer to an array of user data per task	–
Metadata array	Pointer to an array of metadata per task	Array length is `tasks_num` * `metadata_num` in `doca_eth_txq_set_metadata_num()` See `doca_eth_txq_task_batch_metadata_array_get_metadata()` macro.
Offload flags array	Pointer to an array of offload flags per task (if users want to override default values)	Offload flags is a bitmask of values in `enum doca_eth_txq_ol_flags`

Task Output

Name	Description
Status array	Pointer to an array of statuses per task of the finished task batch

Task Completion Success

A task batch is complete if all the send tasks finished successfully and all the packets entered the device's TX hardware. All packets in the "Packet array" are now in the ownership of the user.

Task Completion Failure

If a task batch fails, then one (or more) of the tasks associated with the task batch failed. The user can look at "Status array" to see which task/packet caused the failure.

Also, the following behavior is expected:

- The context enters stopping state
- The packet's `doca_buf` objects are not modified

Task Limitations

In addition to all the Send Task Limitations:

- Task batch completion occurs only when all the tasks are completed (no partial completion)

LSO Send Task Batch

This is an extended task batch for LSO Send Task which allows batched sending of LSO packets from a `doca_dev`.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task batch	Calling `doca_eth_txq_task_batch_lso_send_set_conf()`	`doca_eth_txq_cap_is_type_supported()` checking support for Regular Send mode
Number of task batches	`num_task_batches` in `doca_eth_txq_task_batch_lso_send_set_conf()` Number of task batches can be expanded using `doca_eth_txq_task_batch_lso_send_num_expand()`.	–
Max number of tasks per task batch	`num_task_batches` in `doca_eth_txq_task_batch_lso_send_set_conf()`	–

Task Input

Name	Description	Notes
Tasks number	Number of send tasks "behind" the task batch	This number equals the number of packets to send
Batch user data	User data associated for the task batch	–
Packets payload array	Pointer to an array of buffers pointing at the "large" packet's payload to send per task	The sent packet payload is the memory in the data segment of each buffer

Name	Description	Notes
Packets headers array	Pointer to an array of gather lists, each of which when combined assembles a "large" packet's headers to send per task	See `struct doca_gather_list`
User data array	Pointer to an array of user data per task	–
Metadata array	Pointer to an array of metadata per task	Array length is `tasks_num` * `metadata_num` in `doca_eth_txq_set_metadata_num()` See `doca_eth_txq_task_batch_metadata_array_get_metadata()` macro.
Offload flags array	Pointer to an array of offload flags per task (if users want to override default values)	Offload flags is a bit mask of values in `enum doca_eth_txq_ol_flags`
MSS array	Pointer to an array of MSS per task (if users want to override default values)	–

Task Output

Name	Description
Status array	Pointer to an array of status per task of the finished task batch

Task Completion Success

A task batch is complete if all the LSO send tasks finished successfully and all the packets entered the device's TX hardware. All packet payload in "Packets payload array" and packet headers in "Packets headers array" are now in the ownership of the user.

Task Completion Failure

If a task batch fails, then one (or more) of the tasks associated with the task batch failed, and the user can look at the "Status array" to try and figure out which task/packet caused the failure.

Also, the following behavior is expected:

- The context enters stopping state
- The packets payload `doca_buf` objects are not modified
- The packets headers `doca_gather_list` objects are not modified

Task Limitations

In addition to all the LSO Send Task Limitations:

- Task batch completion happens only when all the tasks are completed (no partial completion)

5.4.9.7.4 Event Batch

DOCA ETH exposes asynchronous event batches to notify about changes that happen asynchronously.

5.4.9.7.4.1 DOCA ETH RXQ

Managed Receive Event Batch

This is an extended event batch for Managed Receive Event which allows receiving packets from a `doca_dev` (without requiring the application to manage the memory the packets are written to).

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event batch	Calling `doca_eth_rxq_event_batch_managed_recv_register()`	`doca_eth_rxq_cap_is_type_supported()` checking support for Managed Memory Pool Receive mode
Max events number: Equal to the maximum number of completed events per event batch completion	`events_number_max` in `doca_eth_rxq_event_batch_managed_recv_register()`	-
Min events number: Equal to the minimum number of completed events per event batch completion	`events_number_min` in `doca_eth_rxq_event_batch_managed_recv_register()`	-

Event Trigger Condition

The event batch is triggered every time several packets (number between "Min events number" and "Max events number") are received.

Event Batch Success Handler

The success callback (provided in the event of batch registration) is invoked and the user is expected to perform the following:

1. Identify the number of received packets by `events_number`.
2. Use the `pkt_array` parameter to process the received packets.
3. Use `event_batch_user_data` to get the application context.
4. Query the L3/L4 checksum results of the packets using `l3_ok_array` and `l4_ok_array`.
5. Query metadata array of metadata values associated with the packet using `metadata_array`.
6. Query flow tag value associated with the packet using `flow_tag_array`.
7. Query RX hash value associated with the packet using `rx_hash_array`.
8. Query packet timestamp associated with the packet using `timestamp_array`.

9. Free the buffers from `pkt_array` (a `doca_buf` object) and return it to the library. This can be done in two ways:
    - Iterating over the buffers in `pkt_array` and freeing them using `doca_buf_dec_refcount()`.
    - Freeing all the buffers in `pkt_array` together (gives better performance) using `doca_eth_rxq_event_batch_managed_recv_pkt_array_free()`.

Event Batch Failure Handler

The failure callback (provided in the event batch registration) is invoked, and the following happens:

- The context enters stopping state
- The `pkt_array` parameter is NULL
- The `l3_ok_array` parameter is NULL
- The `l4_ok_array` parameter is NULL
- The `event_batch_user_data` parameter contains the value provided by the application when registering the event

5.4.9.7.4.2 DOCA ETH TXQ

There are no event batches in ETH TXQ at the moment.

5.4.9.8 State Machine

The DOCA ETH library follows the Context state machine as described in DOCA Core Context State Machine.

The following section describes how to move to the state and what is allowed in each state.

5.4.9.8.1 Idle

In this state it is expected that application either:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to Configurations
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Creating the context
Running	Calling stop after: • All tasks are completed and freed • All `doca_buf` objects returned by Managed Receive Event callback are freed
Stopping	Calling progress until: • All tasks are completed and freed • All `doca_buf` objects returned by Managed Receive Event callback are freed

5.4.9.8.2 Starting

This state cannot be reached.

5.4.9.8.3 Running

In this state it is expected that application will do the following:

- Allocate and submit tasks
- Call progress to complete tasks and/or receive events

Allowed operations:

- Allocate previously configured task
- Submit a task
- Call `doca_eth_rxq_apply_queue_id()` to connect the RX queue to DOCA Flow
- Call stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

5.4.9.8.4 Stopping

In this state, it is expected that application:

- Calls progress to complete all inflight tasks (tasks complete with failure)
- Frees any completed tasks
- Frees `doca_buf` objects returned by Managed Receive Event callback

Allowed operations:

- Call progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without either: • Freeing all tasks • Freeing all `doca_buf` objects returned by Managed Receive Event callback

5.4.9.9 Alternative Datapath Options

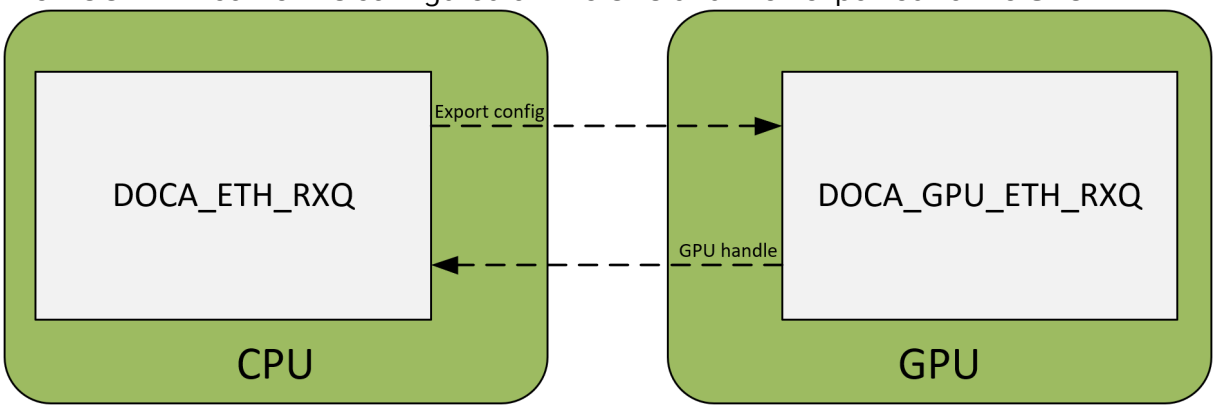
In addition to the CPU datapath (mentioned in Execution Phase), DOCA ETH supports running on GPU datapath. This allows applications to release the CPU from datapath management and allow low latency GPU processing of network traffic.

To export the handles, the application should call `doca_ctx_set_datapath_on_gpu()` before `doca_ctx_start()` to program the library to set up a GPU operated context.

To get the GPU context handle, the user should call `doca_rxq_get_gpu_handle()` which returns a pointer to a handle in the GPU memory space.

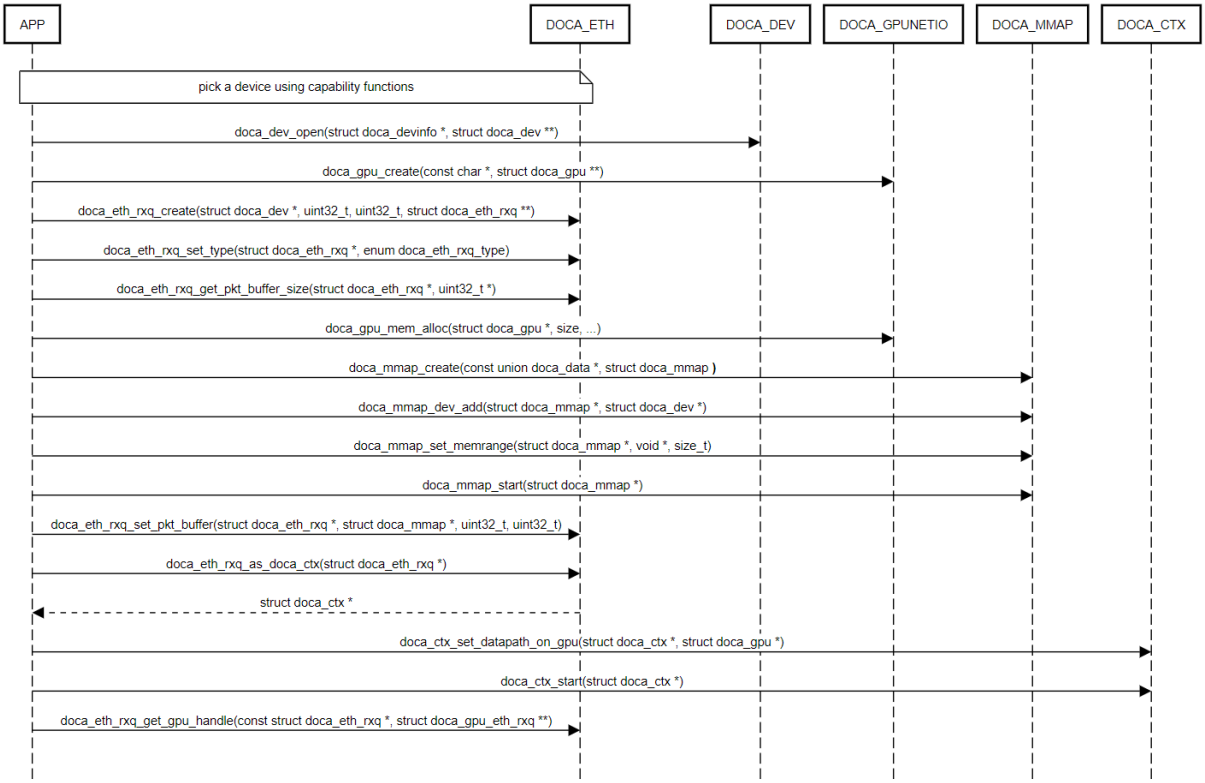
> ⚠ The datapath cannot be managed concurrently for the GPU and the CPU.

The DOCA ETH context is configured on the CPU and then exported to the GPU:



The following example shows the expected flow for a GPU-managed datapath with packets being scattered to GPU memory (for `doca_eth_rxq`):

1. Create a DOCA GPU device handler.
2. Create `doca_eth_rxq` and configure its parameters.
3. Set the datapath of the context to GPU.
4. Start the context.
5. Get a GPU handle of the context.



For more information regarding the GPU datapath see DOCA GPUNetIO.

5.4.9.10 DOCA ETH Samples

This section describes DOCA ETH samples based on the DOCA ETH library.

The samples illustrate how to use the DOCA ETH API to do the following:

- Send "regular" packets (smaller than MTU) using DOCA ETH TXQ
- Send "large" packets (larger than MTU) using DOCA ETH TXQ
- Receive packets using DOCA ETH RXQ in Regular Receive mode
- Receive packets using DOCA ETH RXQ in Managed Memory Pool Receive mode

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.9.10.1 Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.

- DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.

2. To build a given sample (in this case, `eth_txq_send_ethernet_frames`) run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_eth/eth_txq_send_ethernet_frames
meson /tmp/build
ninja -C /tmp/build
```

   The binary `eth_txq_send_ethernet_frames` is created under `/tmp/build/`.

3. Sample (e.g., `eth_txq_send_ethernet_frames`) usage:

```
Usage: doca_eth_txq_send_ethernet_frames [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device                      IB device name - default: mlx5_0
  -m, --mac-addr                    Destination MAC address to associate with the ethernet frames -
default: FF:FF:FF:FF:FF:FF
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/<sample_name> -h
```

5.4.9.10.2 Samples

> ⚠
> - The following samples are for the CPU datapath. For GPU datapath samples, see DOCA GPUNetIO.
> - These samples are also available on GitHub.

5.4.9.10.2.1 ETH TXQ Send Ethernet Frames

This sample illustrates how to send a "regular" packet (smaller than MTU) using DOCA ETH TXQ.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the required DOCA Core structures.
3. Populating DOCA memory map with one buffer to the packet's data.
4. Writing the packet's content into the allocated buffer.
5. Allocating elements from DOCA buffer inventory for the buffer.
6. Initializing and configuring DOCA ETH TXQ context.
7. Starting the DOCA ETH TXQ context.

8. Allocating DOCA ETH TXQ send task.
9. Submitting DOCA ETH TXQ send task into progress engine.
10. Retrieving DOCA ETH TXQ send task from the progress engine.
11. Handling the completed task using the provided callback.
12. Stopping the DOCA ETH TXQ context.
13. Destroying DOCA ETH TXQ context.
14. Destroying all DOCA Core structures.

- `/opt/mellanox/doca/samples/doca_eth/eth_txq_send_ethernet_frames/meson.build`

5.4.9.10.2.2 ETH TXQ LSO Send Ethernet Frames

This sample illustrates how to send a "large" packet (larger than MTU) using DOCA ETH TXQ.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the required DOCA Core structures.
3. Populating DOCA memory map with one buffer to the packet's payload.
4. Writing the packet's payload into the allocated buffer.
5. Allocating elements from DOCA Buffer inventory for the buffer.
6. Allocating DOCA gather list consisting of one node to the packet's headers.
7. Writing the packet's headers into the allocated gather list node.
8. Initializing and configuring DOCA ETH TXQ context.
9. Starting the DOCA ETH TXQ context.
10. Allocating DOCA ETH TXQ LSO send task.
11. Submitting DOCA ETH TXQ LSO send task into progress engine.
12. Retrieving DOCA ETH TXQ LSO send task from the progress engine.
13. Handling the completed task using the provided callback.
14. Stopping the DOCA ETH TXQ context.
15. Destroying DOCA ETH TXQ context.
16. Destroying all DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_eth/eth_txq_lso_send_ethernet_frames/eth_txq_lso_send_ethernet_frames_sample.c`

- `/opt/mellanox/doca/samples/doca_eth/eth_txq_lso_send_ethernet_frames/eth_txq_lso_send_ethernet_frames_main.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_txq_lso_send_ethernet_frames/meson.build`

5.4.9.10.2.3 ETH TXQ Batch Send Ethernet Frames

This sample illustrates how to send a batch of "regular" packets (smaller than MTU) using DOCA ETH TXQ.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the required DOCA Core structures.
3. Populating DOCA memory map with multiple buffers, each representing a packet's data.
4. Writing the packets' content into the allocated buffers.
5. Allocating elements from DOCA Buffer inventory for the buffers.
6. Initializing and configuring DOCA ETH TXQ context.
7. Starting the DOCA ETH TXQ context.
8. Allocating DOCA ETH TXQ send task batch.
9. Copying all buffers' pointers to task batch's `pkt_arry`.
10. Submitting DOCA ETH TXQ send task batch into the progress engine.
11. Retrieving DOCA ETH TXQ send task batch from the progress engine.
12. Handling the completed task batch using the provided callback.
13. Stopping the DOCA ETH TXQ context.
14. Destroying DOCA ETH TXQ context.
15. Destroying all DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_eth/eth_txq_batch_send_ethernet_frames/eth_txq_batch_send_ethernet_frames_sample.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_txq_batch_send_ethernet_frames/eth_txq_batch_send_ethernet_frames_main.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_txq_batch_send_ethernet_frames/meson.build`

5.4.9.10.2.4 ETH TXQ Batch LSO Send Ethernet Frames

This sample illustrates how to send a batch of "large" packets (larger than MTU) using DOCA ETH TXQ.

The sample logic includes:

1. Locating DOCA device.

2. Initializing the required DOCA Core structures.
3. Populating DOCA memory map with multiple buffers, each representing a packet's payload.
4. Writing the packets' payload into the allocated buffers.
5. Allocating elements from DOCA Buffer inventory for the buffers.
6. Allocating DOCA gather lists each consisting of one node for the packet's headers.
7. Writing the packets' headers into the allocated gather list nodes.
8. Initializing and configuring DOCA ETH TXQ context.
9. Starting the DOCA ETH TXQ context.
10. Allocating DOCA ETH TXQ LSO send task.
11. Copying all buffers' pointers to task batch's `pkt_payload_arry`.
12. Copying all gather lists' pointers to task batch's `headers_arry`.
13. Submitting DOCA ETH TXQ LSO send task batch into the progress engine.
14. Retrieving DOCA ETH TXQ LSO send task batch from the progress engine.
15. Handling the completed task batch using the provided callback.
16. Stopping the DOCA ETH TXQ context.
17. Destroying DOCA ETH TXQ context.
18. Destroying all DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_eth/eth_txq_batch_lso_send_ethernet_frames/eth_txq_batch_lso_send_ethernet_frames_sample.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_txq_batch_lso_send_ethernet_frames/eth_txq_batch_lso_send_ethernet_frames_main.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_txq_batch_lso_send_ethernet_frames/meson.build`

5.4.9.10.2.5 ETH RXQ Regular Receive

This sample illustrates how to receive a packet using DOCA ETH RXQ in Regular Receive mode.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the required DOCA Core structures.
3. Populating DOCA memory map with one buffer to the packet's data.
4. Allocating element from DOCA Buffer inventory for each buffer.
5. Initializing DOCA Flow.
6. Initializing and configuring DOCA ETH RXQ context.
7. Starting the DOCA ETH RXQ context.

8. Starting DOCA Flow.
9. Creating a pipe connecting to DOCA ETH RXQ's RX queue.
10. Allocating DOCA ETH RXQ receive task.
11. Submitting DOCA ETH RXQ receive task into the progress engine.
12. Retrieving DOCA ETH RXQ receive task from the progress engine.
13. Handling the completed task using the provided callback.
14. Stopping DOCA Flow.
15. Stopping the DOCA ETH RXQ context.
16. Destroying DOCA ETH RXQ context.
17. Destroying DOCA Flow.
18. Destroying all DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_regular_receive/eth_rxq_regular_receive_sample.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_regular_receive/eth_rxq_regular_receive_main.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_regular_receive/meson.build`

5.4.9.10.2.6 ETH RXQ Managed Receive

This sample illustrates how to receive packets using DOCA ETH RXQ in Managed Memory Pool Receive mode.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the required DOCA Core structures.
3. Calculating the required size of the buffer to receive the packets from DOCA ETH RXQ.
4. Populating DOCA memory map with a packets buffer.
5. Initializing DOCA Flow.
6. Initializing and configuring DOCA ETH RXQ context.
7. Registering DOCA ETH RXQ managed receive event.
8. Starting the DOCA ETH RXQ context.
9. Starting DOCA Flow.
10. Creating a pipe connecting to DOCA ETH RXQ's RX queue.
11. Retrieving DOCA ETH RXQ managed receive events from the progress engine.
12. Handling the completed events using the provided callback.
13. Stopping DOCA Flow.
14. Stopping the DOCA ETH RXQ context.
15. Destroying DOCA ETH RXQ context.
16. Destroying DOCA Flow.
17. Destroying all DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_managed_mempool_receive/eth_rxq_managed_mempool_receive_sample.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_managed_mempool_receive/eth_rxq_managed_mempool_receive_main.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_managed_mempool_receive/meson.build`

5.4.9.10.2.7 ETH RXQ Batch Managed Receive

This sample illustrates how to receive batches of packets using DOCA ETH RXQ in Managed Memory Pool Receive mode.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the required DOCA Core structures.
3. Calculating the required size of the buffer to receive the packets from DOCA ETH RXQ.
4. Populating DOCA memory map with a packets buffer.
5. Initializing DOCA Flow.
6. Initializing and configuring DOCA ETH RXQ context.
7. Registering DOCA ETH RXQ managed receive event batch.
8. Starting the DOCA ETH RXQ context.
9. Starting DOCA Flow.
10. Creating a pipe connecting to DOCA ETH RXQ's RX queue.
11. Retrieving DOCA ETH RXQ managed receive event batches from the progress engine.
12. Handling the completed event batches using the provided callback.
13. Stopping DOCA Flow.
14. Stopping the DOCA ETH RXQ context.
15. Destroying DOCA ETH RXQ context.
16. Destroying DOCA Flow.
17. Destroying all DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_batch_managed_mempool_receive/eth_rxq_batch_managed_mempool_receive_sample.c`
- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_batch_managed_mempool_receive/eth_rxq_batch_managed_mempool_receive_main.c`

- `/opt/mellanox/doca/samples/doca_eth/eth_rxq_batch_managed_mempool_receive/meson.build`

5.4.10 DOCA GPUNetIO

This document provides an overview and configuration instructions for DOCA GPUNetIO API.

5.4.10.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

DOCA GPUNetIO enables real-time GPU processing for network packets, making it ideal for application domains such as:

- Signal processing
- Network security
- Information gathering
- Input reconstruction

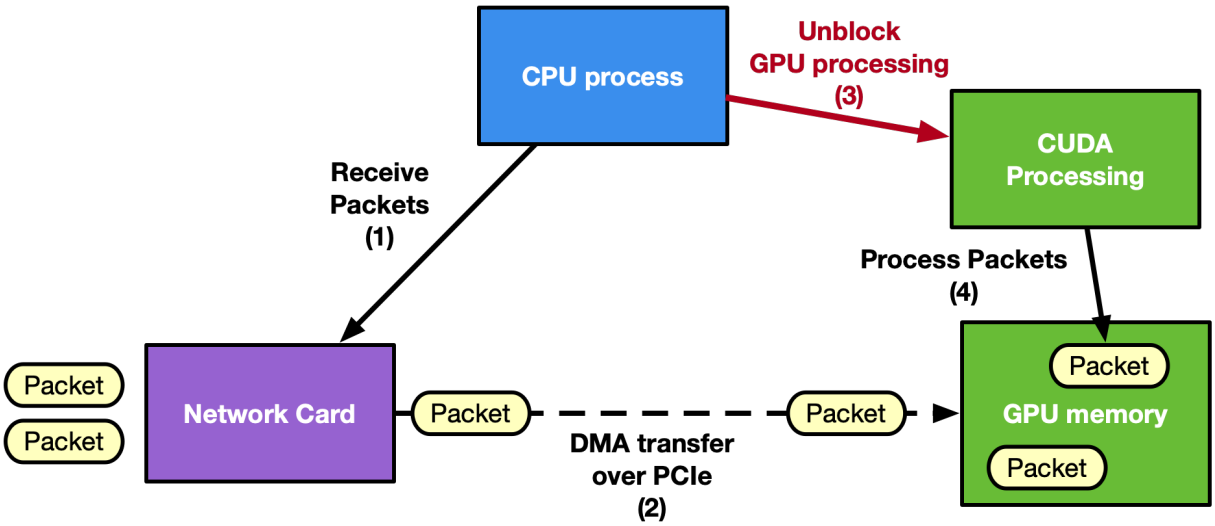
Traditional approaches often rely on a CPU-centric model, where the CPU coordinates with the NIC to receive packets in GPU memory using GPUDirect RDMA. Afterward, the CPU notifies a CUDA kernel on the GPU to process the packets. However, on low-power platforms, this CPU dependency can become a bottleneck, limiting GPU performance and increasing latency.

DOCA GPUNetIO addresses this challenge by offering a GPU-centric solution that removes the CPU from the critical path. By combining multiple NVIDIA technologies, it provides a highly efficient and scalable method for network packet processing.

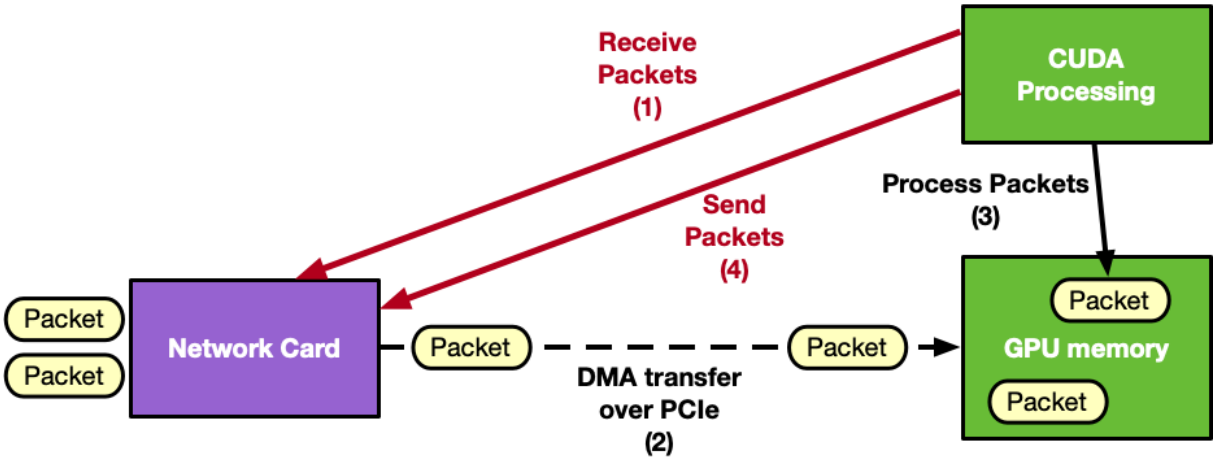
Technologies integrated with DOCA GPUNetIO:

- GPUDirect RDMA – Enables direct packet transfer between the NIC and GPU memory, eliminating unnecessary memory copies
- GPUDirect Async Kernel-Initiated (GDAKI) – Allows CUDA kernels to control network operations without CPU intervention
    - GDAKI is also named IBGDA when used with the RDMA protocol
- GDRCopy Library – Allows the CPU to access GPU memory directly
- NVIDIA BlueField DMA Engine – Supports GPU-triggered memory copies

The following is an example diagram of a CPU-centric approach:



The following is an example diagram of a GPU-centric approach:



Key features of DOCA GPUNetIO include:

- GPUDirect Async Kernel-Initiated (GDAKI)
  - GDAKI network communications – a GPU CUDA kernel can control network communications to send or receive data
    - GPU can control Ethernet communications (Ethernet/IP/UDP/TCP/ICMP)
    - GPU can control RDMA communications (InfiniBand or RoCE are supported)
    - CPU intervention is unnecessary in the application critical path
- GPUDirect RDMA
  - Enables direct data transfers to and from GPU memory without CPU staging copies.
- DMA Engine Control
  - CUDA kernels can initiate memory copies using BlueField's DMA engine
- Semaphores for Low-Latency Communication

    - Supports efficient message passing between CUDA kernels or between CUDA kernels and CPU threads
- Smart Memory Allocation
    - Allocates aligned GPU memory buffers, optimizing memory access
    - GDRCopy library to allocate a GPU memory buffer accessible from the CPU
- Accurate Send Scheduling
    - Provides precise control over Ethernet packet transmission based on user-defined timestamps.

NVIDIA applications that use DOCA GPUNetIO include:

- Aerial 5G SDK – For ultra-low latency 5G network operations
- NIXL – NVIDIA Inference Xfer Library (NIXL) is targeted for accelerating point to point communications in AI inference frameworks (e.g., NVIDIA Dynamo)
- Holoscan Advanced Network Operator – Powering real-time data processing in edge AI environments
- NVQLink – New GPU RoCE transceiver Holoscan sensor bridge operator
- UCX – new GDAKI module via GPUNetIO functions
- NCCL – GIN transport enabled via GPUNetIO GPU communications

For more information about DOCA GPUNetIO, refer to the following NVIDIA blog posts:

- Inline GPU Packet Processing with NVIDIA DOCA GPUNetIO
- Unlocking GPU-Accelerated RDMA with NVIDIA DOCA GPUNetIO
- Realizing the Power of Real-time Network Processing with NVIDIA DOCA GPUNetIO

5.4.10.2 Changes From Previous Releases

5.4.10.2.1 Changes in 3.3.0

- Added DGX Spark for GPUNetIO section to the application programming guide.
- Enabled NVIDIA® ConnectX®-8 reliable doorbell feature for GPUNetIO and Verbs integrations.
- Updated GPU packet processing application to measure receive bandwidth for UDP traffic.
- Extended GPU packet processing documentation with instructions for running T-Rex or `dpdk-testpmd` packet generators.

⚠ The function `doca_gpu_dev_eth_txq_wqe_prepare_wait_time` within `doca_gpunetio_dev_eth_txq.cuh` may fail to operate correctly if the `wseg` structure is not explicitly initialized to zero, potentially impacting Accurate Send Scheduling performance.

To work around this issue, manually patch the header file to explicitly set `struct doca_gpu_dev_eth_txq_wqe_wait_seg wseg = {0};`.

5.4.10.3 General Performance and Best Practices

Adhere to the following guidelines to maximize performance and streamline development with DOCA GPUNetIO.

5.4.10.3.1 Build Configuration

- Use release builds: Always compile applications and samples by setting `buildtype = 'release'` in the `meson.build` file. This ensures maximum throughput and minimal latency compared to the default debug mode.

5.4.10.3.2 Hardware and System Setup

- Driver Selection for `dmabuf`: Install the `nvidia-open` drivers to utilize `dmabuf`. If the environment relies on the closed-source NVIDIA drivers (`cuda-drivers`), the system does not support `dmabuf`; use `nvidia-peermem` instead.
- Optimize PCIe topology: For peak throughput, ensure the GPU and NIC share a PIX or PXB topology (connected via a single PCIe bridge). Avoid NODE or SYS topologies, as routing data across NUMA nodes or SMP interconnects reduces efficiency.
- Expand BAR1 size: If an application fails to map memory buffers to the NIC, verify the GPU's BAR1 size using `nvidia-smi -q`. Enable Resizable BAR in the system BIOS to allocate sufficient space.
- Systems Without GPUDirect RDMA: For hardware that does not support GPUDirect RDMA (such as DGX Spark), use the `DOCA_GPU_MEM_TYPE_CPU_GPU` memory type and enable CPU proxy mode for transmissions.

5.4.10.3.3 Programming Guidelines

- CUDA context initialization: Ensure an active CUDA context exists on the target device before calling DOCA GPUNetIO functions (such as `doca_gpu_create`). Initialize this context effectively by calling `cudaFree(0)`.
- Optimize execution scopes: When utilizing high-level Ethernet APIs, select the widest possible execution scope (Warp or Block) rather than Thread scope. This minimizes contention on atomic operations and significantly increases doorbell ringing efficiency.
- Strict pointer management: Strictly separate memory access boundaries to prevent segmentation faults. Use `memptr_gpu` exclusively within CUDA kernels, and use `memptr_cpu` solely for CPU-side management.

5.4.10.3.4 Permissions

- Root requirements: Execute all Ethernet samples and applications with `sudo` or root privileges, as they rely on DOCA Flow.
- Non-root alternatives: Verbs, RDMA, and DMA operations can run without root access. To enable this functionality, configure the NVIDIA driver with the option `NVreg_RegistryDwords="PeerMappingOverride=1;"`.

5.4.10.4 Navigation Hub

Choose the path that matches your current goal:

Goal	Description	Link
Set up my system	Install packages, configure NIC firmware (ConnectX/BlueField), and verify PCIe topology	Installation and Setup
Learn the concepts	Understand GDAKI, CPU vs. GPU control paths, and the GPUNetIO memory model	Architecture and Design
Start coding	Reference CPU and GPU functions for Ethernet, RDMA, Verbs, and DMA	API Reference
Run a demo	Walk through build instructions and execute provided sample applications	Sample Guide

5.4.10.5 GPUNetIO Installation and Setup

DOCA GPUNetIO is included in the `doca-all` package, which is available from the DOCA downloads portal for all supported operating systems.

To install the required DOCA GPUNetIO components, use the package manager for your OS.

- For Ubuntu/Debian:

```
apt install doca-all doca-sdk-gpunetio libdoca-sdk-gpunetio-dev
```

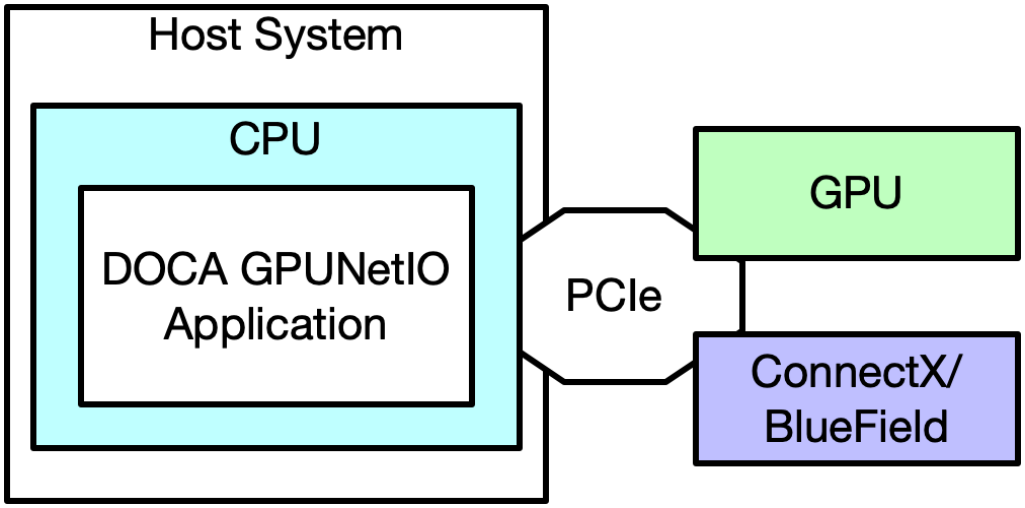
- For RHEL:

```
yum install doca-all doca-sdk-gpunetio doca-sdk-gpunetio-devel
```

Build Type and Performance

To achieve the best performance when building any DOCA GPUNetIO sample or application, you must set the `buildtype` to `release` in the `meson.build` file (e.g., `buildtype = 'release'`). Building in the default `debug` mode will result in significantly lower performance.

To run a DOCA GPUNetIO application, the system must be configured with both a GPU and a NIC (either NVIDIA® ConnectX® or NVIDIA® BlueField®), connected to the system via PCIe.



The system's internal hardware topology should be GPUDirect-RDMA-friendly to maximize the internal throughput between the GPU and the NIC. To verify the type of connection between the GPU and NIC:

```
$ nvidia-smi topo -m
        GPU0    NIC0    NIC1    CPU Affinity    NUMA Affinity   GPU NUMA ID
GPU0     X      NODE    NODE    12-23,36-47     1               N/A
NIC0    NODE     X      PIX
NIC1    NODE    PIX      X

Legend:

  X    = Self
  SYS  = Connection traversing PCIe as well as the SMP interconnect between NUMA nodes (e.g., QPI/UPI)
  NODE = Connection traversing PCIe as well as the interconnect between PCIe Host Bridges within a NUMA node
  PHB  = Connection traversing PCIe as well as a PCIe Host Bridge (typically the CPU)
  PXB  = Connection traversing multiple PCIe bridges (without traversing the PCIe Host Bridge)
  PIX  = Connection traversing at most a single PCIe bridge
  NV#  = Connection traversing a bonded set of # NVLinks

NIC Legend:
```

```
NIC0: mlx5_0
NIC1: mlx5_1
```

To maximize throughput between the GPU and NIC, the system should have a PIX (or PXB) topology with a dedicated PCIe connection. A PHB topology is still acceptable if the GPU and NIC are on the same PCIe Host Bridge and NUMA node, although performance may vary depending on the platform. For optimal performance, it's recommended to avoid NODE and SYS topologies, as they may negatively impact performance despite the application remaining functional.

Environment Support

DOCA GPUNetIO has been fully tested on bare-metal systems and within Docker containers. Support for virtualized environments is currently considered experimental.

5.4.10.5.1 NIC Configuration

5.4.10.5.1.1 ConnectX NIC

Ensure the ConnectX firmware is compatible with the current DOCA release. NVIDIA recommends using ConnectX-6 Dx or later adapters.

1. Start MST:

```
$ sudo mst start
```

2. Check MST status to get the MST device identifier:

```
$ sudo mst status -v
```

Example output:

```
MST modules:
------------
    MST PCI module is not loaded
    MST PCI configuration module loaded
PCI devices:
------------
DEVICE_TYPE             MST                           PCI       RDMA            NET                 
NUMA
ConnectX6DX(rev:0)      /dev/mst/mt4125_pciconf0.1    b5:00.1   mlx5_1          net-ens6f1                0
ConnectX6DX(rev:0)      /dev/mst/mt4125_pciconf0      b5:00.0   mlx5_0          net-ens6f0                0
```

3. Configure ConnectX NIC:
   - For Ethernet transport, run the following commands, replacing `<mst_device>` with the actual MST device name (e.g., `/dev/mst/mt4125_pciconf0`):

```
mlxconfig -d <mst_device> s KEEP_ETH_LINK_UP_P1=1 KEEP_ETH_LINK_UP_P2=1 KEEP_IB_LINK_UP_P1=0
KEEP_IB_LINK_UP_P2=0
# This is required only if application uses the Accurate Send Scheduling feature
```

```
mlxconfig -d <mst_device> --yes set ACCURATE_TX_SCHEDULER=1 REAL_TIME_CLOCK_ENABLE=1
```

> The following example assumes that the adapter is dual port. If single port, only P1 options apply.

- For InfiniBand transport, run:

```
mlxconfig -d <mst_device> s KEEP_ETH_LINK_UP_P1=0 KEEP_ETH_LINK_UP_P2=0 KEEP_IB_LINK_UP_P1=1
KEEP_IB_LINK_UP_P2=1
# Accurate Send Scheduling feature can't be used with InfiniBand
```

> The following example assumes that the adapter is dual port. If single port, only P1 options apply.

4. Perform a cold reboot to apply the changes:

```
ipmitool power cycle
```

5.4.10.5.1.2 BlueField NIC

To use NVIDIA BlueField-2 or BlueField-3 with DOCA GPUNetIO, the DPU must be in NIC mode to expose the internal ConnectX to the host application.

1. Start MST:

```
$ sudo mst start
```

2. Check MST status to get the mst device identifier:

```
$ sudo mst status -v
```

Example output:

```
MST modules:
------------
    MST PCI module is not loaded
    MST PCI configuration module loaded
PCI devices:
------------
DEVICE_TYPE                MST                           PCI       RDMA            NET
NUMA
BlueField3(rev:1)          /dev/mst/mt41692_pciconf0.1   9f:00.1   mlx5_1          net-ens6f1np1
1
BlueField3(rev:1)          /dev/mst/mt41692_pciconf0     9f:00.0   mlx5_0          net-ens6f0np0
1
```

3. Configure BlueField NIC:
   - For Ethernet transport:

```
sudo mlxconfig -d /dev/mst/mt41692_pciconf0 --yes set LINK_TYPE_P1=2 LINK_TYPE_P2=2
 INTERNAL_CPU_MODEL=1 INTERNAL_CPU_PAGE_SUPPLIER=1 INTERNAL_CPU_ESWITCH_MANAGER=1
 INTERNAL_CPU_IB_VPORT0=1 INTERNAL_CPU_OFFLOAD_ENGINE=DISABLED
# This is required only if application uses the Accurate Send Scheduling feature
sudo mlxconfig -d /dev/mst/mt41692_pciconf0 --yes set ACCURATE_TX_SCHEDULER=1
 REAL_TIME_CLOCK_ENABLE=1
```

   - For InfiniBand transport:

```
sudo mlxconfig -d /dev/mst/mt41692_pciconf0 --yes set LINK_TYPE_P1=1 LINK_TYPE_P2=1
 INTERNAL_CPU_MODEL=1 INTERNAL_CPU_PAGE_SUPPLIER=1 INTERNAL_CPU_ESWITCH_MANAGER=1
 INTERNAL_CPU_IB_VPORT0=1 INTERNAL_CPU_OFFLOAD_ENGINE=DISABLED
# Accurate Send Scheduling feature can't be used with Infiniband
```

4. Do a cold reboot to apply the changes:

```
ipmitool power cycle
```

5. Example verification command for Ethernet.

```
sudo mlxconfig -d /dev/mst/mt41692_pciconf0 q LINK_TYPE_P1 LINK_TYPE_P2 INTERNAL_CPU_MODEL
INTERNAL_CPU_PAGE_SUPPLIER INTERNAL_CPU_ESWITCH_MANAGER INTERNAL_CPU_IB_VPORT0 INTERNAL_CPU_OFFLOAD_ENGINE
ACCURATE_TX_SCHEDULER REAL_TIME_CLOCK_ENABLE
```

Example output (Ethernet):

```
        LINK_TYPE_P1                                ETH(2)
        LINK_TYPE_P2                                ETH(2)
        INTERNAL_CPU_MODEL                          EMBEDDED_CPU(1)
        INTERNAL_CPU_PAGE_SUPPLIER                  EXT_HOST_PF(1)
        INTERNAL_CPU_ESWITCH_MANAGER                EXT_HOST_PF(1)
        INTERNAL_CPU_IB_VPORT0                      EXT_HOST_PF(1)
        INTERNAL_CPU_OFFLOAD_ENGINE                 DISABLED(1)
        ACCURATE_TX_SCHEDULER                       True(1)
        REAL_TIME_CLOCK_ENABLE                      True(1)
```

5.4.10.5.2 PCIe Configuration

On some x86 systems, the Access Control Services (ACS) must be disabled to ensure direct communication between the NIC and GPU, whether they reside on the same converged accelerator DPU or on different PCIe slots in the system. The recommended solution is to disable ACS control via BIOS (e.g., Supermicro or HPE) on your PCIe bridge. Alternatively, it is also possible to disable it via command line, but it may not be as effective as the BIOS option.

The following `lspci -tvvv` output illustrates a typical system topology:

```
$ lspci -tvvv...+-[0000:b0]-+-00.0  Intel Corporation Device 09a2
 |           +-00.1  Intel Corporation Device 09a4
 |           +-00.2  Intel Corporation Device 09a3
 |           +-00.4  Intel Corporation Device 0998
 |           \-02.0-[b1-b6]----00.0-[b2-b6]--+-00.0-[b3]--+-00.0  Mellanox Technologies MT42822 BlueField-2
integrated ConnectX-6 Dx network controller
 |                                          |            +-00.1  Mellanox Technologies MT42822 BlueField-2
integrated ConnectX-6 Dx network controller
 |                                          |            \-00.2  Mellanox Technologies MT42822 BlueField-2 SoC
Management Interface
 |                                          \-01.0-[b4-b6]----00.0-[b5-b6]----08.0-[b6]----00.0  NVIDIA
Corporation Device 20b8
```

The PCIe switch address to consider is `b2:00.0` (entry point of the DPU). ACSCtl must have all negative values:

PCIe set

```
setpci -s b2:00.0 ECAP_ACS+0x6.w=0000
```

To verify that the setting has been applied correctly:

PCIe check

```
$ sudo lspci -s b2:00.0 -vvvv | grep -i ACSCtl
ACSCtl: SrcValid- TransBlk- ReqRedir- CmpltRedir- UpstreamFwd- EgressCtrl- DirectTrans-
```

Please refer to this page and this page for more information.

If the application still does not report any received packets, try to disable IOMMU. On some systems, it can be done from the BIOS looking for the the `VT-d` or `IOMMU` from the NorthBridge configuration and change that setting to `Disable` and save it. The system may also require adding `intel_iommu=off` or `amd_iommu=off` to the kernel options. That can be done through the grub command line as follows:

IOMMU

```
$ sudo vim /etc/default/grub
# GRUB_CMDLINE_LINUX_DEFAULT="iommu=off intel_iommu=off <more options>"
$ sudo update-grub
$ sudo reboot
```

5.4.10.5.3 GPU Configuration

5.4.10.5.3.1 CUDA Dependency

DOCA GPUNetIO components have a dependency on CUDA. These dependencies differ for the CPU-side shared library versus the GPU-side datapath components.

- CPU Shared Library (`libdoca_gpunetio.so`) This library has a dependency on `libcuda.so` (CUDA Driver API). Because it does not use the CUDA Runtime API, it is not subject to potential versioning issues associated with the runtime.
- GPU Datapath Components The data path functions are delivered as both header files and a static library, which have different requirements:
  - Header-only APIs (GPUNetIO Ethernet, GPUNetIO Verbs): These are inlined functions. Since they are compiled with your application, they are flexible and can be used with any recent CUDA version (e.g., CUDA 12.x or 13.x).
  - Static Library APIs (GPUNetIO DMA, CommCh, RDMA): This library is pre-built with CUDA 13.0. Therefore, any application using functions from this static library must be built with CUDA 13.0 or newer.

It is generally recommended to use CUDA 12.6 or newer wherever possible to take advantage of new features.

To decrease initial application startup latency, it is highly recommended to enable NVIDIA driver persistence mode:

```
nvidia-smi -pm 1
```

5.4.10.5.3.2 GDRCopy Installation

To enable direct CPU access to GPU memory without using CUDA APIs, DOCA requires the GDRCopy kernel module and library.

1. Install necessary packages:

```
sudo apt install -y check kmod
```

2. Clone the GDRCopy repository:

```
git clone https://github.com/NVIDIA/gdrcopy.git /opt/mellanox/gdrcopy
```

3. Build GDRCopy:

```
cd /opt/mellanox/gdrcopy && make
```

4. Load the GDRCopy kernel module:

```
./insmod.sh
```

5. Check if the `gdrdrv` and `nvidia-peermem` modules are loaded:

```
lsmod | egrep gdrdrv
```

Example output:

```
gdrdrv                 24576  0
nvidia              55726080  4 nvidia_uvm,nvidia_peermem,gdrdrv,nvidia_modeset
```

6. Export the GDRCopy library path:

```
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:/opt/mellanox/gdrcopy/src
```

7. Ensure CUDA library paths are in the environment variables:

```
export PATH="/usr/local/cuda/bin:${PATH}"
export LD_LIBRARY_PATH="/usr/local/cuda/lib:/usr/local/cuda/lib64:${LD_LIBRARY_PATH}"
export CPATH="$(echo /usr/local/cuda/targets/{x86_64,sbsa}-linux/include | sed 's/ /:/'):${CPATH}"
```

GDRCopy is optional. If not installed, DOCA GPUNetIO cannot allocate memory using the `DOCA_GPU_MEM_TYPE_GPU_CPU` flag. If GDRCopy is not detected, DOCA GPUNetIO will log warning messages.

If GDRCopy is not required for your application, you can safely ignore the related warning messages. To use GDRCopy, ensure its installation path is included in the `LD_LIBRARY_PATH` environment variable or specified using the `GDRCOPY_PATH_L` environment variable.

5.4.10.5.3.3 GPU Memory Mapping

To enable the NIC to send and receive packets using GPU memory, a memory mapping mechanism must be used. DOCA supports two methods:

1. `dmabuf` (default method): The preferred, modern method for mapping GPU memory.
2. `nvidia-peermem` (fallback method): A legacy method used if `dmabuf` is not available or fails.

Using dmabuf

This is the primary method for mapping GPU memory. The prerequisites for this approach are:

- Linux Kernel version 6.2 or later
- `libibverbs` version 1.14.44 or later
- CUDA Toolkit:
  - Version 12.5 or older: Must be installed with the `-m=kernel-open` flag (implying open-source NVIDIA driver mode).
  - Version 12.6 or newer: Open kernel mode is enabled by default.

dmabuf NVIDIA driver

Please ensure your system has `nvidia-open` drivers installed. If it shows `cuda-drivers` instead, it means the NVIDIA driver is installed as close source version and then dmabuf can't be used.

Using nvidia-peermem

This method is used if `dmabuf` is unavailable. It requires the `nvidia-peermem` kernel module, which is installed with the CUDA Toolkit, to be loaded:

Launch nvidia-peermem

```
sudo modprobe nvidia-peermem
```

Implementation and Fallback Logic

The recommended implementation is to attempt to get a `dmabuf` file descriptor first. If that fails, the application should fall back to the `nvidia-peermem` method.

The following code snippet demonstrates how to use `dmabuf` for GPU memory mapping with DOCA mmap, including the fallback logic:

GPU Configuration

```
/* Get the dmabuf file-descriptor for the GPU memory buffer from CUDA */
result = doca_gpu_dmabuf_fd(gpu_dev, gpu_buffer_addr, gpu_buffer_size, &(dmabuf_fd));

if (result != DOCA_SUCCESS) {
    /* Fallback to nvidia-peermem legacy method if dmabuf fails */
    doca_mmap_set_memrange(gpu_buffer_mmap, gpu_buffer_addr, gpu_buffer_size);
} else {
    /* Create DOCA mmap using dmabuf */
    doca_mmap_set_dmabuf_memrange(gpu_buffer_mmap, dmabuf_fd, gpu_buffer_addr, 0, gpu_buffer_size);
}
```

Handling dmabuf Failure

A failure in `doca_gpu_dmabuf_fd` (the `if` block in the example) likely indicates that the NVIDIA driver is not in open-source mode.

When `doca_mmap_start` is subsequently called, DOCA will attempt to map the GPU memory. If `dmabuf` was not set, it will automatically fall back to the legacy `nvidia-peermem` method. In this case, the following warning message is logged:

GPU Configuration

```
[DOCA][WRN][linux_devx_adapter.cpp:374] devx adapter 0x5566a16018e0: Registration using dmabuf is not supported,
falling back to legacy registration
```

If your application can rely on `nvidia-peermem` and does not strictly require `dmabuf`, this warning message can be safely ignored.

Sample Implementations

- GPUNetIO Ethernet samples use DOCA mmap with `dmabuf` and `nvidia-peermem` as the fallback (following the logic in the code example above).
- GPUNetIO Verbs samples show an alternative verbs-based method, using `ibv_reg_dmabuf_mr` (for `dmabuf`) and `ibv_reg_mr` (as the fallback).

5.4.10.5.3.4 GPU BAR1 Size

Every time a GPU buffer is mapped to the NIC (e.g., buffers associated with send or receive queues), a portion of the GPU BAR1 mapping space is used. Therefore, it is important to check that the BAR1 mapping is large enough to hold all the bytes the DOCA GPUNetIO application is trying to map. To verify the BAR1 mapping space of a GPU you can use `nvidia-smi`:

BAR1 mapping

```
$ nvidia-smi -q

==============NVSMI LOG==============
.....
Attached GPUs                           : 1
```

```
GPU 00000000:CA:00.0
    Product Name                          : NVIDIA A100 80GB PCIe
    Product Architecture                  : Ampere
    Persistence Mode                      : Enabled
.....
    BAR1 Memory Usage
        Total                             : 131072 MiB
        Used                              : 1 MiB
        Free                              : 131071 MiB
```

By default, some GPUs (e.g. RTX models) may have a very small BAR1 size:

BAR1 mapping

```
$ nvidia-smi -q | grep -i bar -A 3
    BAR1 Memory Usage
    Total : 256 MiB
    Used : 6 MiB
    Free : 250 MiB
```

If the BAR1 size is not enough, DOCA GPUNetIO applications may exit with errors because DOCA mmap fails to map the GPU memory buffers to the NIC (e.g., `Failed to start mmap DOCA Driver call failure`). To overcome this issue, the GPU BAR1 must be increased from the BIOS. The system should have "Resizable BAR" option enabled. For further information, refer to this NVIDIA forum post.

5.4.10.5.3.5 Running without Root Privileges

All DOCA GPUNetIO samples and applications using Ethernet rely on DOCA Flow. Therefore, they must be executed with `sudo` or root privileges.

However, Verbs, RDMA and DMA samples can be run without `sudo` privileges if a specific option is enabled in the NVIDIA driver:

1. Create a configuration file for the NVIDIA driver:

   ```
   cat <<EOF | sudo tee /etc/modprobe.d/nvidia.conf
   options nvidia NVreg_RegistryDwords="PeerMappingOverride=1;"
   EOF
   ```

2. Perform a cold reboot to ensure the changes take effect.
3. Verify that the configuration has been applied using the following command:

   ```
   $ grep RegistryDwords /proc/driver/nvidia/params
   ```

   You should see the following output confirming the setting:

   ```
   RegistryDwords: "PeerMappingOverride=1;"
   ```

5.4.10.5.4 DGX Spark

Due to hardware topology limitations, DGX Spark does not support GPUDirect RDMA. However, DOCA GPUNetIO applications can still execute on these systems by utilizing

CPU pinned memory (`DOCA_GPU_MEM_TYPE_CPU_GPU`) instead of GPU memory. This applies to both queue allocation and packet/data memory.

5.4.10.5.4.1 Ethernet Configuration

When creating Rx or Tx queues with DOCA Ethernet, you must use the setters in `doca_eth_rxq_gpu_data_path.h` and `doca_eth_txq_gpu_data_path.h` to allocate queues on the CPU-GPU shared memory:

DOCA Ethernet queue memory setters

```
doca_error_t doca_eth_rxq_gpu_set_rq_mem_type(struct doca_eth_rxq *eth_rxq, enum doca_gpu_mem_type rq_mem_type);
doca_error_t doca_eth_txq_gpu_set_sq_mem_type(struct doca_eth_txq *eth_txq, enum doca_gpu_mem_type sq_mem_type);
```

For Tx queues, you must also enable CPU proxy mode to handle transmission:

DOCA Ethernet CPU proxy mode

```
doca_error_t doca_eth_txq_gpu_set_uar_on_cpu(struct doca_eth_txq *eth_txq);
```

See the `gpunetio_simple_send_sample` for an implementation of CPU proxy on the data path.

5.4.10.5.4.2 Verbs RDMA Configuration

A similar approach applies to GPUNetIO Verbs applications, with the distinction that the application is responsible for explicitly allocating the queue memory (QP UMEM) using the `DOCA_GPU_MEM_TYPE_CPU_GPU` memory type.

For the send side, CPU proxy mode is also supported. Refer to the following GPUNetIO Verbs examples for implementation details:

- `gpunetio_verbs_put_bw_sample`
- `gpunetio_verbs_put_counter_bw_sample`
- `gpunetio_verbs_write_bw_sample`
- `gpunetio_verbs_write_lat_sample`

5.4.10.6 GPUNetIO Architecture and Design

5.4.10.6.1 Architecture

A DOCA GPUNetIO network application is split into two fundamental phases:

- Configuration Phase (CPU): The CPU handles all initial setup, such as device configuration, memory allocation, and launching CUDA kernels.
- Data Path Phase (GPU): The GPU and NIC interact directly to execute high-speed packet processing functions.

DOCA GPUNetIO provides the building blocks to create a full data path pipeline that runs entirely on the GPU, often in combination with other libraries like DOCA Ethernet, DOCA RDMA Verbs, DOCA RDMA or DOCA DMA.

5.4.10.6.1.1 Setup and Component Model

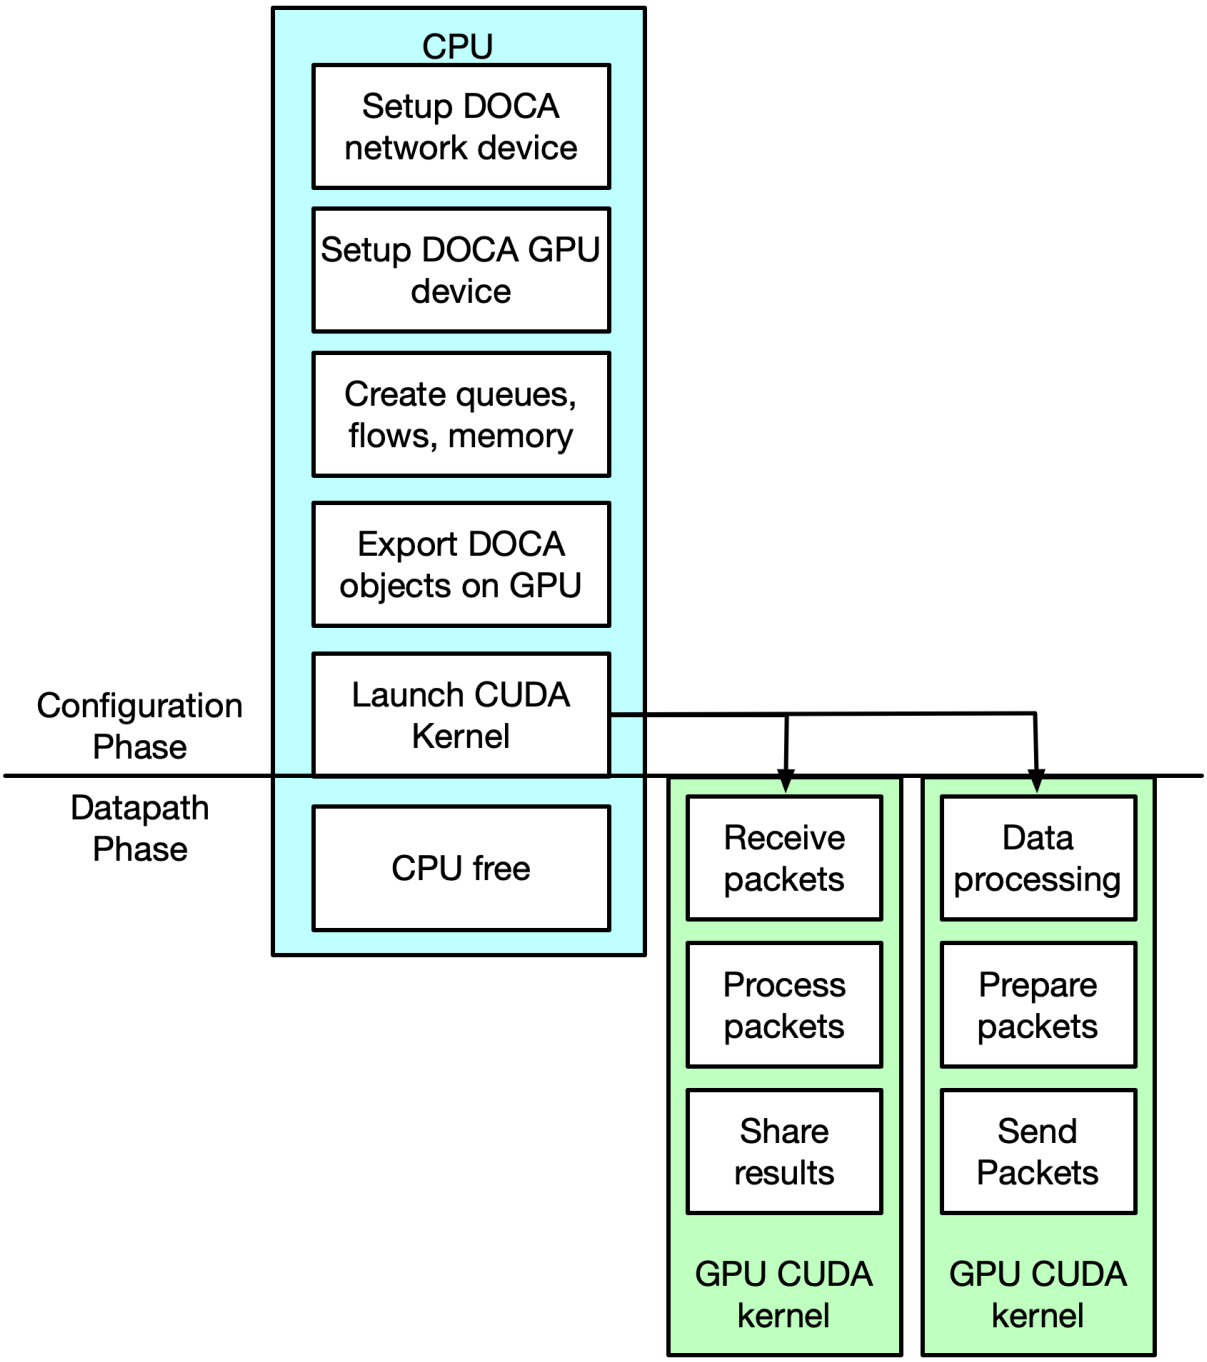
During the setup phase, the CPU-based application must:

1. Prepare all required objects (e.g., queues, contexts) on the CPU.
2. Export a GPU-specific handle for these objects.
3. Launch a CUDA kernel, passing the object's GPU handle to it so the kernel can work with the object during the data path phase.

This "CPU-setup, GPU-run" model is why DOCA GPUNetIO is composed of several distinct components:

- `libdoca_gpunetio.so` (CPU Control Path) A shared library containing control-path functions. The CPU application uses these to prepare the GPU, allocate memory, and configure objects.
- `libdoca_gpunetio_device.a` (GPU Data Path – Static Library) A static library containing data-path functions for GPUNetIO RDMA, GPUNetIO DMA, and GPUNetIO CommCh. These functions are invoked by the GPU from within a CUDA kernel.
- `doca_gpunetio_dev_*.cuh` (GPU Data Path – Headers) A set of header files providing inline data-path functions for GPUNetIO Ethernet and GPUNetIO Verbs. These are compiled directly into the application's CUDA kernels.

The following diagram presents the typical flow:



5.4.10.6.1.2 Library Linking

- The pkgconfig file for the CPU shared library is `doca-gpunetio.pc`.
- There is no pkgconfig file for the GPU static library (`libdoca_gpunetio_device.a`). If your application requires these CUDA device functions, you must explicitly link this library.
  - Default path: `/opt/mellanox/doca/lib/x86_64-linux-gnu/libdoca_gpunetio_device.a`

5.4.10.6.2 GDAKI Data Path for Different Protocols

DOCA GPUNetIO provides GPU GDAKI (GPU Direct Access Kernel Interface) functions to control objects for various transports and protocols that were created using other DOCA libraries. This section explains the correlation between DOCA GPUNetIO and these other libraries.

5.4.10.6.2.1 Ethernet GDAKI Communications

To enable GPU-accelerated communications over the Ethernet transport, an application must use a combination of three DOCA libraries:

- DOCA GPUNetIO: For GPU-specific handles and data path functions.
- DOCA Ethernet: To create and manage the underlying TX/RX queues.
- DOCA Flow: To steer packets to the correct GPU-managed queues.

Control Path Phase: Initial CPU Configuration

Before any data path operations can occur on the GPU, the CPU must first configure all the necessary resources.

1. Create a DOCA Core device handler for the network card.
2. Create a DOCA GPUNetIO device handler for the GPU.
3. Use the DOCA Ethernet library to:
    - Create the required Send Queues (TXQ) and/or Receive Queues (RXQ).
    - Set the data path for these queue handlers to the GPU.
    - Export a GPU-specific handle that represents these queues.
4. Use the DOCA Flow library to create and install flow steering rules that direct the desired types of packets to the newly created DOCA Ethernet receive queues.

Data Path Phase: GPU Kernel Execution

After the configuration phase is complete, the application can launch a CUDA Kernel, passing the GPU handles for the Ethernet queues as input arguments. This allows DOCA GPUNetIO CUDA device functions to operate directly on the queues from within the kernel.

All GPUNetIO Ethernet CUDA device functions are provided as inlined functions in the following header files:

- `doca_gpunetio_dev_eth_rxq.cuh`
- `doca_gpunetio_dev_eth_txq.cuh`

These functions are provided in two distinct APIs:

- Low-level API: Provides fine-grained control over fundamental `mlx5` elements, such as posting Work Queue Entries (WQEs), ringing the network card's doorbell, and polling for Completion Queue Entries (CQEs).

- High-level API: Provides more complex, pre-packaged functions that implement advanced features:
  - Shared Send QP: Allows a single Send Queue to be safely accessed concurrently by different CUDA threads, warps, or blocks.
  - Cooperative Receive QP: Allows a single thread, all threads in a warp, or all threads in a block to cooperate for parallel packet reception from a single Receive Queue.
  - Memory Consistency (MCST): A feature for pre-Hopper GPUs to manage memory mappings on the receive side.

Both APIs support CPU proxy mode, a fallback mechanism for systems where direct DoorBell ringing from the GPU is not possible.

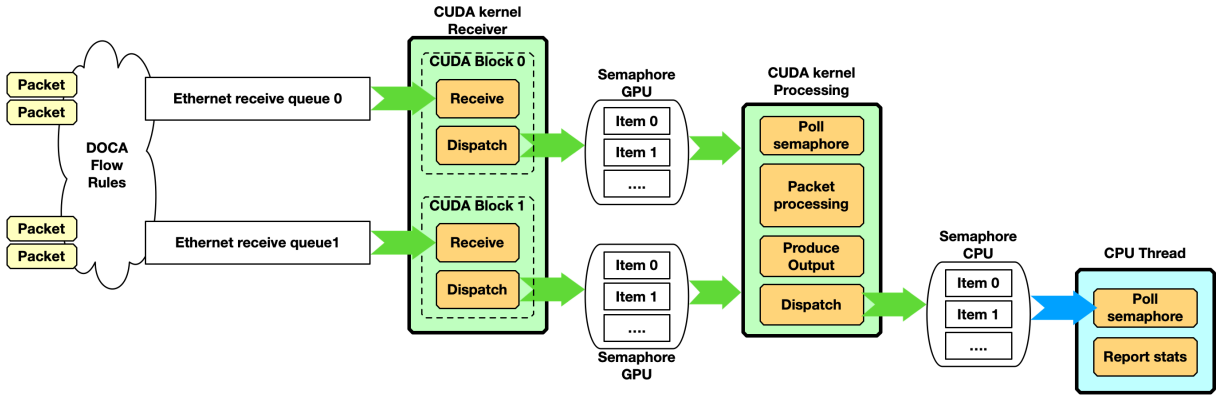
> For examples of how to use both the high-level and low-level GPUNetIO Ethernet APIs, refer to the "GPUNetIO Sample Guide".

Example Use Cases and Further Reading

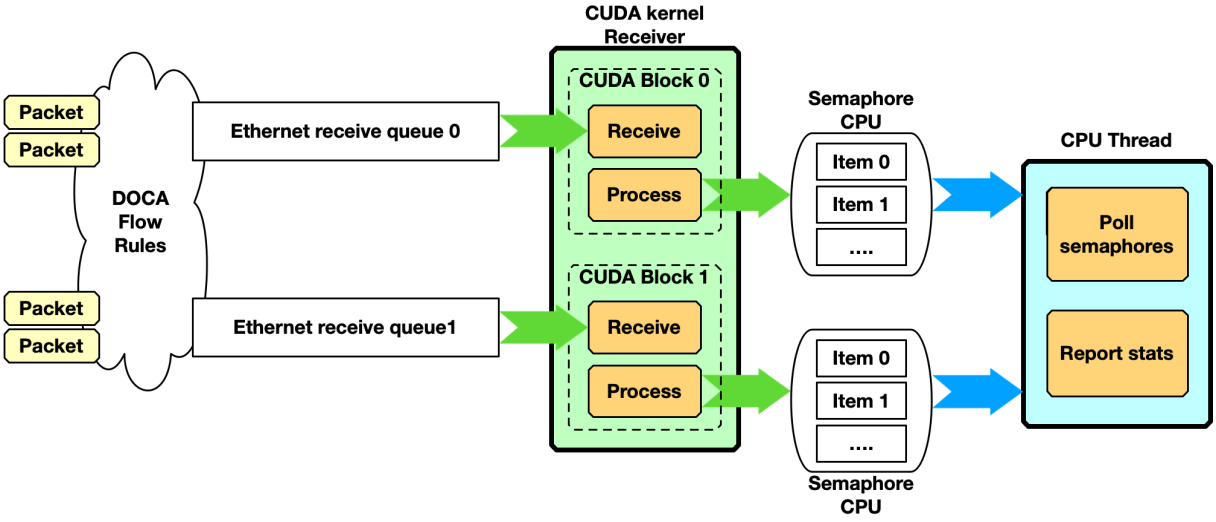
Refer to the DOCA GPU Packet Processing Application Guide (`doca_gpu_packet_processing`) and samples (`doca_gpunetio_simple_send`, `doca_gpunetio_simple_receive`, `doca_gpunetio_send_wait_time`) for examples of Ethernet GPU communications.

> For a deeper understanding of the underlying Ethernet send and receive structures, objects, and functions, refer to the DOCA Ethernet library documentation.

An example diagram when multiple queues and/or semaphores are used to receive Ethernet traffic:



Receiving and dispatching packets to another CUDA kernel is not required. A simpler scenario can have a single CUDA kernel receiving and processing packets:



5.4.10.6.2.2 RDMA Verbs GDAKI Communications (IBGDA)

DOCA GPUNetIO provides GPU data path functions for objects created with the DOCA RDMA and DOCA RDMA Verbs libraries. This enables GPU communications over RDMA transport protocols (IB or RoCE).

DOCA GPUNetIO and DOCA RDMA

This approach uses the high-level DOCA RDMA library, which abstracts most low-level `mlx5` and IBVerbs details. The GPUNetIO CUDA data path functions follow a similarly high-level API.

Key characteristics:

- Provides a high-level API for generic RDMA operations (Write, Send, Read, Recv).
- Delivered as a closed-source CUDA static library (`libdoca_gpunetio_device.a`).
- Does not include built-in shared queue management. Applications must manually manage simultaneous access to queues from different CUDA threads.
- Best suited for simpler GDAKI applications performing basic RDMA operations, as it requires less deep knowledge of IBVerbs or `mlx5` details.

Weak vs. Strong Operation Modes

Some RDMA GPU functions offer two operation modes:

- Weak Mode: The application is responsible for calculating the next available position in the queue.
  - Helper functions (e.g., `doca_gpu_rdma_get_info`) provide the next available position and queue size mask (for index wrapping).
  - The developer must specify the exact queue descriptor number, ensuring no descriptors are skipped.
  - More complex, but offers better performance and allows developers to optimize for GPU memory coalescing.

- Strong Mode: The GPU function automatically enqueues the RDMA operation in the next available position.
    - Simpler to manage, as the developer does not need to track the position.
    - May introduce extra latency due to atomic operations. It also does not guarantee that sequential operations use sequential memory locations.

> ⚠ All strong mode functions operate at the CUDA block level. It is not possible to access the same RDMA queue from two different CUDA blocks simultaneously.

Configuration and Usage

1. Create a device handler for the network card using DOCA Core.
2. Create a GPU device handler for the GPU card using DOCA GPUNetIO.
3. Use DOCA RDMA to:
    - Create send and/or receive queue handlers.
    - Set the queue handlers' data path to the GPU.
    - Export a GPU handler representing those queues.

After configuration, launch a CUDA Kernel, passing the GPU handlers for the RDMA queues as input arguments. Use the functions defined in `doca_gpunetio_dev_rdma.cuh` (starting with `doca_gpu_dev_rdma_*`) for RDMA communications in the kernel.

Example Use Cases

Refer to the `doca_gpunetio_rdma_client_server_write` sample for examples of GPUNetIO RDMA functions.

> ✓ For a deeper understanding of RDMA operations, refer to the DOCA RDMA documentation.

DOCA GPUNetIO and DOCA Verbs

This approach uses the lower-level DOCA RDMA Verbs library. The GPUNetIO Verbs CUDA data path functions are provided as inlined functions in the `doca_gpunetio_dev_verbs_*.cuh` header files.

These functions are offered as two different APIs:

- Low-level API: For direct manipulation of fundamental RDMA `mlx5` elements, such as posting Work Queue Entries (WQEs), ringing doorbells, and polling Completion Queues (CQEs). This supports both one-sided (Read, Write, Atomic) and two-sided (Send, Recv) operations.
- High-level API: More complex helper functions that implement common patterns:

- Shared QP: Allows a single QP to be safely accessed concurrently by different CUDA threads or warps.
- Combined Operations: Building blocks for concatenating multiple operations (e.g., `put_signal`, which combines an RDMA Write and an Atomic Fetch-and-Add).
- Memory Consistency (MCST): A feature for pre-Hopper GPUs to manage memory mappings on the RDMA Get or Receive side.
- ConnectX-8 reliable doorbell feature: no need to update the DBREC

Both APIs support CPU proxy mode, a fallback mechanism for systems where direct DoorBell ringing from the GPU is not possible. The `samples/doca_gpunetio/verbs_high_level.cpp` file provides helper functions (e.g., `doca_gpu_verbs_create_qp_hl()`) that simplify the CPU-side setup for these Verbs QPs.

The GPUNetIO Verbs APIs are currently experimental. Please report any issues encountered to help improve code quality and robustness.

Configuration and Usage

1. Create a device handler for the network card using DOCA Core.
2. Create a GPU device handler for the GPU card using DOCA GPUNetIO.
3. Use DOCA RDMA Verbs to:
    - Create send and/or receive queue handlers.
    - Set the queue handlers' data path to the GPU.
    - Export a GPU handler representing those queues.

After configuration, launch a CUDA Kernel, passing the GPU handlers for the Verbs queues as input arguments.

Example Use Cases

Refer to samples `doca_gpunetio_verbs_*` for examples of GPUNetIO Verbs functions.

For a deeper understanding of Verbs operations, refer to the DOCA RDMA Verbs documentation.

5.4.10.6.2.3 DMA GDAKI Memory Copies

To enable GPU-triggered memory copies using the DMA engine, an application requires DOCA GPUNetIO and DOCA DMA libraries.

Initial CPU Configuration Phase

1. Create a device handler for the network card using DOCA Core.
2. Create a GPU device handler for the GPU card using DOCA GPUNetIO.

3. Use DOCA DMA to:
    - Create DMA queue handlers.
    - Set queue handlers' data path on the GPU.
    - Export a GPU handler representing those queues.

Data Path Phase on GPU

After completing the configuration phase, launch a CUDA Kernel, passing the GPU handlers for DMA queues as input arguments. This enables DOCA GPUNetIO CUDA device functions to operate within the CUDA Kernel.

For DMA memory copies, use functions defined in `doca_gpunetio_dev_dma.cuh`.

Example Use Case

Refer to the sample `doca_gpunetio_dma_memcpy` for an example of triggering DMA memory copies from a CUDA Kernel.

For a deeper understanding of DMA operations, refer to the DOCA DMA documentation.

5.4.10.7 GPUNetIO API Reference

This section details the specific structures and operations related to the main DOCA GPUNetIO API on CPU and GPU. GPUNetIO headers are:

- `doca_gpunetio.h` – CPU functions to create GPU handlers, allocate GPU memory, etc..
- `doca_gpunetio_dev_eth_rxq.cuh` – Open source GPU functions to manage a DOCA Ethernet receive queue
- `doca_gpunetio_dev_eth_txq.cuh` – Open source GPU functions to manage a DOCA Ethernet send queue
- `doca_gpunetio_dev_verbs_*.cuh` – Open source GPU functions to manage a DOCA RDMA Verbs object
- `doca_gpunetio_dev_buf.cuh` – GPU functions to manage a DOCA buffer array
- `doca_gpunetio_dev_sem.cuh` – GPU functions to manage a DOCA GPUNetIO semaphore
- `doca_gpunetio_dev_rdma.cuh` – GPU functions to manage a DOCA RDMA queue
- `doca_gpunetio_dev_dma.cuh` – GPU functions to manage a DOCA DMA queue

This section lists the main functions of DOCA GPUNetIO. All DOCA Core, Ethernet, Verbs, RDMA and DMA objects used in combination with GPUNetIO have a GPU export function to obtain a GPU handler for that object.

5.4.10.7.1 CPU Functions

In this section there is the list of DOCA GPUNetIO functions that can be used on the CPU only.

5.4.10.7.1.1 doca_gpu_mem_type

This enum lists all the possible memory types that can be allocated with GPUNetIO.

```
enum doca_gpu_mem_type {
    DOCA_GPU_MEM_TYPE_GPU        = 0,
    DOCA_GPU_MEM_TYPE_GPU_CPU    = 1,
    DOCA_GPU_MEM_TYPE_CPU_GPU    = 2,
};
```

With regards to the syntax, the text string after the `DOCA_GPU_MEM_TYPE_` prefix signifies `<where-memory-resides>_<who-has-access>`.

- `DOCA_GPU_MEM_TYPE_GPU` – memory resides on the GPU and is accessible from the GPU only
- `DOCA_GPU_MEM_TYPE_GPU_CPU` – memory resides on the GPU and is accessible also by the CPU
- `DOCA_GPU_MEM_TYPE_CPU_GPU` – memory resides on the CPU and is accessible also by the GPU

Typical usage of the `DOCA_GPU_MEM_TYPE_GPU_CPU` memory type is to send a notification from the CPU to the GPU (e.g., a CUDA kernel periodically checking to see if the exit condition set by the CPU is met).

5.4.10.7.1.2 doca_gpu_create

This is the first function a GPUNetIO application must invoke to create an handler on a GPU device. The function initializes a pointer to a structure in memory with type `struct doca_gpu *`.

```
doca_error_t doca_gpu_create(const char *gpu_bus_id, struct doca_gpu **gpu_dev);
```

- `gpu_bus_id` – `<PCIe-bus>:<device>.<function>` of the GPU device you want to use in your application
- `gpu_dev [out]` – GPUNetIO handler to that GPU device

To get the PCIe address, users can use the commands `lspci` or `nvidia-smi`.

5.4.10.7.1.3 doca_gpu_mem_alloc

This CPU function allocates different flavors of memory.

```
doca_error_t doca_gpu_mem_alloc(struct doca_gpu *gpu_dev, size_t size, size_t alignment, enum doca_gpu_mem_type
mtype, void **memptr_gpu, void **memptr_cpu)
```

- `gpu_dev` – GPUNetIO device handler
- `size` – Size, in bytes, of the memory area to allocate
- `alignment` – Memory address alignment to use. If 0, default one will be used
- `mtype` – Type of memory to allocate
- `memptr_gpu [out]` – GPU pointer to use to modify that memory from the GPU if memory is allocated on or is visible by the GPU
- `memptr_cpu [out]` – CPU pointer to use to modify that memory from the CPU if memory is allocated on or is visible by the CPU. Can be NULL if memory is GPU-only

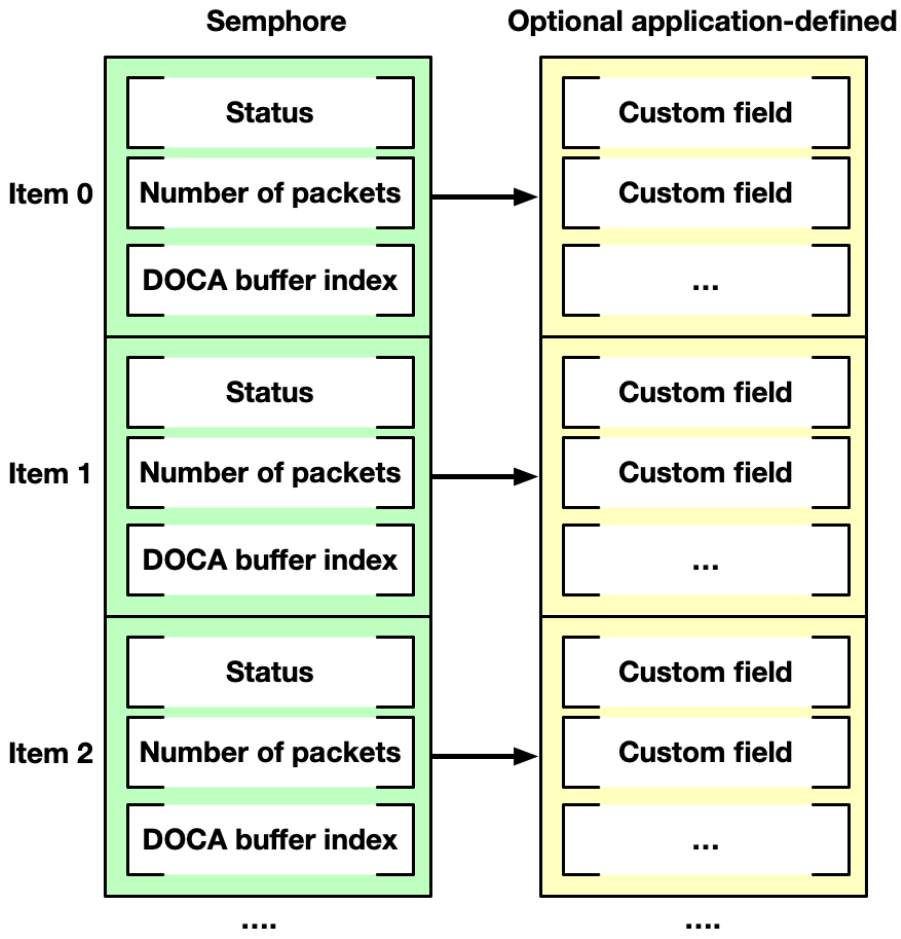
Make sure to use the right pointer on the right device! If an application tries to access the memory using the `memptr_gpu` address from the CPU, a segmentation fault will result.

5.4.10.7.1.4 doca_gpu_semaphore_create

Creates a new instance of a DOCA GPUNetIO semaphore. A semaphore is composed by a list of items each having, by default, a status flag, number of packets, and the index of a `doca_gpu_buf` in a `doca_gpu_buf_arr`.

For example, a GPUNetIO semaphore can be used in applications where a CUDA kernel is responsible for receiving packets in a `doca_gpu_buf_arr` array associated with an Ethernet receive queue object, `doca_gpu_eth_rxq` (see section "doca_gpu_dev_eth_rxq_receive_*"), and dispatching packet info to a second CUDA kernel which processes them.

Another way to use a GPUNetIO semaphore is to exchange data across different entities like two CUDA kernels or a CUDA kernel and a CPU thread. The reason for this scenario may be that the CUDA kernel needs to provide the outcome of the packet processing to the CPU which would in turn compile a statistics report. Therefore, it is possible to associate a custom application-defined structure with each item in the semaphore. This way, the semaphore can be used as a message passing object.



Entities communicating through a semaphore must adopt a poll/update mechanism according to the following logic:

- Update:
  a. Populate the next item of the semaphore (packets' info and/or custom application-defined info).
  b. Set status flag to READY.
- Poll:
  a. Wait for the next item to have a status flag equal to `READY`.
  b. Read and process info.
  c. Set status flag to `DONE`.

```
doca_error_t doca_gpu_semaphore_create(struct doca_gpu *gpu_dev, struct doca_gpu_semaphore **semaphore)
```

- `gpu_dev` – GPUNetIO handler
- `semaphore [out]` – GPUNetIO semaphore handler associated to the GPU device

5.4.10.7.1.5 doca_gpu_semaphore_set_memory_type

This function defines the type of memory for the semaphore allocation.

```
doca_error_t doca_gpu_semaphore_set_memory_type(struct doca_gpu_semaphore *semaphore, enum doca_gpu_mem_type mtype)
```

- `semaphore` – GPUNetIO semaphore handler
- `mtype` – Type of memory to allocate the custom info structure
  - If the application must share packet info only across CUDA kernels, then `DOCA_GPU_MEM_GPU` is the suggested memory type.
  - If the application must share info from a CUDA kernel to a CPU (e.g., to report statistics or output of the pipeline computation), then `DOCA_GPU_MEM_CPU_GPU` is the suggested memory type

5.4.10.7.1.6 doca_gpu_semaphore_set_items_num

This function defines the number of items in a semaphore.

```
doca_error_t doca_gpu_semaphore_set_items_num(struct doca_gpu_semaphore *semaphore, uint32_t num_items)
```

- `semaphore` – GPUNetIO semaphore handler
- `num_items` – Number of items to allocate

5.4.10.7.1.7 doca_gpu_semaphore_set_custom_info

This function associates an application-specific structure to semaphore items as explained under "doca_gpu_semaphore_create".

```
doca_error_t doca_gpu_semaphore_set_custom_info(struct doca_gpu_semaphore *semaphore, uint32_t nbytes, enum
 doca_gpu_mem_type mtype)
```

- `semaphore` – GPUNetIO semaphore handler
- `nbytes` – Size of the custom info structure to associate
- `mtype` – Type of memory to allocate the custom info structure
  - If the application must share packet info only across CUDA kernels, then `DOCA_GPU_MEM_GPU` is the suggested memory type
  - If the application must share info from a CUDA kernel to a CPU (e.g., to report statistics or output of the pipeline computation), then `DOCA_GPU_MEM_CPU_GPU` is the suggested memory type

5.4.10.7.1.8 doca_gpu_semaphore_get_status

From the CPU, query the status of a semaphore item. If the semaphore is allocated with `DOCA_GPU_MEM_GPU`, this function results in a segmentation fault.

```
doca_error_t doca_gpu_semaphore_get_status(struct doca_gpu_semaphore *semaphore_cpu, uint32_t idx, enum
 doca_gpu_semaphore_status *status)
```

- `semaphore_cpu` – GPUNetIO semaphore CPU handler
- `idx` – Semaphore item index

- `status [out]` – Output semaphore status

5.4.10.7.1.9 doca_gpu_semaphore_get_custom_info_addr

From the CPU, retrieve the address of the custom info structure associated to a semaphore item. If the semaphore or the custom info is allocated with `DOCA_GPU_MEM_GPU` this function results in a segmentation fault.

```
doca_error_t doca_gpu_semaphore_get_custom_info_addr(struct doca_gpu_semaphore *semaphore_cpu, uint32_t idx, void
 **custom_info)
```

- `semaphore_cpu` – GPUNetIO semaphore CPU handler
- `idx` – Semaphore item index
- `custom_info [out]` – Output semaphore custom info address

5.4.10.7.1.10 doca_gpu_verbs_export_qp

The `doca_gpu_verbs_export_qp` function creates a GPUNetIO handler from a DOCA RDMA Verbs QP object. It takes a DOCA RDMA Verbs QP as input and returns a DOCA GPUNetIO Verbs QP object (`struct doca_gpu_verbs_qp`) allocated on the CPU. To use this object in a CUDA kernel, the application must extract a GPU device handler (`struct doca_gpu_dev_verbs_qp`) using the `doca_gpu_verbs_get_qp_dev` function.

```
doca_error_t doca_gpu_verbs_export_qp(struct doca_gpu *gpu_dev, struct doca_dev *dev, struct doca_verbs_qp *qp,
enum doca_gpu_dev_verbs_nic_handler nic_handler, void *gpu_qp_umem_dev_ptr, struct doca_verbs_cq *cq_sq, struct
 doca_verbs_cq *cq_rq, struct doca_gpu_verbs_qp **qp_out);
```

- `gpu_dev`: GPUNetIO device handler.
- `dev`: DOCA device handler.
- `qp`: DOCA RDMA Verbs QP handler.
- `nic_handler`: Type of NIC handler.
- `gpu_qp_umem_dev_ptr`: GPU memory pointer to UMEM.
- `cq_sq` and `cq_rq`: CQs associated with the Send and Receive Queues in the QP.

  While either `cq_sq` or `cq_rq` can be NULL, they cannot both be NULL simultaneously.

- `qp_out`: DOCA GPUNetIO Verbs QP handler in CPU memory.

5.4.10.7.1.11 doca_gpu_verbs_get_qp_dev

Extracts a GPU device handler (`struct doca_gpu_dev_verbs_qp`) from a DOCA GPUNetIO Verbs QP object.

```
doca_error_t doca_gpu_verbs_get_qp_dev(struct doca_gpu_verbs_qp *qp, struct doca_gpu_dev_verbs_qp **qp_gpu);
```

- `qp`: DOCA GPUNetIO Verbs QP handler.

- `qp_gpu`: DOCA GPUNetIO Verbs QP GPU device handler in GPU memory.

5.4.10.7.1.12 doca_gpu_verbs_unexport_qp

Unexports a previously exported DOCA GPUNetIO Verbs QP object (`struct doca_gpu_verbs_qp`).

```
doca_error_t doca_gpu_verbs_export_qp(ruct doca_gpu *gpu_dev, struct doca_gpu_verbs_qp *qp);
```

- `gpu_dev`: GPUNetIO device handler.
- `qp`: DOCA GPUNetIO Verbs QP handler in CPU memory.

5.4.10.7.1.13 doca_gpu_verbs_bridge_export_qp

The `doca_gpu_verbs_bridge_export_qp` function creates a DOCA GPUNetIO Verbs QP object from application-defined parameters, acting as a bridge between IBVerbs/mlx5 objects and DOCA GPUNetIO. This allows applications to create required objects like QP, CQ, and UAR using IBVerbs and mlx5 commands and then pass the relevant information to this DOCA GPUNetIO function.

The function returns a DOCA GPUNetIO Verbs QP object (`struct doca_gpu_verbs_qp`) allocated on the CPU. To use this object in a CUDA kernel, the application must extract a GPU device handler (`struct doca_gpu_dev_verbs_qp`) using the `doca_gpu_verbs_get_qp_dev` function.

It is the application's responsibility to ensure that all passed parameters are correctly created and set.

```
doca_error_t doca_gpu_verbs_bridge_export_qp(struct doca_gpu *gpu_dev, uint32_t sq_qpn, void *sq_wqe_addr, uint16_t
sq_wqe_num, uint32_t *sq_dbrec, uint64_t *sq_db, size_t uar_size, uint32_t sq_cqn, void *sq_cqe_addr, uint32_t
sq_cqe_num, uint32_t *sq_cq_dbrec, uint32_t rq_qpn, void *rq_wqe_addr, uint16_t rq_wqe_num, uint32_t *rq_dbrec,
uint32_t rcv_wqe_size, uint32_t rq_cqn, void *rq_cqe_addr, uint32_t rq_cqe_num, uint32_t *rq_cq_dbrec, enum
 doca_gpu_dev_verbs_nic_handler nic_handler, struct doca_gpu_verbs_qp **qp_out);
```

- `gpu_dev`: GPUNetIO device handler.
- `sq_qpn`: Send QP queue number.
- `sq_wqe_addr`: Send QP WQE buffer memory address.
- `sq_wqe_num`: Send QP number of WQEs.
- `sq_dbrec`: Send QP Doorbell Record address.
- `sq_db`: Send QP Doorbell address.
- `uar_size`: Size of UAR.
- `sq_cqn`: Send CQ number.
- `sq_cqe_addr`: Send CQ CQE buffer memory address.
- `sq_cqe_num`: Send CQ number of CQEs.
- `qp_out`: DOCA GPUNetIO Verbs QP handler in CPU memory.

5.4.10.7.2 DOCA PE

A DOCA Ethernet Txq context, exported for GPUNetIO usage, can be tracked via DOCA PE on the CPU side to check if there are errors when sending packets or to retrieve notification info after sending a packet with any of the `doca_gpu_dev_eth_txq_*_enqueue_*` functions on the GPU. An example can be found in the DOCA GPU packet processing application with ICMP traffic.

A DOCA Comch Producer or Consumer context, exported for GPUNetIO usage must still be attached to a DOCA PE on the CPU to ensure that remote producer and consumer connections and disconnections are handled properly.

5.4.10.7.3 GPU Functions – Ethernet

This section provides a list of DOCA GPUNetIO functions that can be used for Ethernet GDAKI network operations within GPU CUDA kernels.

5.4.10.7.3.1 Header Files

- `doca_gpunetio_eth_def.h`: Contains constants, enums, and structure definitions.
- `doca_gpunetio_dev_eth_common.cuh`: Provides CUDA utility functions common to both Txq and Rxq header files.
- `doca_gpunetio_dev_eth_txq.cuh`: Provides CUDA functions for Ethernet send operations. This includes both high-level (with shared QP feature) and low-level (post WQE, ring DB, poll CQ, etc.) functions.
- `doca_gpunetio_dev_eth_rxq.cuh`: Provides CUDA functions for Ethernet receive operations.

Experimental API

The new GPUNetIO Ethernet APIs are experimental. Please report any issues encountered during use, as your feedback is crucial for enhancing the code's quality and robustness.

Private Functions

When using the GPUNetIO Ethernet header files, avoid calling functions that start with `doca_priv_*`. These are internal functions intended for use by the public API only.

Debug Macro

The `doca_gpunetio_eth_def.h` file contains the macro `#define DOCA_GPUNETIO_ETH_ENABLE_DEBUG 0`. This default setting disables debug prints, including CQE errors. To enable error messages, set this macro to `1`.

5.4.10.7.3.2 Execution Scope and Shared Queue

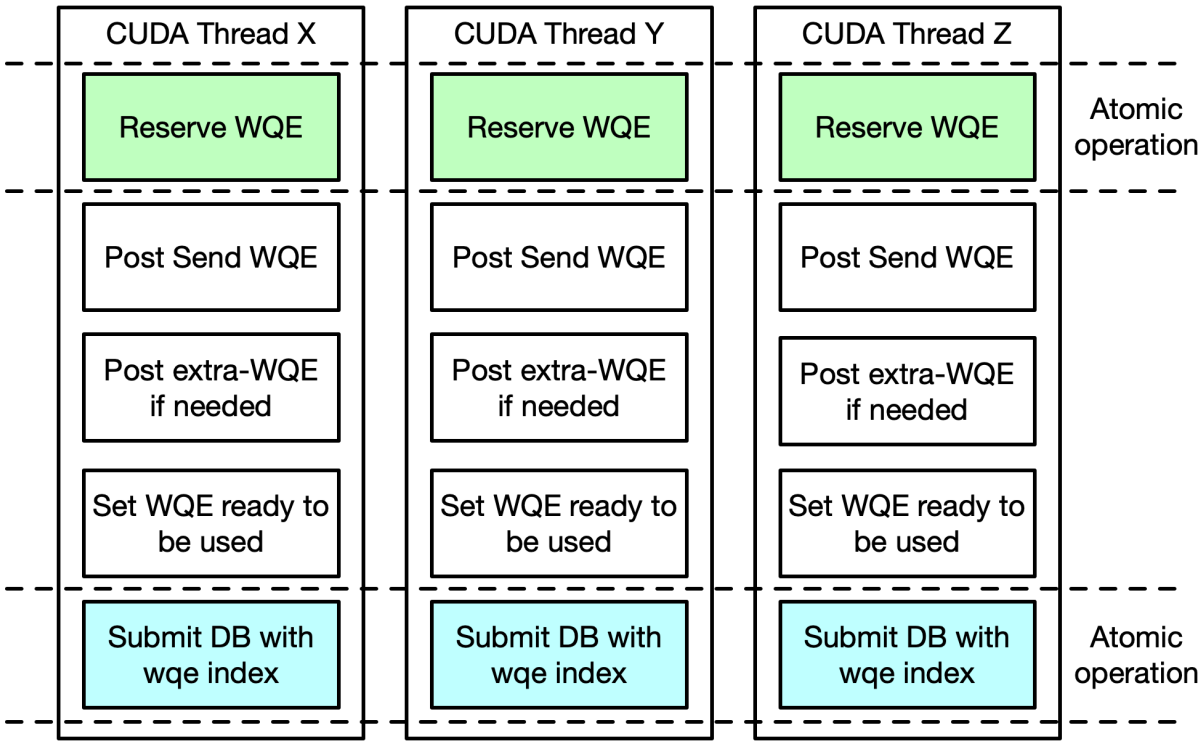
The execution scope for high-level GPUNetIO Ethernet APIs (thread, warp, or block) is specified via the `doca_gpu_dev_eth_exec_scope` enum as a template argument. This tells the function how many threads are participating in the operation.

- Send (Txq): The high-level send API supports the shared queue feature. This allows different threads, belonging to different scopes, to concurrently access the same Txq without race conditions.
- Receive (Rxq): The high-level receive API does not support the shared queue feature. If a thread, warp, or block is using an Rxq, other threads, warps, or blocks cannot use the same Rxq in parallel.

The following subsections detail the send execution scopes.

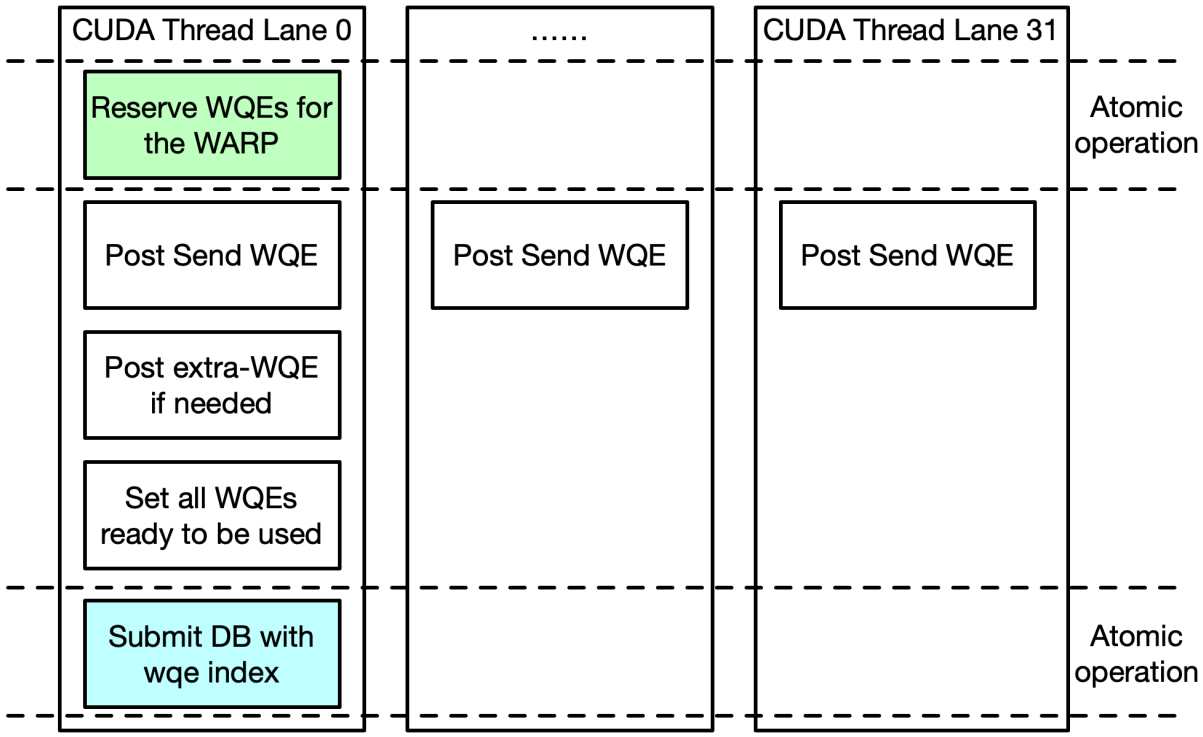
Thread Scope (`DOCA_GPUNETIO_ETH_EXEC_SCOPE_THREAD`)

- Each thread acts as a standalone entity.
- Each thread posts one or more WQEs and is responsible for its own submit (doorbell ring).
- Performance: This is the slowest approach due to high contention on atomic operations.



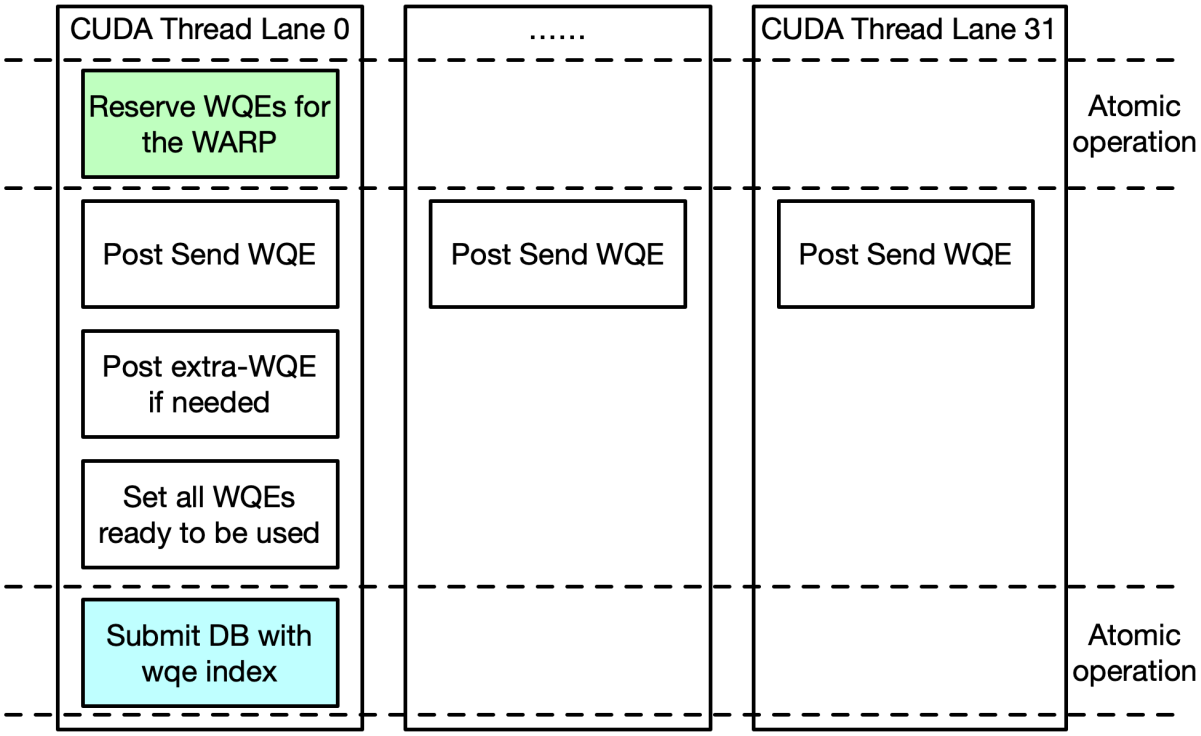
Warp Scope (`DOCA_GPUNETIO_ETH_EXEC_SCOPE_WARP`)

- All threads within the warp must call the function.
- Each thread posts a WQE to a different location, but only the first thread (`lane_idx 0`) performs the submit operation.
- Performance: Reduces contention to a per-warp basis.



Block Scope (`DOCA_GPUNETIO_ETH_EXEC_SCOPE_BLOCK`)

- All threads within the block must call the function.
- Each thread posts a WQE to a different location, but only the first thread (`threadIdx 0`) performs the submit operation.
- Performance: Reduces contention to a per-block basis.



5.4.10.7.3.3 Ring DB and CPU Proxy

The `doca_gpu_dev_eth_nic_handler` enum, passed as a template argument, determines who is responsible for ringing the network card's doorbell.

The available modes are:

- `DOCA_GPUNETIO_ETH_NIC_HANDLER_AUTO` : Automatically detects the best doorbell ringing option.
- `DOCA_GPUNETIO_ETH_NIC_HANDLER_CPU_PROXY` : Enables CPU proxy mode. GPU submit functions provide information to the CPU, which then rings the doorbell.
- `DOCA_GPUNETIO_ETH_NIC_HANDLER_GPU_SM_DB` : Enables regular GDAKI mode, where CUDA threads ring the doorbell directly.

CPU Proxy Mode

When `CPU_PROXY` mode is enabled, a CPU thread must invoke `doca_eth_txq_gpu_cpu_proxy_progress` in a loop to detect the GPU's information and ring the doorbell. The `GPUNetIO Ethernet Simple Send` sample demonstrates this feature.

5.4.10.7.3.4 Memory Consistency (MCST) Algorithm

During a receive operation, the network card writes packet data via PCIe to the application's mapped memory. For pre-Hopper GPUs (see CUGPUDirectRDMAWritesOrdering), memory consistency (MCST) must be ensured when a CUDA kernel is receiving data into GPU memory.

DOCA GPUNetIO provides two ways to enable the MCST algorithm:

1. CPU configuration phase: When creating the DOCA Ethernet Rxq, use the function `doca_eth_rxq_gpu_enable_mcst_qp` to create an internal queue dedicated to the MCST algorithm.

```
cudaGetDeviceProperties(&prop, cuda_id);
// If pre-Hopper GPU with __CUDA_ARCH__ < 900
if (prop.major < 9)
    doca_eth_rxq_gpu_enable_mcst_qp(rxq->eth_rxq_cpu);
```

2. GPU data path phase: Pass the `doca_gpu_dev_eth_mcst_mode` enum as a template argument to the `recv` function.

5.4.10.7.3.5 Receive, High-level Function: doca_gpu_dev_eth_rxq_recv

This function receives Ethernet packets in a CUDA kernel and is available in different flavors for per-thread, per-warp, or per-block scopes.

```
template <enum doca_gpu_dev_eth_exec_scope exec_scope = DOCA_GPUNETIO_ETH_EXEC_SCOPE_THREAD,
      enum doca_gpu_dev_eth_mcst_mode mcst_mode = DOCA_GPUNETIO_ETH_MCST_DISABLED,
      enum doca_gpu_dev_eth_nic_handler nic_handler = DOCA_GPUNETIO_ETH_NIC_HANDLER_AUTO,
      bool enable_attributes = false>
__device__ inline doca_error_t doca_gpu_dev_eth_rxq_recv(struct doca_gpu_eth_rxq *rxq,
                           uint32_t max_rx_pkts,
                           uint64_t timeout_ns,
                           volatile uint64_t *out_first_pkt_idx,
                           uint32_t *out_pkt_num,
                           struct doca_gpu_dev_eth_rxq_attr *out_attr);
```

Parameters:

- `rxq` : The Ethernet receive queue GPU handler.
- `max_rx_pkts` : Maximum number of packets to receive. The function guarantees the returned packet count is <= this number.
- `timeout_ns` : Nanoseconds to wait for packets before returning.
- `out_first_pkt_idx` [out]: Index of the first packet received. For block or warp scopes, this variable must be in shared or global memory to be visible to all threads.
- `out_pkt_num` [out]: The actual number of packets received. For block or warp scopes, this variable must be in shared or global memory.

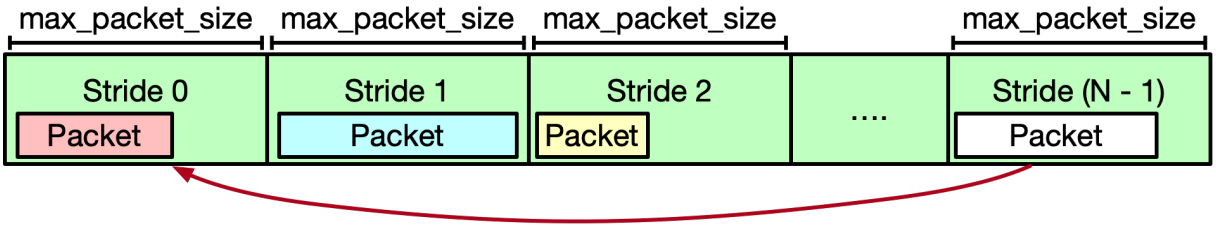
- `out_attr` [out]: If `enable_attributes` is true, this structure is filled with per-packet attributes. The application must ensure this array is large enough to hold attributes for `max_rx_pkts`.

Notes

- If both `max_rx_pkts` and `timeout_ns` are set to `0`, the function will hang.
- For `BLOCK` or `WARP` scopes, the `max_rx_pkts` value should be at least the number of threads in the scope (e.g., `blockDim.x` or `warpSize`), as every thread will try to receive at least once.
- This function does not support the shared QP feature. Access to the `rxq` must be exclusive to the calling thread, warp, or block. No other scope can work on the same `rxq` in parallel.

Packet Indexing and Circular Buffer

When the Rxq is created on the CPU, its GPU memory is divided into fixed-size strides (based on `max_packet_size`). The `doca_gpu_dev_eth_rxq_recv` function guarantees that these strides are filled sequentially with new packets.



The function returns the following output parameters to identify the received packets:

- `out_first_packet_idx`: The index of the first stride (packet) filled.
- `out_pkt_num`: The total number of packets received.

For example, if `out_first_packet_idx` is `X` and `out_pkt_num` is `Y`, the function has received `Y` packets, filling the GPU memory buffer strides from index `X` to `(X + Y - 1)`.

> ⚠ The output parameters `out_first_packet_idx` and `out_pkt_num` must be visible to all threads in the scope (e.g., via CUDA shared memory for warp and block scopes).

The receive buffer is treated as a circular buffer. Once the last stride is filled, the queue wraps around to the first stride.

⚠ It is the application's responsibility to consume packets before they are overwritten by the queue wrapping around. This requires proper dimensioning of the Rxq GPU buffer and scaling across multiple receive queues.

5.4.10.7.3.6 Receive: `doca_gpu_dev_eth_rxq_get_pkt_addr`

This utility function retrieves the memory address of a specific packet in a specific stride.

```
__device__ inline uint64_t doca_gpu_dev_eth_rxq_get_pkt_addr(struct doca_gpu_eth_rxq *rxq, uint64_t packet_idx);
```

Parameter:

- `rxq` : Ethernet receive queue GPU handler.
- `packet_idx` : Index of the stride where the packet resides.

5.4.10.7.3.7 Send, High-level Function: `doca_gpu_dev_eth_txq_send`

This function sends Ethernet packets from a CUDA kernel, with flavors for per-thread, per-warp, or per-block scopes. It enables the shared queue feature, allowing concurrent access to the same Txq.

```
template <enum doca_gpu_dev_eth_resource_sharing_mode resource_sharing_mode =
DOCA_GPUNETIO_ETH_RESOURCE_SHARING_MODE_GPU,
      enum doca_gpu_dev_eth_sync_scope sync_scope = DOCA_GPUNETIO_ETH_SYNC_SCOPE_GPU,
      enum doca_gpu_dev_eth_nic_handler nic_handler = DOCA_GPUNETIO_ETH_NIC_HANDLER_AUTO,
      enum doca_gpu_dev_eth_exec_scope exec_scope = DOCA_GPUNETIO_ETH_EXEC_SCOPE_THREAD>
__device__ static inline void doca_gpu_dev_eth_txq_send(struct doca_gpu_eth_txq *txq,
                           uint64_t addr,
                           uint32_t mkey,
                           size_t size,
                           enum doca_gpu_eth_send_flags flags,
                           doca_gpu_dev_eth_ticket_t *out_ticket)
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `addr` : Memory address of the packet to send.
- `mkey` : Memory key of the packet.
- `size` : Size of the packet in bytes.
- `flags` : Send flags from the `doca_gpu_eth_send_flags` enum.
- `out_ticket` : Returns the WQE index (position) in the send queue where the packet was posted.

5.4.10.7.3.8 Send, High-level Function: `doca_gpu_dev_eth_txq_wait_send`

This function combines the "Accurate Send Scheduling" feature (wait on timestamp) with the send operation. The first thread in the scope posts a "wait on time" barrier, and then all threads in the scope post their send. This function also enables the shared queue feature.

```
template <enum doca_gpu_dev_eth_resource_sharing_mode resource_sharing_mode =
DOCA_GPUNETIO_ETH_RESOURCE_SHARING_MODE_GPU,
      enum doca_gpu_dev_eth_sync_scope sync_scope = DOCA_GPUNETIO_ETH_SYNC_SCOPE_GPU,
      enum doca_gpu_dev_eth_nic_handler nic_handler = DOCA_GPUNETIO_ETH_NIC_HANDLER_AUTO,
      enum doca_gpu_dev_eth_exec_scope exec_scope = DOCA_GPUNETIO_ETH_EXEC_SCOPE_THREAD>
__device__ static inline void doca_gpu_dev_eth_txq_wait_send(struct doca_gpu_eth_txq *txq,
                                const uint64_t wait_on_time_ts,
                                uint64_t addr,
                                uint32_t mkey,
                                size_t size,
                                enum doca_gpu_eth_send_flags flags,
                                doca_gpu_dev_eth_ticket_t *out_ticket);
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `wqe_ptr` : Memory pointer to the WQE (can be obtained via `doca_gpu_dev_eth_txq_get_wqe_ptr`).
- `wqe_idx` : Index of the WQE.
- `addr` : Packet memory address.
- `mkey` : Packet memory key.
- `nbytes` : Packet size in bytes.
- `flags` : Send flags from the `doca_gpu_eth_send_flags` enum.

5.4.10.7.3.9 Send, Low-level Function: `doca_gpu_dev_eth_txq_wqe_prepare_send`

This low-level function posts a send WQE. It is used by the high-level functions but can also be called directly by the application.

```
__device__ __inline__ static doca_error_t doca_gpu_dev_eth_txq_wqe_prepare_send(
    const struct doca_gpu_eth_txq *txq,
    struct doca_gpu_dev_eth_txq_wqe *wqe_ptr,
    const uint16_t wqe_idx,
    const uint64_t addr,
    const uint32_t mkey,
    const uint32_t nbytes,
    const enum doca_gpu_eth_send_flags flags);
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `wqe_ptr` : Memory pointer to the WQE (can be obtained via `doca_gpu_dev_eth_txq_get_wqe_ptr`).
- `wqe_idx` : Index of the WQE.
- `addr` : Packet memory address.
- `mkey` : Packet memory key.
- `nbytes` : Packet size in bytes.
- `flags` : Send flags from the `doca_gpu_eth_send_flags` enum.

5.4.10.7.3.10 Send, Low-level Function: `doca_gpu_dev_eth_txq_wqe_prepare_wait_time`

This low-level function posts a "wait on time" WQE to create a time barrier. It is used by `doca_gpu_dev_eth_txq_wait_send` but can also be called directly.

```
__device__ __inline__ static doca_error_t doca_gpu_dev_eth_txq_wqe_prepare_wait_time(
    const struct doca_gpu_eth_txq *txq,
    struct doca_gpu_dev_eth_txq_wqe *wqe_ptr,
    const uint16_t wqe_idx,
    const uint64_t wait_on_time_ts,
    const enum doca_gpu_eth_send_flags flags);
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `wqe_ptr` : Memory pointer to the WQE (can be obtained via `doca_gpu_dev_eth_txq_get_wqe_ptr`).
- `wqe_idx` : Index of the WQE.
- `wait_on_time_ts` : Timestamp barrier. The timestamp can be calculated on the GPU (via `doca_gpu_dev_eth_txq_calculate_timestamp`) or CPU (via `doca_eth_txq_calculate_timestamp`).
- `flags` : Send flags from the `doca_gpu_eth_send_flags` enum.

5.4.10.7.3.11 Send, Low-level Function: `doca_gpu_dev_eth_txq_submit`

This function "rings the doorbell" to notify the network card to execute all WQEs posted since the last submit. It supports the shared queue feature; internal atomics allow multiple threads to call it in parallel, and the doorbell register will be updated only by the thread with the greatest WQE index. It also allows choosing between GPU and CPU Proxy handlers via the template parameter.

```
template <enum doca_gpu_dev_eth_resource_sharing_mode resource_sharing_mode =
DOCA_GPUNETIO_ETH_RESOURCE_SHARING_MODE_GPU,
      enum doca_gpu_dev_eth_sync_scope sync_scope = DOCA_GPUNETIO_ETH_SYNC_SCOPE_GPU,
      enum doca_gpu_dev_eth_nic_handler nic_handler = DOCA_GPUNETIO_ETH_NIC_HANDLER_AUTO>
__device__ static inline void doca_gpu_dev_eth_txq_submit(struct doca_gpu_eth_txq *txq, uint64_t prod_index);
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `prod_index` : The Producer Index (WQE index) to write into the network card's doorbell register.

5.4.10.7.3.12 Send, Low-level Functions: `...update_dbr` , `...ring_db` , and `...submit_proxy`

These functions can replace `doca_gpu_dev_eth_txq_submit` in special situations, such as when the application has a well-determined send pattern and does not need atomics for shared queue access. The typical sequence is `doca_gpu_dev_eth_txq_update_dbr` (updates DBREC) followed by `doca_gpu_dev_eth_txq_ring_db` (updates Doorbell Register).

```
template <enum doca_gpu_dev_eth_sync_scope sync_scope = DOCA_GPUNETIO_ETH_SYNC_SCOPE_GPU>
__device__ static inline void doca_gpu_dev_eth_txq_update_dbr(struct doca_gpu_eth_txq *txq, uint32_t prod_index);
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `prod_index` : The WQE index to write into the network card DBREC.

```
template <enum doca_gpu_dev_eth_sync_scope sync_scope = DOCA_GPUNETIO_ETH_SYNC_SCOPE_GPU>
__device__ static inline void doca_gpu_dev_eth_txq_ring_db(struct doca_gpu_eth_txq *txq, uint64_t prod_index);
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `prod_index` : The WQE index to write into the network card doorbell register.

`doca_gpu_dev_eth_txq_ring_db` works for direct GPU doorbell ringing. To ring the doorbell via CPU proxy, `doca_gpu_dev_eth_txq_submit_proxy` must be used instead:

```
template <enum doca_gpu_dev_eth_resource_sharing_mode resource_sharing_mode =
DOCA_GPUNETIO_ETH_RESOURCE_SHARING_MODE_GPU,
      enum doca_gpu_dev_eth_sync_scope sync_scope = DOCA_GPUNETIO_ETH_SYNC_SCOPE_GPU>
__device__ static inline void doca_gpu_dev_eth_txq_submit_proxy(struct doca_gpu_eth_txq *txq, uint64_t prod_index);
```

Parameter:

- `txq` : Ethernet send queue GPU handler.
- `prod_index` : The WQE index to write into the CPU proxy shared memory.

5.4.10.7.3.13 Send, Low-level Functions: Poll Completion

These functions allow waiting for send operations to complete. A Completion (CQE) is generated only if the `DOCA_GPUNETIO_ETH_SEND_FLAG_NOTIFY` flag was used when posting the WQE.

`doca_gpu_dev_eth_txq_poll_completion` waits for a number of CQEs. It operates at thread scope but supports the shared queue feature (each thread locks `num_cqe` slots to poll).

```
template <enum doca_gpu_dev_eth_cq_poll_mode cqe_poll = DOCA_GPUNETIO_ETH_CQ_POLL_ALL,
      enum doca_gpu_dev_eth_resource_sharing_mode resource_sharing_mode =
DOCA_GPUNETIO_ETH_RESOURCE_SHARING_MODE_GPU,
      enum doca_gpu_dev_eth_sync_scope sync_scope = DOCA_GPUNETIO_ETH_SYNC_SCOPE_GPU>
__device__ static inline doca_error_t doca_gpu_dev_eth_txq_poll_completion(struct doca_gpu_eth_txq *txq,
                                        const uint32_t num_cqe,
                                        enum doca_gpu_dev_eth_wait_flags wait_mode,
                                        uint32_t *num_completed);
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `num_cqe` : Number of CQEs to wait for.
- `wait_mode` : Wait in blocking or non-blocking mode (flags from `doca_gpu_dev_eth_wait_flags`).
- `num_completed` : Number of CQEs detected.

⚠ When `num_cqe` > 1, setting the `cqe_poll` template to `DOCA_GPUNETIO_ETH_CQ_POLL_ALL` can reduce latency, as the function will only poll the *latest* CQE (`num_cqe - 1`) instead of polling sequentially.

`doca_gpu_dev_eth_txq_poll_completion_at` allows the application to poll for a specific CQE position. It does not support the shared queue feature.

```
template <enum doca_gpu_dev_eth_resource_sharing_mode resource_sharing_mode =
DOCA_GPUNETIO_ETH_RESOURCE_SHARING_MODE_GPU,
      enum doca_gpu_dev_eth_sync_scope sync_scope = DOCA_GPUNETIO_ETH_SYNC_SCOPE_GPU>
__device__ static inline doca_error_t doca_gpu_dev_eth_txq_poll_completion_at(struct doca_gpu_eth_txq *txq,
                                                const uint64_t cqe_idx,
                                                enum doca_gpu_dev_eth_wait_flags wait_mode);
```

Parameters:

- `txq` : Ethernet send queue GPU handler.
- `cqe_idx` : Index of the CQE to poll.
- `wait_mode` : Wait in blocking or non-blocking mode (flags from `doca_gpu_dev_eth_wait_flags`).

5.4.10.7.4 GPU Functions – Verbs

GPUNetIO Verbs data path functions are defined as inline implementations in header files named `doca_gpunetio_dev_verbs_*` .

5.4.10.7.4.1 Header Files

- `doca_gpunetio_verbs_def.h` : Contains constants, enums, and structure definitions.
- `doca_gpunetio_dev_verbs_qp.cuh` : Provides CUDA functions for interacting with a QP, including WQE creation and ringing the network card doorbell.
- `doca_gpunetio_dev_verbs_cq.cuh` : Offers CUDA functions for interacting with a CQ, including CQE polling and validation.
- `doca_gpunetio_dev_verbs_onesided.cuh` : Enables one-sided operations (e.g., `put`) with the shared QP feature at the CUDA thread and warp levels.
- `doca_gpunetio_dev_verbs_twosided.cuh` : Enables two-sided operations (e.g., `send` / `recv`) with the shared QP feature at the CUDA thread and warp levels.
- `doca_gpunetio_dev_verbs_counter.cuh` : Provides CUDA functions for counter-like operations via RDMA atomics with the shared QP feature. This requires "Core Direct" to be enabled as a QP attribute.

⛔ **Experimental API**

The GPUNetIO Verbs APIs are currently experimental. Please report any issues encountered during use, as your feedback is crucial for enhancing the code's quality and robustness.

Private Functions

When using the GPUNetIO Verbs header files, avoid calling functions that start with `doca_priv_*`. These are internal functions intended for use by the public API only.

Debug Macro

The `doca_gpunetio_verbs_def.h` file contains the macro `#define DOCA_GPUNETIO_VERBS_ENABLE_DEBUG 0`. This default setting disables debug prints, including CQE errors. To enable error messages, set this macro to `1`.

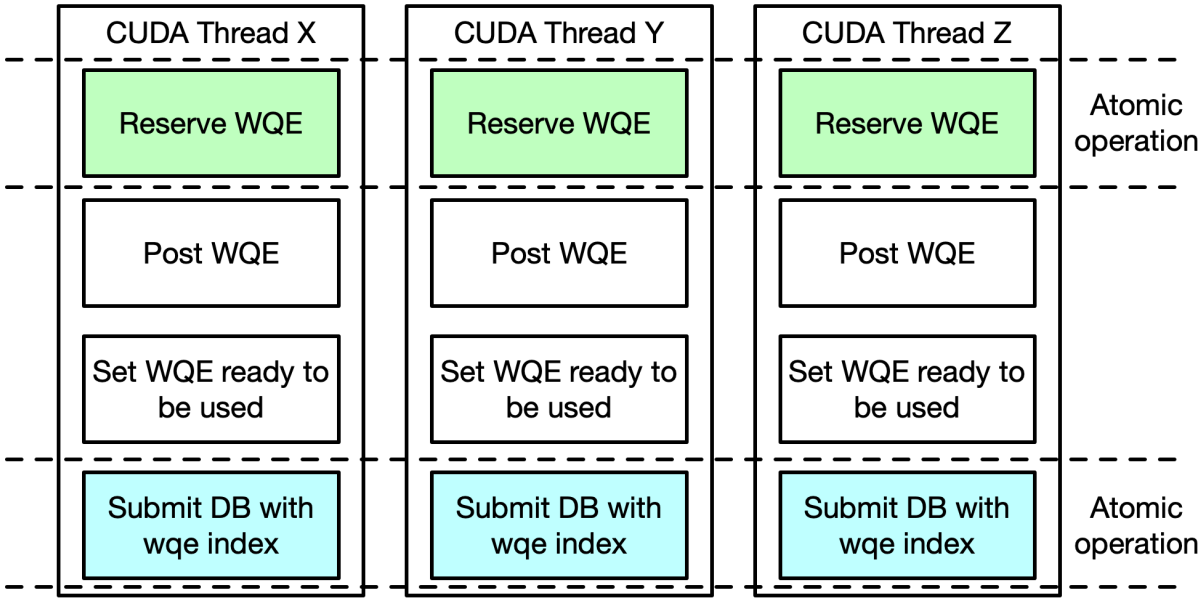
5.4.10.7.4.2 Execution Scope and Shared Queue

The high-level GPUNetIO Verbs API can be executed at a thread or warp scope by specifying a value from the `doca_gpu_dev_verbs_exec_scope` enum as a template argument. This tells the function how many threads are participating in the operation.

The high-level API also supports the shared queue feature, allowing different threads from different scopes to concurrently access the same queue without race conditions.

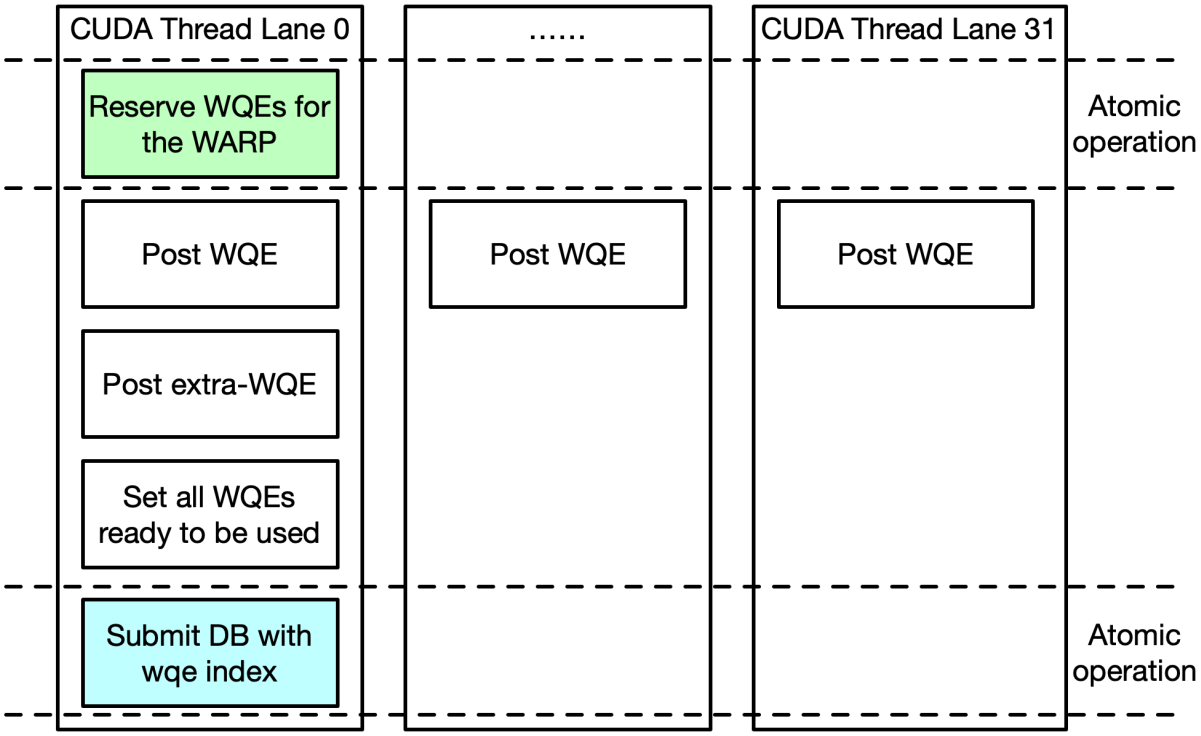
Thread Scope (`DOCA_GPUNETIO_VERBS_EXEC_SCOPE_THREAD`)

- Each thread acts as a standalone entity, posting WQEs and ringing the doorbell.
- This is the slowest approach due to high contention on atomic operations.



Warp Scope (`DOCA_GPUNETIO_VERBS_EXEC_SCOPE_WARP`)

- All threads within the warp must call the function.
- Each thread posts a WQE to a different location, but only the first thread (`lane_idx 0`) performs the submit (doorbell ring).
- This reduces contention to a per-warp basis.



5.4.10.7.4.3 Ring DB and CPU Proxy

The `doca_gpu_dev_verbs_nic_handler` enum, passed as a template argument, determines who is responsible for ringing the doorbell.

The available modes are:

- `DOCA_GPUNETIO_VERBS_NIC_HANDLER_AUTO` : Automatically detects the best doorbell ringing option.
- `DOCA_GPUNETIO_VERBS_NIC_HANDLER_CPU_PROXY` : Enables CPU proxy mode. GPU submit functions provide information to the CPU, which then rings the doorbell.
- `DOCA_GPUNETIO_VERBS_NIC_HANDLER_GPU_SM_DB` : Enables regular GDAKI mode, where CUDA threads ring the doorbell directly.
- `DOCA_GPUNETIO_VERBS_NIC_HANDLER_GPU_SM_BF` : Experimental BlueFlame doorbell ringing mode (may fail in the current release).

⚠ CPU Proxy Mode When `CPU_PROXY` mode is enabled, a CPU thread must invoke `doca_gpu_verbs_cpu_proxy_progress` in a loop to detect the GPU's information and ring the doorbell. This mode can be enabled via a command-line option in most GPUNetIO Verbs samples.

5.4.10.7.4.4 Memory Consistency (MCST) Algorithm

During an RDMA Read or Receive operation, the network card writes data via PCIe into the application's mapped memory. For pre-Hopper GPUs (see CUGPUDirectRDMAWritesOrdering), memory consistency (MCST) must be ensured when a CUDA kernel is receiving data into GPU memory.

DOCA GPUNetIO Verbs applications can enable the MCST algorithm on the GPU by setting the `doca_gpu_dev_verbs_mcst_mode mcst_mode` template parameter. This parameter is available in functions such as `doca_gpu_dev_verbs_get`, `doca_gpu_dev_verbs_get_wait`, and `doca_gpu_dev_verbs_recv_wait`.

The `gpunetio_verbs_twosided_bw` sample demonstrates this by checking the CUDA architecture:

```
#if __CUDA_ARCH__ < 900
    doca_gpu_dev_verbs_recv_wait<DOCA_GPUNETIO_VERBS_RESOURCE_SHARING_MODE_GPU,
DOCA_GPUNETIO_VERBS_NIC_HANDLER_AUTO, DOCA_GPUNETIO_VERBS_MCST_ENABLED>(
                                qp, doca_gpu_dev_verbs_addr{.addr = (uint64_t)dump_flag, .key = dump_flag_mkey});
#else
    doca_gpu_dev_verbs_recv_wait<DOCA_GPUNETIO_VERBS_RESOURCE_SHARING_MODE_GPU,
DOCA_GPUNETIO_VERBS_NIC_HANDLER_AUTO, DOCA_GPUNETIO_VERBS_MCST_DISABLED>(
                                qp, doca_gpu_dev_verbs_addr{.addr = 0, .key = 0});
#endif
```

5.4.10.7.4.5 Queue Type

Many functions (e.g., submit doorbell, poll CQ) can apply to either the Send Queue or Receive Queue of a QP. A template argument from the `doca_gpu_dev_verbs_qp_type` enum is used to specify which queue to use.

- `DOCA_GPUNETIO_VERBS_QP_SQ` : Uses the Send Queue from the input QP.
- `DOCA_GPUNETIO_VERBS_QP_RQ` : Uses the Receive Queue from the input QP.

5.4.10.7.4.6 ConnectX-8 Reliable Doorbell

The ConnectX-8 Reliable Doorbell feature optimizes the send data path by allowing applications to skip the Queue Pair Doorbell Record (QP DBREC) update. This reduces the number of operations the GPU must execute to ring the doorbell for send WQEs (Write, Read, Send, etc.).

The implementation steps are as follows:

1. Verify support: Check if the device supports the feature using `doca_verbs_device_attr_get_is_send_dbr_mode_supported()`.

2. Enable feature: Set the new QP attribute using `doca_verbs_qp_init_attr_set_send_dbr_mode()`.
3. Handle GPU data path: If enabled, use the GPUNetIO handler mode `DOCA_GPUNETIO_VERBS_NIC_HANDLER_GPU_SM_NO_DBR`.

The `gpunetio_verbs_write_lat` and `gpunetio_verbs_put_counter_lat` examples demonstrate this feature. Enable it via the command line option `-r 1`.

5.4.10.7.4.7 Header: `doca_gpunetio_dev_verbs_qp.cuh`

This header provides functions for QP manipulation, categorized into three groups:

- `doca_gpu_dev_verbs_wqe_prepare_*`: Prepares and posts various RDMA WQEs (Write, Read, Send, Recv, Atomic, Wait, Dump) on QP memory.
- `doca_gpu_dev_verbs_submit`: Updates network card registers for doorbell submission (regular, CPU proxy, and BlueFlame) for both SQ and RQ.
- `doca_gpu_dev_verbs_wait_*`: Waits for CQEs to arrive on the SQ or RQ's completion queue.

For detailed explanations, refer to the header file. Examples can be found in the `doca_gpunetio_verbs_write_bw` and `doca_gpunetio_verbs_write_lat` samples.

5.4.10.7.4.8 Header: `doca_gpunetio_dev_verbs_cq.cuh`

This header provides functions for manipulating Completion Queues (CQs). Specifically, the `doca_gpu_dev_verbs_poll_*` functions are used to poll CQEs, waiting for the completion of WQEs in the connected QP.

5.4.10.7.4.9 Header: `doca_gpunetio_dev_verbs_onesided.cuh`

This header provides shared-QP-aware functions for one-sided RDMA operations at the thread and warp levels.

- `doca_gpu_dev_verbs_put`: Posts an RDMA Write WQE and submits. In `WARP` scope, only the first thread submits.
- `doca_gpu_dev_verbs_put_signal`: Similar to `put`, but adds an RDMA Atomic Fetch and Add. In THREAD scope, each thread posts a Write, an Atomic, and submits. In WARP scope, each thread posts a Write, but only the first thread posts the Atomic and submits.
- `doca_gpu_dev_verbs_get`: Posts an RDMA Read WQE and submits. In `WARP` scope, only the first thread submits. Optionally posts a Dump WQE to ensure data consistency (e.g., ensures Read data is present in memory after CQE arrival, e.g., enum CUGPUDirectRDMAWritesOrdering).

For details, refer to the header file. Examples are in the `doca_gpunetio_verbs_put_bw`, `doca_gpunetio_verbs_put_signal_bw`, and `doca_gpunetio_verbs_put_signal_lat` samples.

5.4.10.7.4.10 Header: `doca_gpunetio_dev_verbs_twosided.cuh`

This header provides shared-QP-aware functions for two-sided RDMA operations at the thread and warp levels.

- `doca_gpu_dev_verbs_send`: Posts an RDMA Send WQE and submits. In WARP scope, only the first thread submits.
- `doca_gpu_dev_verbs_recv`: Posts an RDMA Receive WQE and submits. In WARP scope, only the first thread submits.

Requirement flow for two-sided communication:

1. Peer A posts one or more RDMA Receive WQEs.
2. Peer A notifies Peer B that it is ready to receive.
3. Peer B waits for this notification.
4. Peer B posts one or more RDMA Send WQEs.

The notification can be sent via RDMA Write or Atomic. An example using RDMA Write is in the `doca_gpunetio_verbs_twosided_bw` sample.

5.4.10.7.4.11 Header: `doca_gpunetio_dev_verbs_counter.cuh`

This header provides shared-QP functions that use the counter feature. This allows a CQE arrival on a main QP to trigger a WQE on a companion QP. This requires Core Direct to be enabled via `doca_verbs_qp_init_attr_set_core_direct_master()`.

- `doca_gpu_dev_verbs_put_counter`: Posts an RDMA Write on the main QP and an RDMA Atomic FetchAdd on the companion QP. The Atomic is executed only after the Write's CQE arrives, allowing for buffer reuse.
- `doca_gpu_dev_verbs_submit_multi_qps`: Submits both the main and companion QP in a single call.

For details, refer to the header file. Examples are in the `doca_gpunetio_verbs_put_counter_bw` and `doca_gpunetio_verbs_put_counter_lat` samples.

5.4.10.7.5 GPU Functions – RDMA

This section provides a list of DOCA GPUNetIO functions that can be used on the GPU only within a CUDA kernel to execute RDMA operations. These functions offer a strong and a weak mode.

```
__device__ doca_error_t __device__ doca_error_t doca_gpu_dev_rdma_get_info(struct doca_gpu_dev_rdma *rdma, uint32_t
connection_index, uint32_t *curr_position, uint32_t *mask_max_position)
```

- `rdma` – RDMA queue GPU handler
- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.
- `curr_position` – Next available position in the queue
- `mask_max_position` – Mask of the total number of positions in the queue

```
__device__ doca_error_t __device__ doca_error_t doca_gpu_dev_rdma_recv_get_info(struct doca_gpu_dev_rdma_r *rdma_r,
uint32_t *curr_position, uint32_t *mask_max_position)
```

- `rdma_r` – RDMA receive queue GPU handler
- `curr_position` – Next available position in the queue
- `mask_max_position` – Mask of the total number of positions in the queue

5.4.10.7.5.1 doca_gpu_dev_rdma_write_*

To RDMA write data onto a remote memory location from a CUDA kernel, DOCA GPUNetIO offers strong and weak modes for enqueuing operations on the RDMA queue. For both modes, the scope is the single CUDA thread.

```
__device__ doca_error_t doca_gpu_dev_rdma_write_strong(struct doca_gpu_dev_rdma *rdma,
                                                       uint32_t connection_index,
                                                       struct doca_gpu_buf *remote_buf, uint64_t remote_offset,
                                                       struct doca_gpu_buf *local_buf, uint64_t local_offset,
                                                       size_t length, uint32_t imm,
                                                       const enum doca_gpu_dev_rdma_write_flags flags)
```

- `rdma` – RDMA queue GPU handler
- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.
- `remote_buf` – Remote DOCA buffer from a DOCA GPU buffer array to write data to
- `remote_offset` – Offset, in bytes, to write data to in the remote buffer
- `local_buf` – Local DOCA buffer from a DOCA GPU buffer array from which to fetch data to write
- `local_offset` – Offset, in bytes, to fetch data from in the local buffer
- `length` – Number of bytes to write
- `imm` – Immediate value `uint32_t`
- `flags` – One of the flags in the `doca_gpu_dev_rdma_write_flags` enum

```
__device__ doca_error_t doca_gpu_dev_rdma_write_weak(struct doca_gpu_dev_rdma *rdma,
                                                     uint32_t connection_index,
                                                     struct doca_gpu_buf *remote_buf, uint64_t remote_offset,
                                                     struct doca_gpu_buf *local_buf, uint64_t local_offset,
                                                     size_t length, uint32_t imm,
                                                     const enum doca_gpu_dev_rdma_write_flags flags,
                                                     uint32_t position);
```

- `rdma` – RDMA queue GPU handler

- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.
- `remote_buf` – Remote DOCA buffer from a DOCA GPU buffer array to write data to
- `remote_offset` – Offset, in bytes, to write data to in the remote buffer
- `local_buf` – Local DOCA buffer from a DOCA GPU buffer array where to fetch data to write
- `local_offset` – Offset, in bytes, to fetch data in the local buffer
- `length` – Number of bytes to write
- `imm` – Immediate value `uint32_t`
- `flags` – One of the flags in the `doca_gpu_dev_rdma_write_flags` enum
- `position` – Position in the queue to place the RDMA operation. Range: 0 - `mask_max_position`.

5.4.10.7.5.2 doca_gpu_dev_rdma_read_*

To RDMA read data onto a remote memory location from a CUDA kernel, DOCA GPUNetIO offers strong and weak modes to enqueue operations on the RDMA queue. For both modes, the scope is the single CUDA thread.

```
__device__ doca_error_t doca_gpu_dev_rdma_read_strong(struct doca_gpu_dev_rdma *rdma,
                                                      uint32_t connection_index,
                                                      struct doca_gpu_buf *remote_buf, uint64_t remote_offset,
                                                      struct doca_gpu_buf *local_buf, uint64_t local_offset,
                                                      size_t length,
                                                      const uint32_t flags_bitmask)
```

- `rdma` – RDMA queue GPU handler
- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.
- `remote_buf` – Remote DOCA buffer from a DOCA GPU buffer array where to read data
- `remote_offset` – Offset in bytes to read data to in the remote buffer
- `local_buf` – Local DOCA buffer from a DOCA GPU buffer array where to store remote data
- `local_offset` – Offset in bytes to store data in the local buffer
- `length` – Number of bytes to be read
- `flags_bitmask` – Must be 0; reserved for future use

```
__device__ doca_error_t doca_gpu_dev_rdma_read_weak(struct doca_gpu_dev_rdma *rdma,
                                                    uint32_t connection_index,
                                                    struct doca_gpu_buf *remote_buf, uint64_t remote_offset,
                                                    struct doca_gpu_buf *local_buf, uint64_t local_offset,
                                                    size_t length,
                                                    const uint32_t flags_bitmask,
                                                    uint32_t position);
```

- `rdma` – RDMA queue GPU handler

- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.
- `remote_buf` – Remote DOCA buffer from a DOCA GPU buffer array where to read data
- `remote_offset` – Offset in bytes to read data to in the remote buffer
- `local_buf` – Local DOCA buffer from a DOCA GPU buffer array where to store remote data
- `local_offset` – Offset in bytes to store data in the local buffer
- `length` – Number of bytes to be read
- `flags_bitmask` – Must be 0; reserved for future use
- `position` – Position in the queue to place the RDMA operation. Range: 0 - `mask_max_position`.

5.4.10.7.5.3 doca_gpu_dev_rdma_send_*

To RDMA send data from a CUDA kernel, DOCA GPUNetIO offers strong and weak modes for enqueuing operations on the RDMA queue. For both modes, the scope is the single CUDA thread.

```
__device__ doca_error_t doca_gpu_dev_rdma_send_strong(struct doca_gpu_dev_rdma *rdma,
                                                      uint32_t connection_index,
                                                      struct doca_gpu_buf *local_buf, uint64_t local_offset,
                                                      size_t length, uint32_t imm,
                                                      const enum doca_gpu_dev_rdma_write_flags flags)
```

- `rdma` – RDMA queue GPU handler
- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.
- `local_buf` – Local DOCA buffer from a DOCA GPU buffer array from which to fetch data to send
- `local_offset` – Offset in bytes to fetch data in the local buffer
- `length` – Number of bytes to send
- `imm` – Immediate value `uint32_t`
- `flags` – One of the flags in the `doca_gpu_dev_rdma_write_flags` enum

```
__device__ doca_error_t doca_gpu_dev_rdma_send_weak(struct doca_gpu_dev_rdma *rdma,
                                                    uint32_t connection_index,
                                                    struct doca_gpu_buf *local_buf, uint64_t local_offset,
                                                    size_t length, uint32_t imm,
                                                    const enum doca_gpu_dev_rdma_write_flags flags,
                                                    uint32_t position);
```

- `rdma` – RDMA queue GPU handler
- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.
- `local_buf` – Local DOCA buffer from a DOCA GPU buffer array from which to fetch data to send

- `local_offset` – Offset in bytes to fetch data in the local buffer
- `length` – Number of bytes to send
- `imm` – Immediate value `uint32_t`
- `flags` – One of the flags in the `doca_gpu_dev_rdma_write_flags` enum
- `position` – Position in the queue to place the RDMA operation. Range: 0 - `mask_max_position`.

5.4.10.7.5.4 doca_gpu_dev_rdma_commit_*

Once all RDMA write, send or read requests have been enqueue in the RDMA queue, a synchronization point must be reached to consolidate and execute those requests. Only 1 CUDA thread can invoke this function at a time.

```
__device__ doca_error_t doca_gpu_dev_rdma_commit_strong(struct doca_gpu_dev_rdma *rdma, uint32_t connection_index)
```

- `rdma` – RDMA queue GPU handler
- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.

```
__device__ doca_error_t doca_gpu_dev_rdma_commit_weak(struct doca_gpu_dev_rdma *rdma, uint32_t connection_index,
uint32_t num_ops)
```

- `rdma` – RDMA queue GPU handler
- `connection_index` – In case of RDMA CM, the connection index must be specified. By default, it is 0.
- `num_ops` – Number of RDMA requests enqueued since the last commit

5.4.10.7.5.5 doca_gpu_dev_rdma_wait_all

After a commit, RDMA requests are executed by the network card as applications move forward doing other operations. If the application needs to verify all RDMA operations have been done by the network card, this "wait all" function can be used to wait for all previous posted operations. Only 1 CUDA thread can invoke this function at a time.

```
__device__ doca_error_t doca_gpu_dev_rdma_wait_all(struct doca_gpu_dev_rdma *rdma, uint32_t *num_commits)
```

- `rdma` – RDMA queue GPU handler
- `num_commits` – Output parameter; the number of commit operations completed

> This function is optional, and it can be used to ensure all the RDMA Send/Write/Read operations have actually been executed before moving forward with the application.

5.4.10.7.5.6 doca_gpu_dev_rdma_recv_*

To receive data from an RDMA send, send with immediate, or write with immediate, the destination peer should post a receive operation. DOCA GPUNetIO RDMA receive operations must be done with a `doca_gpu_dev_rdma_r` handler. This handler can be obtained with the function `doca_gpu_dev_rdma_get_recv`.

> ⚠ All receive operations must use this object.

```
__device__ doca_error_t doca_gpu_dev_rdma_get_recv(struct doca_gpu_dev_rdma *rdma, struct doca_gpu_dev_rdma_r
**rdma_r)
```

- `rdma` – RDMA queue GPU handler
- `rdma_r` – RDMA receive queue GPU handler

Even for the receive side, in this case, DOCA GPUNetIO offers strong and weak modes for enqueuing operations on the RDMA queue. For both modes, the scope is the single CUDA thread.

```
__device__ doca_error_t doca_gpu_dev_rdma_recv_strong(struct doca_gpu_dev_rdma_r *rdma_r,
                                                      struct doca_gpu_buf *recv_buf,
                                                      size_t recv_length,
                                                      uint64_t recv_offset,
                                                      const uint32_t flags_bitmask)
```

- `rdma_r` – RDMA receive queue GPU handler
- `recv_buf` – Local DOCA buffer from a DOCA GPU buffer array from which to fetch data to send
- `recv_length` – Number of bytes to send
- `recv_offset` – Offset in bytes to fetch data in the local buffer
- `flags_bitmask` – Must be 0; reserved for future use

```
__device__ doca_error_t doca_gpu_dev_rdma_recv_weak(struct doca_gpu_dev_rdma_r *rdma_r,
                                                    struct doca_gpu_buf *recv_buf,
                                                    size_t recv_length,
                                                    uint64_t recv_offset,
                                                    const uint32_t flags_bitmask,
                                                    uint32_t position);
```

- `rdma_r` – RDMA receive queue GPU handler
- `recv_buf` – Local DOCA buffer from a DOCA GPU buffer array from which to fetch data to send
- `recv_length` – Number of bytes to send
- `recv_offset` – Offset in bytes to fetch data in the local buffer
- `flags_bitmask` - Must be 0; reserved for future use
- `position` – Position in the queue to place the RDMA operation. Range: 0 - `mask_max_position`.

5.4.10.7.5.7 doca_gpu_dev_rdma_recv_commit_*

After posting several RDMA receive operations, a commit function must be invoked to activate the receive in the queue. Only 1 CUDA thread can invoke this function at a time.

```
__device__ doca_error_t doca_gpu_dev_rdma_recv_commit_strong(struct doca_gpu_dev_rdma_r *rdma_r)
```

- `rdma_r` – RDMA receive queue GPU handler

```
__device__ doca_error_t doca_gpu_dev_rdma_recv_commit_weak(struct doca_gpu_dev_rdma_r *rdma_r, uint32_t num_ops)
```

- `rdma_r` – RDMA receive queue GPU handler
- `num_ops` – Number of RDMA receive requests enqueued since the last commit

5.4.10.7.5.8 doca_gpu_dev_rdma_recv_wait_all

This function waits for the completion of all previously posted RDMA receive operation. Only 1 CUDA thread can invoke this function at a time. It works in blocking or non-blocking mode.

```
 enum doca_gpu_dev_rdma_recv_wait_flags {
    DOCA_GPU_RDMA_RECV_WAIT_FLAG_NB = 0,  /**< Non-Blocking mode: the wait receive function
doca_gpu_dev_rdma_recv_wait
                                           *  checks if the receive operation happened (data has been received)
                                           *  and exit from the function. If nothing has been received,
                                           *  the function doesn't block the execution.
                                           */
    DOCA_GPU_RDMA_RECV_WAIT_FLAG_B  = 1, /**< Blocking mode: the wait receive function doca_gpu_dev_rdma_recv_wait
                                          *  blocks the execution waiting for the receive operations to be
executed.
                                          */
};
```

Function:

```
__device__ doca_error_t doca_gpu_dev_rdma_recv_wait_all(struct doca_gpu_dev_rdma_r *rdma_r, const enum
 doca_gpu_dev_rdma_recv_wait_flags flags, uint32_t *num_ops, uint32_t *imm_val)
```

- `rdma_r` – RDMA receive queue GPU handler
- `flags` – receive flags
- `num_ops` – Output parameter. Function reports number of completed operations.
- `imm_val` – Output parameter. Application-provided buffer where the function can store received immediate values, if any (or 0xFFFFFFFF if no immediate value is received). If `nullptr`, the function ignores this parameter.

5.4.10.7.6 GPU Functions – DMA

This section provides a list of DOCA GPUNetIO functions that can be used on the GPU only within a CUDA kernel to execute DMA operations.

5.4.10.7.6.1 doca_gpu_dev_dma_memcpy

This function allows a CUDA kernel to trigger a DMA memory copy operation through the DMA GPU engine. There is no strong/weak mode here, the DMA is assuming the strong behavior by default.

```
__device__ doca_error_t doca_gpu_dev_dma_memcpy(struct doca_gpu_dma *dma, struct doca_gpu_buf *src_buf, uint64_t
src_offset, struct doca_gpu_buf *dst_buf, uint64_t dst_offset, size_t length);
```

- `dma` – DMA queue GPU handler
- `src_buf` – memcpy source buffer
- `src_offset` – fetch data starting from this source buffer offset
- `dst_buf` – memcpy destination buffer
- `dst_offset` – copy data starting from this destination buffer offset
- `lenght` – number of bytes to copy

5.4.10.7.6.2 doca_gpu_dev_dma_commit

After posting several DMA memory copies, a commit function must be invoked to execute the operations enqueued in the DMA queue. Only 1 CUDA thread can invoke this function at a time.

```
__device__ doca_error_t doca_gpu_dev_dma_commit(struct doca_gpu_dma *dma);
```

- `dma` – DMA queue GPU handler

5.4.10.7.7 GPU Functions – Comch

This section lists the DOCA GPUNetIO functions that can be used within a CUDA kernel to execute DOCA Comch Producer or Consumer operations. For more information on the Producer/Consumer model, refer to the DOCA Comch documentation.

Threading Limitation

Only one CUDA thread can invoke these functions per Producer or Consumer object.

5.4.10.7.7.1 Consumer: `doca_dev_gpu_comch_consumer_post_recv`

This function allows a DOCA Comch Consumer to post a buffer to receive a message from a remote producer.

```
__device__ doca_error_t doca_dev_gpu_comch_consumer_post_recv(
    struct doca_comch_gpu_consumer *consumer,
    uint32_t mkey,
    uintptr_t addr,
    uint32_t recv_len
```

```
);
```

Parameters:

- `consumer` : The Consumer GPU handle.
- `mkey` : The mkey associated with the buffer to be posted.
- `addr` : The address of the buffer to receive the message into.
- `recv_len` : The maximum message size that can be written to the buffer.

5.4.10.7.7.2 Consumer: `doca_dev_gpu_comch_consumer_recv_wait`

This function allows a DOCA Comch Consumer to wait for a message to be received from a remote producer.

```
__device__ doca_error_t doca_dev_gpu_comch_consumer_recv_wait(
    struct doca_comch_gpu_consumer *consumer,
    uint32_t *mkey,
    uintptr_t *addr,
    uint32_t *recv_len,
    uint8_t **imm_data,
    uint32_t *imm_data_len,
    const enum doca_gpu_dev_comch_wait_flags flags
);
```

Parameters:

- `con sumer` : The Consumer GPU handle.
- `mkey` [out]: The mkey of the buffer that the message has been received into.
- `addr` [out]: The address of the buffer that the message has been received into.
- `recv_len` [out]: The length of the message that has been received.
- `imm_data` : Pointer to a buffer for any immediate data included with the message.
- `imm_data_len` [in/out]:
  - Input: The maximum size of immediate data that can be received.
  - Output: The actual size of immediate data received.
- `flags` : A `doca_gpu_dev_comch_wait_flags` value (e.g., blocking or non-blocking).

5.4.10.7.7.3 Producer: `doca_dev_gpu_comch_producer_send`

This function allows a DOCA Comch Producer to send a message to a remote consumer.

```
__device__ doca_error_t doca_dev_gpu_comch_producer_send(
    struct doca_comch_gpu_producer *producer,
    uint32_t mkey,
    uintptr_t addr,
    uint32_t send_len,
    uint8_t *imm_data,
    uint32_t imm_data_len,
    uint32_t consumer_id,
    uint64_t user_msg_id
);
```

Paramters:

- `producer` : The Producer GPU handle.
- `mkey` : The mkey associated with the buffer to be sent.

- `addr` : The address of the buffer to be sent.
- `send_len` : The number of bytes to send from the buffer.
- `imm_data` : Immediate data to include with the message.
- `imm_data_len` : Size of the immediate data to include.
- `consumer_id` : The ID of the remote consumer to send the message to.
- `user_msg_id` : A user-defined ID that will be returned by `doca_dev_gpu_comch_producer_poll` when this message has been successfully sent.

5.4.10.7.7.4 Producer: `doca_dev_gpu_comch_producer_poll`

This function allows a DOCA Comch Producer to poll for the completion of a send operation.

```
__device__ doca_error_t doca_dev_gpu_comch_producer_poll(
    struct doca_comch_gpu_producer *producer,
    uint64_t *user_msg_id,
    const enum doca_gpu_dev_comch_wait_flags flags
);
```

Parameters:

- `producer` : The Producer GPU handle.
- `user_msg_id` [out]: The `user_msg_id` that was set in the corresponding `doca_dev_gpu_comch_producer_send` function.
- `flags` : A `doca_gpu_dev_comch_wait_flags` value (e.g., blocking or non-blocking).

5.4.10.7.7.5 doca_gpu_dev_comch_wait_flags

This `enum` is used as the `flags` parameter in both the `doca_gpu_dev_comch_consumer_recv_wait` and `doca_gpu_dev_comch_producer_poll` functions. It determines how the function behaves if no operation has completed.

```
enum doca_gpu_dev_comch_wait_flags {
    DOCA_GPU_COMCH_WAIT_FLAG_NB = 0, /**< Non-Blocking mode: the wait function  checks if any of the operations
                                      * have been completed (data has been sent/received) and exit from the
                                      * function. If nothing has been sent/received, the function doesn't block
                                      * the execution.
                                      */
    DOCA_GPU_COMCH_WAIT_FLAG_B = 1,  /**< Blocking mode: the wait function blocks the execution waiting for a
                                      * send/receive operations to be completed.
                                      */
};
```

5.4.10.8 GPUNetIO Sample Guide

This section contains two samples that show how to enable simple GPUNetIO features. Be sure to correctly set the following environment variables:

Build the sample

```
export PATH=${PATH}:/usr/local/cuda/bin
export CPATH="$(echo /usr/local/cuda/targets/{x86_64,sbsa}-linux/include | sed 's/ /:/'):${CPATH}"
export PKG_CONFIG_PATH=${PKG_CONFIG_PATH}:/usr/lib/pkgconfig:/opt/mellanox/grpc/lib/{x86_64,aarch64}-linux-gnu/
pkgconfig:/opt/mellanox/dpdk/lib/{x86_64,aarch64}-linux-gnu/pkgconfig:/opt/mellanox/doca/lib/{x86_64,aarch64}-
linux-gnu/pkgconfigexport LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:/usr/local/cuda/lib64:/opt/mellanox/gdrcopy/src:/opt/
mellanox/dpdk/lib/{x86_64,aarch64}-linux-gnu:/opt/mellanox/doca/lib/{x86_64,aarch64}-linux-gnu
```

All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

GPU architecture

Please ensure the arch of your GPU is included in the `meson.build` file before building the samples (e.g., `sm_80` for Ampere, `sm_89` for L40, `sm_90` for H100, etc).

5.4.10.8.1 Ethernet Send Wait Time

The sample shows how to enable Accurate Send Scheduling (or wait-on-time) feature in the context of a GPUNetIO application. Accurate Send Scheduling is the ability of an NVIDIA NIC to send packets in the future according to application-provided timestamps.

This feature is supported on ConnectX-7 and later.

This sample demonstrates how to send packets from the GPU using Accurate Send Scheduling by calling the high-level `doca_gpu_dev_eth_txq_wait_send` function with a `BLOCK` execution scope.

This NVIDIA blog post offers an example for how this feature has been used in 5G networks.

5.4.10.8.1.1 Synchronizing Clocks

Before starting the sample, it is important to properly synchronize the CPU clock with the NIC clock. This way, timestamps provided by the system clock are synchronized with the time in the NIC.

For this purpose, at least the `phc2sys` service must be used. To install it on an Ubuntu system:

phc2sys

```
sudo apt install linuxptp
```

To start the `phc2sys` service properly, a config file must be created in `/lib/systemd/system/phc2sys.service`. Assuming the network interface is `ens6f0` :

phc2sys

```
[Unit]
Description=Synchronize system clock or PTP hardware clock (PHC)
Documentation=man:phc2sys

[Service]
Restart=always
RestartSec=5s
Type=simple
ExecStart=/bin/sh -c "taskset -c 15 /usr/sbin/phc2sys -s /dev/ptp$(ethtool -T ens6f0 | grep PTP | awk '{print $4}')
-c CLOCK_REALTIME -n 24 -O 0 -R 256 -u 256"

[Install]
WantedBy=multi-user.target
```

Now `phc2sys` service can be started:

phc2sys

```
sudo systemctl stop systemd-timesyncd
sudo systemctl disable systemd-timesyncd
sudo systemctl daemon-reload
sudo systemctl start phc2sys.service
```

To check the status of `phc2sys` :

phc2sys

```
$ sudo systemctl status phc2sys.service
```

Output:

phc2sys

```
● phc2sys.service - Synchronize system clock or PTP hardware clock (PHC)
     Loaded: loaded (/lib/systemd/system/phc2sys.service; disabled; vendor preset: enabled)

delay   770 +/-   3
```

```
Apr 05 16:35:57 doca-vr-045 phc2sys[337829]: [457400.191] CLOCK_REALTIME rms    8 max   20 freq +110528 +/-  33
delay   770 +/-   3
Apr 05 16:35:58 doca-vr-045 phc2sys[337829]: [457401.221] CLOCK_REALTIME rms    8 max   19 freq +110512 +/-  38
delay   770 +/-   3
Apr 05 16:35:59 doca-vr-045 phc2sys[337829]: [457402.253] CLOCK_REALTIME rms    9 max   20 freq +110538 +/-  47
delay   770 +/-   4
Apr 05 16:36:00 doca-vr-045 phc2sys[337829]: [457403.281] CLOCK_REALTIME rms    8 max   21 freq +110517 +/-  38
delay   769 +/-   3
Apr 05 16:36:01 doca-vr-045 phc2sys[337829]: [457404.311] CLOCK_REALTIME rms    8 max   17 freq +110526 +/-  26
delay   769 +/-   3
...
```

At this point, the system and NIC clocks are synchronized so timestamps provided by the CPU are correctly interpreted by the NIC.

The timestamps you get may not reflect the real time and day. To get that, you must properly set the `ptp4l` service with an external grand master on the system. Doing that is out of the scope of this sample.

5.4.10.8.1.2 Running the Sample

To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

phc2sys

```
# Ensure DOCA is in the pkgconfig environment variable
cd /opt/mellanox/doca/samples/doca_gpunetio/gpunetio_send_wait_time
meson build
ninja -C build
```

The sample sends 8 bursts of 32 raw Ethernet packets or 1kB to a dummy Ethernet address, `10:11:12:13:14:15`, in a timed way. Program the NIC to send every `t` nanoseconds (command line option `-t`).

The following example programs a system with GPU PCIe address `ca:00.0` and NIC PCIe address `17:00.0` to send 32 packets every 5 milliseconds:

Run

```
# Ensure DOCA and DPDK are in the LD_LIBRARY_PATH environment variable
$ sudo ./build/doca_gpunetio_send_wait_time -n 17:00.0 -g ca:00.0 -t 5000000[09:22:54:165778][1316878][DOCA][INF]
[gpunetio_send_wait_time_main.c:195][main] Starting the sample
[09:22:54:438260][1316878][DOCA][INF][gpunetio_send_wait_time_main.c:224][main] Sample configuration:
        GPU ca:00.0
        NIC 17:00.0
        Timeout 5000000ns
EAL: Detected CPU lcores: 128
...

[09:23:04:883339][1316878][DOCA][INF][gpunetio_send_wait_time_main.c:239][main] Sample finished successfully
```

To verify that packets are actually sent at the right time, use a packet sniffer on the other side (e.g., `tcpdump`):

phc2sys

```
$ sudo tcpdump -i enp23s0f1np1 -A -s 64

17:12:23.480318 IP5 (invalid)
Sent from DOCA GPUNetIO.........................
....
17:12:23.480368 IP5 (invalid)
Sent from DOCA GPUNetIO.........................
# end of first burst of 32 packets, bump to +5ms
17:12:23.485321 IP5 (invalid)
Sent from DOCA GPUNetIO.........................
...
17:12:23.485369 IP5 (invalid)
Sent from DOCA GPUNetIO.........................
# end of second burst of 32 packets, bump to +5ms
17:12:23.490278 IP5 (invalid)
Sent from DOCA GPUNetIO.........................
...
```

The output should show a jump of approximately 5 milliseconds every 32 packets.

⚠ `tcpdump` may increase latency in sniffing packets and reporting the receive timestamp, so the difference between bursts of 32 packets reported may be less than expected, especially with small interval times like 500 microseconds (`-t 500000`).

5.4.10.8.2 Ethernet Simple Receive

This sample application demonstrates the fundamental steps to build a DOCA GPUNetIO receiver application. It creates one queue for UDP packets and uses a single CUDA kernel to receive those packets from the GPU.

The sample uses the high-level `doca_gpu_dev_eth_rxq_recv` function, and its execution scope (thread, warp, or block) can be set at runtime using the `-e` command-line parameter.

printf in CUDA Kernels

Invoking `printf` from a CUDA kernel is not good practice for release software as it slows down the kernel's overall execution. It should only be used for debugging. To enable packet info printing in this sample, the `DOCA_GPUNETIO_SIMPLE_RECEIVE_DEBUG` macro must be set to `1`.

5.4.10.8.2.1 Build Instructions

Build the sample

```
# Ensure DOCA is in the pkgconfig environment variable
```

```
cd /opt/mellanox/doca/samples/doca_gpunetio/gpunetio_simple_receive
meson build
ninja -C build
```

5.4.10.8.2.2 Execution and Testing

This guide assumes a two-machine setup:

- Receiver Machine: Runs the `doca_gpunetio_simple_receive` application.
- Packet Generator Machine: Uses an application like `nping` to send UDP packets.

Packet Generator Machine Example

On the packet generator machine, use `nping` to send 10 UDP packets to the receiver's IP address (assumed to be `192.168.1.1` in this example).

Command:

nping generator

```
$ nping --udp -c 10 -p 2090 192.168.1.1 --data-length 1024 --delay 500ms
```

Output:

```
Starting Nping 0.7.80 ( https://nmap.org/nping ) at 2023-11-20 11:05 UTC
SENT (0.0018s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (0.5018s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (1.0025s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (1.5025s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (2.0032s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (2.5033s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (3.0040s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (3.5040s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (4.0047s) UDP packet with 1024 bytes to 192.168.1.1:2090
SENT (4.5048s) UDP packet with 1024 bytes to 192.168.1.1:2090

Max rtt: N/A | Min rtt: N/A | Avg rtt: N/A
UDP packets sent: 10 | Rcvd: 0 | Lost: 10 (100.00%)
Nping done: 1 IP address pinged in 5.50 seconds
```

Receiver Machine Example

On the receiver machine, run the sample with the appropriate PCI addresses for the NIC and GPU. This example uses `BLOCK` scope (`-e 2`).

Command:

nping generator

```
# Ensure DOCA is in the LD_LIBRARY_PATH environment variable
$ sudo ./doca_gpunetio_simple_receive -n 9f:00.0 -g 8a:00.0 -e 2
```

Output:

nping generator

5.4.10.8.3 Ethernet Simple Send

This sample implements a simple GPU Ethernet packet generator that constantly sends a flow of raw Ethernet packets. It demonstrates two different implementation "flavors" for sending packets: one using the low-level API and one using the high-level API.

The behavior is controlled by the `-q` command-line option:

- `-q 0` (Low-level API): Disables the shared queue feature and executes using the low-level send functions.
- `-q 1` (High-level API): Enables the shared queue feature. When this is set, the execution scope (thread, warp, or block) can also be chosen using the `-e` option.

5.4.10.8.3.1 Build Instructions

DOCA Simple Receive

```
# Ensure DOCA is in the pkgconfig environment variable
cd /opt/mellanox/doca/samples/doca_gpunetio/gpunetio_simple_send
meson build
ninja -C build
```

5.4.10.8.3.2 Execution Example

Assuming a system with a NIC at PCIe address `9f:00.0` and a GPU at `8a:00.0`, the following command launches the sample to send 1024-byte packets (`-s 1024`) using 1024 CUDA threads (`-t 1024`). It enables the high-level API (`-q 1`) with a `BLOCK` execution scope (`-e 2`).

Command:

DOCA Simple Receive

```
# Ensure DOCA is in the LD_LIBRARY_PATH environment variable
$ sudo ./doca_gpunetio_simple_send -n 9f:00.0 -g 8a:00.0 -s 1024 -t 1024 -q 1 -e 2
```

Output:

```

successfully
```

Performance Verification

To verify that packets are being sent, you can check the traffic throughput on the same machine using the `mlnx_perf` command. (Assuming the NIC at `9f:00.0` has the interface name `ens6f0np0`):

nping generator

```
$ mlnx_perf -i ens6f0np0
      tx_vport_unicast_packets: 21,033,677
        tx_vport_unicast_bytes: 21,538,485,248 Bps    = 172,307.88 Mbps
                tx_packets_phy: 21,033,286
                  tx_bytes_phy: 21,622,256,208 Bps    = 172,978.4 Mbps
              tx_prio0_bytes: 21,617,084,940 Bps    = 172,936.67 Mbps
            tx_prio0_packets: 21,028,292
                        UP 0: 172,936.67            Mbps = 100.00%
                        UP 0: 21,028,292            Tran/sec = 100.00%
```

Note on Performance

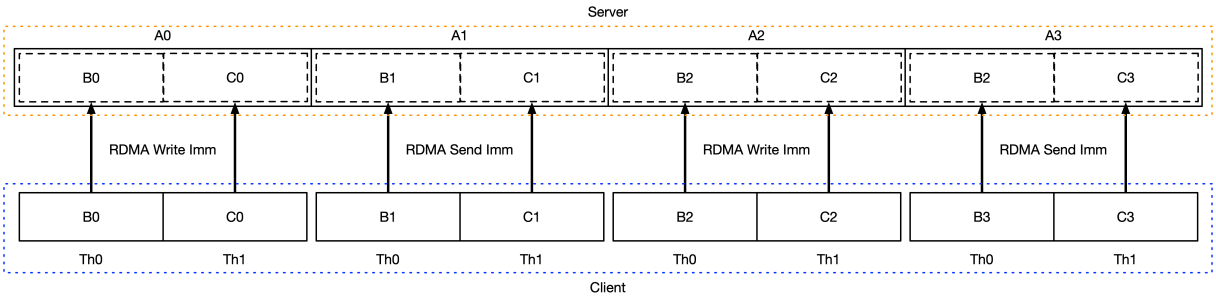
Throughput will vary between different systems based on factors like the PCIe connection between the GPU and NIC, the NIC model, and the GPU model. This sample can be used to evaluate your system's send performance by varying the packet size and number of CUDA threads.

5.4.10.8.4 RDMA Client Server

This sample exhibits how to use the GPUNetIO RDMA API to receive and send/write with immediate using a single RDMA queue.

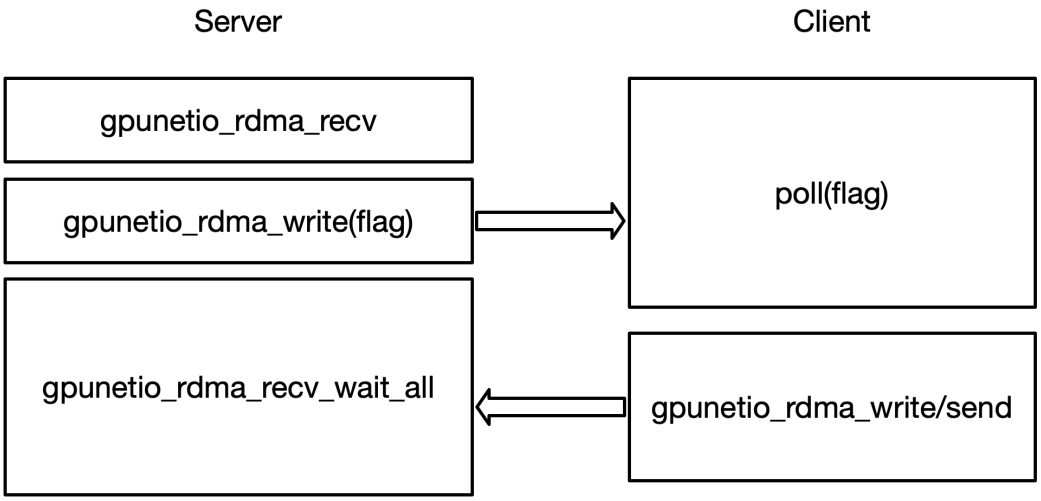
The server has a GPU buffer array A composed by `GPU_BUF_NUM doca_gpu_buf` elements, each 1kB in size. The client has two GPU buffer arrays, B and C, each composed by `GPU_BUF_NUM doca_gpu_buf` elements, each 512B in size.

The goal is for the client to fill a single server buffer of 1kB with two GPU buffers of 512B as illustrated in the following figure:



To show how to use RDMA write and send, even buffers are sent from the client with write immediate, while odd buffers are sent with send immediate. In both cases, the server must pre-post the RDMA receive operations.

For each buffer, the CUDA kernel code repeats the handshake:



Once all buffers are filled, the server double checks that all values are valid. The server output should be as follows:

```
DOCA RDMA Server side
```

```
# Ensure DOCA and DPDK are in the LD_LIBRARY_PATH environment variable
$ cd /opt/mellanox/doca/samples/doca_gpunetio/gpunetio_rdma_client_server_write
$ ./build/doca_gpunetio_rdma_client_server_write -gpu 17:00.0 -d mlx5_0

⚠ With RDMA, the network device must be specified by name (e.g., `mlx5_0`) instead of the PCIe address (as is the case for Ethernet).

It is also possible to enable the RDMA CM mode, establishing two connections with the same RDMA GPU handler. An example on the client side:

DOCA RDMA Client side with CM

```
# Ensure DOCA and DPDK are in the LD_LIBRARY_PATH environment variable

$ cd /opt/mellanox/doca/samples/doca_gpunetio/gpunetio_rdma_client_server_write

Thread 1 post rdma send imm 4
Client posted and completed 4 RDMA commits on connection 1. Waiting on the exit flag.
[11:30:35:122448][3853018][DOCA][INF][gpunetio_rdma_client_server_write_main.c:512][main] Sample finished
successfully
```

In case of RDMA CM, the command option `-cm` must be specified on the server side.

Printing from a CUDA kernel is not recommended for performance. It may make sense for debugging purposes and for simple samples like this one.

5.4.10.8.5 Verbs Samples

The `doca_gpunetio_verbs_*` examples demonstrate how to use the GPUNetIO Verbs API in various scenarios. These samples require a client-server setup, with the client needing the `-c <server IP>` parameter.

The following parameters are supported by all Verbs samples:

- `-n`: Network card handler type (0: AUTO, 1: CPU Proxy, 2: GPU DB). Default is 0 (AUTO).
- `-e`: Execution mode for shared QP (0: per-thread, 1: per-warp). Default is 0 (per-thread).
- `-d`: Network card device name.
- `-g`: GPU device PCIe address.
- `-gid`: GID index for DOCA RDMA (optional).
- `-i`: Number of iterations (optional).
- `-t`: Number of CUDA threads (optional).

Please read the specific sample section below to check for extra parameters.

For the examples in this guide, it is assumed that the GPU PCIe address is `8A:00.0` and the network card PCIe address is specified accordingly.

> **Note on running with RoCE**
>
> If the samples are running on a RoCE connection (e.g. the ConnectX/BlueField is set in Ethernet mode instead of Infiniband mode) you may get this (or similar) error: `FW failed to modify object, status=BAD_PARAM_ERR (0x3), syndrome=0x1f3b5d` .
>
> To fix it, please remove the `doca_verbs_ah_attr_set_dlid` function from the `connect_verbs_qp` function in the `samples/doca_gpunetio/verbs_common.c` file.

5.4.10.8.5.1 Bandwidth Samples

The samples ending with `_bw` measure the bandwidth of specific GPUNetIO Verbs API functions. In these samples, the client prepares and sends data from a CUDA kernel, while the server waits on the CPU to receive the data, validate it upon receiving a Ctrl+C signal, and reports the outcome.

Key Characteristics

- The client outputs the MB/s achieved for preparing and sending messages of various sizes.
- The server outputs a message indicating the execution outcome.
- All bandwidth samples support the previously listed command-line parameters.

Simplifying QP/CQ/UAR Creation

To simplify the integration of DOCA RDMA Verbs with GPUNetIO, high-level functions like `doca_gpu_verbs_create_qp_hl()` and `doca_gpu_verbs_create_qp_group_hl()` are provided in `samples/doca_gpunetio/verbs_high_level.cpp`. These functions encapsulate the necessary steps for creating QP/CQ/UAR, making it easier for developers to combine DOCA RDMA Verbs and GPUNetIO in their applications.

doca_gpunetio_verbs_write_bw

The `doca_gpunetio_verbs_write_bw` test measures the bandwidth of RDMA Write operations using the GPUNetIO Verbs API. It launches a CUDA kernel with 1 block and 512 threads by default, where all threads post RDMA Write WQEs in different positions and the last thread submits them. The test then polls the CQE corresponding to the last WQE to ensure all previous WQEs have been executed correctly.

Example command lines:

- Server:

```
doca_gpunetio_verbs_write_bw -g 8A:00.0 -d mlx5_0
```

- Client (additional command-line options can be added):

```
doca_gpunetio_verbs_write_bw -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

doca_gpunetio_verbs_put_bw

The `doca_gpunetio_verbs_put_bw` test measures the bandwidth of RDMA Write operations (referred to as "Put") using the GPUNetIO Verbs API with the shared QP feature. It launches a CUDA kernel with 2 blocks, each containing 256 threads. The test can also measure individual function latencies by setting the `KERNEL_DEBUG_TIMES` macro to 1.

Example command lines:

- Server:

```
doca_gpunetio_verbs_put_bw -g 8A:00.0 -d mlx5_0
```

- Client (additional command-line options can be added):

```
doca_gpunetio_verbs_put_bw -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

doca_gpunetio_verbs_put_signal_bw

The `doca_gpunetio_verbs_put_signal_bw` test measures the bandwidth of Put + Signal operations (RDMA Write + RDMA Atomic with shared QP) using the GPUNetIO Verbs API. It launches a CUDA kernel with 2 blocks, each containing 256 threads.

Example command lines:

- Server:

```
doca_gpunetio_verbs_put_signal_bw -g 8A:00.0 -d mlx5_0
```

- Client (additional command-line options can be added):

```
doca_gpunetio_verbs_put_signal_bw -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

Note on CUDA Kernel Loop

The sample works correctly, but there is a minor mistake in the CUDA kernel loop. The corrected loop should be:

```
do {
    final_val = doca_gpu_dev_verbs_atomic_read<uint64_t,
DOCA_GPUNETIO_VERBS_RESOURCE_SHARING_MODE_GPU>(&prev_flag_buf[tidx]);
    doca_gpu_dev_verbs_fence_acquire<DOCA_GPUNETIO_VERBS_SYNC_SCOPE_SYS>();
} while((final_val != (iter_thread - 1)) && (final_val != ((iter_thread * 2) - 1)));
```

doca_gpunetio_verbs_put_counter_bw

The `doca_gpunetio_verbs_put_counter_bw` test measures the bandwidth of Put + Counter operations (RDMA Write + Wait WQE + RDMA Atomic with shared QP) using the GPUNetIO Verbs API. It launches a CUDA kernel with 2 blocks, each containing 256 threads.

Example command lines:

- Server:

```
doca_gpunetio_verbs_put_counter_bw -g 8A:00.0 -d mlx5_0
```

- Client (additional command-line options can be added):

```
doca_gpunetio_verbs_put_counter_bw -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

Note on CUDA Kernel Loop

The sample works correctly, but there is a minor mistake in the CUDA kernel loop. The corrected loop should be:

```
do {
    final_val = doca_gpu_dev_verbs_atomic_read<uint64_t,
DOCA_GPUNETIO_VERBS_RESOURCE_SHARING_MODE_GPU>(&prev_flag_buf[tidx]);
    doca_gpu_dev_verbs_fence_acquire<DOCA_GPUNETIO_VERBS_SYNC_SCOPE_SYS>();
} while((final_val != (iter_thread - 1)) && (final_val != ((iter_thread * 2) - 1)));
```

doca_gpunetio_verbs_twosided_bw

The `doca_gpunetio_verbs_twosided_bw` test measures the bandwidth of client-server data exchange via Send/Recv operations using the GPUNetIO Verbs API with the shared QP feature. It launches a CUDA kernel with 2 blocks, each containing 256 threads.

Example command lines:

- Server:

```
doca_gpunetio_verbs_twosided_bw -g 8A:00.0 -d mlx5_0
```

- Client (additional command-line options can be added):

```
doca_gpunetio_verbs_twosided_bw -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

doca_gpunetio_verbs_get_bw

This sample application measures the bandwidth of one-sided RDMA Read ("Get") operations. It uses the GPUNetIO Verbs API with the shared QP feature.

The application launches a CUDA kernel configured with 2 blocks, each containing 256 threads.

Example usage:

- Server:

```
doca_gpunetio_verbs_get_bw -g 8A:00.0 -d mlx5_0
```

- Client (connects to the server's IP, e.g., `192.168.1.63`):

```
doca_gpunetio_verbs_get_bw -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

Additional CLI options can be added.

5.4.10.8.5.2 Latency Samples

The samples ending with `_lat` measure the latency of specific GPUNetIO Verbs API functions by performing a ping-pong exchange between client and server. These tests launch a CUDA kernel with a single CUDA thread and do not support the `-e` and `-t` command-line options.

Both client and server output the round-trip time (RTT) latency (half and full) in microseconds for preparing and exchanging messages of different sizes. The server also outputs a message indicating the execution outcome.

doca_gpunetio_verbs_write_lat

The `doca_gpunetio_verbs_write_lat` test measures the latency of RDMA Write operations using the GPUNetIO Verbs API without the shared QP feature. It is similar to perftest.

This sample support the reliable doorbell feature with command-line option `-r <0|1>` .

Example command lines:

- Server:

```
doca_gpunetio_verbs_write_lat -g 8A:00.0 -d mlx5_0
```

- Client (additional command-line options can be added):

```
doca_gpunetio_verbs_write_lat -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

doca_gpunetio_verbs_put_signal_lat

The `doca_gpunetio_verbs_put_signal_lat` test measures the latency of Put and Signal operations (RDMA Write + RDMA Atomic with shared QP) using the GPUNetIO Verbs API. It uses high-level API functions from `doca_gpunetio_dev_verbs_onesided.cuh` and launches a CUDA kernel with a single CUDA thread.

Example command lines:

- Server:

```
doca_gpunetio_verbs_put_signal_lat -g 8A:00.0 -d mlx5_0
```

- Client (additional command-line options can be added):

```
doca_gpunetio_verbs_put_signal_lat -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

doca_gpunetio_verbs_put_counter_lat

The `doca_gpunetio_verbs_put_counter_lat` test measures the latency of Put + Counter operations (RDMA Write + Wait WQE + RDMA Atomic with shared QP) using the GPUNetIO Verbs API. It utilizes high-level API functions from `doca_gpunetio_dev_verbs_counter.cuh` and the Core Direct counter feature, even with a single CUDA thread.

This sample support the reliable doorbell feature with command-line option `-r <0|1>` .

Example command lines:

- Server:

```
doca_gpunetio_verbs_put_counter_lat -g 8A:00.0 -d mlx5_0
```

- Client: (additional command-line options can be added):

```
doca_gpunetio_verbs_put_counter_lat -g 8A:00.0 -d mlx5_0 -c 192.168.1.63
```

5.4.10.8.6 GPU DMA Copy

This sample exhibits how to use the DOCA DMA and DOCA GPUNetIO libraries to DMA copy a memory buffer from the CPU to the GPU (with DOCA DMA CPU functions) and from the GPU to the CPU (with DOCA GPUNetIO DMA device functions) from a CUDA kernel. This sample requires a DPU as it uses the DMA engine on it.

DOCA RDMA Client side

```
$ cd /opt/mellanox/doca/samples/doca_gpunetio/gpunetio_dma_memcpy

# Build the sample and then execute

$ ./build/doca_gpunetio_dma_memcpy -g 17:00.0 -n ca:00.0
[15:44:04:189462][862197][DOCA][INF][gpunetio_dma_memcpy_main.c:164][main] Starting the sample

5.4.11 DOCA App Shield

This guide provides instructions on using the DOCA App Shield API.

5.4.11.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

DOCA App Shield API offers a solution for strong intrusion detection capabilities using the DPU services to collect and analyze data from the host's (or a VM on the host) memory in real time. This solution provides intrusion detection and forensics investigation in a way that is:

- Robust against attacks on a host machine
- Able to detect a wide range of attacks (including zero-day attacks)
- Least disruptive to the execution of host application (where current detection solutions hinder the performance of host applications)
- Transparent to the host, such that the host does not need to install anything (other than providing some files obtained from the `doca_apsh_config.py` tool)

App Shield uses a DMA device to access the host's memory and analyze it.

The App Shield API provides multiple functions that help with gathering data extracted from system's memory (e.g., processes list, modules list, connections). This data helps with detecting attacks on critical services or processes in a system (e.g., services that enforce integrity or privacy of the execution of different applications).

5.4.11.2 Prerequisites

1. Configure the NVIDIA® BlueField® networking platform's (DPU or SuperNIC) firmware.
    a. On BlueField, configure the PF base address register and NVMe emulation. Run:

    ```
    dpu> mlxconfig -d /dev/mst/mt41686_pciconf0 s PF_BAR2_SIZE=2 PF_BAR2_ENABLE=1
    ```

    If working with VFs, configure NVME emulation, SR-IOV, and number of VFs. Run:

    ```
    dpu> mlxconfig -d /dev/mst/mt41686_pciconf0 s NVME_EMULATION_ENABLE=1 SRIOV_EN=1 NUM_OF_VFS=<vf-number>
    ```

b. Perform graceful shutdown and a cold boot from the host.

> These configurations can be checked using the following command:
>
> ```
> dpu> mlxconfig -d /dev/mst/mt41686_pciconf0 q | grep -E "NVME|BAR|SRIOV|NUM_OF_VFS"
> ```

2. Download target system (host/VM) symbols.
   - For Ubuntu:

     ```
     host> sudo tee /etc/apt/sources.list.d/ddebs.list << EOF
     deb http://ddebs.ubuntu.com/ $(lsb_release -cs) main restricted universe multiverse
     deb http://ddebs.ubuntu.com/ $(lsb_release -cs)-updates main restricted universe multiverse
     deb http://ddebs.ubuntu.com/ $(lsb_release -cs)-proposed main restricted universe multiverse
     EOF
     host> sudo apt install ubuntu-dbgsym-keyring
     host> sudo apt-get update
     host> sudo apt-get install linux-image-$(uname -r)-dbgsym
     ```

   - For CentOS:

     ```
     host> yum install --enablerepo=base-debuginfo kernel-devel-$(uname -r) kernel-debuginfo-$(uname -r)
     kernel-debuginfo-common-$(uname -m)-$(uname -r)
     ```

   - No action is needed for Windows
3. Perform IOMMU passthrough. This stage is only necessary if IOMMU is not enabled by default (e.g., when the host is using an AMD CPU).

> Skip this step if you are not sure whether it is needed. Return to it only if DMA fails with a message similar to the following in `dmesg`:
>
> ```
> host> dmesg
> [ 3839.822897] mlx5_core 0000:81:00.0: AMD-Vi: Event logged [IO_PAGE_FAULT domain=0x0047
> address=0x2a0aff8 flags=0x0000]
> ```

   a. Locate your OS's `grub` file (most likely `/boot/grub/grub.conf`, `/boot/grub2/grub.cfg`, or `/etc/default/grub`) and open it for editing. Run:

   ```
   host> vim /etc/default/grub
   ```

   b. Search for the line defining `GRUB_CMDLINE_LINUX_DEFAULT` and add the argument `iommu=pt`. For example:

   ```
   GRUB_CMDLINE_LINUX_DEFAULT="iommu=pt <intel/amd>_iommu=on"
   ```

   c. Run:

> Prior to performing a power cycle, make sure to do a graceful shutdown.

   - For Ubuntu:

```
host> sudo update-grub
```

- For CentOS:

```
host> grub2-mkconfig -o /boot/grub2/grub.cfg
```

4. BlueField currently supports up to 4-level virtual memory layers. Therefore, it is necessary to check if the target system uses a 5-level virtual memory layer and to adjust the configuration accordingly:
   a. Check the virtual memory layer:

   ```
   grep la57 /proc/cpuinfo
   ```

   Verify the `la57` flag in the output. If something like this appears:

   ```
   flags : ... la57 ...
   ```

   This indicates that the target system is using a 5-level virtual memory layer and that 5-level paging must be deactivated.
   b. To deactivate 5-level paging, modify the kernel parameters using GRUB. Add the following line to your GRUB configuration:

   ```
   GRUB_CMDLINE_LINUX_DEFAULT="no5lvl"
   ```

   c. Update GRUB configuration:

   ```
   update-grub
   ```

   d. Reboot the system to apply the changes.
5. Prepare target:
   a. Install DOCA on the target system.
   b. Create the ZIP and JSON files. Run:

   ```
   target-system> cd /opt/mellanox/doca/tools/
   target-system> python3 doca_apsh_config.py --pid <pid-of-process-to-monitor> --os <windows/linux>
   --path <path to dwarf2json executable  or pdbparse-to-json.py>
   target-system> cp /opt/mellanox/doca/tools/*.* <shared-folder-with-baremetal>
   dpu> scp <shared-folder-with-baremetal>/* <path-to-app-shield-binary>
   ```

   If the target system does not have DOCA installed, the script can be copied from BlueField.
   The required `dwaf2json` and `pdbparse-to-json.py` are not provided with DOCA.

   > ⚠ If the kernel and process `.exe` have not changed, there is no need to redo this step.

5.4.11.3 Dependencies

The library requires firmware version 24.32.1010 or higher.

5.4.11.4 API

For the library API reference, refer to the DOCA APSH API documentation in the NVIDIA DOCA Library APIs.

> ⚠ The pkg-config (`*.pc` file) for the APSH library is `doca-apsh`.

The following subsections provide more details about the library API.

5.4.11.4.1 doca_apsh_dma_dev_set

To attach a DOCA DMA device to App Shield, calling this function is mandatory and must be done before calling `doca_apsh_start`.

```
doca_apsh_dma_dev_set(doca_apsh_ctx, doca_dev)
```

- `doca_apsh_ctx [in]` – App Shield opaque context struct
- `doca_dev [in]` – struct for DOCA Device with DMA capabilities

5.4.11.4.2 Capabilities Per System

For each initialized system, App Shield retrieves an array of the requested object according to the getter's name:

Getter Function Name	Functions Information	Functions Signature	Return Type
Get modules	Returns an array with information about the system modules (drivers) loaded into the kernel of the OS.	`doca_error_t doca_apsh_modules_get(struct doca_apsh_system *system, struct doca_apsh_module ***modules, int *modules_size);`	• Array of `struct doca_apsh_module` • `int` – size of the returned array • `doca_error` status

Getter Function Name	Functions Information	Functions Signature	Return Type
Get processes	Returns an array with information about each process running on the system.	`doca_error_t doca_apsh_processes_get(struct doca_apsh_system *system, struct doca_apsh_process ***processes, int *processes_size);`	• Array of `struct doca_apsh_process` • `int` – size of the returned array • `doca_error` status
Get library	For a specified process, this function returns an array with information about each library loaded into this process.	`doca_error_t doca_apsh_libs_get(struct doca_apsh_process *process, struct doca_apsh_lib ***libs, int *libs_size);`	• Array of `struct doca_apsh_lib` • `int` – size of the returned array • `doca_error` status
Get threads	For a specified process, this function returns an array with information about each thread running within this process.	`doca_error_t doca_apsh_threads_get(struct doca_apsh_process *process, struct doca_apsh_thread ***threads, int *threads_size);`	• Array of `struct doca_apsh_thread` • `int` – size of the returned array • `doca_error` status
Get virtual memory areas/ virtual address description	For a specified process, this function returns an array with information about each virtual memory area within this process.	`doca_error_t doca_apsh_vads_get(struct doca_apsh_process *process, struct doca_apsh_vad ***vads, int *vads_size);`	• Array of `struct doca_apsh_vma` • `int` – size of the returned array • `doca_error` status

Getter Function Name	Functions Information	Functions Signature	Return Type
Get privileges	For a specified process, this function returns an array with information about each possible privilege for this process, as described here. ⚠ Available on a Windows host only.	`doca_error_t doca_apsh_privileges_get(struct doca_apsh_process *process, struct doca_apsh_privilege ***privileges, int *privileges_size);`	• Array of `struct doca_apsh_privilege` • `int` – size of the returned array • `doca_error` status
Get environment variables	For a specified process, this function returns an array with information about each environment variable within this process. ⚠ Available on a Windows host only.	`doca_error_t doca_apsh_envars_get(struct doca_apsh_process *process, struct doca_apsh_envar ***envars, int *envars_size);`	• Array of `struct doca_apsh_envar` • `int` – size of the returned array • `doca_error` status
Get handles	For a specified process, this function returns an array with information about each handle this process holds. ⚠ Available on a Windows host only.	`doca_error_t doca_apsh_handles_get(struct doca_apsh_process *process, struct doca_apsh_handle ***handles, int *handles_size);`	• Array of `struct doca_apsh_handle` • `int` – size of the returned array • `doca_error` status
Get LDR modules	For a specified process, this function returns an array with information about each loaded module within this process. ⚠ Available on a Windows host only.	`doca_error_t doca_apsh_ldrmodules_get(struct doca_apsh_process *process, struct doca_apsh_ldrmodule ***ldrmodules, int *ldrmodules_size);`	• Array of `struct doca_apsh_ldrmodule` • `int` – size of the returned array • `doca_error` status

Getter Function Name	Functions Information	Functions Signature	Return Type
Process attestation	For a specified process, this function attests the memory pages of the process according to a precomputed golden hash file given as an input. ⚠ Single-threaded processes are supported at beta level.	`doca_error_t doca_apsh_attestation_get(struct doca_apsh_process *process, const char *exec_hash_map_path, struct doca_apsh_attestation ***attestation, int *attestation_size);`	• Array of `struct doca_apsh_attestation` • `int` – size of the returned array • `doca_error` status
Attestation refresh	Refreshes a single attestation handler of a process with a new snapshot.	`doca_error_t doca_apsh_attst_refresh(struct doca_apsh_attestation ***attestation, int *attestation_size);`	• Array of `struct doca_apsh_attestation` • `int` – size of the returned array • `doca_error` status

<table>
<tr><th>Getter Function Name</th><th>Functions Information</th><th>Functions Signature</th><th>Return Type</th></tr>

• <code>int</code> – size of the returned array
• <code>doca_error</code> status</td>
</tr>
</table>

Getter Function Name	Functions Information	Functions Signature	Return Type
Get process parameters	For a specified process, this function returns a struct object (not an array) with information about the process' parameters (ones not included in the "get processes" capability). ⚠ Available on a Windows host only. ⚠ This feature is currently supported at beta level.	`doca_error_t doca_apsh_process_parameters_get(struct doca_apsh_process *process, struct doca_apsh_process_parameters **process_parameters);`	• An object of `struct doca_apsh_process_parameters` • `doca_error` status
Get security identifier (SID)	For a specified process, this function returns an array with information about each SID (security identifier) included in the process's security context. ⚠ Available on a Windows host only.	`doca_error_t doca_apsh_sids_get(struct doca_apsh_process *process, struct doca_apsh_sid ***sids, int *sids_size);`	• Array of `struct doca_apsh_sid` • `int` – size of the returned array • `doca_error` status
Perform Yara scan	For a specified process, this function returns an array with information about each Yara rule match found in the process' memory. ⚠ Available on a Windows host and Ubuntu 22.04 DPU.	`doca_error_t doca_apsh_yara_get(struct doca_apsh_process *process, enum doca_apsh_yara_rule *yara_rules_arr, uint32_t yara_rules_arr_size, uint64_t scan_type, struct doca_apsh_yara ***yara_matches, int *yara_matches_size);` ⚠ To get a better understanding of the arguments, refer to documentation in `doca_apsh.h`.	• Array of `struct doca_apsh_yara` • `int` – size of the returned array • `doca_error` status
Get containers	Returns an array with information about each container running on the system. ⚠ Available on a Linux host only. ⚠ Only available for containers on the following runtimes: • runc • containerd	`doca_error_t doca_apsh_containers_get(struct doca_apsh_system *system, struct doca_apsh_container ***containers, int *containers_size);`	• Array of `struct doca_apsh_container` • `int` – size of the returned array • `doca_error` status

Getter Function Name	Functions Information	Functions Signature	Return Type
Get container's processes	For a specified container, this function returns an array with information about each process running within this container. ⚠ Available on a Linux host only. ⚠ Only available for containers on the following runtimes: • runc • containerd	`doca_error_t doca_apsh_container_processes_get(struct doca_apsh_container *container, struct doca_apsh_process ***processes, int *processes_size);`	• Array of `struct doca_apsh_process` • `int` – size of the returned array • `doca_error` status

<table>
<tr><th>Getter Function Name</th><th>Functions Information</th><th>Functions Signature</th><th>Return Type</th></tr>
<tr>
<td>Get Process NetScan</td>
<td>This function scans the system's physical memory (Windows) or kernel memory space (Linux) and returns an array with information about each socket that resides in the memory.

⚠ Only available on hosts with either Linux OS or one of the following Windows 10 OS builds:
<table>
<tr><th>Arch</th><th>Build No.</th></tr>
<tr><td>x86</td><td>10240</td></tr>
<tr><td></td><td>10586</td></tr>
<tr><td></td><td>14393</td></tr>
<tr><td></td><td>15063</td></tr>
<tr><td></td><td>17134</td></tr>
<tr><td></td><td>19041</td></tr>
<tr><td>x64</td><td>15063</td></tr>
<tr><td></td><td>16299</td></tr>
<tr><td></td><td>17134</td></tr>
<tr><td></td><td>17763</td></tr>
<tr><td></td><td>18362</td></tr>
<tr><td></td><td>18363</td></tr>
<tr><td></td><td>19041</td></tr>
</table>

⚠ This feature is currently supported at beta level.</td>
<td><pre>doca_error_t
doca_apsh_process_netscan_get(struct
doca_apsh_process *process, struct
doca_apsh_netscan ***connections, int
 *connections_size);</pre></td>
<td>• Array of <code>struct doca_apsh_netscan</code>
• <code>int</code> – size of the returned array
• <code>doca_error</code> status</td>
</tr>
<tr>
<td>Get interfaces</td>
<td>Returns an array with information about each interface running on the system.

⚠ Available on a Linux host only.</td>
<td><pre>doca_error_t
doca_apsh_interfaces_get(struct
doca_apsh_system *system,
struct doca_apsh_interface ***interfaces,
int *interfaces_size);</pre></td>
<td>• Array of <code>struct doca_apsh_interface</code>
• <code>int</code> – size of the returned array
• <code>doca_error</code> status</td>
</tr>
</table>

The following attribute getters return a specific attribute of an object, obtained from the array returned from the getter functions listed above, depending on the requested attribute:

```
doca_apsh_process_info_get(struct doca_apsh_proccess *process, enum doca_apsh_process_attr attr);
doca_apsh_module_info_get(struct doca_apsh_module *module, enum doca_apsh_module_attr attr);
doca_apsh_lib_info_get(struct doca_apsh_lib *lib, enum doca_apsh_lib_attr attr);
doca_apsh_thread_info_get(struct doca_apsh_thread *thread, enum doca_apsh_lib_attr attr);
doca_apsh_vad_info_get(struct doca_apsh_vad *vad, enum doca_apsh_vad_attr attr);
doca_apsh_privilege_info_get(struct doca_apsh_privilege *privilege, enum doca_apsh_privilege_attr attr);
doca_apsh_envar_info_get(struct doca_apsh_envar *envar, enum doca_apsh_envar_attr attr);
doca_apsh_handle_info_get(struct doca_apsh_handle *handle, enum doca_apsh_handle_attr attr);
doca_apsh_ldrmodule_info_get(struct doca_apsh_ldrmodule *ldrmodule, enum doca_apsh_ldrmodule_attr attr);
doca_apsh_attst_info_get(struct doca_apsh_attestation *attestation, enum doca_apsh_attestation_attr attr);
doca_apsh_netscan_info_get(struct doca_apsh_netscan *connection, enum doca_apsh_netscan_attr attr)
doca_apsh_process_parameters_info_get(struct doca_apsh_process_parameters *process_parameters, enum
 doca_apsh_process_parameters_attr attr);
doca_apsh_sid_info_get(struct doca_apsh_sid *sid, enum doca_apsh_sid_attr attr);
doca_apsh_yara_info_get(struct doca_apsh_yara *yara, enum doca_apsh_yara_attr attr);
doca_apsh_container_info_get(struct doca_apsh_container *container, enum doca_apsh_container_attr attr);
```

The return type of the attribute getter can be found in `doca_apsh_attr.h`.

Usage example:

```
const uint pid = doca_apsh_process_info_get(processes[i], DOCA_APSH_PROCESS_PID);
const char *proc_name = doca_apsh_process_info_get(processes[i], DOCA_APSH_PROCESS_COMM);
```

5.4.11.5 App Shield Initialization and Teardown

To use App Shield, users must initialize and configure two main structs. This section presents these structs and explains how to interact with them.

5.4.11.5.1 doca_apsh_ctx

`doca_apsh_ctx` is the basic struct used by App Shield which defines the DMA device used to perform the memory forensics techniques required to run App Shield.

> ⚠ The same `doca_apsh_ctx` struct may be used to run multiple App Shield instances over different systems (e.g., two different VMs on the host).

1. To acquire an instance of the `doca_apsh_ctx` struct, use the following function:

   ```
   struct doca_apsh_ctx *doca_apsh_create(void);
   ```

2. To configure the `doca_apsh_ctx` instance with DMA device to use:

   ```
   doca_error_t doca_apsh_dma_dev_set(struct doca_apsh_ctx *ctx, struct doca_dev *dma_dev);
   ```

3. To start the `doca_apsh_ctx` instance, call the following function:

   ```
   doca_error_t doca_apsh_start(struct doca_apsh_ctx *ctx);
   ```

4. To destroy the `doca_apsh_ctx` instance when it is no longer needed, call:

```
void doca_apsh_destroy(struct doca_apsh_ctx *ctx);
```

5.4.11.5.2 doca_apsh_system

The `doca_apsh_system` struct is built on the `doca_apsh_ctx` instance. This struct is created per system running App Shield. `doca_apsh_system` defines multiple attributes used by App Shield to perform memory analysis over the specific system successfully.

1. To acquire an instance of the `doca_apsh_system` struct, use the following function:

```
const uint pid = doca_apsh_process_info_get(processes[i], DOCA_APSH_PROCESS_PID);
const char *proc_name = doca_apsh_process_info_get(processes[i], DOCA_APSH_PROCESS_COMM);
```

2. To configure different attributes for the system instance:
   - OS type – specifies the system's OS type.

     ```
     doca_error_t doca_apsh_sys_os_type_set(struct doca_apsh_system *ctx, enum doca_apsh_system_os
     os_type);
     ```

     ⚠ Currently supported types: Windows or Linux.

   - System representor – specifies the representor of the device connected to the system for App Shield to run on (which can be a representor of VF/PF). For information on querying the DOCA device, refer to the DOCA Core. After acquiring the DOCA device, use the following function to configure it into the system instance:

     ```
     doca_error_t doca_apsh_sys_dev_set(struct doca_apsh_system *system, struct doca_dev_rep *dev);
     ```

   - System symbols map – includes information about the OS that App Shield is attempting to run on (e.g., Window 10 Build 18363) and the size and fields of the OS structures, which helps App Shield with the memory forensic techniques it uses to access and analyze these structures in the system's memory. This can be obtained by running the `doca_apsh_config.py` on the system machine.
     After obtaining it, there are two options to provide the file:
     - The first option is to explicitly specify the file path:

       ```
       doca_error_t doca_apsh_sys_os_symbol_map_set(struct doca_apsh_system *system, const char
       *system_os_symbol_map_path);
       ```

     - The second option is to provide a folder where the file is located:

```
doca_error_t doca_apsh_sys_os_symbol_map_folder_set(struct doca_apsh_system *system, const
char *system_os_symbol_folder_path);
```

> ⚠ In this option, the file name must be maintained as `doca_apsh_config.py`.

- Memory regions – includes the physical addresses of the memory regions which are mapped for system memory RAM. This is needed to prevent App Shield from accessing other memory regions, such as memory mapped I/O regions. This can be obtained by running the `doca_apsh_config.py` tool on the system machine.
  After obtaining it, run:

```
doca_error_t doca_apsh_sys_mem_region_set(struct doca_apsh_system *system, const char
*system_mem_region_path);
```

- KPGD file (optional and relevant only for Linux OS) – contains the KPGD physical address and the virtual address of `init_task`. This information is required since App Shield extracts data from the kernel struct in the physical memory. Thus, the kernel page directory table must translate the virtual addresses of these structs. This can be obtained by running the `doca_apsh_config.py` tool on the system machine with the flag `find_kpgd=1`. Since setting this attribute is optional, App Shield can work without it, but providing it speeds up App Shield's initialization process.
  After obtaining it, run:

```
doca_error_t doca_apsh_sys_kpgd_file_set(struct doca_apsh_system *system, const char
*system_kpgd_file_path);
```

3. To start the `doca_apsh_system`:

```
doca_error_t doca_apsh_system_start(struct doca_apsh_system *system);
```

4. To destroy the `doca_apsh_system` instance when it is no longer needed, call:

```
void doca_apsh_system_destroy(struct doca_apsh_system *system);
```

5.4.11.5.3 doca_apsh_config.py Tool

The `doca_apsh_config.py` tool is a python3 script which can be used to obtain all the attributes needed to run `doca_apsh_system` instance.

The following parameters are necessary to use the tool:

Parameter	Description
`pid` (optional)	The process ID of the process we want to run attestation capability on
`os` (mandatory)	The OS type of the machine (i.e., Linux or Windows)
`find_kpgd` (optional)	Relevant for Linux OS only, AS flag to enable/disable creating `kpgd_file.conf`. Default 0.
`files` (mandatory)	A list of files for the tool to create. File options: `hash`, `symbols`, `memregions`, `kpgd_file` (only relevant for Linux). ⚠ Make sure that the value set is appropriate for your setup.
`path` (mandatory)	• Linux – path to the `dwarf2json` executable. Default `./dwarf2json`. This file can be obtained by compiling the following project using Go. • Windows – path to `pdbparse-to-json.py`. Default `./pdbparse-to-json.py`. This file can be found here. ⚠ Make sure that the value set is appropriate for your setup.

The tool creates the following files:

- Symbol map – this file changes once the system kernel is updated or a kernel module is installed. The file does not change on system reboot.
- Memory regions – this file changes when adding or removing hardware or drivers that affect the system's memory map (e.g., when adding register addresses). The file does not change on system reboot.
- `hash.zip` – this file is required for attestation but is unnecessary for all other capabilities. The ZIP file contains the required data to attest to a single process. The file changes on library or executable update.
- `kpgd_file.conf` (relevant for Linux OS only) – helps with faster initialization of the library. The file changes on system reboot.

5.4.11.6 DOCA App Shield Samples

This section provides DOCA App Shield library sample implementations on top of BlueField.

ℹ All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.11.6.1 Sample Prerequisites

Follow the guidelines in section "Prerequisites" then copy the generated JSON files, `symbols.json` and `mem_regions.json`, to the `/tmp/` directory.

5.4.11.6.2 Running the Sample

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_apsh/<sample_name>
meson /tmp/build
ninja -C /tmp/build
```

   ⚠ The binary `doca_<sample_name>` will be created under `/tmp/build/`.

3. Sample (e.g., `apsh_libs_get`) usage:

```
Usage: doca_apsh_libs_get [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pid                         Process ID of process to be analyzed
  -f, --vuid                        VUID of the System device
  -d, --dma                         DMA device name
  -s, --osty <windows|linux>        System OS type - windows/linux
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name> -h
```

5.4.11.6.3 Samples

✓ These sample are also https://github.com/NVIDIA-DOCA/doca-samples/tree/master/samples/doca_apsh.

5.4.11.6.3.1 Apsh Libs Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of loadable libraries of a specific process.

The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device via given vendor unique identifier (VUID).
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of system process using Apsh API and searching for a specific process with the given PID.
8. Getting the list of process-loadable libraries using `doca_apsh_libs_get` Apsh API call.
9. Querying the libraries for 3 selected fields using `doca_apsh_lib_info_get` Apsh API call.
10. Printing libraries' attributes to the terminal.
11. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_libs_get/apsh_libs_get_sample.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_libs_get/apsh_libs_get_main.c`

- `/opt/mellanox/doca/samples/doca_apsh/apsh_common.c`; `/opt/mellanox/doca/samples/doca_apsh/apsh_common.h`

5.4.11.6.3.2 Apsh Modules Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of installed modules on a monitored system.
The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device via given VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and start Apsh system handler.

7. Getting the the list of system-installed modules using `doca_apsh_modules_get` Apsh API call.
8. Querying the names of modules using `doca_apsh_module_info_get` Apsh API call.
9. Printing the attributes of up to 5 modules attributes to the terminal.
10. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_modules_get/apsh_modules_get_sample.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_modules_get/apsh_modules_get_main.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_modules_get/meson.build`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_common.c`; `/opt/mellanox/doca/samples/doca_apsh/apsh_common.h`

5.4.11.6.3.3 Apsh Pslist

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of running processes on a monitored system.
The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device via given VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of processes running on the system using `doca_apsh_processes_get` Apsh API call.
8. Querying the processes for 4 chosen attributes using `doca_apsh_proc_info_get` Apsh API call.
9. Printing the attributes of up to 5 processes to the terminal.
10. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_pslist/apsh_pslist_sample.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_pslist/apsh_pslist_main.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_pslist/meson.build`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_common.c`; `/opt/mellanox/doca/samples/doca_apsh/apsh_common.h`

5.4.11.6.3.4 Apsh Threads Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of threads of a specific process.
The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device via given VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of system processes using Apsh API and searching for a specific process with the given PID.
8. Getting the list of process threads using `doca_apsh_threads_get` Apsh API call.
9. Querying the threads for up to 3 selected fields using `doca_apsh_thread_info_get` Apsh API call.
10. Printing thread attributes to the terminal.
11. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_threads_get/apsh_threads_get_sample.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_threads_get/apsh_threads_get_main.c`

- `/opt/mellanox/doca/samples/doca_apsh/apsh_common.c`; `/opt/mellanox/doca/samples/doca_apsh/apsh_common.h`

5.4.11.6.3.5 Apsh Vads Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of virtual address descriptors (VADs) of a specific process.
The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and start the Apsh context.
4. Opening DOCA remote PCIe device via given VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of system processes using Apsh API and searching for a specific process with the given PID.
8. Getting the list of process VADs using `doca_apsh_vads_get` Apsh API call.

9. Querying the VADs for 3 selected fields using `doca_apsh_vad_info_get` Apsh API call.
10. Printing the attributes of up to 5 VADs to the terminal.
11. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_vads_get/apsh_vads_get_sample.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_vads_get/apsh_vads_get_main.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_vads_get/meson.build`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_common.c`; `/opt/mellanox/doca/samples/doca_apsh/apsh_common.h`

5.4.11.6.3.6 Apsh Envars Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of environment variables of a specific process.

> ⚠ This sample works only on target systems with Windows OS.

The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device via given VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of system processes using Apsh API and searching for a specific process with the given PID.
8. Getting the list of process envars using `doca_apsh_envars_get` Apsh API call.
9. Querying the envars for 2 selected fields using `doca_apsh_envar_info_get` Apsh API call.
10. Printing the envars attributes to the terminal.
11. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_envars_get/apsh_envars_get_sample.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_envars_get/apsh_envars_get_main.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_envars_get/meson.build`

- `/opt/mellanox/doca/samples/doca_apsh/apsh_common.c`; `/opt/mellanox/doca/samples/doca_apsh/apsh_common.h`

5.4.11.6.3.7 Apsh Privileges Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of privileges of a specific process.

> ⚠ This sample works only on target systems with Windows OS.

The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device via given VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of system processes using Apsh API and searching for a specific process with the given PID.
8. Getting the list of process privileges using the `doca_apsh_privileges_get` Apsh API call.
9. Querying the privileges for 5 selected fields using the `doca_apsh_privilege_info_get` Apsh API call.
10. Printing the privileges attributes to the terminal.
11. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_privileges_get/apsh_privileges_get_sample.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_privileges_get/apsh_privileges_get_main.c`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_privileges_get/meson.build`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_common.c`; `/opt/mellanox/doca/samples/doca_apsh/apsh_common.h`

5.4.11.6.3.8 Apsh Containers Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of running containers on a monitored system, as well as getting a list of processes for each container.

> ⚠ This sample works only on target systems with Linux OS.

The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device using specific VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of containers running on the system using `doca_apsh_containers_get` Apsh API call.
8. Querying the containers for container ID attribute using `doca_apsh_container_info_get` Apsh API call.
9. Getting list of processes for each container using `doca_apsh_container_processes_get` Apsh API call.
10. Printing the attributes of up to 5 processes to the terminal.
11. Cleaning up.

5.4.11.6.3.9 Apsh Netscan Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of open network connections on a monitored system.

> ⚠ This sample works only on target systems with Linux OS and specific Windows OS builds.

The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device using specific VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of open connections on the system using `doca_apsh_netscan_get` Apsh API call.

8. Querying the connections for some of the connection attributes using `doca_apsh_netscan_info_get` Apsh API call.
9. Printing the attributes of all connection to the terminal.
10. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_netscan_get/apsh_netscan_get_sample.c`

- `/opt/mellanox/doca/samples/doca_apsh/apsh_netscan_get/meson.build`
- `/opt/mellanox/doca/samples/doca_apsh/apsh_common.c`; `/opt/mellanox/doca/samples/doca_apsh/apsh_common.h`

5.4.11.6.3.10 Apsh Process Netscan Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of open network connections of a specific process.

> ⚠ This sample works only on target systems with Linux OS and specific Windows OS builds.

The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device via given VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of system processes using Apsh API and searching for a specific process with the given PID.
8. Getting the list of process connections using `doca_apsh_process_netscan_get` Apsh API call.
9. Querying the connections for some of the connection attributes using `doca_apsh_netscan_info_get` Apsh API call.
10. Printing connection attributes to the terminal.
11. Cleaning up.

References:

- `/opt/mellanox/doca/samples/doca_apsh/apsh_process_netscan_get/apsh_process_netscan_get_sample.c`

5.4.11.6.3.11 Apsh Interfaces Get

This sample illustrates how to properly initialize DOCA App Shield and use its API to get the list of interfaces in the system.

> ⚠ This sample works only on target systems with Linux OS.

The sample logic includes:

1. Opening DOCA device with DMA ability.
2. Creating DOCA Apsh context.
3. Setting and starting the Apsh context.
4. Opening DOCA remote PCIe device via given VUID.
5. Creating DOCA Apsh system handler.
6. Setting fields and starting Apsh system handler.
7. Getting the list of system interfaces using `doca_apsh_interfaces_get` Apsh API call.
8. Printing interfaces attributes to the terminal.
9. Cleaning up.

5.4.12 DOCA Compress

This guide provides instructions on how to use the DOCA Compress API.

5.4.12.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

DOCA Compress library provides an API to compress and decompress data using hardware acceleration, supporting both host and NVIDIA® BlueField® DPU memory regions.

The library provides an API for executing compress operations on DOCA buffers, where these buffers reside in either the DPU memory or host memory.

Using DOCA Compress, compress and decompress memory operations can be easily executed in an optimized, hardware-accelerated manner.

This document is intended for software developers wishing to accelerate their application's compress memory operations.

5.4.12.2 Prerequisites

The DOCA Compress library follows the architecture of a DOCA Core Context. It is recommended to read the following sections before proceeding:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

5.4.12.3 Changes From Previous Releases

5.4.12.3.1 Changes in 2.9.0

N/A

5.4.12.4 Environment

DOCA Compress-based applications can run either on the host machine or on the BlueField DPU target.

Compress can only be run with a DPU configured with DPU mode as described in BlueField Modes of Operation.

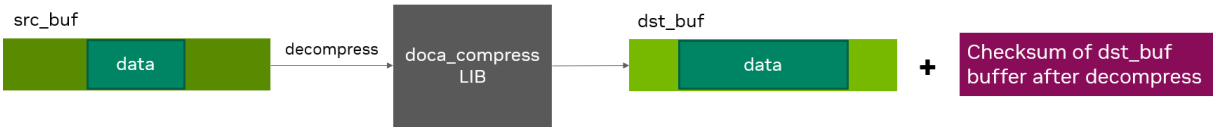
5.4.12.5 Architecture

DOCA Compress is a DOCA Context as defined by DOCA Core. See NVIDA DOCA Core Context for more information.

DOCA Compress leverages DOCA Core architecture to expose asynchronous tasks that are offloaded to hardware.

Compress operation:

Decompress operation:



5.4.12.5.1 Supported Compress/Decompress Algorithms

For BlueField-2 devices, this library supports:

- Compress operation using the deflate algorithm
- Decompress operation using the deflate algorithm

For BlueField-3 devices, this library supports:

- Decompress operation using the deflate algorithm
- Decompress operation using the LZ4 algorithm

5.4.12.5.2 Supported Checksum Methods

Depending on the task type, the following checksum methods are produced and may be retrieved using the relevant getter functions:

- Adler – produced by the deflate compress and decompress tasks
- CRC – produced by all tasks
- xxHash – produced by the LZ4 decompress tasks

Refer to "Tasks" section for more information.

5.4.12.5.3 Objects

5.4.12.5.3.1 Device and Device Representor

The library requires a DOCA device to operate, the device is used to access memory and perform the actual copy. See DOCA Core Device Discovery for information.

For same BlueField DPU, it does not matter which device is used (PF/VF/SF), as all these devices utilize the same hardware component. If there are multiple DPUs, it is possible to create a Compress instance per DPU, providing each instance with a device from a different DPU.

To access memory that is not local (from the host to the DPU or vice versa), then the DPU side of the application must pick a device with an appropriate representor.
See DOCA Core Device Representor Discovery.

The device must stay valid as long as the Compress instance is not destroyed.

5.4.12.5.3.2 Memory Buffers

All compress/decompress tasks require two DOCA buffers containing the destination and the source. Depending on the allocation pattern of the buffers, refer to the Inventory Types table.

Buffers must not be modified or read during the compress/decompress operation.

5.4.12.5.4 Source and Destination Location

DOCA Compress can process DOCA buffers that reside on the host, the DPU, or both.

5.4.12.5.4.1 Local Host

Source and destination buffers reside on the host and the compress library runs on the host.

5.4.12.5.4.2 Local DPU

Source and destination buffers reside on the DPU and the compress library runs on the DPU.

5.4.12.5.4.3 Remote

Source at Host, Destination at DPU

- The source resides on the host and is exported (DOCA mmap export) to the DPU
- The destination resides on the DPU

- The compress library runs on the DPU and compresses/decompresses the host source to the DPU destination

Source at DPU, Destination at Host

- The source resides on the DPU
- The destination resides on the host and is exported (DOCA mmap export) to the DPU
- Compress library runs on the DPU and compresses/decompresses the DPU source to the host destination

5.4.12.6 Configuration Phase

To start using the library, the user must go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context, to allow execution of tasks and retrieval of events.

5.4.12.6.1 Configurations

The context can be configured to match the use case of the application.

To find if a configuration is supported or what its min/max value is, refer to Device Support.

5.4.12.6.1.1 Mandatory Configurations

The following configurations must be set by the application before attempting to start the context:

- At least one task/event type must be configured. See configuration of Tasks.
- A device with appropriate support must be provided upon creation

5.4.12.6.2 Device Support

DOCA Compress requires a device to operate. To pick a device, see DOCA Core Device Discovery.

As device capabilities may change in the future (see DOCA Core Device Support), it is recommended to select your device using the following APIs:

5.4.12.6.2.1 Supported Tasks

- `doca_compress_cap_task_compress_deflate_is_supported`

- `doca_compress_cap_task_decompress_deflate_is_supported`
- `doca_compress_cap_task_decompress_lz4_stream_is_supported`
- `doca_compress_cap_task_decompress_lz4_block_is_supported`

5.4.12.6.2.2 Supported Buffer Size

- `doca_compress_cap_task_compress_deflate_get_max_buf_size`
- `doca_compress_cap_task_decompress_deflate_get_max_buf_size`
- `doca_compress_cap_task_decompress_lz4_stream_get_max_buf_size`
- `doca_compress_cap_task_decompress_lz4_block_get_max_buf_size`

5.4.12.6.3 Buffer Support

Tasks support buffers with the following features:

Buffer Type	Source Buffer	Destination Buffer
Linked List Buffer	Yes	No
Local mmap Buffer	Yes	Yes
mmap From PCI Export Buffer	Yes	Yes
mmap From RDMA Export Buffer	No	No

5.4.12.7 Execution Phase

This section describes execution on CPU or DPU using DOCA Core Progress Engine.

5.4.12.7.1 Tasks

5.4.12.7.1.1 Task Batching

DOCA Compress supports task batching mode, which is a task submit mode of work that allows aggregating multiple DOCA tasks of the same type and handling them as a single unit.

> For more information on task batching, refer to DOCA Core Task.

DOCA Compress supports only the `DOCA_TASK_SUBMIT_FLAG_NONE`, `DOCA_TASK_SUBMIT_FLAG_FLUSH` flag.

5.4.12.7.1.2 Compress Deflate Task

This task facilitates compressing memory, with the deflate algorithm, using buffers as described in section "Buffer Support".

> ⚠ DOCA compress returns only the payload. To create a compressed file, (e.g., gzip), the developer must add a gzip header/trailer.

Task Configuration

Description	API to set the configuration	API to query support
Enable the task	`doca_compress_task_compress_deflate_set_conf`	`doca_compress_cap_task_compress_deflate_is_supported`
Number of tasks	`doca_compress_task_compress_deflate_set_conf`	`doca_compress_get_max_num_tasks (max total num tasks)`
Maximal buffer size	–	`doca_compress_cap_task_compress_deflate_get_max_buf_size`
Maximum buffer list size	–	`doca_compress_cap_task_compress_deflate_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to the memory to be compressed	Only the data residing in the data segment is compressed
Destination buffer	Buffer pointing to where compressed memory will be stored	The data is compressed to the tail segment extending the data segment

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The source data is compressed to destination
- The destination buffer data segment is extended to include the compressed data
- Adler can be retrieved by calling `doca_compress_task_compress_deflate_get_adler_cs`
- CRC can be retrieved by calling `doca_compress_task_compress_deflate_get_crc_cs`

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the source and destination should not be read/written to
- Source and destination must not overlap
- Other limitations are described in DOCA Core Task

5.4.12.7.1.3 Decompress Deflate Task

This task facilitates decompressing memory, with the deflate algorithm, using buffers as described in section "Buffer Support".

> DOCA decompress expects the payload alone. To decompress a file (e.g. gzip), the developer must strip the header/trailer.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_compress_task_decompress_deflate_set_conf`	`doca_compress_cap_task_decompress_deflate_is_supported`
Number of tasks	`doca_compress_task_decompress_deflate_set_conf`	`doca_compress_get_max_num_tasks (max-total-num-tasks)`
Maximal buffer size	–	`doca_compress_cap_task_decompress_deflate_get_max_buf_size`
Maximum buffer list size	–	`doca_compress_cap_task_decompress_deflate_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
source buffer	Buffer pointing to the memory to be decompressed	Only the data residing in the data segment is decompressed
destination buffer	Buffer pointing to where decompressed memory will be stored	The data is decompressed to the tail segment extending the data segment

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The source data is decompressed to destination
- The destination buffer data segment is extended to include the decompressed data
- Adler can be retrieved by calling `doca_compress_task_decompress_deflate_get_adler_cs`
- CRC can be retrieved by calling `doca_compress_task_decompress_deflate_get_crc_cs`

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the source and destination should not be read/written to
- Source and destination must not overlap
- Other limitations are described in DOCA Core Task

5.4.12.7.1.4 Decompress LZ4 Tasks

These tasks facilitate decompressing memory with the LZ4 algorithm, using buffers as described in section "Buffer Support".

The main differences between the tasks is the input data format –

- The decompress LZ4 stream task expects a stream of one or more blocks, without the frame (i.e., the magic number, frame descriptor, and content checksum)
- The decompress LZ4 block task expects a single, compressed, data-only block (i.e., without block size or block checksum)

Decompress LZ4 Stream Task

This task facilitates decompressing memory with the LZ4 algorithm, using buffers as described in section "Buffer Support".

⚠ The decompress LZ4 stream task expects a stream of one or more blocks without the frame (i.e., the magic number, frame descriptor, and content checksum).

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_compress_task_decompress_lz4_stream_set_conf`	`doca_compress_cap_task_decompress_lz4_stream_is_supported`
Number of tasks	`doca_compress_task_decompress_lz4_stream_set_conf`	`doca_compress_get_max_num_tasks (max total num tasks)`
Maximal buffer size	–	`doca_compress_cap_task_decompress_lz4_stream_get_max_buf_size`
Maximum buffer list size	–	`doca_compress_cap_task_decompress_lz4_stream_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Has block checksum Flag	A flag to indicate whether or not the blocks in the stream have a checksum	1 if the task should expect blocks in the stream to have a checksum; 0 otherwise
Are blocks independent flag	A flag to indicate whether or not each block depends on previous blocks in the stream	1 the the task should expect blocks to be independent; 0 otherwise (dependent blocks)
Source buffer	Buffer pointing to the memory to be decompressed	Only the data residing in the data segment is decompressed
Destination buffer	Buffer pointing to where decompressed memory will be stored	The data is decompressed to the tail segment extending the data segment

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully:

- The source data is decompressed to destination
- The destination buffer data segment is extended to include the decompressed data
- CRC can be retrieved by calling `doca_compress_task_decompress_lz4_stream_get_crc_cs`

- xxHash can be retrieved by calling `doca_compress_task_decompress_lz4_stream_get_xxh_cs`

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the source and destination should not be read/written to
- Source and destination must not overlap
- Other limitations are described in DOCA Core Task

Decompress LZ4 Block Task

This task facilitates decompressing memory with the LZ4 algorithm, using buffers as described in section "Buffer Support".

> ⚠ The decompress LZ4 block task expects a single, compressed, data-only block (i.e., without block size or block checksum).

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_compress_task_decompress_lz4_block_set_conf`	`doca_compress_cap_task_decompress_lz4_block_is_supported`
Number of tasks	`doca_compress_task_decompress_lz4_block_set_conf`	`doca_compress_get_max_num_tasks (max total num tasks)`
Maximal buffer size	–	`doca_compress_cap_task_decompress_lz4_block_get_max_buf_size`
Maximum buffer list size	–	`doca_compress_cap_task_decompress_lz4_block_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to the memory to be decompressed	Only the data residing in the data segment will be decompressed
Destination buffer	Buffer pointing to where decompressed memory will be stored	The data is decompressed to the tail segment extending the data segment

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully:

- The source data is decompressed to destination
- The destination buffer data segment is extended to include the decompressed data
- CRC can be retrieved by calling `doca_compress_task_decompress_lz4_block_get_crc_cs`
- xxHash can be retrieved by calling `doca_compress_task_decompress_lz4_bloxk_get_xxh_cs`

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the source and destination should not be read/written to
- Source and destination must not overlap
- Other limitations are described in DOCA Core Task

5.4.12.7.2 Events

DOCA Compress exposes asynchronous events to notify about changes that happen unexpectedly according to DOCA Core architecture.

The only events DOCA Compress expose are common events (DOCA CTX state changed). See more info in DOCA Core Event.

5.4.12.8 State Machine

The DOCA Compress library follows the Context state machine described in DOCA Core Context State Machine.

This section describes how to move states and what is allowed in each state.

5.4.12.8.1 States

5.4.12.8.1.1 Idle

In this state, it is expected that application:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to Configurations
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all tasks have been freed
Stopping	Call progress until all tasks are completed and freed

5.4.12.8.1.2 Starting

This state cannot be reached.

5.4.12.8.1.3 Running

In this state, it is expected that application:

- Allocates and submit tasks
- Calls progress to complete tasks and/or receive events

Allowed operations:

- Allocate previously configured task
- Submit a task
- Call stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

5.4.12.8.1.4 Stopping

In this state, it is expected that application:

- Calls progress to complete all inflight tasks (tasks will complete with failure)
- Frees any completed tasks

Allowed operations:

- Call progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without freeing all tasks

5.4.12.9 Alternative Datapath Options

DOCA Compress only supports datapath on CPU, see Execution Phase.

5.4.12.10 DOCA Compress Samples

The following samples illustrate how to use the DOCA Compress API to compress and decompress files.

> ⚠ DOCA Compress handles payload only unless the `zc` flag is used (available only for deflate samples). In that case, a zlib header and trailer are added in compression and it is considered as part of the input when decompressing.

> ℹ All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.12.10.1 Running the Sample

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.

- DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.

2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_compress/<sample_name>
meson /tmp/build
ninja -C /tmp/build
```

> The binary `doca_<sample_name>` is created under `/tmp/build/`.

3. Sample (e.g., `doca_compress_deflate`) usage:
   - Common arguments

```
Usage: doca_<sample_name> [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI device address
  -f, --file                        Input file to compress/decompress
  -o, --output                      Output file
  -c, --output-checksum             Output checksum
```

   - Sample-specific arguments

Sample	Argument	Description
Compress/ Decompress Deflate	`-wf`, `-with-frame`	Write/read a file with a frame, compatible with default zlib settings
Decompress LZ4 Stream	`-bc`, `--has-block-checksum`	Flag to indicate if blocks have a checksum
	`-bi`, `--are-blocks-independent`	Flag to indicate if blocks are independent
	`-wf`, `-with-frame`	Read a file compatible with an LZ4 frame

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name> -h
```

5.4.12.10.2 Samples

These samples are also available on GitHub.

5.4.12.10.2.1 Compress/Decompress Deflate

This sample illustrates how to use DOCA Compress library to compress or decompress a file.

The sample logic includes:

1. Locating a DOCA device.
2. Initializing the required DOCA Core structures.
3. Populating DOCA memory map with two relevant buffers; one for the source data and one for the result.
4. Allocating elements in DOCA buffer inventory for each buffer.
5. Allocating and initializing a DOCA Compress deflate task or a DOCA Decompress deflate task.
6. Submitting the task.
7. Running the progress engine until the task is completed.
8. Writing the result into an output file, `out.txt`.
9. Destroying all DOCA Compress and DOCA Core structures.

References:

- `/opt/mellanox/doca/samples/doca_compress/compress_deflate/compress_deflate_sample.c`
- `/opt/mellanox/doca/samples/doca_compress/compress_deflate/compress_deflate_main.c`
- `/opt/mellanox/doca/samples/doca_compress/compress_deflate/meson.build`
- `/opt/mellanox/doca/samples/doca_compress/decompress_deflate/decompress_deflate_sample.c`
- `/opt/mellanox/doca/samples/doca_compress/decompress_deflate/decompress_deflate_main.c`
- `/opt/mellanox/doca/samples/doca_compress/decompress_deflate/meson.build`
- `/opt/mellanox/doca/samples/doca_compress/compress_common.h`
- `/opt/mellanox/doca/samples/doca_compress/compress_common.c`

5.4.12.10.2.2 Decompress LZ4 Stream

This sample illustrates how to use DOCA Compress library to decompress a file using the LZ4 stream decompress task.

The sample logic includes:

1. Locating a DOCA device.
2. Initializing the required DOCA Core structures.
3. Populating DOCA memory map with two relevant buffers; one for the source data and one for the result.
4. Allocating elements in DOCA buffer inventory for each buffer.
5. Allocating and initializing an DOCA Decompress LZ4 stream task.
6. Submitting the task.
7. Running the progress engine until the task is completed.
8. Writing the result into an output file, `out.txt`.
9. Destroying all DOCA Compress and DOCA Core structures.

References:

- `/opt/mellanox/doca/samples/doca_compress/decompress_lz4_stream/decompress_lz4_stream_sample.c`
- `/opt/mellanox/doca/samples/doca_compress/decompress_lz4_stream/decompress_lz4_stream_main.c`
- `/opt/mellanox/doca/samples/doca_compress/decompress_lz4_stream/meson.build`
- `/opt/mellanox/doca/samples/doca_compress/compress_common.h`
- `/opt/mellanox/doca/samples/doca_compress/compress_common.c`

5.4.12.10.3 Backward Compatibility

5.4.12.10.3.1 Decompress LZ4 Task

The decompress LZ4 task has been removed. To facilitates decompressing memory with the LZ4 algorithm, use the decompress LZ4 stream task or the decompress LZ4 block task instead.

5.4.13 DOCA SHA

This guide provides instructions on building and developing applications that calculate message digest using the SHA1, SHA2-256, or SHA2-512 algorithms.

5.4.13.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

The library provides an API for executing SHA operations on DOCA buffers, where the buffers reside in either local memory (i.e., within the same host) or host memory accessible by the NVIDIA® BlueField®-2 device (remote memory). Using DOCA SHA, complex cryptographic hash operations can be easily executed in an optimized, hardware-accelerated manner.

> ⚠ NVIDIA BlueField-3 does not support this library because it has no SHA acceleration engine.

This document is intended for software developers wishing to accelerate their applications' SHA calculations typically used in digital signature schemes or hash-based message authentication code calculations.

5.4.13.2 Prerequisites

This library follows the architecture of the DOCA Core context:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

5.4.13.3 Environment

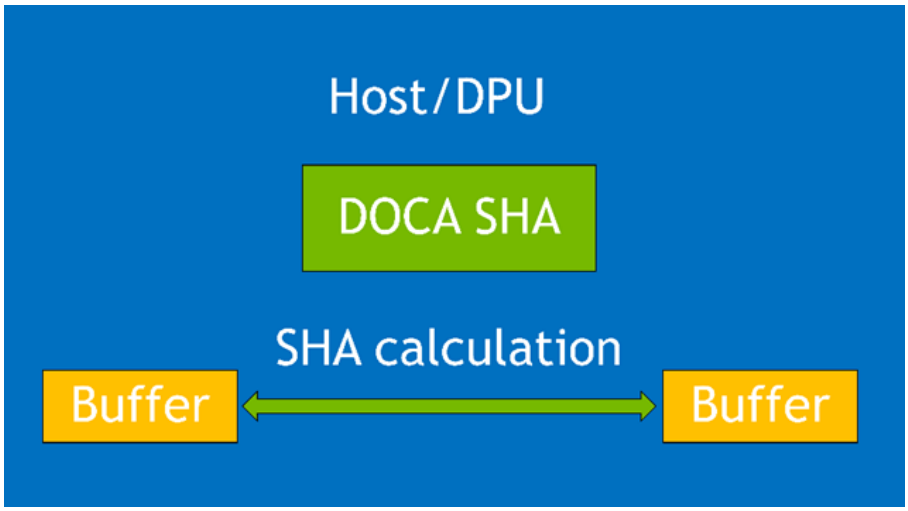
DOCA SHA-based applications can run either on the host machine or on the BlueField-2 DPU target. You must configure the DPU in DPU mode to run DOCA SHA calculations from the host to BlueField (or from BlueField to host).

5.4.13.4 Architecture

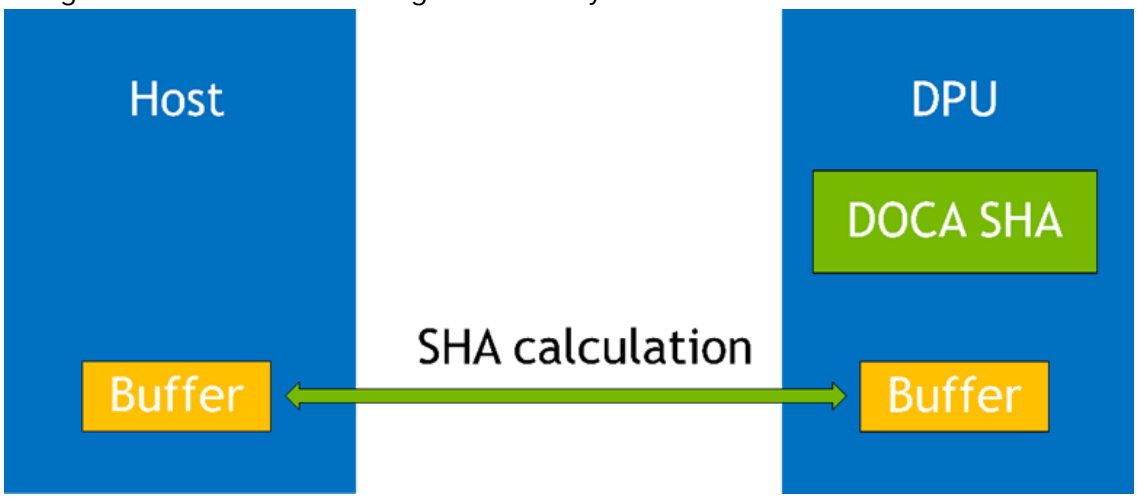
DOCA SHA is a DOCA Core Context. This library leverages the DOCA Core architecture to expose asynchronous tasks or events offloaded to hardware.

SHA can be used to calculate message digest as illustrated in the following diagrams:

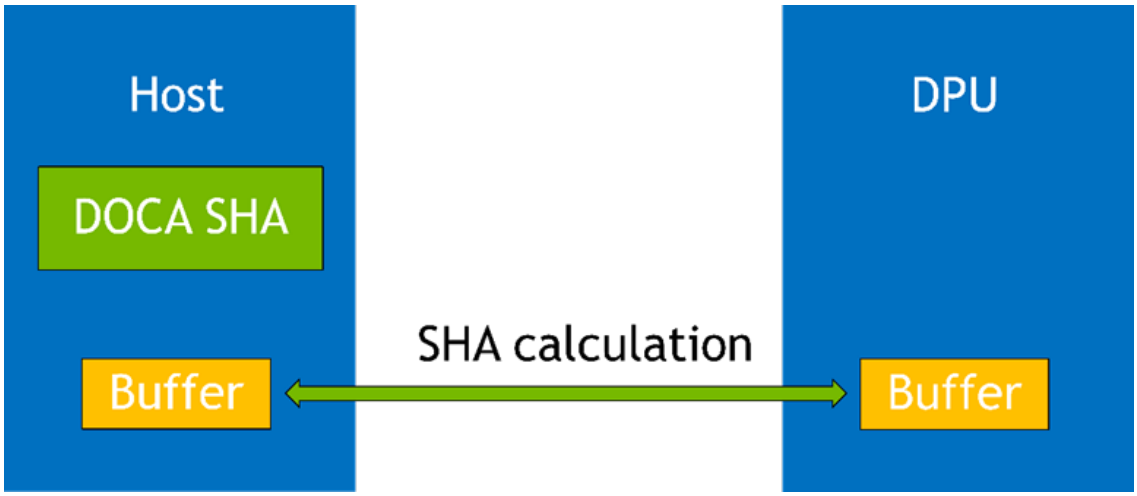
- SHA from local memory to local memory:



- Using the DPU to do SHA using the memory between the host and the DPU:



- Using the host to do SHA calculation using memory between the host and the DPU:



5.4.13.4.1 Objects

5.4.13.4.1.1 Device and Representor

The library requires a DOCA device to operate. The device is used to access memory and perform the actual SHA calculation. See DOCA Core Device Discovery.

For the same BlueField DPU, it does not matter which device is used (i.e., PF/VF/SF) as these devices utilize the same hardware component. If there are multiple DPUs, then it is possible to create a SHA instance per DPU, providing each instance with a device from a different DPU.

To access non-local memory (i.e., from the host to DPU or vice versa), the DPU side of the application must choose a device with an appropriate representor (see DOCA Core Device Representor Discovery). The device must stay valid for as long as the SHA instance is not destroyed.

5.4.13.4.1.2 Memory Buffers

The SHA task requires at least two DOCA buffers containing the destination and the source.

The destination is always a single `doca_buf`. The source can be a single `doca_buf` or a `linked_list` of `doca_buf`. All destination and source `doca_buf`s can be allocated from `doca_buf_inventory`.

> For the usage of `doca_buf_inventory`, please refer to the DOCA Core Inventory Types table.

Buffers must not be modified or read during the SHA operation. For information on what kind of memory is supported, refer to the table in section "Buffer Support".

5.4.13.5 Configuration Phase

To start using the library, users must go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context to allow the execution of tasks and retrieval of events.

5.4.13.5.1 Configurations

The context can be configured to match the application use case.

To find if a configuration is supported or its min/max value, refer to Device Support.

5.4.13.5.1.1 Mandatory Configurations

These configurations must be set by the application before attempting to start the context:

- You must configure at least one task/event type. See configuration of tasks and/or events in Tasks and Events respectively for information.
- A device with appropriate support must be provided upon creation.

5.4.13.5.2 Device Support

DOCA SHA requires a device to operate. For information on choosing a device, see DOCA Core Device Discovery.

As device capabilities may change in the future (see DOCA Core Device Support), NVIDIA recommends selecting your device using the following methods:

- `doca_sha_cap_task_hash_get_supported`
- `doca_sha_cap_task_partial_hash_get_supported`

Some devices allow for different capabilities, for example:

- The maximum number of tasks
- The maximum source buffer size
- The minimum destination buffer size
- The maximum supported number of elements in DOCA linked-list buffer
- Check whether SHA1, SHA2-256 or SHA2-512 is supported

5.4.13.5.3 Buffer Support

Tasks support buffers with the following features:

Buffer Type	Source Buffer	Destination Buffer
Local mmap buffer	Yes	Yes
Mmap from PCIe export buffer	Yes	Yes
Mmap from RDMA export buffer	No	No
Linked list buffer	Yes	No

5.4.13.6 Execution Phase

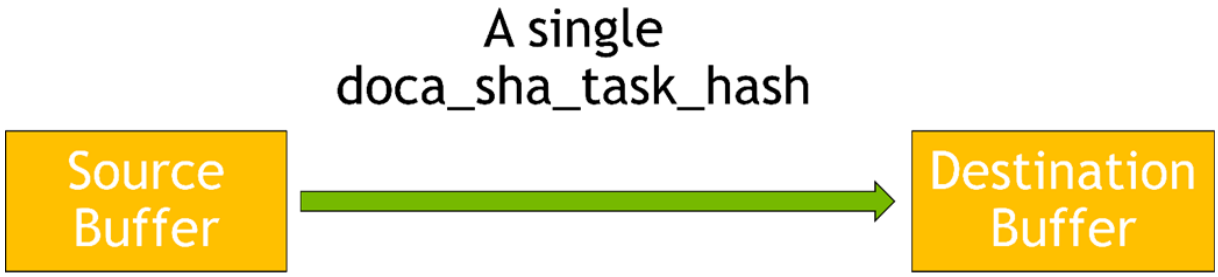
This section describes execution on the CPU using DOCA Core Progress Engine.

5.4.13.6.1 Tasks

DOCA SHA exposes asynchronous tasks that leverage DPU hardware according to DOCA Core architecture.

5.4.13.6.1.1 SHA Task

The SHA task `doca_sha_task_hash` allows one-shot SHA calculation using buffers as described in Buffer Support. One-shot means that the source buffer is used as a whole input. Therefore, the SHA operation is completed after this task completion event arrives.



Task Configuration

Description	API to Set Configuration	API to Query Support
Enable the task	`doca_sha_task_hash_set_conf`	`doca_sha_cap_task_hash_get_supported`
Number of tasks	`doca_sha_task_hash_set_conf`	`doca_sha_cap_get_max_num_tasks`
Maximal source buffer size	–	`doca_sha_cap_get_max_src_buf_size`
Maximum source buffer list size	–	`doca_sha_cap_get_max_list_buf_num_elem`
Minimum destination buffer size	–	`doca_sha_cap_get_min_dst_buf_size`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to the memory to be used for SHA calculation	Only the data residing in the data segment is to be used
Destination buffer	Buffer pointing to the memory used for writing the SHA calculation result	The SHA result is appended to the tail segment
SHA algorithm type	SHA algorithm to be used in SHA calculation	Must be one of `DOCA_SHA_ALGORITHM_SHA1`, `DOCA_SHA_ALGORITHM_SHA256`, `DOCA_SHA_ALGORITHM_SHA512`

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The SHA calculation of data from the source buffer is successfully completed and the result is written to the destination buffer
- The destination buffer data segment is extended to include the SHA result data

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

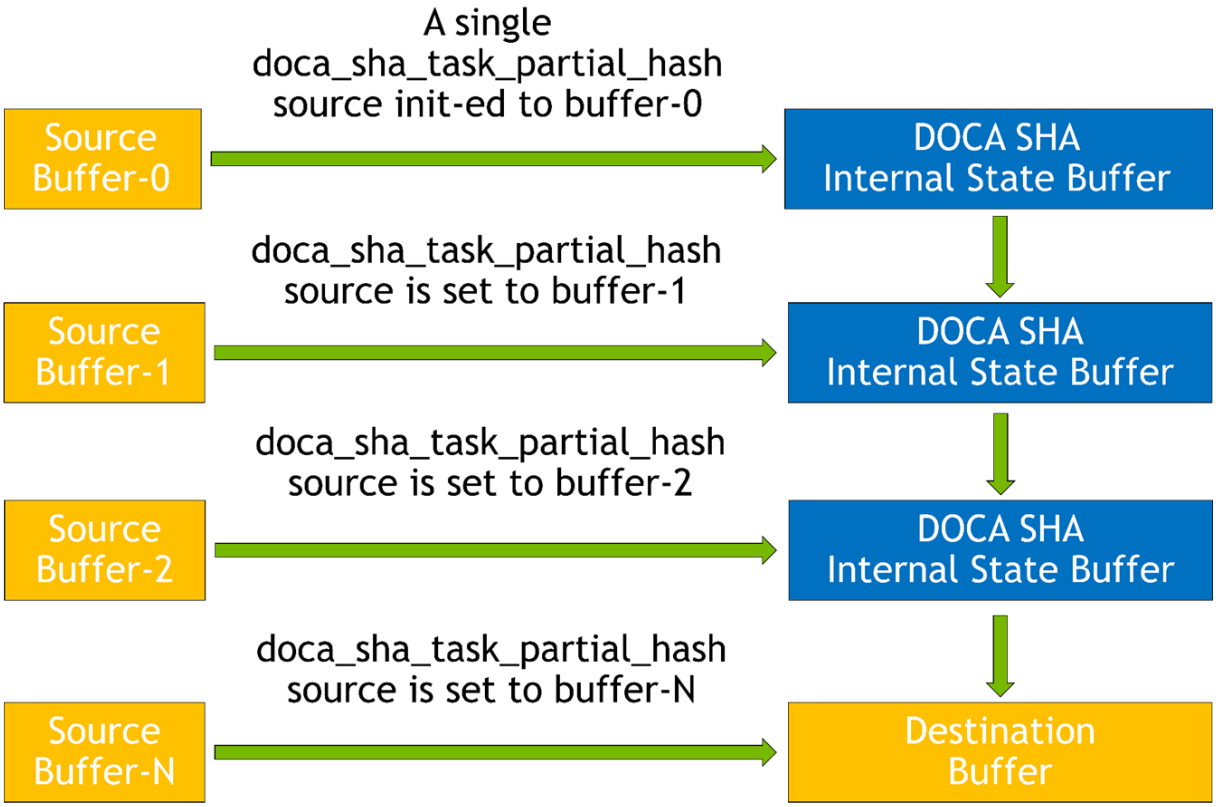
Task Limitations

- The operation is not atomic
- Once the task is submitted, the source and destination should not be read/written to
- Other limitations are described in DOCA Core Task

5.4.13.6.1.2 Partial-SHA Task

The partial-SHA task `doca_sha_task_partial_hash` allows stateful SHA calculation for a collection of messages using buffers.

Stateful means that the input data is composed of many segments (may be spatial or timely non-consecutive), therefore, its SHA calculation requires more than one one-shot SHA operation to finish. During any stateful operation, other independent SHA tasks can also be executed.



Task Configuration

Description	API to Set Configuration	API to Query Support
Enable the task	`doca_sha_task_partial_hash_set_conf`	`doca_sha_cap_task_partial_hash_get_supported`
Number of tasks	`doca_sha_task_partial_hash_set_conf`	`doca_sha_cap_get_max_num_tasks`
Maximal source buffer size	–	`doca_sha_cap_get_max_src_buf_size`
Maximum source buffer list size	–	`doca_sha_cap_get_max_list_buf_num_elem`
Minimum destination buffer size	–	`doca_sha_cap_get_min_dst_buf_size`
SHA block size		`doca_sha_cap_get_partial_hash_block_size`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to the memory to be used for SHA calculation	Only the data residing in the data segment is to be used. And the data length for the non-last data segment must be multiple of the SHA block size queried by `doca_sha_cap_get_partial_hash_block_size`
Destination buffer	Buffer pointing to the memory is used for writing the SHA calculation result	The SHA result is appended to the tail segment. During the whole calculation process, this buffer cannot be modified.
SHA algorithm type	SHA algorithm to be used in SHA calculation	Must be one of `DOCA_SHA_ALGORITHM_SHA1`, `DOCA_SHA_ALGORITHM_SHA256`, `DOCA_SHA_ALGORITHM_SHA512`
Whether the current source buffer is the last segment	Indicate whether the current source Buffer is the last segment data to be used for partial-SHA calculation	Use `doca_sha_task_partial_hash_set_is_final_buf` to set this property
Set source buffer	Use to set the subsequent source segment buffer after the initial `doca_sha_task_partial_hash` task is allocated	`doca_sha_task_partial_hash_set_src`

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The SHA calculation of data from the source buffer is successfully completed and the result is written to the destination buffer
- The destination buffer data segment is extended to include the SHA result data

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects is not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task is submitted, the source and destination should not be read/written to
- Other limitations are described in DOCA Core Task

5.4.13.6.2 Events

DOCA SHA exposes asynchronous events to notify about changes that happen unexpectedly according to the DOCA Core architecture.

The only events SHA exposes are common events as described in DOCA Core Event.

5.4.13.7 State Machine

The DOCA SHA library follows the context state machine as described in DOCA Core Context State Machine.

The following section describes moving states and what is allowed in each state.

5.4.13.7.1 Idle

In this state, it is expected that the application either:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all tasks have been freed
Stopping	Call progress until all tasks are completed and freed

5.4.13.7.2 Starting

This state cannot be reached.

5.4.13.7.3 Running

In this state, it is expected that the application:

- Allocates and submits tasks
- Calls progress to complete tasks and/or receive events

Allowed operations:

- Allocating previously configured task
- Submitting a task
- Calling stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

5.4.13.7.4 Stopping

In this state, it is expected that the application:

- Calls progress to complete all inflight tasks (tasks complete with failure)
- Frees any completed tasks

Allowed operations:

- Calling progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without freeing all tasks

5.4.13.8 Alternative Datapath Options

DOCA SHA only supports datapath on the CPU. See Execution Phase for details.

5.4.13.9 DOCA SHA Samples

This section describes DOCA SHA samples based on the DOCA SHA library. The samples in this section illustrate how to use the DOCA SHA API to do the following:

- Calculate SHA of contents of a buffer, and write the result to another buffer
- Segment the the contents of a buffer, and do partial-SHA calculation of this collection of segments, then write the result to another buffer

The DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.13.9.1 Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_sha/<sample_name>
meson/tmp/build
ninja -C/tmp/build
```

> The binary `doca_<sample_name>` is created under `/tmp/build/`.

3. The following sample displays `doca_sha_create` usage:

```
Usage: doca_sha_create [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                      Print a help synopsis
  -v, --version                   Print program version information
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>               Parse command line flags from an input json file

Program Flags:
  -d, --data                      user data
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name>-h
```

5.4.13.9.2 Samples

> These samples are also available on GitHub.

5.4.13.9.2.1 SHA Create

This sample illustrates how to perform an SHA calculation with DOCA SHA.

The sample logic includes:

1. Locating DOCA device.
2. Initializing required DOCA Core structures.
3. Setting the `task_pool` configuration for `doca_sha_task_hash`.

4. Populating DOCA memory map with two relevant buffers.
5. Allocating element in DOCA buffer inventory for each buffer.
6. Allocating and initializing a `doca_sha_task_hash`.
7. Submitting the task.
8. Retrieving task result once it is done.

Reference:

- `/opt/mellanox/doca/samples/doca_sha/sha_create/sha_create_sample.c`
- `/opt/mellanox/doca/samples/doca_sha/sha_create/sha_create_main.c`
- `/opt/mellanox/doca/samples/doca_sha/sha_create/meson.build`

5.4.13.9.2.2 SHA-Partial Create

This sample illustrates how to perform a partial-SHA calculation for a collection of data segments with DOCA SHA.

The sample logic includes:

1. Locating DOCA device.
2. Initializing the required DOCA Core structures.
3. Setting the `task_pool` configuration for `doca_sha_task_partial_hash`.
4. Chopping the source data into a collection of data segments according to the selected SHA algorithm's block size
5. Populating DOCA memory map with needed buffers for all source data segments and destination buffer.
6. Allocating element in DOCA buffer inventory for the first source buffer and destination buffer.
7. Allocating and initializing a `doca_sha_task_partial_hash` with the first source buffer and the destination buffer.
8. Iteratively repeating the following sub-steps until all data segments are consumed:
    a. Submitting the `doca_sha_task_partial_hash`.
    b. Waiting for the submitted task to finish.
    c. Allocating a `doca_buf` for the next source segment and use `doca_sha_task_partial_hash_set_src` to set it as source buffer of the above allocated task.
    d. If it is the final segment, use `doca_sha_task_partial_hash_set_is_final_buf` to mark it in the allocate task.
9. Retrieving the result of the final iteration in the destination buffer as the full partial-SHA calculation result.
10. Destroying all SHA and DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_sha/sha_partial_create/sha_partial_create_sample.c`
- `/opt/mellanox/doca/samples/doca_sha/sha_partial_create/sha_partial_create_main.c`
- `/opt/mellanox/doca/samples/doca_sha/sha_partial_create/meson.build`

5.4.14 DOCA Erasure Coding

This guide provides instructions on how to use the DOCA Erasure Coding API.

5.4.14.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

The DOCA Erasure Coding (known also as forward error correction or FEC) library provides an API to encode and decode data using hardware acceleration, supporting both host and NVIDIA® BlueField®-3 (and higher) DPU memory regions.

DOCA Erasure Coding recovers lost data fragments by creating generic redundancy fragments (backup). Each redundancy block that the library creates can help recover any block in the original data should a total loss of fragment occur. This increases data redundancy and reduces data overhead.

The library provides an API for executing erasure coding (EC) operations on DOCA buffers residing in either the DPU or host memory.

This document is intended for software developers wishing to accelerate their application's EC memory operations.

5.4.14.1.1 Glossary

The following terms aid in the understanding of the information on this page:

Term	Definition
Data	Original data, original blocks, blocks of original data to be protected/preserved
Coding matrix	Coefficients, the matrix used to generate the redundancy blocks and recovery
Redundancy blocks	Codes; encoded data; the extra blocks that help recover data loss
Encoding	The process of creating the redundancy blocks. Encoded data is referred to as the original blocks or redundancy blocks.

Term	Definition
Decoding	The process of recovering the data. Decoded data is referred to as the original blocks alone.

5.4.14.2 Prerequisites

DOCA Erasure Coding library follows the architecture of a DOCA Core Context, it is recommended read the following sections before:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

5.4.14.3 Changes From Previous Releases

5.4.14.3.1 Changes in 2.10.0

N/A

5.4.14.4 Environment

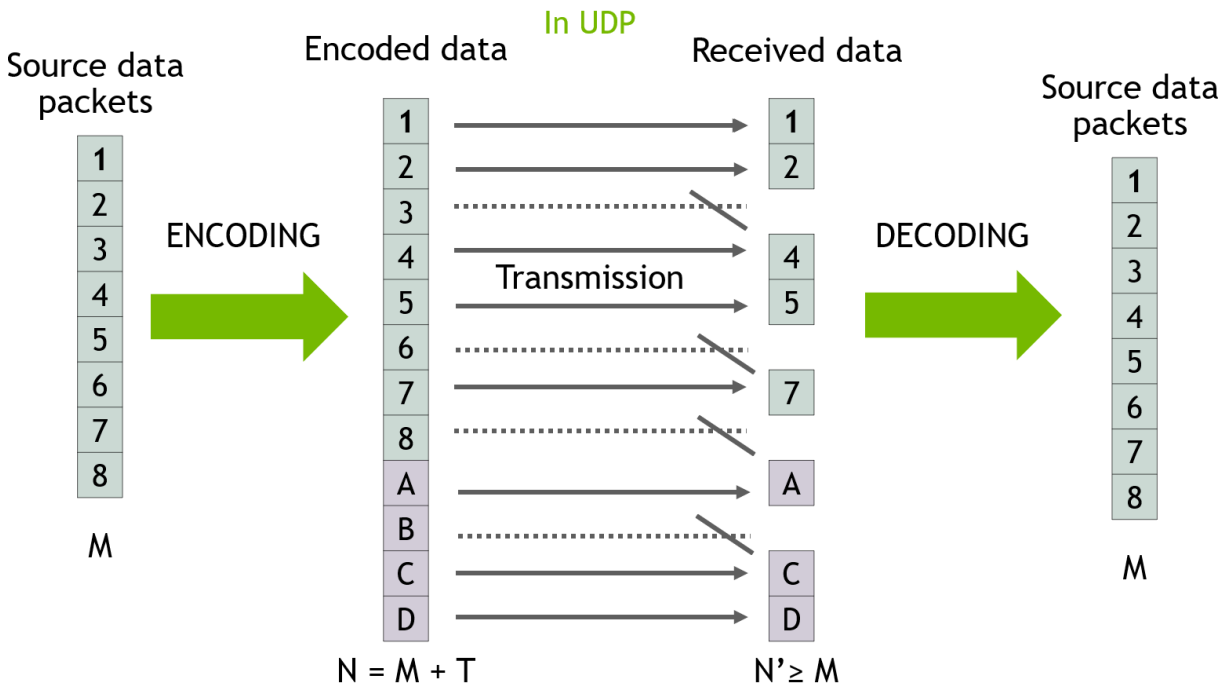
DOCA Erasure Coding-based applications can run either on the host machine or on the BlueField target (NVIDIA® BlueField®-3 and above).

Erasure Coding can be run with BlueField configured in either NIC or DPU mode (as described in BlueField Modes of Operation).

5.4.14.5 Architecture

DOCA Erasure Coding is a DOCA Context as defined by DOCA Core. This library leverages the DOCA Core architecture to expose asynchronous tasks/events that are offloaded to hardware.

The following diagram presents a high-level view of the EC transmission flow:

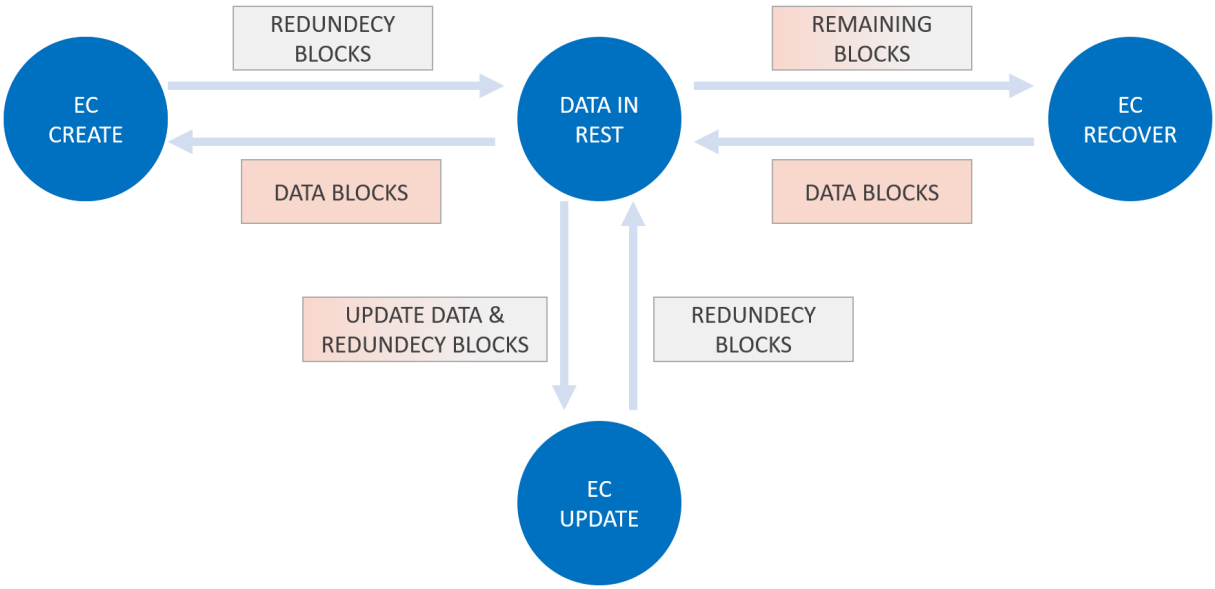


1. M packets are sent from the source (8 in this case).
2. Before the source send them, the source encode the data by adding to it T redundancy packets (4 in this case).
3. The packets are transmitted to the destination in UDP protocol. Some packets are lost and N' packets are received (in this case 4 packets are lost and 8 are received).
4. The destination decodes the data using all the packets available (both original data in green and redundancy data in red) and gets back the M original data packets.

5.4.14.5.1 Flows

Regular EC flow consists of the following elements:

1. Creating redundancy blocks from data (EC create).
2. Updating redundancy blocks from updated data (EC update).
3. Recovering data blocks from redundancy blocks (EC recover).



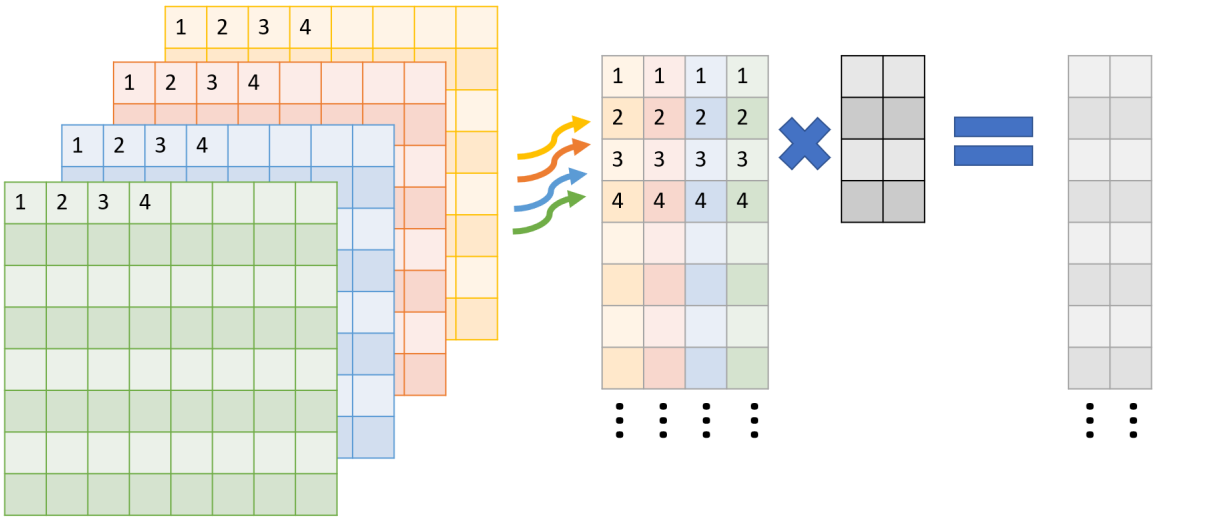
The following sections examine an M:K (where M is the original data and K is redundancy) EC.

5.4.14.5.2 Create Redundancy Blocks

The user must perform the following:

1. Input M data blocks via `doca_buf` (filled with data, each block size B).
2. Output K empty blocks via `doca_buf` (each block size B).
3. Use DOCA Erasure Coding to create a coding matrix of M by K via `doca_buf`.
4. Use DOCA Erasure Coding Create task to get the K output redundancy blocks.

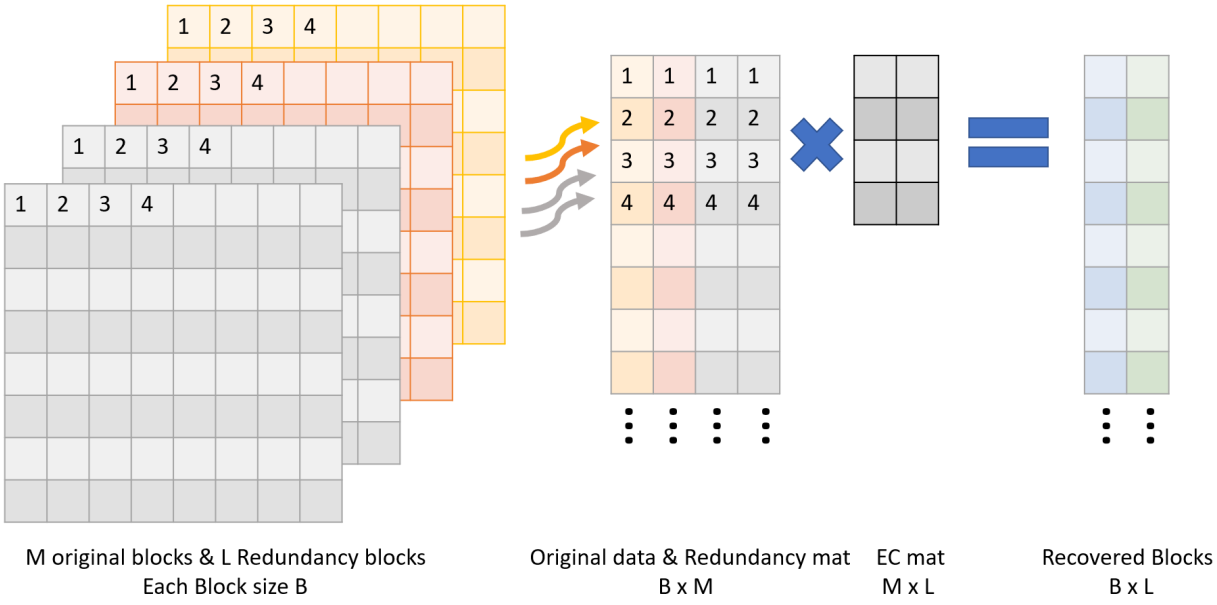
> ⚠ This step can be repeated in a stream use case, as the DPU would not be the recovery or update point.



5.4.14.5.3 Recover Block

The user must perform the following:

1. Input M-L original blocks via `doca_buf` (blocks that were not impaired).
2. Input L≤K (any) redundancy blocks via `doca_buf` (redundancy blocks originating from create/update tasks).
3. Input bitmask or array, indicating which blocks to recover.
4. Output L empty blocks via `doca_buf` (same size of data block).
5. Use DOCA Erasure Coding to create a recover coding matrix of M by L via `doca_buf` (unique per bitmask).
6. Use DOCA Erasure Coding Recover task to get the L output recovered data blocks.



5.4.14.5.4 Objects

5.4.14.5.4.1 Device and Device Representor

The DOCA Erasure Coding library requires a DOCA device to operate. The device is used to access memory and perform the encoding and decoding operations. See DOCA Core Device Discovery.

For same Bluefield card, it does not matter which device is used (PF/VF/SF), as all these devices utilize the same HW component. If there are multiple DPUs, then it is possible to create an EC instance per DPU, providing each instance with a device from a different DPU. To access memory that is not local (from the host to the DPU and vice versa), the DPU side of the application must pick a device with an appropriate representor.
See DOCA Core Representor Device Discovery.

The device must stay valid until the EC instance is destroyed.

5.4.14.5.4.2 Memory Buffers

Executing any DOCA EC task requires two DOCA buffers, a source buffer and a destination buffer.

Depending on the allocation pattern of the buffers, refer to the Inventory Types table.

Buffers must not be modified or read during the execution of any task.

5.4.14.6 Configuration Phase

To start using the library, first, you need to go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context, to allow execution of tasks and retrieval of events.

5.4.14.6.1 Configurations

The context can be configured to match the application use case.

To find if a configuration is supported, or what the min/max value, please refer to Device Support.

5.4.14.6.1.1 Mandatory Configurations

These configurations are mandatory and must be set by the application before attempting to start the context:

- At least 1 task/event type needs to be configured. See configuration of Tasks.

- A device with appropriate support must be provided on creation.

5.4.14.6.2 Device Support

DOCA Erasure Coding needs a device to operate. For picking a device, see DOCA Core Device Discovery.

Erasure Coding can be used in BlueField-3 with some limitations (see architecture). Any device can be used PF/VF/SF.

As device capabilities may change in the future, it is recommended to choose your device using the following methods:

- `doca_ec_cap_task_galois_mul_is_supported`
- `doca_ec_cap_task_create_is_supported`
- `doca_ec_cap_task_update_is_supported`
- `doca_ec_cap_task_recover_is_supported`

Some devices can allow different capabilities as follows:

- The maximum buffer list length
- The maximum block size

> ⚠ Current BlueField-3 limitations:
>
> - Data block count range: 1-128
> - Redundancy block count: 1-32
> - Block size: 64B-128MB

5.4.14.6.3 Buffer Support

Tasks support buffers with the following features:

Buffer Type	Source Buffer	Destination Buffer
Linked list buffer	Depends on the device; check the `max_buf_list_len` capability	Depends on the device; check the `max_buf_list_len` capability
Local mmap buffer	Yes	Yes
Mmap from PCIe export buffer	Yes	Yes
Mmap from RDMA export buffer	No	No

5.4.14.7 Execution Phase

This section describes execution on CPU or DPU using the DOCA Core Progress Engine.

5.4.14.7.1 Matrix Generate

All tasks require a coding matrix.

5.4.14.7.1.1 Matrix Type

DOCA EC provides 2 matrix types which are elaborated on in the following subsections.

Cauchy

Cauchy encoding matrix is constructed so that $a_{ij} = \frac{1}{(x_i + y_j)}$.

Where:

- $0 \leq i <$ number of data blocks
- $0 \leq j <$ number of redundancy blocks
- $x_i = i$
- $y_j = j +$ number of data blocks

Vandermonde

Vandermonde encoding matrix is constructed so that $a_{ij} = (i+1)^j$.

Where:

- $0 \leq i <$ number of data blocks
- $0 \leq j <$ number of redundancy blocks

Vandermonde matrix does not guarantee that every submatrix is invertible (i.e., the decode task may fail in some settings).

5.4.14.7.1.2 Matrix Functionality

Create

An encoding matrix is necessary for executing the create task, to create redundancy blocks.

The matrices used for updates and recovery are based on an encoding matrix.

The following subsections describe the available options for creating matrices.

Generic

Generic creation, with the `doca_ec_matrix_create()` function, is used for simple setup using one of matrix types provided by the library.

Input:

Name	Description
Type	One of matrix types provided by the library
Data block count	The number of original data blocks
Redundancy block count	The number of redundancy blocks

Custom

Custom creation, with the `doca_ec_matrix_create_from_raw()` function, is used if the desired type of matrix is not provided by the library.

Input:

Name	Description	Notes
Data	The data of a coding matrix	The size of the data should be `data_block_count` * `rdnc_block_count`
Data block count	The number of original data blocks	–
Redundancy block count	The number of redundancy blocks	–

Update

This matrix is necessary for executing the update task, to update the redundancy blocks after a change in the data blocks.

The matrix is created using the `doca_ec_matrix_create_update()` function.

Input:

Name	Description	Notes
Coding matrix	A coding matrix created by `doca_ec_matrix_create()` or `doca_ec_matrix_create_from_raw()`	–
Update indices	An array specifying the indices of the updated data blocks	• The indices must be in ascending order • The indices should match the order of the data blocks in the matrix creation function
Number of updates	The number of updated blocks. The length of the update indices array.	–

Recover

This matrix is necessary for executing the recover task, to recover original data blocks.

The matrix is created using the `doca_ec_matrix_create_recover()` function.

Input:

Name	Description	Notes
Coding matrix	A coding matrix created by `doca_ec_matrix_create()` or `doca_ec_matrix_create_from_raw()`	–
Missing indices	An array specifying the indices of the missing data blocks	• The indices must be in ascending order • The indices should match the order of the data blocks in the matrix creation function
Number of missing	The number of updated blocks. The length of the update indices array.	–

5.4.14.7.2 Tasks

5.4.14.7.2.1 Task Batching

DOCA Erasure Coding supports task batching mode, which is a task submit mode of work that allows aggregating multiple DOCA tasks of the same type and handling them as a single unit.

> For more information on task batching, refer to DOCA Core Task.

DOCA Erasure Coding supports the flags `DOCA_TASK_SUBMIT_FLAG_NONE`, `DOCA_TASK_SUBMIT_FLAG_FLUSH` and `DOCA_TASK_SUBMIT_FLAG_OPTIMIZE_REPORTS`.

5.4.14.7.2.2 Galois Mul Task

This task executes Galois multiplication between the original blocks and the coding matrix.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_ec_task_galois_mul_set_conf`	`doca_ec_cap_task_galois_mul_is_supported`
Maximum block size	–	`doca_ec_cap_get_max_block_size`
Maximum buffer list length	–	`doca_ec_cap_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
coding matrix	A coding matrix as created by `doca_ec_matrix_create()` or `doca_ec_matrix_create_from_raw()`	–
source buffer	Source original data buffer, holding a sequence containing all original blocks (e.g., `block_1`, `block_2`, etc.); the order matters	• The data length of `src_buf` should be a multiplication of the block size • The data length should also be aligned to 64B and with a minimum size of 64B
destination buffer	A destination buffer for the multiplication outcome blocks. The sequence containing all multiplication outcome blocks (`dst_block_1`, `dst_block_2`, etc.) is written to it upon successful completion of the task.	• The data is written to the tail segment extending the data segment • The minimal available memory in `dst_buf` should be the number of redundancy blocks * the block size, aligned to 64B and, in any case, at least 64B.

Example for required buffer length

If a Galois multiplication task matrix is 10x4 (i.e., 10 original blocks, 4 multiplication outcome blocks), and the block size is 64KB:

- `src_buf` data length should be 10x64KB = 640KB
- The available memory for writing in `dst_buf` should be at least 4x64KB = 256KB

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The destination buffer holds a sequence containing all multiplication outcome blocks (e.g., `dst_block_1`, `dst_block_2`, etc.)
- The destination buffer data segment is extended to include the outcome blocks

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic

- Once the task has been submitted, the source and destination buffer should not be read from/written to
- Source and destination buffers must not overlap
- Other limitations are described in DOCA Core Task

5.4.14.7.2.3 Create Task

This task creates redundancy blocks for the given original data blocks using a given coding matrix.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_ec_task_create_set_conf`	`doca_ec_cap_task_create_is_supported`
Maximum block size	–	`doca_ec_cap_get_max_block_size`
Maximum buffer list length	–	`doca_ec_cap_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
coding matrix	A coding matrix created by `doca_ec_matrix_create()` or `doca_ec_matrix_create_from_raw()`	–
original data blocks	Source original data buffer, holding a sequence containing all original blocks (`block_1` , `block_2` , etc.); the order matters	• The data length of `original_data_blocks` should be a multiplication of the block size • The data length should also be aligned to 64B and with a minimum size of 64B
redundancy blocks	A destination buffer for the redundancy blocks. The sequence containing all redundancy blocks (`rdnc_block_1` , `rdnc_block_2` , etc.) is written to it upon successful completion of the task.	• The data will be written to the tail segment extending the data segment • The minimal available memory in `rdnc_blocks` should be the number of redundancy blocks * the block size, aligned to 64B and, in any case, at least 64B

Example for required buffer lengths

If a create task matrix is 10x4 (i.e., 10 original blocks, 4 redundancy blocks), and the block size is 64KB:

- `original_data_blocks` data length should be 10x64KB = 640KB

- The available memory for writing in `redundancy_blocks` should be at least 4x64KB = 256KB

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The destination buffer holds a sequence containing all redundancy blocks (`rdnc_block_1` , `rdnc_block_2` , etc.)
- The destination buffer data segment is extended to include the redundancy blocks

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task is submitted, the source and destination buffers should not be read from/written to
- Source and destination buffers must not overlap
- Other limitations are described in DOCA Core Task

5.4.14.7.2.4 Update Task

This task executes updates the redundancy blocks for the given original data blocks, using an update coding matrix.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_ec_task_update_set_conf`	`doca_ec_cap_task_update_is_supported`
Maximum block size	–	`doca_ec_cap_get_max_block_size`
Maximum buffer list length	–	`doca_ec_cap_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
update matrix	An update coding matrix created by `doca_ec_matrix_create_update()` or `doca_ec_matrix_create_from_raw()`	-
original updated and RDNC blocks	A source buffer with data, holding a sequence containing the original data block and its updated data block, for each block that was updated, followed by the old redundancy blocks (`old_data_block_i` , `updated_data_block_i` , `old_data_block_j` , `updated_data_block_j` , ..., `rdnc_block_1` , `rdnc_block_2` , etc.)	• The data length of `original_updated_and_rdnc_blocks` should be a multiplication of the block size • The data length should also be aligned to 64B and with a minimum size of 64B
updated RDNC blocks	A destination buffer for the updated redundancy blocks. The sequence containing the updated redundancy blocks (`rdnc_block_1` , `rdnc_block_2` , etc.) is written to it upon successful completion of the task	• The data is written to the tail segment extending the data segment • The minimal available memory in `updated_rdnc_blocks` should be the number of redundancy blocks * the block size, aligned to 64B and, in any case, at least 64B

Example for required buffer lengths

using an update task matrix, in which 3 data block were updated and there are 4 redundancy blocks, and the block size is 64KB:

- `original_updated_and_rdnc_blocks` data length should be (3+3+4=10)x64KB = 640KB
- The available memory for writing in `updated_rdnc_blocks` should be at least 4x64KB = 256KB

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The destination buffer holds a sequence containing the updated redundancy blocks (`rdnc_block_1` , `rdnc_block_2` , etc.)
- The destination buffer data segment is extended to include the updated redundancy blocks

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects is not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task has been submitted, the source and destination buffers should not be read from/written to
- Source and destination buffers must not overlap
- Other limitations described in DOCA Core Task

5.4.14.7.2.5 Recover Task

This task executes recovers data blocks for, using given available original data blocks and redundancy blocks and a given coding matrix.

Task Configuration

Description	API to Set the Configuration	API to Query Support
Enable the task	`doca_ec_task_recover_set_conf`	`doca_ec_cap_task_recover_is_supported`
Maximum block size	–	`doca_ec_cap_get_max_block_size`
Maximum buffer list length	–	`doca_ec_cap_get_max_buf_list_len`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
recover matrix	A coding matrix create by `doca_ec_matrix_create()` or `doca_ec_matrix_create_from_raw()`	–
available blocks	A source buffer with data, holding a sequence containing available data blocks and redundancy blocks (`data_block_a` , `data_block_b` , `data_block_c` , ..., `rdnc_block_x` , `rdnc_block_y` , etc.)	• The total number of blocks given should be equal to the number of original data blocks • The data length of `available_blocks` should be a multiplication of the block size • The data length should also be aligned to 64B and with a minimum size of 64B

Name	Description	Notes
recovered data blocks	A destination buffer for the recovered data blocks. The sequence containing the recovered data blocks (`data_block_i`, `data_block_j`, etc.) is written to it upon successful completion of the task	• The data is written to the tail segment extending the data segment • The minimal available memory in `recovered_data_blocks` should be the number of missing data blocks * the block size, aligned to 64B and, in any case, at least 64B.

Example for required buffer lengths

Using a recover task matrix, based on an original 10x4 coding matrix (i.e., 10 original blocks, 4 redundancy blocks), and a block size of 64KB:

- 10 available blocks should be given in total (e.g., 7 data blocks and 3 redundancy blocks)
- `available_blocks` data length should be 10x64KB = 640KB
- The available memory for writing in `recovered_data_blocks` should be at least 3x64KB = 192KB

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task is completed successfully the data is transformed to destination.

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task is submitted, the source and destination buffers should not be read from/written to
- Source and destination must not overlap
- The number of blocks that can be recovered is limited to the number of redundancy blocks created
- Other limitations are described in DOCA Core Task

5.4.14.8 DOCA Erasure Coding Samples

This section provides DOCA Erasure Coding sample implementation on top of the BlueField-3 DPU (and higher).

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.14.8.1 Sample Prerequisites

N/A

5.4.14.8.2 Running the Sample

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_erasure_coding/<sample_name>
meson /tmp/build
ninja -C /tmp/build
```

> The binary `doca_<sample_name>` is created under `/tmp/build/`.

3. Sample (e.g., `doca_erasure_coding_recover`) usage:

```
Usage: doca_erasure_coding_recover [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI device address - default: 03:00.0
  -i, --input                       Input file/folder to ec - default: self
  -o, --output                      Output file/folder to ec - default: /tmp
  -b, --both                        Do both (encode & decode) - default: false
  -x, --matrix                      Matrix - {cauchy, vandermonde} - default: cauchy
  -t, --data                        Data block count - default: 2
  -r, --rdnc                        Redundancy block count - default: 2
  -d, --delete-index                Indices of data blocks to delete; comma-separated (i.e., 0,3,4) -
default: 0
  -ns, --num-src-buf                Number of doca_buf for source buffer
  -nd, --num-dst-buf                Number of doca_buf for destination buffer
```

Current BlueField-3 limitations:

- Data block count range – 1-128
- Redundancy block count – 1-32
- Block size – 64B-128MB
- The command line option "--num-src-buf" and "--num-dst-buf" are used to show linked-list usage of doca-buf. The maximum supported number of elements is 64.

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name> -h
```

5.4.14.8.3 Samples

These samples are also available on GitHub.

5.4.14.8.3.1 Erasure Coding Recover

This sample illustrates how to use DOCA Erasure Coding (EC) library to encode and decode a file block (and entire file).

The sample logic includes 3 steps:

1. Encoding – create redundancy.
2. Deleting – simulating disaster.
3. Decoding – recovering data.

The encode logic includes:

1. Locating a DOCA device.
2. Initializing the required DOCA Core structures, such as the progress engine (PE), memory maps, and buffer inventory.
3. Reading source original data file and splitting it to a specified number of blocks, `<data block count>`, specified for the sample to the output directory.
4. Populating two DOCA memory maps with a memory range, one for the source data and one for the result.
5. Allocating buffers from DOCA buffer inventory for each memory range.
6. Creating an EC object.
7. Connecting the EC context to the PE.
8. Setting a state change callback function for the PE, with the following logic:
    - Printing a log with every state change

- Indicating that the user may stop progress the PE once it is back in idle state

9. Setting the configuration to the EC create task, including setting callback functions as follows:
    - Successful completion callback:
        i. Writing the resulting redundancy blocks to the output directory (count is specified by `<redundancy block count>`).
        ii. Freeing the task.
        iii. Saving the result of the task and the callback. If there was an error in step a., the relevant error value is saved.
        iv. Stopping the context.
    - Failed completion callback:
        i. Saving the result of the task and the callback.
        ii. Freeing the task.
        iii. Stopping the context.
10. Creating EC encoding matrix by the matrix type specified to the sample.
11. Allocating and submitting an EC create task.
12. Progressing the PE until the context returns to idle state, either as a result of a successful run in which all tasks have been successfully completed, or as a result of a fatal error.
13. Destroying all EC and DOCA Core structures.

The delete logic includes:

1. Deleting the block files specified with `<indices of data blocks to delete>`.

The decode logic includes:

1. Locating a DOCA device.
2. Initializing the required DOCA Core structures, such as the PE, memory maps, and buffer inventory.
3. Reading the output directory (source remaining data) and determining the block size and which blocks are missing (needing recovery).
4. Populating two DOCA memory maps with a memory range, one for the source data and one for the result.
5. Allocating buffers from DOCA buffer inventory for each memory range.
6. Creating an EC object.
7. Connecting the EC context to the PE.
8. Setting a state change callback function for the PE, with the following logic:
    - Printing a log with every state change
    - Indicating that the user may stop progress the PE once it is back in idle state
9. Setting the configuration to the EC recover task, including setting callback functions as following:
    - Successful completion callback:

i. Writing the resulting recovered blocks to the output directory.
ii. Writing the recovered file to the output path.
iii. Freeing the task.
iv. Saving the result of the task and the callback. If there was an error in step a., the relevant error value is saved.
v. Stopping the context.

- Failed completion callback:
  i. Saving the result of the task and the callback.
  ii. Freeing the task.
  iii. Stopping the context.

10. Creating EC encoding matrix by the matrix type specified to the sample.
11. Creating EC decoding matrix, with `doca_ec_matrix_create_recover()`, using the encoding matrix.
12. Allocating and submitting an EC recover task.
13. Progressing the PE until the context returns to idle state, either as a result of a successful run in which all tasks have been successfully completed, or as a result of a fatal error.
14. Destroying all DOCA EC and DOCA Core structures.

5.4.15 DOCA AES-GCM

This guide provides instructions on building and developing applications that require data encryption and decryption using the AES-GCM algorithm.

5.4.15.1 Introduction

The quality status of DOCA libraries is listed here.

The DOCA AES-GCM library is supported at alpha level and on NVIDIA BlueField-3 devices or higher.

The library provides an API for executing AES-GCM operations on DOCA buffers, where the buffers reside in either local memory (i.e., within the same host) or host memory accessible by the DPU (remote memory). Use DOCA AES-GCM to execute complex encrypt/decrypt operations in an optimized, hardware-accelerated manner.

5.4.15.2 Prerequisites

This library follows the architecture of a DOCA Core context, it is recommended to read the following sections before:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

5.4.15.3 Changes From Previous Releases

5.4.15.3.1 Changes in 2.9.0

N/A

5.4.15.4 Environment

DOCA AES-GCM-based applications can run either on the host machine or DPU target.

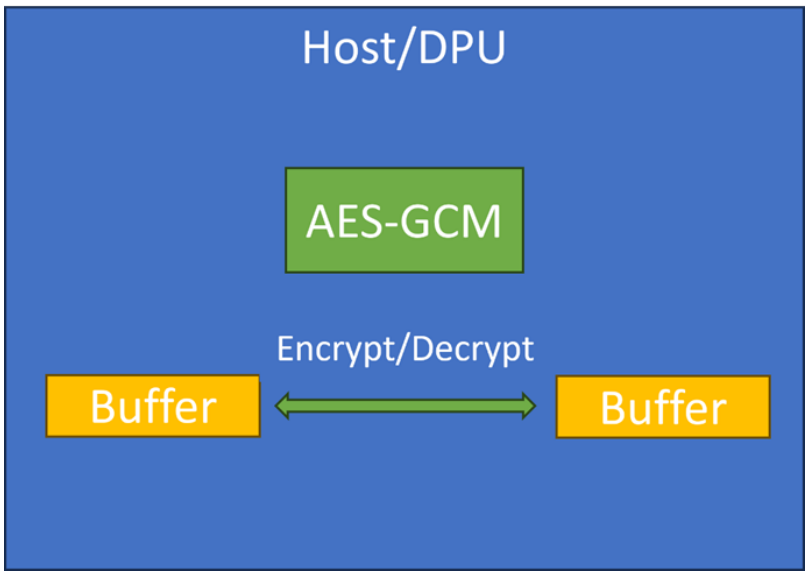
Encrypting/decrypting from the host to DPU and vice versa can only be run when the DPU is configured in DPU mode.

5.4.15.5 Architecture

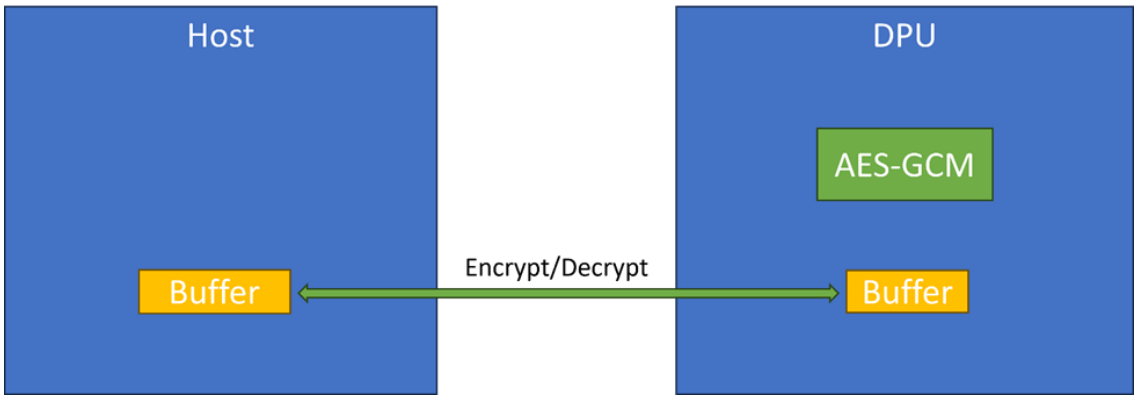
DOCA AES-GCM is a DOCA Core Context. This library leverages the DOCA Core architecture to expose asynchronous tasks/events that are offloaded to hardware.

AES-GCM can be used to encrypt/decrypt data as illustrated in the following diagrams:

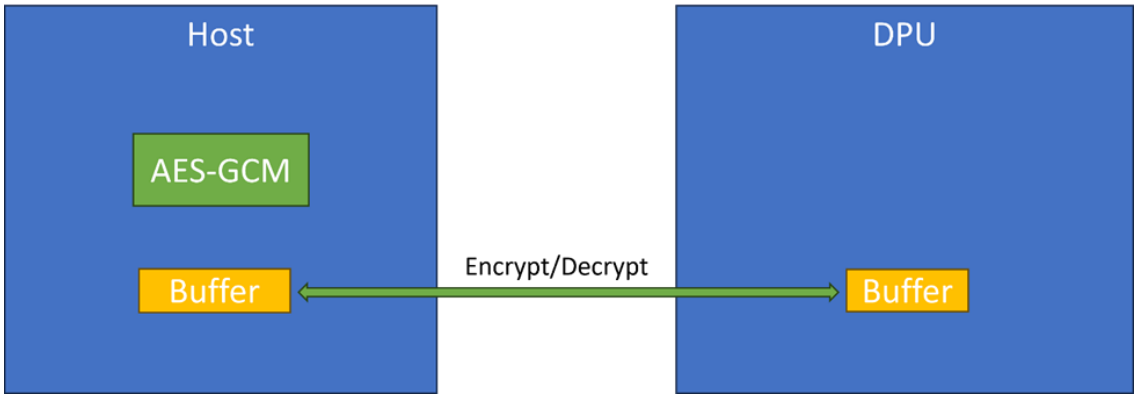
- Encrypt/decrypt from local memory to local memory:



- Using the DPU to copy memory between the host and the DPU:



- Using the host to copy memory between the host and the DPU:



5.4.15.5.1 Objects

5.4.15.5.1.1 Device and Representor

The library requires a DOCA device to operate. The device is used to access memory and perform the actual encrypt/decrypt. See DOCA Core Device Discovery.

For the same BlueField DPU, it does not matter which device is used (i.e., PF/VF/SF) as all these devices utilize the same hardware component. If there are multiple DPUs, then it is possible to create a AES-GCM instance per DPU, providing each instance with a device from a different DPU.

To access memory that is not local (i.e., from the host to DPU or vice versa), the DPU side of the application must pick a device with an appropriate representor (see DOCA Core Device Representor Discovery). The device must stay valid as long as AES-GCM instance is not destroyed.

5.4.15.5.1.2 Memory Buffers

The encrypt/decrypt task requires two DOCA buffers containing the destination and the source.

Depending on the allocation pattern of the buffers, consider the DOCA Core Inventory Types table.

To find what kind of memory is supported, refer to the buffer support table.

> ⚠ Buffers must not be modified or read during the encrypt/decrypt operation.

5.4.15.6 Configuration Phase

To start using the library users must go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context to allow execution of tasks and retrieval of events.

5.4.15.6.1 Configurations

The context can be configured to match the application use case.

To find if a configuration is supported or its min/max value, refer to Device Support.

5.4.15.6.1.1 Mandatory Configurations

These configurations must be set by the application before attempting to start the context:

- At least one task/event type must be configured. See configuration of Tasks and/or Events.
- A device with appropriate support must be provided upon creation

5.4.15.6.2 Device Support

DOCA AES-GCM requires a device to operate. For picking a device, see DOCA Core Device Discovery.

As device capabilities may change in the future (see DOCA Core Device Support) it is recommended to select your device using the following method:

- `doca_aes_gcm_cap_task_encrypt_is_supported`
- `doca_aes_gcm_cap_task_decrypt_is_supported`

Some devices can allow different capabilities as follows:

- The maximum number of tasks
- The maximum buffer size
- The maximum supported number of elements in DOCA linked-list buffer
- The maximum initialization vector length
- Check if authentication tag of size 96-bit is supported
- Check if authentication tag of size 128-bit is supported
- Check if a given AES-GCM key type is supported

5.4.15.6.3 Buffer Support

Tasks support buffers with the following features:

Buffer Type	Source Buffer	Destination Buffer
Local mmap buffer	Yes	Yes
Mmap from PCIe export buffer	Yes	Yes
Mmap from RDMA export buffer	No	No
Linked list buffer	Yes	Yes

5.4.15.7 Execution Phase

This section describes execution on the CPU using DOCA Core Progress Engine.

5.4.15.7.1 Tasks

DOCA AES-GCM exposes asynchronous tasks that leverage DPU hardware according to the DOCA Core architecture.

5.4.15.7.1.1 Encrypt Task

The encrypt task allows data encryption using buffers as described in Buffer Support.

Task Configuration

Description	API to Set Configuration	API to Query Support
Enable the task	`doca_aes_gcm_task_encrypt_set_conf`	`doca_aes_gcm_cap_task_encrypt_is_supported`
Number of tasks	`doca_aes_gcm_task_encrypt_set_conf`	`doca_aes_gcm_cap_get_max_num_tasks`
Maximal buffer size	–	`doca_aes_gcm_cap_task_encrypt_get_max_buf_size`
Maximum buffer list size	–	`doca_aes_gcm_cap_task_encrypt_get_max_list_buf_num_elem`
Maximum initialization vector length	–	`doca_aes_gcm_cap_task_encrypt_get_max_iv_length`
Enable authentication tag size	–	`doca_aes_gcm_cap_task_encrypt_is_tag_96_supported` `doca_aes_gcm_cap_task_encrypt_is_tag_128_supported`
Enable key type	–	`doca_aes_gcm_cap_task_encrypt_is_key_type_supported`

Task Input

Common input as described in DOCA Core Task

Name	Description	Notes
source buffer	Buffer pointing to the memory to be encrypted	Only the data residing in the data segment is encrypted
destination buffer	Buffer pointing to where memory is encrypted to	The encrypted data is appended to the tail segment
key	Key to encrypt the data	Created by the function `doca_aes_gcm_key_create` Users should use the same key to encrypt and decrypt the data
initialization vector (IV)	Initialization vector to be used by the AES-GCM algorithm	Users should use the same IV to encrypt and decrypt the data

Name	Description	Notes
initialization vector length	Initialization vector length that must be supplied for the AES-GCM algorithm	Represented in bytes, 0B-12B values are supported
authentication tag size	Authentication tag size to be supplied for the AES-GCM algorithm. The tag is automatically calculated and appended to the result buffer.	Represented in bytes, only 12B and 16B values are supported
additional authenticated data size	Additional authenticated data size to be supplied for the AES-GCM algorithm. This data, which should be present at the beginning of the source buffer, is will not encrypted but is authenticated.	Represented in bytes

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The data from the source buffer is encrypted and written to the destination buffer
- The destination buffer data segment is extended to include the encrypted data

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects are not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task is submitted, the source and destination should not be read/written to
- Other limitations are described in DOCA Core Task

5.4.15.7.1.2 Decrypt Task

The decrypt task allows data decryption. Using buffers as described in Buffer Support.

Task Configuration

Description	API to Set Configuration	API to Query Support
Enable the task	`doca_aes_gcm_task_decrypt_set_conf`	`doca_aes_gcm_cap_task_decrypt_is_supported`
Number of tasks	`doca_aes_gcm_task_decrypt_set_conf`	`doca_aes_gcm_cap_get_max_num_tasks`

Description	API to Set Configuration	API to Query Support
Maximal buffer size	–	`doca_aes_gcm_cap_task_decrypt_get_max_buf_size`
Maximum buffer list size	–	`doca_aes_gcm_cap_task_decrypt_get_max_list_buf_num_elem`
Maximum initialization vector length	–	`doca_aes_gcm_cap_task_decrypt_get_max_iv_length`
Enable authentication tag size	–	`doca_aes_gcm_cap_task_decrypt_is_tag_96_supported` `doca_aes_gcm_cap_task_decrypt_is_tag_128_supported`
Enable key type	–	`doca_aes_gcm_cap_task_decrypt_is_key_type_supported`

Task Input

Common input as described in DOCA Core Task.

Name	Description	Notes
Source buffer	Buffer pointing to the memory to be decrypted	Only the data residing in the data segment is decrypted
Destination buffer	Buffer pointing to where memory is decrypted to	The decrypted data is appended to the tail segment extending the data segment
Key	Key to decrypt the data	Created by the function `doca_aes_gcm_key_create` The user should use the same key to encrypt and decrypt the data
Initialization vector (IV)	Initialization vector to be used by the AES-GCM algorithm	The user should use the same IV to encrypt and decrypt the data
Initialization vector length	Initialization vector length that must be supplied for the AES-GCM algorithm	Represented in bytes, 0B-12B values are supported
Authentication tag size	Authentication tag size to be supplied for the AES-GCM algorithm. The tag, present at the end of the source buffer, is verified and is not present in the destination buffer.	Represented in bytes, only 12B and 16B values are supported
Additional authenticated data size	Additional authenticated data size to be supplied for the AES-GCM algorithm. This data, present at the beginning of the source buffer, is not encrypted but is authenticated.	Represented in bytes

Task Output

Common output as described in DOCA Core Task.

Task Completion Success

After the task completes successfully, the following happens:

- The data from the source buffer is decrypted and written to the destination buffer
- The destination buffer data segment is extended to include the decrypted data

Task Completion Failure

If the task fails midway:

- The context may enter stopping state if a fatal error occurs
- The source and destination `doca_buf` objects is not modified
- The destination buffer contents may be modified

Task Limitations

- The operation is not atomic
- Once the task is submitted, the source and destination should not be read/written to
- Other limitations are described in DOCA Core Task

5.4.15.7.2 Events

DOCA AES-GCM exposes asynchronous events to notify about changes that happen unexpectedly according to the DOCA Core architecture.

The only events AES-GCM exposes are common events as described in DOCA Core Event.

5.4.15.8 State Machine

The DOCA AES-GCM library follows the Context state machine as described in DOCA Core Context State Machine.

The following section describes moving states and what is allowed in each state.

5.4.15.8.1 Idle

In this state, it is expected that the application either:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to Configurations
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all tasks have been freed
Stopping	Call progress until all tasks are completed and freed

5.4.15.8.2 Starting

This state cannot be reached.

5.4.15.8.3 Running

In this state, it is expected that the application:

- Allocates and submits tasks
- Calls progress to complete tasks and/or receive events

Allowed operations:

- Allocating previously configured task
- Submitting a task
- Calling stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

5.4.15.8.4 Stopping

In this state, it is expected that the application:

- Calls progress to complete all inflight tasks (tasks complete with failure)
- Frees any completed tasks

Allowed operations:

- Calling progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and fatal error occurs
Running	Call stop without freeing all tasks

5.4.15.9 Alternative Datapath Options

DOCA AES-GCM only supports datapath on the CPU. See Execution Phase.

5.4.15.10 DOCA AES-GCM Samples

This section describes DOCA AES-GCM samples based on the DOCA AES-GCM library.

The samples in this section illustrate how to use the DOCA AES-GCM API to do the following:

- Encrypt contents of a buffer to another buffer
- Decrypt contents of a buffer to another buffer

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.15.10.1 Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_aes_gcm/<sample_name>
meson/tmp/build
ninja -C/tmp/build
```

> The binary `doca_<sample_name>` is created under `/tmp/build/`.

3. Sample (e.g., `doca_aes_gcm_encrypt`) usage:

```
Usage: doca_aes_gcm_encrypt [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI device address - default: 03:00.0
  -f, --file                        Input file to encrypt/decrypt
  -o, --output                      Output file - default: /tmp/out.txt
```

```
  -k, --key                         Raw key to encrypt/decrypt with, represented in hex format (32
 characters for 128-bit key, and 64 for 256-bit key) - default: 256-bit key, equals to zero
  -i, --iv                          Initialization vector, represented in hex format (0-24 characters for
0-96-bit IV) - default: 96-bit IV, equals to zero
  -t, --tag size                    Authentication tag size. Tag size is in bytes and can be 12B or 16B -
default: 12
  -a, --aad size                    Additional authenticated data size - default: 0
  -ns, --num-src-buf                Number of doca_buf for source buffer
  -nd, --num-dst-buf                Number of doca_buf for destination buffer
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name>-h
```

> The command line options `--num-src-buf` and `--num-dst-buf` show linked-list usage of `doca-buf`. The maximum supported number of elements is 64.

5.4.15.10.2 Samples

> These samples are also available on GitHub.

5.4.15.10.2.1 AES-GCM Encrypt

This sample illustrates how to encrypt data with AES-GCM.

The sample logic includes:

1. Locating DOCA device.
2. Initializing required DOCA Core structures.
3. Setting the AES-GCM encrypt tasks configuration.
4. Populating DOCA memory map with two relevant buffers.
5. Allocating element in DOCA buffer inventory for each buffer.
6. Creating DOCA AES-GCM key.
7. Allocating and initializing AES-GCM encrypt task.
8. Submitting AES-GCM encrypt task.
9. Retrieving AES-GCM encrypt task once it is done.
10. Checking task result.
11. Destroying all AES-GCM and DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_aes_gcm/aes_gcm_encrypt/aes_gcm_encrypt_sample.c`
- `/opt/mellanox/doca/samples/doca_aes_gcm/aes_gcm_encrypt/aes_gcm_encrypt_main.c`

- `/opt/mellanox/doca/samples/doca_aes_gcm/aes_gcm_encrypt/meson.build`

5.4.15.10.2.2 AES-GCM Decrypt

This sample illustrates how to decrypt data with AES-GCM.

The sample logic includes:

1. Locating DOCA device.
2. Initializing needed DOCA Core structures.
3. Setting the AES-GCM decrypt tasks configuration.
4. Populating DOCA memory map with two relevant buffers.
5. Allocating element in DOCA buffer inventory for each buffer.
6. Creating DOCA AES-GCM key.
7. Allocating and initializing AES-GCM decrypt task.
8. Submitting AES-GCM decrypt task.
9. Retrieving AES-GCM decrypt task once it is done.
10. Checking task result.
11. Destroying all AES-GCM and DOCA Core structures.

Reference:

- `/opt/mellanox/doca/samples/doca_aes_gcm/aes_gcm_decrypt/aes_gcm_decrypt_sample.c`
- `/opt/mellanox/doca/samples/doca_aes_gcm/aes_gcm_decrypt/aes_gcm_decrypt_main.c`
- `/opt/mellanox/doca/samples/doca_aes_gcm/aes_gcm_decrypt/meson.build`

5.4.16 DOCA Rivermax

This guide provides instructions on building and developing applications that require media/data streaming.

5.4.16.1 Introduction

> The quality status of DOCA libraries is listed here.

DOCA Rivermax (RMAX) is the DOCA API for NVIDIA® Rivermax®, an optimized networking SDK designed specifically for media and data streaming applications. Rivermax leverages the hardware streaming acceleration technology within NVIDIA® BlueField® DPUs. This technology enables direct data transfers to and from the GPU,

delivering best-in-class throughput and latency while minimizing CPU utilization for streaming workloads.

Key library features include the use of hardware-accelerated packet placement and header/payload splitting.

This document is intended for software developers who wish to accelerate their networking operations.

5.4.16.2 Prerequisites

This library follows the architecture of DOCA Core Context. It is recommended to read the following content before proceeding:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem
- Rivermax library User Manual

5.4.16.3 Environment

5.4.16.3.1 System Requirements

- DOCA Rivermax applications run only on the target DPU.
- A valid Rivermax library license is required. Refer to the NVIDIA Rivermax SDK page to obtain a license.
- Ensure an IP address is configured on the network interface being used.

5.4.16.3.2 Performance Configuration

To achieve maximum performance, it is recommended to enable at least 800 huge pages (2 MB each).

```
dpu> echo 1000000000 > /proc/sys/kernel/shmmax
dpu> echo 800 > /proc/sys/vm/nr_hugepages
```

5.4.16.3.3 User Privileges

By default, DOCA Rivermax applications must run with root privileges.

To execute the application as a regular user, you must perform the following configuration steps:

1. Grant the required Linux capabilities (`cap_net_raw` and `cap_sys_nice`) to the application binary.

```
# Set capabilities
sudo setcap cap_net_raw,cap_sys_nice=ep /path/to/application

# Verify
getcap /path/to/application
```

2. The application requires read access to the network interface's Virtual Product Data (VPD) file.

```
# Set permissions
sudo chmod 644 /sys/class/net/${INTERFACE}/device/vpd

# Verify
ls -l /sys/class/net/${INTERFACE}/device/vpd
```

> Permissions on the `/sys` filesystem reset on every reboot. You must re-apply this `chmod` command after a system restart.

5.4.16.4 Linux Kernel Capabilities Requirement

To use the DOCA Rivermax library without root privileges, the following capabilities are required

Capability	Description
`CAP_NET_RAW`	Required for raw socket operations
`CAP_SYS_NICE`	Required for real-time scheduling and priority adjustments

5.4.16.5 Architecture

- DOCA Rivermax Input Stream is a DOCA Context as defined by DOCA Core
- DOCA Rivermax leverages DOCA Core architecture to expose asynchronous events that are offloaded to hardware
- DOCA Rivermax can be used to define input streams that allow packet acquisition on an IP port. Furthermore, the input stream can be split to TCP/UDP 5-tuples to allow separate handling of flows.

5.4.16.5.1 Objects

- `doca_rmax_flow` – is a flow object that represents an IP/port tuple

- `doca_rmax_in_stream` – is a `doca_ctx` that represents the input stream and can be thought of as a receive queue which scatters the received data into memory. Each stream can receive one or more flows.

5.4.16.6 Library Features

5.4.16.6.1 Header/Payload Split

The library allows incoming packets to be split into separate header and payload segments (memory blocks). It can then direct each segment into its corresponding destination buffer.

5.4.16.6.2 Hardware-Accelerated Packet Placement

This feature uses hardware acceleration to place incoming packets directly into the receive buffer according to their sequence numbers. This saves significant processing time that would otherwise be spent on software-based data reordering.

The library supports two types of sequence numbers for placement:

- RTP: The 16-bit sequence number from a standard RTP packet header (RFC 3550).
- ST 2110-20: The 32-bit sequence number used in SMPTE ST 2110-20 video streams.

> **Data Placement vs. Receive Events**
>
> This feature only handles the placement of packet *data* in the receive buffer. The application should not expect the packet *receive events* (completions) to arrive in any specific order.

5.4.16.7 Configuration Phase

To start using the library users must first go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context to allow execution of tasks and retrieval of events.

5.4.16.7.1 Configurations

The context can be configured to match the application use case.

To find if a configuration is supported or its min/max value, refer to section "Device Support".

5.4.16.7.1.1 Mandatory Configurations

These configurations must be set by the application before attempting to start the context:

- An event type must be configured. See configuration of Events.
- The library must be initialized before use and released at the end.
- The memory buffer(s) that hold packet data
- The number of stream elements
- Minimal packet segment size(s)
- Maximal packet segment size(s)

5.4.16.7.1.2 Optional Configurations

If the following configurations are not set, then a default value is used:

- CPU affinity for Rivermax internal thread. Should be done before library initialization.
- The input stream packet's data scatter type – defaults to raw.
- The input stream timestamp format – defaults to raw counter.
- The number of segments (memory blocks) to split the packet into.
- Hardware-accelerated packet placement order - disabled by default.

5.4.16.7.2 Device Support

DOCA Rivermax Input Stream requires a device to operate. For picking a device see DOCA Core Device Discovery.

The device must be from within the DPU: Either a PF or SF.

It is recommended to choose your device using the following method:

- `doca_devinfo_get_ipv4_addr()`

Some devices can allow different capabilities as follows:

- PTP clock support.

5.4.16.7.3 Buffer Support

Memory block support buffers with the following features:

Buffer Type	Memory Block
Local mmap buffer	Yes

Buffer Type	Memory Block
Mmap from PCIe export buffer	Yes
Mmap from RDMA export buffer	No
Linked list buffer	Yes (header/payload split mode)

5.4.16.8 Execution Phase

This section describes execution on CPU using DOCA Core Progress Engine.

5.4.16.8.1 Events

DOCA Rivermax exposes asynchronous events to notify about changes that happen unexpectedly according to the DOCA Core architecture.

Common events are described in DOCA Core Event.

5.4.16.8.1.1 Rx Data

The Rx Data event is used by the stream to notify application that data has been received from the network.

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_rmax_in_stream_event_rx_data_register`	–

Event Trigger Condition

The event is triggered anytime packet(s) arrive.

Event Output

Common output as described in DOCA Core Event.

In case of success, the following is provided:

- Number of packets received
- Time of arrival of the first packet
- Time of arrival of the last packet
- Sequence number of the first packet
- Array of memory blocks as configured by input stream

In case of error, the following is provided:

- An error code
- A human readable message

⚠ The parameters are valid only inside the event callback.

Event Handling

Once an event is triggered, the application may decide to process the received data.

5.4.16.8.2 Runtime Configurations

These configurations can be made after the context has been started:

- The minimal number of packets that the input stream may return in Rx event.
- The maximal number of packets that the input stream may return in Rx event.
- The receive timeout. The number of µsecs that library would do busy wait (polling) for reception of at least `min_packets` number of packets.

5.4.16.9 State Machine

The DOCA RMAX library follows the Context state machine as described in DOCA Core Context State Machine

The following section describes how to move to the state and what is allowed in each state.

5.4.16.9.1 Idle

In this state, it is expected that application either:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to Configurations
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop

5.4.16.9.2 Starting

This state is not expected to be reached.

5.4.16.9.3 Running

In this state, it is expected that application:

- Calls progress to receive events

Allowed operations:

- Calling stop
- Changing runtime configurations as described in Runtime Configurations

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration

5.4.16.9.4 Stopping

This state is not expected to be reached.

5.4.16.10 DOCA Rivermax Samples

The samples illustrate how to use the DOCA Rivermax API to:

- List available devices, including their IP and supported capabilities
- Set CPU affinity for the internal Rivermax thread to achieve better performance
- Set the PTP clock device to be used internally in DOCA Rivermax
- Create a stream, create a flow and attach it to the created stream, and finally to start receiving data buffers (based on the attached flow)
- Create a stream in header-data split mode when packet headers and payload are split to different RX buffers
- Create a stream using hardware-accelerated packet placement mode

All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.16.10.1 Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_rmax/<sample_name>
meson /tmp/build
ninja -C /tmp/build
```

> The binary `doca_<sample_name>` is created under `/tmp/build/`.

3. Sample (e.g., `doca_rmax_create_stream`) usage:

```
Usage: doca_rmax_create_stream [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                            Print a help synopsis
  -v, --version                         Print program version information
  -l, --log-level                       Set the (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                     Parse command line flags from an input json file

Program Flags:
  -p, --pci_addr <PCI-ADDRESS>          PCI device address
```

> When running DOCA Rivermax samples, the IPv4 address 192.168.105.2 must be configured to an available uplink prior to running it for the samples to run as expected:
>
> ```
> $ifconfig p0 192.168.105.2
> ```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/<sample_name> -h
```

5.4.16.10.2 Samples

> These samples are also available on GitHub.

5.4.16.10.2.1 List Devices

This sample illustrates how to list all available devices, dump their IPv4 addresses, and tell whether the PTP clock is supported.

The sample logic includes:

1. Initializing DOCA Rivermax library.
2. Iterating over the available devices.
3. Dumping their IPv4 addresses
4. Dumping whether a PTP clock is supported for each device.
5. Releasing DOCA Rivermax library.

References:

- `/opt/mellanox/doca/samples/doca_rmax/rmax_list_devices/rmax_list_devices_sample.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_list_devices/rmax_list_devices_main.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_list_devices/meson.build`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_common.h` ; `/opt/mellanox/doca/samples/doca_rmax/rmax_common.c`

5.4.16.10.2.2 Set CPU Affinity

This sample illustrates how to set the CPU affinity mask for Rivermax internal thread to achieve better performance. This parameter must be set before library initialization otherwise it will not be applied.

The sample logic includes:

1. Setting CPU affinity using the DOCA Rivermax API.
2. Initializing DOCA Rivermax library.
3. Releasing DOCA Rivermax library.

References:

- `/opt/mellanox/doca/samples/doca_rmax/rmax_set_affinity/rmax_set_affinity_sample.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_set_affinity/rmax_set_affinity_main.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_set_affinity/meson.build`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_common.h` ; `/opt/mellanox/doca/samples/doca_rmax/rmax_common.c`

5.4.16.10.2.3 Set Clock

This sample illustrates how to set the PTP clock device to be used internally in DOCA Rivermax.

The sample logic includes:

1. Opening a DOCA device with a given PCIe address.
2. Initializing the DOCA Rivermax library.
3. Setting the device to use for obtaining PTP time.
4. Releasing the DOCA Rivermax library.

References:

- `/opt/mellanox/doca/samples/doca_rmax/rmax_set_clock/rmax_set_clock_sample.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_set_clock/rmax_set_clock_main.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_set_clock/meson.build`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_common.h`; `/opt/mellanox/doca/samples/doca_rmax/rmax_common.c`

5.4.16.10.2.4 Create Stream

This sample illustrates how to create a stream, create a flow and attach it to the created stream, and finally to start receiving data buffers (based on the attached flow).

The sample logic includes:

1. Opening a DOCA device with a given PCIe address.
2. Initializing the DOCA Rivermax library.
3. Creating an input stream.
4. Creating the context from the created stream.
5. Initializing DOCA Core related objects.
6. Setting the attributes of the created stream.
7. Creating a flow and attaching it to the created stream.
8. Starting to receive data buffers.
9. Clean up—detaches flow and destroys it, destroys created stream and DOCA Core related objects.

References:

- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream/rmax_create_stream_sample.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream/rmax_create_stream_main.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream/meson.build`

- `/opt/mellanox/doca/samples/doca_rmax/rmax_common.h`; `/opt/mellanox/doca/samples/doca_rmax/rmax_common.c`

5.4.16.10.2.5 Create Stream - Header-data Split Mode

This sample illustrates how to create a stream in header-data split mode when packet headers and payload are split to different RX buffers.

The sample logic includes:

1. Opening a DOCA device with a given PCIe address.
2. Initialize the DOCA Rivermax library.
3. Creating an input stream.
4. Creating a context from the created stream.
5. Initializing DOCA Core related objects.
6. Setting attributes of the created stream. Chaining buffers and setting header size to non-zero is essential to create a stream with header-data split mode.
7. Creating a flow and attaching it to the created stream.
8. Starting to receive data to split buffers.
9. Clean up—detaches flow and destroys it, destroys created stream and DOCA Core related objects.

References:

- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream_hds/rmax_create_stream_hds_sample.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream_hds/rmax_create_stream_hds_main.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream_hds/meson.build`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_common.h`; `/opt/mellanox/doca/samples/doca_rmax/rmax_common.c`

5.4.16.10.2.6 Create Stream - Hardware Packet Placement Order Mode

This sample demonstrates how to enable hardware-accelerated packet placement for a DOCA Rivermax stream. In this mode, the NIC uses the sequence number from the RTP header to determine the correct order for placing packets in the receive buffer.

The sample logic includes:

1. Opening a DOCA device with a given PCIe address.
2. Initialize the DOCA Rivermax library.
3. Creating an input stream.
4. Creating a context from the created stream.
5. Initializing DOCA Core related objects.
6. Setting attributes of the created stream (packet placement order, etc.), allocating header and payload buffers.

7. Creating a flow and attaching it to the created stream.
8. Starting to receive data to split buffers.
9. Clean up—detaches flow and destroys it, destroys created stream and DOCA Core related objects.

References:

- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream_hw_order_hds/rmax_create_stream_hw_order_hds_sample.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream_hw_order_hds/rmax_create_stream_hw_order_hds_main.c`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_create_stream_hw_order_hds/meson.build`
- `/opt/mellanox/doca/samples/doca_rmax/rmax_common.h`; `/opt/mellanox/doca/samples/doca_rmax/rmax_common.c`

5.4.17 DOCA Telemetry Exporter

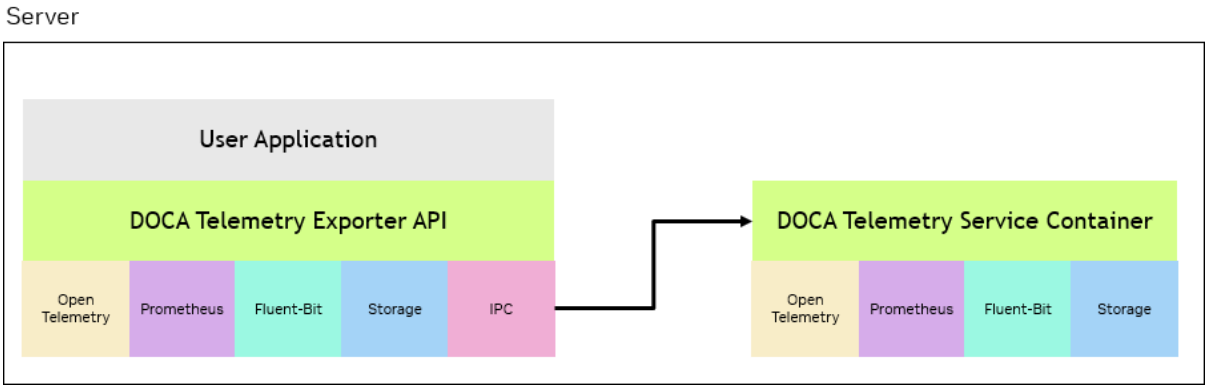
This guide provides an overview and configuration instructions for DOCA Telemetry Exporter API.

5.4.17.1 Introduction

> The quality status of DOCA libraries is listed here.

DOCA Telemetry Exporter API offers a fast and convenient way to transfer user-defined data to DOCA Telemetry Service (DTS). In addition, the API provides several built-in outputs for user convenience, including saving data directly to storage, NetFlow, Fluent Bit forwarding, and Prometheus endpoint.

The following figure shows an overview of the telemetry exporter API. The telemetry exporter client side, based on the telemetry exporter API, collects user-defined telemetry and sends it to DTS which runs as a container on BlueField or host. DTS does further data routing, including export with filtering. DTS can process several user-defined telemetry exporter clients and can collect pre-defined counters by itself. Additionally, telemetry exporter API has built-in data outputs that can be used from telemetry exporter client applications.



The following scenarios are available:

- Send data via IPC transport to DTS. For IPC, refer to Inter-process Communication.
- Write data as binary files to storage (for debugging data format).
- Export data directly from DOCA Telemetry Exporter API application using the following options:
  - Fluent Bit exports data through forwarding
  - NetFlow exports data from NetFlow API. Available from both API and DTS. See details in Data Outputs.
  - Prometheus
    - Server mode – Creates Prometheus endpoint and keeps the most recent data to be scraped by Prometheus.
    - Remote write mode – Pushes Prometheus time-series metrics to a remote Prometheus DB supporting remote-write import.
  - Open Telemetry export

Users can either enable or disable any of the data outputs mentioned above. See Data Outputs to see how to enable each output.

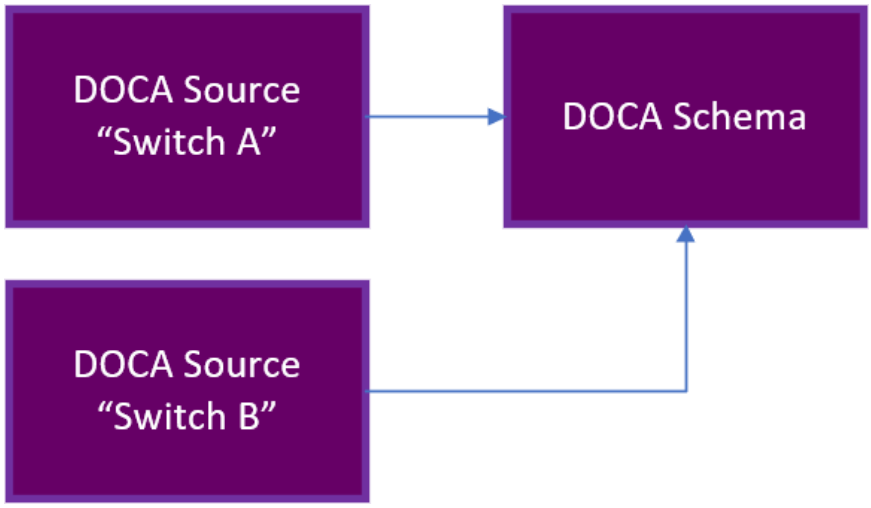
The library stores data in an internal buffer and flushes it to DTS/exporters in the following scenarios:

- Once the buffer is full. Buffer size is configurable with different attributes.
- When `doca_telemetry_exporter_source_flush(void *doca_source)` function is invoked.
- When the telemetry exporter client terminates. If the buffer has data, it is processed before the library's context cleanup.

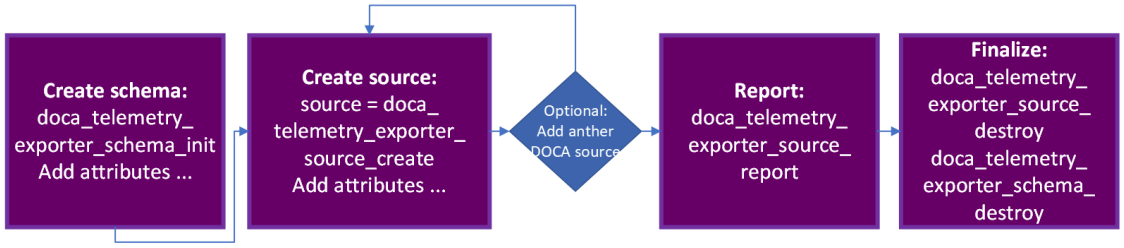
5.4.17.2 Architecture

DOCA Telemetry Exporter API is fundamentally built around four major parts:

- DOCA schema – defines a reusable structure (see doca_telemetry_exporter_type) of telemetry data which can be used by multiple sources



- Source – the unique identifier of the telemetry exporter source that periodically reports telemetry data.
- Report – exports the information to the DTS
- Finalize – releases all the resources



5.4.17.2.1 DOCA Telemetry Exporter API Walkthrough

The NVIDIA DOCA Telemetry Exporter API's definitions can be found in the `doca_telemetry_exporter.h` file.

The following is a basic walkthrough of the needed steps for using the DOCA Telemetry Exporter API.

1. Create `doca_schema`.
    a. Initialize an empty schema with default attributes:

```
struct doca_telemetry_exporter_schema *doca_schema;
doca_telemetry_exporter_schema_init("example_doca_schema_name", &doca_schema);
```

    b. Set the following attributes if needed:
        - `doca_telemetry_exporter_schema_set_buffer_attr_*(…)`
        - `doca_telemetry_exporter_schema_set_file_write_*(…)`
        - `doca_telemetry_exporter_schema_set_ipc_*(…)`

c. Add user event types:

Event type (`struct doca_telemetry_exporter_type`) is the user-defined data structure that describes event fields. The user is allowed to add multiple fields to the event type. Each field has its own attributes that can be set (see example). Each event type is allocated an index (`doca_telemetry_exporter_type_index_t`) which can be used to refer to the event type in future API calls.

```
struct doca_telemetry_exporter_type *doca_type;
struct doca_telemetry_exporter_field *field1;

doca_telemetry_exporter_type_create(&doca_type);
doca_telemetry_exporter_field_create(&field1);

doca_telemetry_exporter_field_set_name(field1, "sport");
doca_telemetry_exporter_field_set_description(field1, "Source port")
doca_telemetry_exporter_field_set_type_name(field1, DOCA_TELEMETRY_EXPORTER_FIELD_TYPE_UINT16);
doca_telemetry_exporter_field_set_array_length(field1, 1);

/* The user loses ownership on field1 after a successful invocation of the function */
doca_telemetry_exporter_type_add_field(type, field1);

/* Add more fields if needed */

/* The user loses ownership on doca_type after a successful invocation of the function */
doca_telemetry_exporter_schema_add_type(doca_schema, "example_event", doca_type, &type_index);
```

d. Apply attributes and types to start using the schema:

```
doca_telemetry_exporter_schema_start(doca_schema)
```

2. Create `doca_source` :

a. Initialize:

```
struct doca_telemetry_exporter_source *doca_source;
doca_telemetry_exporter_source_create(doca_schema, &doca_source);
```

b. Set source ID and tag:

```
doca_telemetry_exporter_source_set_id(doca_source, "example id");
doca_telemetry_exporter_source_set_tag(doca_source, "example tag");
```

c. Apply attributes to start using the source:

```
doca_telemetry_exporter_source_start(doca_source)
```

You may optionally add more `doca_sources` if needed.

3. Collect the data per source and use:

```
doca_telemetry_exporter_source_report(source, type_index, &my_app_test_ev1, num_events)
```

4. Finalize:

a. For every source:

```
doca_telemetry_exporter_source_destroy(source)
```

b. Destroy:

```
doca_telemetry_exporter_schema_destroy(doca_schema)
```

Example implementation may be found in the `telemetry_export` DOCA sample (`telemetry_export_sample.c`).

5.4.17.2.2 DOCA Telemetry Exporter NetFlow API Walkthrough

The DOCA telemetry exporter API also supports NetFlow using DOCA Telemetry Exporter NetFlow API. This API is designed to allow customers to easily support the NetFlow protocol at the endpoint side. Once an endpoint produces NetFlow data using the API, the corresponding exporter can be used to send the data to a NetFlow collector.

The NVIDIA DOCA Telemetry Exporter Netflow API's definitions can be found in the `doca_telemetry_exporter_netflow.h` file.

The following are the steps to use the NetFlow API:

1. Initiate the API with an appropriate source ID:

   ```
   doca_telemetry_exporter_netflow_init(source_id)
   ```

2. Set the relevant attributes:
   - `doca_telemetry_exporter_netflow_set_buffer_*(…)`
   - `doca_telemetry_exporter_netflow_set_file_write_*(…)`
   - `doca_telemetry_exporter_netflow_set_ipc_*(…)`
   - `doca_telemetry_exporter_netflow_source_set_*()`
3. Start the API to use the configured attribute:

   ```
   doca_telemetry_exporter_netflow_start();
   ```

4. Form a desired NetFlow template and the corresponding NetFlow records.
5. Collect the NetFlow data.

   ```
   doca_telemetry_exporter_netflow_send(…)
   ```

6. (Optional) Flush the NetFlow data to send data immediately instead of waiting for the buffer to fill:

   ```
   doca_telemetry_exporter_netflow_flush()
   ```

7. Clean up the API:

   ```
   doca_telemetry_exporter_netflow_destroy()
   ```

Example implementation may be found in the `telemetry_export_netflow` DOCA sample (`telemetry_export_netflow_sample.c`).

5.4.17.2.3 DOCA Telemetry Exporter Metrics API Walkthrough

The DOCA Telemetry Exporter provides a Metrics API for the programmatic collection and export of performance metrics from applications. This API enables applications to report counters, gauges, and histograms with multi-dimensional labels, supporting export to multiple backends including file storage, IPC, and Prometheus.

5.4.17.2.3.1 Supported Metric Types

- Counter: Monotonically increasing values (e.g., total requests, bytes sent, operations completed).
- Gauge: Current values that can increase or decrease (e.g., memory usage, queue depth, bandwidth).
- Histogram: Distribution of values across configurable buckets (e.g., latency percentiles, message sizes).

5.4.17.2.3.2 Initialization

The Metrics API requires a DOCA Telemetry Exporter source to be initialized before metrics can be reported.

Prerequisites:

1. Initialize the DOCA schema (`doca_telemetry_exporter_schema_init`).
2. Configure and start the schema (`doca_telemetry_exporter_schema_start`).
3. Create the source (`doca_telemetry_exporter_source_create`).
4. Start the source (`doca_telemetry_exporter_source_start`).

> ⚠ At least one export backend (file, IPC, or Prometheus) must be enabled on the schema before creating the metrics context.

Example initialization:

```
struct doca_telemetry_exporter_schema *schema = NULL;
struct doca_telemetry_exporter_source *source = NULL;
doca_error_t result;

// 1. Initialize schema and source
result = doca_telemetry_exporter_schema_init("my_app", &schema);
if (result != DOCA_SUCCESS) { /* Handle error */ }

doca_telemetry_exporter_schema_start(schema);
doca_telemetry_exporter_source_create(schema, &source);
doca_telemetry_exporter_source_set_id(source, "my_source");
doca_telemetry_exporter_source_set_tag(source, "");
doca_telemetry_exporter_source_start(source);

// 2. Create metrics context
result = doca_telemetry_exporter_metrics_create_context(source);
if (result != DOCA_SUCCESS) {
    // Handle error
}

// 3. Configure metrics (Optional)
// Set periodic flush to every 1 second (1000 ms)
doca_telemetry_exporter_metrics_set_flush_interval_ms(source, 1000);
// Add a constant label applied to all metrics from this source
doca_telemetry_exporter_metrics_add_constant_label(source, "application", "my_app");
```

5.4.17.2.3.3 Working with Labels

Label sets define the dimensional structure of metrics. A label set specifies the *names* of the labels (e.g., "interface", "direction"), while the metrics themselves provide the specific *values* (e.g., "eth0", "tx").

Creating Label Set

```
// Define label names
const char *label_names[] = {"interface", "direction"};
doca_telemetry_exporter_label_set_id_t label_set_id;

// Register the label set
result = doca_telemetry_exporter_metrics_add_label_names(
    source,
    label_names,
    2,  // Number of labels
    &label_set_id
);
```

Using Label Values

```
// Define values matching the label names
const char *eth0_tx_labels[] = {"eth0", "tx"};
const char *eth1_rx_labels[] = {"eth1", "rx"};

uint64_t timestamp;
doca_telemetry_exporter_get_timestamp(Чtamp);

// Report metrics using different label combinations
doca_telemetry_exporter_metrics_add_counter(source, timestamp,
    "bytes_total", 1024000, label_set_id, eth0_tx_labels);

doca_telemetry_exporter_metrics_add_counter(source, timestamp,
    "bytes_total", 2048000, label_set_id, eth1_rx_labels);
```

Constant Labels

Constant labels are applied globally to all metrics reported from a specific source.

```
doca_telemetry_exporter_metrics_add_constant_label(source, "hostname", "server01");
doca_telemetry_exporter_metrics_add_constant_label(source, "version", "1.0");
```

5.4.17.2.3.4 Counters

Counters represent cumulative totals. They are strictly monotonically increasing.

API functions:

- `doca_telemetry_exporter_metrics_add_counter()` : Set counter to an absolute value.
- `doca_telemetry_exporter_metrics_add_counter_increment()` : Increment counter by a specified amount.

Example:

```
uint64_t timestamp;
doca_telemetry_exporter_get_timestamp(Чtamp);
const char *label_values[] = {"requests"};

// Set absolute counter value
doca_telemetry_exporter_metrics_add_counter(source, timestamp,
    "operations_total", 42, label_set_id, label_values);

// Increment counter
doca_telemetry_exporter_metrics_add_counter_increment(source, timestamp,
```

```
    "operations_total", 1, label_set_id, label_values);
```

5.4.17.2.3.5 Gauges

Gauges represent instantaneous values that can go up or down, such as memory usage or bandwidth.

API functions:

- `doca_telemetry_exporter_metrics_add_gauge()` : Report a gauge with a `double` precision value.
- `doca_telemetry_exporter_metrics_add_gauge_uint64()` : Report a gauge with a `uint64_t` value.

Example:

```
uint64_t timestamp;
doca_telemetry_exporter_get_timestamp(&timestamp);
const char *label_values[] = {"bandwidth"};

// Double precision gauge
double bandwidth_gbps = 10.5;
doca_telemetry_exporter_metrics_add_gauge(source, timestamp,
    "bandwidth_gbps", bandwidth_gbps, label_set_id, label_values);

// Integer gauge
uint64_t memory_bytes = 1073741824;
doca_telemetry_exporter_metrics_add_gauge_uint64(source, timestamp,
    "memory_usage_bytes", memory_bytes, label_set_id, label_values);
```

5.4.17.2.3.6 Histograms

Histograms track the distribution of values (observations) across configurable buckets.

Creating and Observing a Histogram

```
double latency_buckets[] = {1.0, 5.0, 10.0, 25.0, 50.0, 100.0, 500.0, 1000.0};
const char *label_values[] = {"tcp"};
doca_telemetry_exporter_histogram_id_t histogram_id;

// Create the histogram definition
result = doca_telemetry_exporter_metrics_add_histogram(
    source, timestamp, "latency_ms",
    latency_buckets, 8,  // 8 bucket boundaries
    label_set_id, label_values,
    &histogram_id
);

// Record observations
doca_telemetry_exporter_metrics_histogram_observe(source, histogram_id, 15.3);
doca_telemetry_exporter_metrics_histogram_observe(source, histogram_id, 8.7);
doca_telemetry_exporter_metrics_histogram_observe(source, histogram_id, 42.1);
```

Base Histogram (Templates)

For metrics that require multiple label combinations, use a base histogram as a template.

```
doca_telemetry_exporter_base_histogram_id_t base_histogram_id;

// Create base histogram template
result = doca_telemetry_exporter_metrics_add_base_histogram(
    source, "latency_ms",
    latency_buckets, 8,
    label_set_id,
    1000,  // flush_interval_ms
    &base_histogram_id
);

// Observe with specific label values (creates instance automatically)
```

```
const char *tcp_labels[] = {"tcp"};
doca_telemetry_exporter_histogram_id_t tcp_histogram_id;

doca_telemetry_exporter_metrics_base_histogram_observe(
    source, base_histogram_id, tcp_labels, 15.3, &tcp_histogram_id
);
```

5.4.17.2.3.7 Best Practices

Flushing Metrics

Metrics are buffered internally. Configure periodic automatic flushing for frequent exports, and always flush before program exit.

```
// Configure automatic flush (e.g., every 1 second)
doca_telemetry_exporter_metrics_set_flush_interval_ms(source, 1000);

// Flush manually before destruction
doca_telemetry_exporter_metrics_flush(source);
```

Label Cardinality

Keep the total number of unique label combinations reasonable to avoid high memory usage and backend strain.

- Good: Low cardinality labels (e.g., interface names, status codes).
- Bad: High cardinality labels (e.g., random flow IDs, unique request IDs).
- Recommendation: Keep total unique label combinations under 10,000.

Metric Naming Conventions

For Prometheus compatibility, adhere to the following naming standards:

- Format: `snake_case` (e.g., `network_bandwidth_gbps`).
- Units: Suffix with the unit (e.g., `_bytes`, `_seconds`).
- Counters: End with `_total` (e.g., `requests_total`).
- Gauges: Reflect current state (e.g., `memory_usage_bytes`).

Error Handling

Always check return values (`doca_error_t`) for all metrics functions.

```
if (result != DOCA_SUCCESS) {
    DOCA_LOG_ERR("Failed to add counter: %s", doca_error_get_descr(result));
}
```

Cleanup

Properly destroy resources in reverse order of creation.

```
doca_telemetry_exporter_metrics_flush(source);
doca_telemetry_exporter_metrics_destroy_context(source);
doca_telemetry_exporter_source_destroy(source);
doca_telemetry_exporter_schema_destroy(schema);
```

5.4.17.2.4 DOCA Telemetry Exporter OTLP Logs API Walkthrough

The DOCA Telemetry Exporter provides an OTLP Logs API for the programmatic collection and export of structured log events from applications.

This API enables applications to report log records with resources, scopes, severity levels, and typed attributes, supporting export to OTLP-compatible backends such as OpenTelemetry Collector, Jaeger, and cloud observability platforms.

5.4.17.2.4.1 Supported Concepts

Concept	Description
Resource	Represents the entity generating logs (e.g., service, device, node). Resources carry attributes such as `service.name`, `host.name`, and `device.name`.
Scope	Represents an instrumentation library or functional component. A scope defines the event schema, including attribute keys, attribute types, event name, and default severity.
Event	A log record emitted using a resource and scope. Events provide attribute values that must match the scope schema and may override the default severity.
Attributes	Key-value pairs attached to resources or events. Supported types are `STRING`, `INT`, `DOUBLE`, and `BOOL`.

5.4.17.2.4.2 Initialization

The OTLP Logs API requires a DOCA Telemetry Exporter schema and source to be initialized before log events can be reported.

5.4.17.2.4.3 Prerequisites

1. Initialize the DOCA schema (`doca_telemetry_exporter_schema_init`).
2. Enable opaque events (`doca_telemetry_exporter_schema_set_opaque_events_enabled`)

   ⚠ Required for OTLP logs.
3. Configure and start the schema (`doca_telemetry_exporter_schema_start`).
4. Create the source (`doca_telemetry_exporter_source_create`).
5. Start the source (`doca_telemetry_exporter_source_start`).
6. Create the OTLP logs context (`doca_telemetry_exporter_otlp_logs_create_context`).

5.4.17.2.4.4 Example Initialization

```
struct doca_telemetry_exporter_schema *schema = NULL;
struct doca_telemetry_exporter_source *source = NULL;
```

```
doca_error_t result;

// Initialize schema
result = doca_telemetry_exporter_schema_init("my_app", &schema);
if (result != DOCA_SUCCESS) { /* Handle error */ }

// Configure schema
doca_telemetry_exporter_schema_set_buf_data_root(schema, "/tmp/doca_telemetry_buffer");
doca_telemetry_exporter_schema_set_opaque_events_enabled(schema); // Required

// Start schema and source
doca_telemetry_exporter_schema_start(schema);
doca_telemetry_exporter_source_create(schema, &source);
doca_telemetry_exporter_source_set_id(source, "my_source");
doca_telemetry_exporter_source_set_tag(source, "");
doca_telemetry_exporter_source_start(source);

// Create OTLP logs context
result = doca_telemetry_exporter_otlp_logs_create_context(source);
if (result != DOCA_SUCCESS) { /* Handle error */ }
```

5.4.17.2.4.5 Working with Resources

Resources describe the entity producing log events.

Creating a Resource

```
doca_telemetry_exporter_otlp_logs_resource_id_t resource_id;
result = doca_telemetry_exporter_otlp_logs_add_resource(source, &resource_id);
```

Adding Resource Attributes

```
doca_telemetry_exporter_otlp_logs_add_resource_attribute_string(
    source, resource_id, "service.name", "doca_network_service");

doca_telemetry_exporter_otlp_logs_add_resource_attribute_string(
    source, resource_id, "host.name", "server01");

doca_telemetry_exporter_otlp_logs_add_resource_attribute_string(
    source, resource_id, "device.name", "mlx5_0");

doca_telemetry_exporter_otlp_logs_add_resource_attribute_int(
    source, resource_id, "device.port", 1);

doca_telemetry_exporter_otlp_logs_add_resource_attribute_bool(
    source, resource_id, "is_primary", true);
```

5.4.17.2.4.6 Working with Scopes

Scopes define the event schema and default severity.

Creating a Scope

```
const char *attr_keys[] = {"message", "error_code", "severity"};
doca_telemetry_exporter_otlp_attribute_type_t attr_types[] = {
    DOCA_TELEMETRY_EXPORTER_OTLP_ATTRIBUTE_TYPE_STRING,
    DOCA_TELEMETRY_EXPORTER_OTLP_ATTRIBUTE_TYPE_INT,
    DOCA_TELEMETRY_EXPORTER_OTLP_ATTRIBUTE_TYPE_STRING
};

doca_telemetry_exporter_otlp_logs_scope_id_t scope_id;

result = doca_telemetry_exporter_otlp_logs_add_scope(
    source,
    "doca.telemetry.example",  // scope_name
    "1.0.0",                   // scope_version
    "network_event",           // event_name
    "INFO",                    // default_severity
    attr_keys,
    attr_types,
    3,
    &scope_id
);
```

5.4.17.2.4.7 Writing Log Events

Events must provide attribute values matching the scope schema and order.

Writing Event with Default Severity

```
doca_telemetry_exporter_otlp_attribute_value_t values[3];
values[0].string_value = "Connection established";
values[1].int_value = 0;
values[2].string_value = "INFO";

doca_telemetry_exporter_otlp_logs_write_event(
    source, resource_id, scope_id, values);
```

Writing Event with Custom Severity

```
doca_telemetry_exporter_otlp_attribute_value_t warn_values[3];
warn_values[0].string_value = "Packet loss detected";
warn_values[1].int_value = 2001;
warn_values[2].string_value = "WARN";

doca_telemetry_exporter_otlp_logs_write_event_with_severity(
    source, resource_id, scope_id, warn_values, "WARN");
```

5.4.17.2.4.8 Flushing and Cleanup

```
doca_telemetry_exporter_otlp_logs_flush(source);
doca_telemetry_exporter_otlp_logs_destroy_context(source);
doca_telemetry_exporter_source_destroy(source);
doca_telemetry_exporter_schema_destroy(schema);
```

5.4.17.2.4.9 Best Practices

Flushing Logs

Logs are buffered internally. Flush periodically or before shutdown to ensure delivery.

Severity Usage

Use consistent severity levels (`INFO` , `WARN` , `ERROR`) to simplify downstream filtering and alerting.

5.4.17.2.4.10 Error Handling

Always check `doca_error_t` return values.

```
if (result != DOCA_SUCCESS) { DOCA_LOG_ERR("OTLP logs error: %s", doca_error_get_descr(result)); }
```

5.4.17.3 API

Refer to DOCA Library APIs, for more detailed information on DOCA Telemetry Exporter API.

> ⚠ The pkg-config (`*.pc` file) for the DOCA Telemetry Exporter library is `doca-telemetry-exporter` .

The following sections provide additional details about the library API.

Some attributes are optional as they are initialized with default values. Refer to the documentation of the setter functions of respective attributes for more information.

5.4.17.3.1 DOCA Telemetry Exporter Buffer Attributes

Buffer attributes are used to set the internal buffer size and data root used by all DOCA sources in the schema.

Configuring the attributes is optional as they are initialized with default values.

```
doca_telemetry_exporter_schema_set_buffer_size(doca_schema, 16 * 1024); /* 16KB - arbitrary value */
doca_telemetry_exporter_schema_set_buffer_data_root(doca_schema, "/opt/mellanox/doca/services/telemetry/data/");
```

- `buffer_size [in]` – the size of the internal buffer which accumulates the data before sending it to the outputs. Data is sent automatically once the internal buffer is full. Larger buffers mean fewer data transmissions and vice versa.
- `data_root [in]` – the path to where data is stored (if `file_write_enabled` is set to true). See section "DOCA Telemetry Exporter File Write Attributes".

5.4.17.3.2 DOCA Telemetry Exporter File Write Attributes

File write attributes are used to enable and configure data storage to the file system in binary format.

Configuring the attributes is optional as they are initialized with default values.

```
doca_telemetry_exporter_schema_set_file_write_enabled(doca_schema);
doca_telemetry_exporter_schema_set_file_write_max_size(doca_schema, 1 * 1024 * 1024); /* 1 MB */
doca_telemetry_exporter_schema_set_file_write_max_age(doca_schema, 60 * 60 * 1000000L); /* 1 Hour */
```

- `file_write_enable [in]` – use this function to enable storage. Storage/FileWrite is disabled by default.
- `file_write_max_size [in]` – maximum file size (in bytes) before a new file is created.
- `file_write_max_age [in]` – maximum file age (in microseconds) before a new file is created.

5.4.17.3.3 DOCA Telemetry Exporter IPC Attributes

IPC attributes are used to enable and configure IPC transport. IPC is disabled by default.

Configuring the attributes is optional as they are initialized with default values.

It is important to make sure that the IPC location matches the IPC location used by DTS, otherwise IPC communication will fail.

```
doca_telemetry_exporter_schema_set_ipc_enabled(doca_schema);
doca_telemetry_exporter_schema_set_ipc_sockets_dir(doca_schema, "/path/to/sockets/");
doca_telemetry_exporter_schema_set_ipc_reconnect_time(doca_schema, 100); /* 100 milliseconds */
doca_telemetry_exporter_schema_set_ipc_reconnect_tries(doca_schema, 3);
doca_telemetry_exporter_schema_set_ipc_socket_timeout(doca_schema, 3 * 1000) /* 3 seconds */
```

- `ipc_enabled [in]` – use this function to enable communication. IPC is disabled by default.
- `ipc_sockets_dir [in]` – a directory that contains UDS for IPC messages. Both the telemetry exporter program and DTS must use the same folder. DTS that runs on BlueField as a container has the default folder `/opt/mellanox/doca/services/telemetry/ipc_sockets`.
- `ipc_reconnect_time [in]` – maximum reconnection time in milliseconds after which the client is considered disconnected.
- `ipc_reconnect_tries [in]` – maximum reconnection attempts.
- `ipc_socket_timeout [in]` – timeout for the IPC socket.

5.4.17.3.4 DOCA Telemetry Exporter Source Attributes

Source attributes are used to create proper folder structure. All the data collected from the same host is written to the `source_id` folder under data root.

Sources attributes are mandatory and must be configured before invoking `doca_telemetry_exporter_source_start()`.

```
doca_telemetry_exporter_source_set_id(doca_source, "example_source");
doca_telemetry_exporter_source_set_tag(doca_source, "example_tag");
```

- `source_id [in]` – describes the data's origin. It is recommended to set it to the hostname. In later dataflow steps, data is aggregated from multiple hosts/DPUs and `source_id` helps navigate in it.
- `source_tag [in]` – a unique data identifier. It is recommended to set it to describe the data collected in the application. Several telemetry exporter apps can be deployed on a single node (host/DPU). In that case, each telemetry data would have a unique tag and all of them would share a single `source_id`.

5.4.17.3.5 DOCA Telemetry Exporter Netflow Collector Attributes

DOCA Telemetry Exporter NetFlow API attributes are optional and should only be used for debugging purposes. They represent the NetFlow collector's address while working locally, effectively enabling the local NetFlow exporter.

```
doca_telemetry_exporter_netflow_set_collector_addr("127.0.0.1");
doca_telemetry_exporter_netflow_set_collector_port(6343);
```

- `collector_addr [in]` – NetFlow collector's address (IP or name). Default value is `NULL`.
- `collector_port [in]` – NetFlow collector's port. Default value is `DOCA_NETFLOW_DEFAULT_PORT (2055)`.

5.4.17.3.6 DOCA Telemetry Exporter Source Report

The source report function is the heart of communication with the DTS. The report operation causes event data to be allocated to the internal buffer. Once the buffer is full, data is forwarded onward according to the set configuration.

```
doca_error_t doca_telemetry_exporter_source_report(struct doca_telemetry_exporter_source *doca_source,
                                                   doca_telemetry_exporter_type_index_t index,
                                                   void *data,
                                                   int count);
```

- `doca_source [in]` – a pointer to the `doca_telemetry_exporter_source` which reports the event
- `index [in]` – the event type index received when the schema was created
- `data [in]` – a pointer to the data buffer that needs to be sent
- `count [in]` – numbers of events to be written to the internal buffer

The function returns `DOCA_SUCCESS` if successful, or a `doca_error_t` if an error occurs. If a memory-related error occurs, try a larger buffer size that matches the event's size.

5.4.17.3.7 DOCA Telemetry Exporter Schema Add Type

This function allows adding a reusable telemetry data struct, also known as a schema. The schema allows sending a predefined data structure to the telemetry service. Note that it is mandatory to define a schema for proper functionality of the library. After adding the schemas, one needs to invoke the schema start function.

```
doca_error_t doca_telemetry_exporter_schema_add_type(struct doca_telemetry_exporter_schema *doca_schema,
                                                     const char *new_type_name,
                                                     struct doca_telemetry_exporter_type *type,
                                                     doca_telemetry_exporter_type_index_t *type_index);
```

- `doca_schema [in]` – a pointer to the schema to which the type is added

- `new_type_name [in]` – name of the new type
- `fields [in]` – user-defined fields to be used for the schema. Multiple fields can (and should) be added.
- `type_index [out]` – type index for the created type is written to this output variable

The function returns `DOCA_SUCCESS` if successful, or `doca_error_t` if an error occurs.

5.4.17.3.8 DOCA Telemetry Exporter Metrics

The Metrics API provides functions for programmatic metrics collection and export. These functions are used in conjunction with the core DOCA Telemetry Exporter API to report performance metrics.

Return Values:

All functions return `doca_error_t` with `DOCA_SUCCESS` on success or error codes on failure. Common error codes include:

- `DOCA_ERROR_INVALID_VALUE` – NULL parameters or invalid arguments.
- `DOCA_ERROR_NO_MEMORY` – Memory allocation failure.

See `doca_telemetry_exporter.h` for detailed function signatures and parameters.

The Metrics API functions are organized into the following five categories:

5.4.17.3.8.1 DOCA Telemetry Exporter Metrics Context Management

These functions manage the lifecycle and state of the metrics context.

Function Name	Description
`doca_telemetry_exporter_metrics_create_context`	Creates and initializes the metrics context.
`doca_telemetry_exporter_metrics_destroy_context`	Destroys the metrics context and frees resources.
`doca_telemetry_exporter_metrics_flush`	Flushes remaining buffered metrics to exporters.

5.4.17.3.8.2 DOCA Telemetry Exporter Metrics Configuration

These functions configure the behavior of the metrics collection, including flushing and labeling.

Function Name	Description
`doca_telemetry_exporter_metrics_set_flush_interval_ms`	Sets periodic automatic flush interval in milliseconds.

Function Name	Description
`doca_telemetry_exporter_metrics_set_min_sample_interval_us`	Sets minimum time between samples per time series.
`doca_telemetry_exporter_metrics_add_constant_label`	Adds a constant label to all metrics reported by the source.
`doca_telemetry_exporter_metrics_add_label_names`	Defines a label set (list of label names) and returns its ID.

5.4.17.3.8.3 DOCA Telemetry Exporter Metrics Counters

Functions for reporting monotonically increasing values.

Function Name	Description
`doca_telemetry_exporter_metrics_add_counter`	Reports a counter with an absolute value.
`doca_telemetry_exporter_metrics_add_counter_increment`	Increments a counter by a specified value.

5.4.17.3.8.4 DOCA Telemetry Exporter Metrics Gauges

Functions for reporting values that can arbitrarily increase or decrease.

Function Name	Description
`doca_telemetry_exporter_metrics_add_gauge`	Reports a gauge with a `double` precision value.
`doca_telemetry_exporter_metrics_add_gauge_uint64`	Reports a gauge with a `uint64_t` value.

5.4.17.3.8.5 DOCA Telemetry Exporter Metrics Histograms

Functions for creating, observing, and managing histograms.

Function Name	Description
`doca_telemetry_exporter_metrics_add_histogram`	Creates a histogram instance with specific label values.
`doca_telemetry_exporter_metrics_add_base_histogram`	Creates a base histogram template for use with multiple label sets.
`doca_telemetry_exporter_metrics_histogram_observe`	Records a value in a specific histogram instance.
`doca_telemetry_exporter_metrics_base_histogram_observe`	Records a value in a base histogram using specific label values.
`doca_telemetry_exporter_metrics_histogram_flush`	Flushes data for a specific histogram immediately.

Function Name	Description
`doca_telemetry_exporter_metrics_histogram_remove`	Removes a histogram instance from the context.
`doca_telemetry_exporter_metrics_set_histogram_flush_interval_target`	Sets the flush interval target for a specific histogram.

5.4.17.3.9 DOCA Telemetry Exporter Logs

The Logs API provides functions for programmatic log record collection and export using the OpenTelemetry Protocol (OTLP).

These functions are used together with the core DOCA Telemetry Exporter API to report structured log events.

5.4.17.3.9.1 Return Values

All functions return `doca_error_t` with `DOCA_SUCCESS` on success or an error code on failure.

Common error codes:

- `DOCA_ERROR_INVALID_VALUE` – Invalid arguments or NULL parameters
- `DOCA_ERROR_NO_MEMORY` – Memory allocation failure
- `DOCA_ERROR_BAD_STATE` – Invalid context or state

See `doca_telemetry_exporter.h` for full API definitions.

5.4.17.3.9.2 DOCA Telemetry Exporter Logs Context Management

Functions for managing the lifecycle of the OTLP logs context.

Function Name	Description
`doca_telemetry_exporter_otlp_logs_create_context`	Creates and initializes the OTLP logs context.
`doca_telemetry_exporter_otlp_logs_destroy_context`	Destroys the logs context and frees resources.
`doca_telemetry_exporter_otlp_logs_flush`	Flushes buffered log records to the exporter.

5.4.17.3.9.3 DOCA Telemetry Exporter Logs Resource Management

Functions for defining log resources and their attributes.

Function Name	Description
`doca_telemetry_exporter_otlp_logs_add_resource`	Adds a new resource and returns its ID.

Function Name	Description
`doca_telemetry_exporter_otlp_logs_add_resource_attribute_string`	Adds a string attribute to a resource.
`doca_telemetry_exporter_otlp_logs_add_resource_attribute_int`	Adds an integer attribute to a resource.
`doca_telemetry_exporter_otlp_logs_add_resource_attribute_double`	Adds a double attribute to a resource.
`doca_telemetry_exporter_otlp_logs_add_resource_attribute_bool`	Adds a Boolean attribute to a resource.

5.4.17.3.9.4 DOCA Telemetry Exporter Logs Scope Management

Functions for defining log scopes and schemas.

Function Name	Description
`doca_telemetry_exporter_otlp_logs_add_scope`	Adds a scope with predefined attribute schema and returns its ID.

5.4.17.3.9.5 DOCA Telemetry Exporter Logs Event Writing

Functions for emitting log events.

Function Name	Description
`doca_telemetry_exporter_otlp_logs_write_event`	Writes a log event using the scope default severity.
`doca_telemetry_exporter_otlp_logs_write_event_with_severity`	Writes a log event with explicit severity.

5.4.17.3.9.6 DOCA Telemetry Exporter Logs Data Types

Type Name	Description
`doca_telemetry_exporter_otlp_logs_resource_id_t`	Resource identifier type.
`doca_telemetry_exporter_otlp_logs_scope_id_t`	Scope identifier type.
`doca_telemetry_exporter_otlp_attribute_type_t`	Attribute type enum.
`doca_telemetry_exporter_otlp_attribute_value_t`	Union holding attribute values.
`DOCA_TELEMETRY_EXPORTER_OTLP_LOGS_INVALID_ID`	Invalid ID constant.

5.4.17.4 Telemetry Event Data Format

The internal data format consists of 2 parts: A schema containing metadata, and the actual binary data. When data is written to storage, the data schema is written in JSON format, and the data is written as binary files. In the case of IPC transport, both schema and binary data are sent to DTS. In the case of export, data is converted to the formats required by exporter.

Adding custom event types to the schema can be done using `doca_telemetry_exporter_schema_add_type` API call.

⚠ See available `DOCA_TELEMETRY_EXPORTER_FIELD_TYPE`s in `doca_telemetry_exporter.h`. See example of usage in `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export/telemetry_export_sample.c`.

⚠ It is highly recommended to have the timestamp field as the first field since it is required by most databases. To get the current timestamp in the correct format use:

```
doca_error_t doca_telemetry_exporter_get_timestamp(doca_telemetry_exporter_timestamp_t *timestamp);
```

5.4.17.5 Data Outputs

This section describes available exporters:

- IPC
- NetFlow
- Fluent Bit
- Prometheus Endpoint
- Prometheus Remote-Write
- Open Telemetry

Fluent Bit and Prometheus exporters are presented in both API and DTS. Even though DTS export is preferable, the API has the same possibilities for development flexibility.

5.4.17.5.1 Inter-process Communication

IPC transport automatically transfers the data from the telemetry-exporter-based program to DTS service.

It is implemented as a UNIX domain socket (UDS) sockets for short messages and shared memory for data. DTS and the telemetry-exporter-based program must share the same `ipc_sockets` directory.

When IPC transport is enabled, the data is sent from the DOCA-telemetry-exporter-based application to the DTS process via shared memory.

To enable IPC, use the `doca_telemetry_exporter_schema_set_ipc_enabled` API function.

> ⚠ IPC transport relies on system folders. For the host's usage, run the DOCA-telemetry-exporter-API-based application with `sudo` to be able to use IPC with system folders.

To check the IPC status for the current context, use:

```
doca_error_t doca_telemetry_exporter_check_ipc_status(struct doca_telemetry_exporter_source *doca_source,
                                                      doca_telemetry_exporter_ipc_status_t *status)
```

If IPC is enabled and for some reason connection is lost, it would try to automatically reconnect on every report's function call.

5.4.17.5.1.1 Using IPC with Non-containerized Application

When developing or testing a DOCA Telemetry Exporter-based program that runs natively (outside a container), specific configurations are required to allow IPC with the containerized DTS.

To enable this interaction, the DTS container must be configured to use the host's IPC namespace rather than an isolated shared memory volume.

Docker Deployment (Command Line)

When deploying DTS via the `docker` command, ensure the container uses the host's IPC namespace.

- Recommended method: Use the `--ipc=host` flag.
- Alternative method: Explicitly mount the host's shared memory directory:

  ```
  -v /dev/shm:/dev/shm
  ```

> ⚠ Do not mount non-standard shared memory folders if you intend to use the default system paths.

Kubernetes/Pod Deployment (YAML)

When deploying DTS via a YAML configuration (e.g., on the DPU), you must enable `hostIPC` and remove any specific `volumeMounts` that isolate shared memory (such as `telemetry-ipc-shm`).

Configuration Comparison

- Before change (default Isolated Mode):

```
spec:
  hostNetwork: true
  volumes:
  - name: telemetry-service-config
    hostPath:
      path: /opt/mellanox/doca/services/telemetry/config
      type: DirectoryOrCreate
  # [REMOVE] The following volume isolates shared memory
  - name: telemetry-ipc-shm
    hostPath:
      path: /dev/shm/telemetry
      type: DirectoryOrCreate
  containers:
      volumeMounts:
      - name: telemetry-service-config
        mountPath: /config
      # [REMOVE] The following mount point
      - name: telemetry-ipc-shm
        mountPath: /dev/shm
```

- After change (Host IPC Enabled):

```
spec:
  hostNetwork: true
  hostIPC: true  # [ADD] Enable Host IPC
  volumes:
  - name: telemetry-service-config
    hostPath:
      path: /opt/mellanox/doca/services/telemetry/config
      type: DirectoryOrCreate
  containers:
      volumeMounts:
      - name: telemetry-service-config
        mountPath: /config
```

When developing and testing a non-container DOCA Telemetry-Exporter-based program and its IPC interaction with DTS, some modifications are necessary in DTS's deployment for the program to interact with DTS over IPC:

- Shared memory mapping should be removed: `telemetry-ipc-shm`
- Host IPC should be enabled: `hostIPC`

Host case (docker command)

In case of docker command make sure that DTS uses:

```
--ipc=host
```

and does not mount non-standard shared memory folder.
In addition user can directly specify to mount /dev/shm in docker command for DTS:

```
-v /dev/shm:/dev/shm
```

DPU case (yaml)

File before the change:

```
spec:
  hostNetwork: true
  volumes:
  - name: telemetry-service-config
    hostPath:
      path: /opt/mellanox/doca/services/telemetry/config
      type: DirectoryOrCreate
  ...
  - name: telemetry-ipc-shm
    hostPath:
      path: /dev/shm/telemetry
      type: DirectoryOrCreate
  containers:
  ...
      volumeMounts:
      - name: telemetry-service-config
        mountPath: /config
  ...
      - name: telemetry-ipc-shm
        mountPath: /dev/shm
```

File after the change:

```
spec:
  hostNetwork: true
  hostIPC: true
  volumes:
  - name: telemetry-service-config
    hostPath:
      path: /opt/mellanox/doca/services/telemetry/config
      type: DirectoryOrCreate
  ...
  containers:
  ...
      volumeMounts:
      - name: telemetry-service-config
        mountPath: /config
```

These changes ensure that a DOCA-based program running outside of a container is able to communicate with DTS over IPC.

5.4.17.5.2 NetFlow

When the NetFlow exporter is enabled (NetFlow Collector Attributes are set), it sends the NetFlow data to the NetFlow collector specified by the attributes: Address and port. This exporter must be used when using DOCA Telemetry Exporter NetFlow API.

5.4.17.5.3 Fluent Bit

Fluent Bit export is based on `fluent_bit_configs` with `.exp` files for each destination. Every export file corresponds to one of Fluent Bit's destinations. All found and enabled `.exp` files are used as separate export destinations. Examples can be found after running DTS container under its configuration folder (`/opt/mellanox/doca/services/telemetry/config/fluent_bit_configs/`).

All `.exp` files are documented in-place.

```
DPU# ls -l /opt/mellanox/doca/services/telemetry/config/fluent_bit_configs/
/opt/mellanox/doca/services/telemetry/config/fluent_bit_configs/:
total 56
-rw-r--r-- 1 root root  528 Oct 11 07:52 es.exp
-rw-r--r-- 1 root root  708 Oct 11 07:52 file.exp
-rw-r--r-- 1 root root 1135 Oct 11 07:52 forward.exp
-rw-r--r-- 1 root root  719 Oct 11 07:52 influx.exp
-rw-r--r-- 1 root root  571 Oct 11 07:52 stdout.exp
-rw-r--r-- 1 root root  578 Oct 11 07:52 stdout_raw.exp
-rw-r--r-- 1 root root 2137 Oct 11 07:52 ufm_enterprise.fset
```

Fluent Bit `.exp` files have 2-level data routing:

- `source_tags` in `.exp` files (documented in-place)
- Token-based filtering governed by `.fset` files (documented in `ufm_enterprise.fset`)

To run with Fluent Bit exporter, set `enable=1` in required `.exp` files and set the environment variables before running the application:

```
export FLUENT_BIT_EXPORT_ENABLE=1
export FLUENT_BIT_CONFIG_DIR=/path/to/fluent_bit_configs
export LD_LIBRARY_PATH=/opt/mellanox/collectx/lib
```

5.4.17.5.4 Prometheus Endpoint

Prometheus exporter sets up endpoint (HTTP server) which keeps the most recent events data as text records.

The Prometheus server can scrape the data from the endpoint while the DOCA-Telemetry-Exporter-API-based application stays active.

Check the generic example of Prometheus records:

```
event_name_1{label_1="label_1_val", label_2="label_2_val", label_3="label_3_val", label_4="label_4_val"}
counter_value_1 timestamp_1
event_name_2{label_1="label_1_val", label_2="label_2_val", label_3="label_3_val", label_4="label_4_val"}
counter_value_2 timestamp_2
...
```

Labels are customizable metadata which can be set from data file. Events names could be filtered by token-based name-match according to `.fset` files.

Set the following environment variables before running.

```
# Set the endpoint host and port to enable export.
export PROMETHEUS_ENDPOINT=http://0.0.0.0:9101

# Set the folder which contains fset-files. If set, Prometheus will scrape
# only filtered data according to fieldsets.
export PROMETHEUS_CSET_DIR=/path/to/prometheus_cset
```

To scrape the data without the Prometheus server, use:

```
curl -s http://0.0.0.0:9101/metrics
```

Or:

```
curl -s http://0.0.0.0:9101/{fset_name}
```

5.4.17.5.5 Prometheus Remote Write

The Prometheus remote write exporter sends time-series metrics to a remote Prometheus receiver using the Prometheus remote-write protocol.

To use the Prometheus Remote-Write exporter, set the `CLX_REMOTE_WRITE_RECEIVER` environment variable to the receiver's address before running:

```
export CLX_REMOTE_WRITE_RECEIVER=http://$IP:$PORT/api/v1/write   # set the IP and PORT with the receiver address (default port is 9502)
```

Replace `$IP` and `$PORT` with the receiver's IP address and port (default port is 9090).

5.4.17.5.6 Open Telemetry

Open Telemetry exporter streams telemetry to remote OTLP receiver. The supported transport is http.

To run with Open Telemetry exporter, set the following environment variables before running.

```
export CLX_OPEN_TELEMETRY_RECEIVER=http://$IP:$PORT/v1/metrics   # set the IP and PORT with the receiver address (default port is 9502)
```

5.4.17.6 DOCA Telemetry Exporter Samples

This section provides DOCA Telemetry Exporter sample implementations on top of the BlueField DPU.

The telemetry exporter samples in this document demonstrate an initial recommended configuration that covers two use cases:

- Standard DOCA Telemetry Exporter data
- DOCA Telemetry Exporter for NetFlow data

The telemetry exporter samples run on BlueField. If write-to-file is enabled, telemetry data is stored to BlueField's storage. If inter-process communication (IPC) is enabled, data is sent to the DOCA Telemetry Service (DTS) running on the same BlueField.

For information on initializing and configuring DTS, refer to DOCA Telemetry Service Guide.

All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.17.6.1 Running the Sample

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_telemetry_exporter/<sample_name>
meson /tmp/build
ninja -C /tmp/build
```

   The binary `doca_<sample_name>` will be created under `/tmp/build/`.

3. Sample (e.g., `telemetry_export`) usage:

```
Usage: doca_telemetry_export [DOCA Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name> -h
```

5.4.17.6.2 Samples

These samples are also available on GitHub.

5.4.17.6.2.1 Telemetry Export

This sample illustrates how to use the telemetry exporter API. The sample uses a custom schema for telemetry exporter.

The sample logic includes:

1. Configuring schema attributes.
2. Initializing schema.
3. Creating telemetry exporter source.
4. Creating example events.
5. Reporting example events via DOCA Telemetry Exporter.
6. Destroying source and schema.

Reference:

- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export/telemetry_export_sample.c`
- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export/telemetry_export_main.c`
- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export/meson.build`

5.4.17.6.2.2 Telemetry Export NetFlow

This sample illustrates how to use the NetFlow functionality of the telemetry exporter API.

The sample logic includes:

1. Configuring NetFlow attributes.
2. Initializing NetFlow.
3. Creating telemetry exporter source.
4. Starting NetFlow.
5. Creating example events.
6. Reporting example events via DOCA Telemetry Exporter.
7. Destroying NetFlow.

Reference:

- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_netflow/telemetry_export_netflow_sample.c`
- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_netflow/telemetry_export_netflow_main.c`
- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_netflowt/meson.build`

5.4.17.6.2.3 Telemetry Export Metrics

This sample illustrates how to use the Metrics API of the telemetry exporter to collect and export performance metrics (counters, gauges) with multi-dimensional labels.

The sample logic includes:

1. Initializing the telemetry exporter schema and source.
2. Creating and configuring the metrics context.
3. Setting flush intervals and adding constant labels.
4. Defining dynamic label sets (e.g., for network interfaces).
5. Reporting counter (absolute and incremental) and gauge metrics.
6. Flushing and destroying the metrics context, source, and schema.

Reference:

- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_metrics/telemetry_export_metrics_sample.c`
- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_metrics/telemetry_export_metrics_main.c`
- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_metrics/meson.build`

5.4.17.6.2.4 Telemetry Export OTLP Logs

This sample illustrates how to use the OTLP Logs API of the telemetry exporter to collect and export structured log events as OpenTelemetry Protocol (OTLP) log records with resources, scopes, and typed attributes.

The sample logic includes:

1. Initializing the telemetry exporter schema and source.
2. Enabling opaque events (required for OTLP logs).
3. Creating and configuring the OTLP logs context.
4. Creating a resource and adding resource attributes.
5. Defining an event schema with attribute keys and types.
6. Creating a scope (instrumentation library) with default severity.
7. Writing log events with default and explicit severity levels.
8. Flushing and destroying the logs context, source, and schema.

Reference:

- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_otlp_logs/telemetry_export_otlp_logs_sample.c`
- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_otlp_logs/telemetry_export_otlp_logs_main.c`
- `/opt/mellanox/doca/samples/doca_telemetry_exporter/telemetry_export_otlp_logs/meson.build`

5.4.18 DOCA Telemetry

This guide provides instructions for building and developing applications that require telemetry data collection, supported by the NVIDIA® BlueField and NVIDIA® ConnectX® families of networking platforms.

5.4.18.1 Introduction

> The quality status of DOCA libraries is listed here.

DOCA Telemetry includes a suite of specialized libraries, each designed to access a specific hardware feature or function of a device. Each telemetry library provides a dedicated interface and context, allowing users to gather metrics related to the corresponding operation.

5.4.18.2 Supported Libraries

DOCA Telemetry supports the following libraries:

- DOCA Telemetry Adp Retx - Adaptive Retransmission telemetry
- DOCA Telemetry Diag - High-frequency diagnostic telemetry
- DOCA Telemetry DPA - Data Path Accelerator telemetry
- DOCA Telemetry PCC - Programmable Congestion Control telemetry
- DOCA Telemetry PCI - Peripheral Component Interconnect telemetry

5.4.18.3 DOCA Telemetry Adp Retx

This guide provides instructions for building and developing applications that require telemetry data collection from NVIDIA® BlueField® and NVIDIA® ConnectX® families of networking platforms.

5.4.18.3.1 Introduction

The `doca_telemetry_adp_retx` library provides statistics on Adaptive Retransmission Algorithm timeouts that have been configured on a given DOCA device, corresponding to an NVIDIA® BlueField® or NVIDIA® ConnectX® network card.

The library includes mechanisms for configuring and reading Adaptive Retransmissions in a histogram format. Each histogram read provides a series of bins, where each bin

corresponds to a specific time range. The value of the bin is a count of the retransmissions that occurred due to a timeout falling within that time range.

The histogram can return information about events on all QPs of functions associated with the DOCA device, or it can be configured to track the QPs of a single VHCA ID.

⚠ DOCA Telemetry Adp Retx is supported at an alpha level.

5.4.18.3.2 Prerequisites

To use DOCA Telemetry Adp Retx, the following prerequisites must be met:

- `fwctl` driver installed and loaded (see instructions in NVIDIA MLNX_OFED Documentation v24.07-0.6.1.0)

  ⚠ To verify whether the `fwctl` driver is successfully loaded:

  ```
  $ ls /sys/class/fwctl/
  ```

  Expected output:

  ```
  fwctl0  fwctl1
  ```

  If the directory `/sys/class/fwctl` does not exist or is empty, follow these steps:

  a. Search for the `fwctl` package:

  ```
  $ apt search fwctl
  ```

  The output may indicate either `fwctl-dkms` or `fwctl-modules`.

  b. Install the appropriate package:

  ```
  $ sudo apt install fwctl-dkms
  ```

  Or:

  ```
  $ sudo apt install fwctl-modules
  ```

  c. Load the `mlx5_fwctl` module:

  ```
  $ sudo modprobe mlx5_fwctl
  ```

  d. Confirm the module is loaded:

  ```
  $ lsmod | grep fwctl
  ```

  Expected output:

```
mlx5_fwctl             20480  0
fwctl                  24576  1 mlx5_fwctl
mlx5_core            2211840  2 mlx5_fwctl,mlx5_ib
mlx_compat             20480  17
rdma_cm,ib_ipoib,mlxdevm,nvme,mlxfw,mlx5_fwctl,iw_cm,nvme_core,nvme_fabrics,ib_umad,fwctl
,ib_core,rdma_ucm,ib_uverbs,mlx5_ib,ib_cm,mlx5_core
```

- Firmware version greater than 28.47.1000 for ConnectX-7, 40.47.1000 for ConnectX-8, or 32.47.1000 for BlueField-3

5.4.18.3.3 Environment

DOCA Telemetry-based applications can run on either the host machine (ConnectX-7 or BlueField-3 and newer) or on the DPU (BlueField-3 and newer).

5.4.18.3.4 Architecture

The `doca_telemetry_adp_retx` library provides statistics on Adaptive Retransmission configured devices, including the number of retransmissions and their timeout ranges in a histogram format.

To interact with a device (typically corresponding to a specific NIC port), you must create a `doca_telemetry_adp_retx` context using `doca_telemetry_adp_retx_create()`.

5.4.18.3.5 Configuration Phase

5.4.18.3.5.1 Device Support

A DOCA device is required for the library to operate. For guidance on selecting a device, refer to the "DOCA Core Device Discovery" documentation.

Device support for `doca_telemetry_adp_retx` and its features can be checked with the following capability calls:

- `doca_telemetry_adp_retx_cap_is_supported()`
- `doca_telemetry_adp_retx_cap_histogram_is_supported()`

The maximum number of bins and the supported time units can be queried using:

- `doca_telemetry_adp_retx_cap_get_hist_max_bins()`
- `doca_telemetry_adp_retx_cap_get_hist_time_units()`

5.4.18.3.5.2 Histogram Configuration

The histogram divides retransmission events into bins, each representing a time range. If a retransmission timeout falls within a bin's range, that bin's counter is incremented. The number of bins and their time ranges are configurable.

The bin widths and timespans are determined by five main configuration options:

API Configuration	Description
`doca_telemetry_adp_retx_set_hist_num_bins()`	Number of bins to use in the histogram
`doca_telemetry_adp_retx_set_hist_bin0_width()`	Width (in time units) of the first bin
`doca_telemetry_adp_retx_set_hist_bin1_width()`	Width (in time units) of the second bin; also used as the base for calculating subsequent bins
`doca_telemetry_adp_retx_set_hist_time_unit()`	The time unit for bin0 and bin1 widths (e.g., `nsec`, `usec`, `msec`)
`doca_telemetry_adp_retx_set_hist_bin_width_node()`	The calculation mode for bins after bin1: either `fixed` (same width as bin1) or `double` (exponentially doubling)

Example:

- **Fixed Mode:** 4 bins, `bin0_width` =50, `bin1_width` =100, `time_unit` =msec, `width_mode` =fixed.
  - Bin 0: 0-50 msec
  - Bin 1: 50-150 msec (base + 100)
  - Bin 2: 150-250 msec (base + 100)
  - Bin 3: 250-350 msec (base + 100)

Bin 0	Bin 1	Bin 2	Bin 3
Timeout Range:	***Timeout Range:***	***Timeout Range:***	***Timeout Range:***
0 msec - 49 msec	50 msec - 149 msec	150 msec - 249 msec	> 250 msec
(bin0_width)	*(bin1_width)*	*(bin1_width)*	

- **Double Mode:** 5 bins, `bin0_width` =50, `bin1_width` =100, `time_unit` =msec, `width_mode` =double.
  - Bin 0: 0-50 msec
  - Bin 1: 50-150 msec (base + 100)
  - Bin 2: 150-350 msec (base + 200)
  - Bin 3: 350-750 msec (base + 400)

- Bin 4: 750-1550 msec (base + 800)

Bin 0	Bin 1	Bin 2	Bin 3	Bin 4
Timeout Range:	***Timeout Range:***	***Timeout Range:***	***Timeout Range:***	***Timeout Range:***
0 msec - 49 msec *(bin0_width)*	50 msec - 149 msec *(bin1_width)*	150 msec - 349 msec *(bin1 x 2)*	350 msec - 749 msec *(bin2 x 2)*	> 750 msec

Further options control how the histogram is populated:

API Configuration	Description
`doca_telemetry_adp_retx_set_hist_vhca_id()`	Populates the histogram with retransmissions from a single VHCA ID only
`doca_telemetry_adp_retx_set_hist_clear_on_read()`	Clears (resets to 0) the histogram bin counters after each read
`doca_telemetry_adp_retx_set_hist_count_enable()`	Enables the counters. This must be set for the histogram to start gathering statistics.

5.4.18.3.6 Execution Phase

After configuration, the histogram is loaded and begins running on the device when `doca_telemetry_adp_retx_start()` is called. The bin counters can then be read from the device.

Shared Resource

`doca_telemetry_adp_retx` contexts do not have sole ownership or a locking mechanism on the device histogram. It is possible for another process to update the histogram's configuration while your context is in the execution phase, which can lead to misinterpretation of the bin counters.

The user is responsible for ensuring sole ownership of the histogram and verifying data integrity. An API function is provided to help detect these external changes.

The following functions are used during the execution phase:

API Datapath Functions	Description
`doca_telemetry_adp_retx_read_hist_bins()`	Reads the configured N histogram bin counters as an array of N 64-bit values
`doca_telemetry_adp_retx_detect_hist_conf_change()`	Indicates if the device's active histogram configuration matches the one defined in the context

5.4.18.3.7 State Machine

This section outlines the states of the `doca_telemetry_adp_retx` context.

5.4.18.3.7.1 Idle

The context has been created and is Idle.

In this state, it is expected for the application to:

- Destroy the context.
- Start the context for processing.

Allowed operations:

- Configuring the context according to section "Configuration".

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop

5.4.18.3.7.2 Running

In this state it is expected for the application to:

- Stop the context.

Allowed operations:

- Reading data from the device according to section "Execution".

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Successfully start the context

5.4.18.3.8 Alternative Datapath Options

DOCA Telemetry Adp Retx supports only CPU-based datapaths.

5.4.18.3.9 DOCA Telemetry Adp Retx Sample

The `doca_telemetry_adp_retx` sample demonstrates how to configure the histogram from command-line arguments, run for a set period, and then print the values of the configured bin counters. This sample is also available on GitHub.

5.4.18.3.9.1 Running the Sample

- Before you begin, refer to the following documents:
  - DOCA Installation Guide for Linux: For details on installing BlueField-related software.
  - NVIDIA BlueField Platform Software Troubleshooting Guide: For any issues with installation, compilation, or execution.
- To build a given sample:

```
# Update path if you downloaded from GitHub
cd /opt/mellanox/doca/samples/doca_telemetry/telemetry_adp_retx
meson /tmp/build
ninja -C /tmp/build
```

  The binary `doca_telemetry_adp_retx` is created under `/tmp/build/`.
- Sample usage:

```
Usage: doca_telemetry_adp_retx [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse all command flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI device address
  -u, --time-unit                   Time unit to use - 'nsec', 'usec', 'usec_100', or 'msec'
  -w, --width-mode                  Bin width mode to use - 'fixed', or 'double'
  -n, --number-bins                 The number of bins to configure the histogram for
  -vid, --vhca-id                   VHCA ID to get histogram events from
  -b0, --bin-0-width                Width of bin 0 to configure histogram
  -b1, --bin-1-width                Width of bin 1 to configure histogram
  -t, --wait-time                   Time in seconds to wait before reading histogram bins
```

The sample includes:

1. Locates and opens a DOCA device.
2. Creates a `doca_telemetry_adp_retx` instance.
3. Queries the device for histogram support, max bins, and time unit capabilities.
4. Configures the histogram with the values provided via command line (number of bins, bin widths, time unit, width mode, VHCA ID, clear on read, and counter enable).
5. Waits for the specified time, then reads and displays the value of each bin.
6. Destroys the `doca_telemetry_adp_retx` context.

5.4.18.4 DOCA Telemetry Diag

This guide provides instructions on building and developing applications which require collecting telemetry information provided by NVIDIA® BlueField® and NVIDIA® ConnectX® families of networking platforms.

5.4.18.4.1 Introduction

`doca_telemetry_diag` provides programable access to an on-device mechanism which allows sampling of diagnostic data (e.g., statistics and counters). `doca_telemetry_diag` allows configuring such parameters as required data IDs or sampling period, and retrieving the generated information in several formats.

5.4.18.4.2 Prerequisites

To use DOCA Telemetry Diagnostics, the following prerequisites must be met.

- `fwctl` driver is installed and loaded (see instructions in NVIDIA MLNX_OFED Documentation v24.07-0.6.1.0)

  ⚠ To verify that the `fwctl` driver is successfully loaded, run:

  ```
  $ ls /sys/class/fwctl/
  ```

  Expected output for a 2-port device:

  ```
  fwctl0  fwctl1
  ```

  ```
  $ ls /dev/fwctl/
  ```

  Expected the exactly same for a 2-port device:

  ```
  fwctl0  fwctl1
  ```

  If the directory `/sys/class/fwctl` or `/dev/fwctl` does not exist or is empty (DOCA_ERROR_OPERATING_SYSTEM is expected), to follow these steps:

  a. Check kernel panic message:

  ```
  $ sudo dmesg
  ```

  If there is any kernel panic message related to fwctl, please following the steps in DOCA-Host Installation and Upgrade - DOCA - Confluence to fully re-install the latest doca-host.

  b. If not, please continue the next steps.

  c. Search for the `fwctl` package on Ubuntu.

  ```
  $ apt search fwctl
  ```

  The output may indicate either `fwctl-dkms` or `fwctl-modules`.

d. Install the appropriate package on Ubuntu.

```
$ sudo apt install fwctl-dkms
```

Or:

```
$ sudo apt install fwctl-modules
```

e. Search for the `fwctl` package on RHEL.

```
$ yum search fwctl
```

The output may indicate `kmod-fwctl.x86_64`.

f. Install the appropriate package on RHEL.

```
$ sudo yum install kmod-fwctl.x86_64
```

g. Load the `mlx5_fwctl` module.

```
$ sudo modprobe mlx5_fwctl
```

h. Confirm the module is loaded.

```
$ lsmod | grep fwctl
```

Expected output:

```
mlx5_fwctl             20480  0
fwctl                  24576  1 mlx5_fwctl
mlx5_core            2211840  2 mlx5_fwctl,mlx5_ib
mlx_compat             20480  17
rdma_cm,ib_ipoib,mlxdevm,nvme,mlxfw,mlx5_fwctl,iw_cm,nvme_core,nvme_fabrics,ib_umad,fwctl
,ib_core,rdma_ucm,ib_uverbs,mlx5_ib,ib_cm,mlx5_core
```

If the above steps cannot solve the problem, please still try the steps in DOCA-Host Installation and Upgrade - DOCA - Confluence to fully re-install the latest doca-host.

- Firmware version 28.43.1000 for ConnectX-7 or 32.43.1000 for BlueField-3.

5.4.18.4.3 Environment

DOCA Telemetry-based applications can run either on the host machine (ConnectX-7 or Bluefield-3 and above) or on the DPU target (BlueField-3 and above).

DOCA Telemetry can only be run inside the DPU (on Arm) with the BlueField configured in DPU mode, as described in BlueField Modes of Operation.

5.4.18.4.4 Architecture

Diagnostic data is stored in firmware as a cyclic buffer of samples. Each sample represents the values of all the requested diagnostic data IDs and their corresponding sampling timestamps.

5.4.18.4.4.1 Device and Ownership

The DOCA telemetry library requires a ConnectX/BlueField DOCA device to sample from. The device can be accessed using any of its physical functions (PFs).

> ⚠ If multiple devices exist in a setup, a `doca_telemetry_diag` context should be created for each.

`doca_telemetry_diag` is designed to operate as a singleton per device. Upon creation, the `doca_telemetry_diag` context assumes control of the associated hardware resources to prevent conflicts and ensure accurate data sampling. In rare instances, ownership may be overridden (e.g., if a process crashes before releasing ownership).

> ℹ The `force_ownership` parameter may be used when creating the context from a second process.

> ⚠ Once ownership is enforced for one PF, it cannot be claimed by a different PF. It is recommended to always use PF0 to prevent potential conflicts.

5.4.18.4.5 Configuration Phase

5.4.18.4.5.1 Configuration

The context can be configured to match the application use case.

To discover if a certain configuration is supported, or what the min/max value for it is, refer to section "Device Support".

Sampling mode

The DOCA Telemetry Diagnostics library supports the following operational methods:

- Single sampling – the samples are stored and once the samples' firmware buffer is filled, sampling is terminated.

  > ℹ If required, the context can be restarted to collect new samples until the firmware buffer is filled, overwriting the previous samples.

- Repetitive sampling – when the sample buffer is filled, new samples override old samples.

  > Sampling continues until context is stopped.

- On demand – the device does not collect samples. Upon each query of the diagnostic data, the device fetches a single sample of the data.

Considerations for Repetitive Sampling Mode

When configuring the DOCA Telemetry Diagnostics library to repetitive sampling, it is important to ensure that the firmware buffer is adequately sized to handle the data flow between hardware sampling and software retrieval. The firmware buffer size is dictated by the `log_max_num_samples` property.

1. Determine sampling rates:
   - Hardware sampling rate – the frequency at which the hardware collects data (e.g., every 100 µsec)
   - Software retrieval rate – the average time interval between successive data retrievals by the software (e.g., every 500 msec)
2. Calculate `AverageSamplesPerRetrieval` using the following equation:
   $$AverageSamplesPerRetrieval = \frac{RetrievalInterval}{SamplingInterval}$$
   For example:
   $\frac{500msec}{100\mu sec} = 5000$
3. To ensure smooth data processing and prevent data loss, the firmware buffer should be large enough to accommodate at least twice the average number of samples collected during the retrieval period:
   $$BufferSize = 2 \times AverageSamplesPerRetrieval$$
   For example:
   $2 \times 5000 = 10000$ samples

Moreover, the number of retrieved samples should be enlarged if the retrieving process may spike occasionally. For example, if the process time between retrieval calls is up to 6 times of the average, then the number of samples should be multiplied by 6+1=7.

Sampling Period

The sampling period can be configured using `doca_telemetry_diag_set_sample_period`.

In some cases, depending on the number and type of data IDs configured, the actual sampling period may be higher. The actual sampling period can be queried using `doca_telemetry_diag_get_sample_period` after configuring the data IDs.

After starting the `doca_telemetry_diag` context with `doca_telemetry_diag_start`, the actual sampling period may differ from the desired sampling rate. To address this, you

can dynamically adjust the sampling period
using `doca_telemetry_diag_reconfig_sample_period`.

Synchronized Start

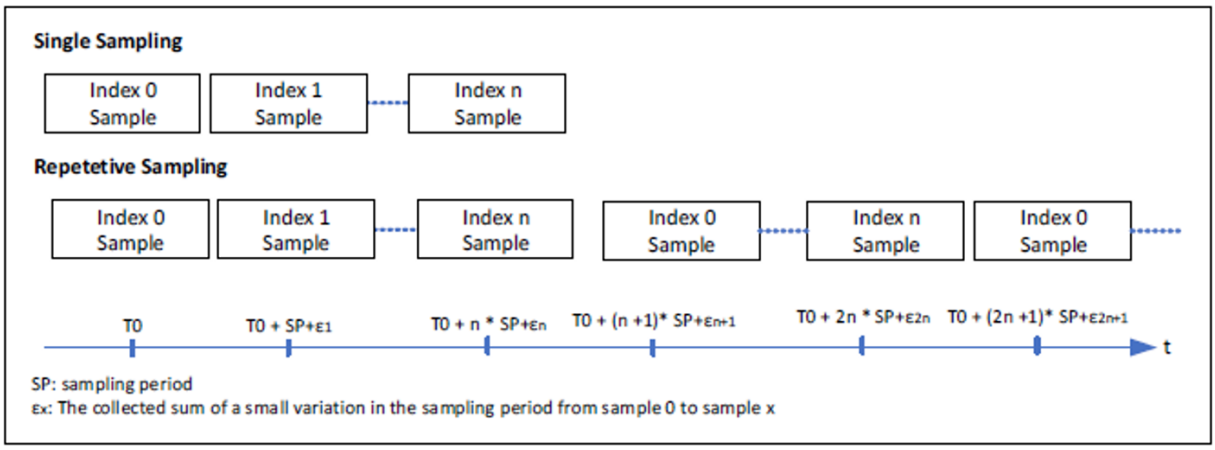
Diagnostics data is sampled by the device every given sampling period. When sampling this way, each data entry in a sample may be recorded at a slightly different time.

Synchronized start mode enables diagnostics counters to begin all data measurements at the same time (i.e., during the same clock cycle). This way, the sample period is guaranteed to be identical for all samples. Synchronized start diagnostic counters can be configured to be cleared at the beginning of each sampling period.

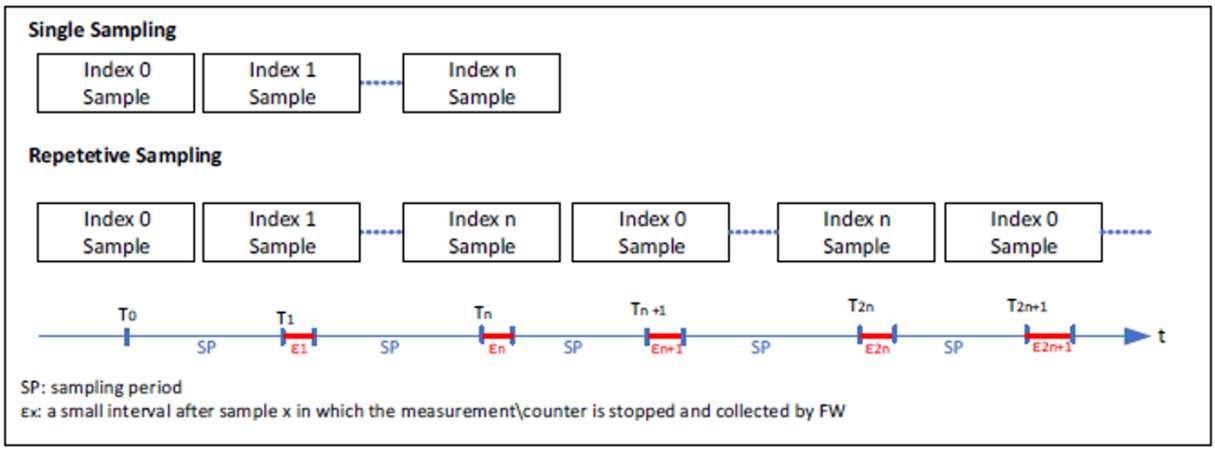
> ⚠ Not all data IDs can be sampled in synchronized start mode. See section "Data IDs" for additional details

The following diagrams illustrate how synchronized start affects the sampling timeline:

Without Synched Start:



With Synched Start:



⚠ In synchronized start mode, counters are stopped during the collection time of each sample (illustrated in red in the diagram). If the application is required to normalize the counter to time, the actual sample period should be considered.

For example, if the `global_icmc_hit` (GIH) counter is sampled and the sample period is 100 µsec, then the `global_icmc_hit` per second, should be calculated as follows: $\frac{(GIH_{Tn+1} - GIH_{Tn})}{100\mu sec}$

Data IDs

The on-device mechanism provides the following diagnostic data classes:

- Counter – monotonically increasing and counting different events in the device.
  - If `doca_telemetry_diag_set_data_clear` is set, the counters are cleared at the beginning of each sampling period (valid only if synchronized start mode is used and operational mode is set to single or repetitive sampling).
- Statistic – other collected diagnostic data about the performance of the device. Statistic diagnostic data is cleared on each sample.

Each diagnostic data is represented by a unique identifier, the data ID. Appendix "List of Supported Data IDs" lists the currently supported data IDs.

After applying the configuration, the list of data IDs to be sampled should be applied by calling `doca_telemetry_diag_apply_counters_list_by_id`.

⚠ Not all combinations of data IDs can be configured. If any of the `data_ids` fail to be configured, the operation fails, returning the index of the failed data ID and the reason of failure. The operation can be retried after omitting the faulty data ID.

⚠ Not all data IDs support synchronized start mode. If synchronized start mode is configured and `doca_telemetry_diag_apply_counters_list_by_id` fails with error `DOCA_ERROR_BAD_CONFIG`, this indicates that the failed data ID does not support synchronized start mode.

Output Formats

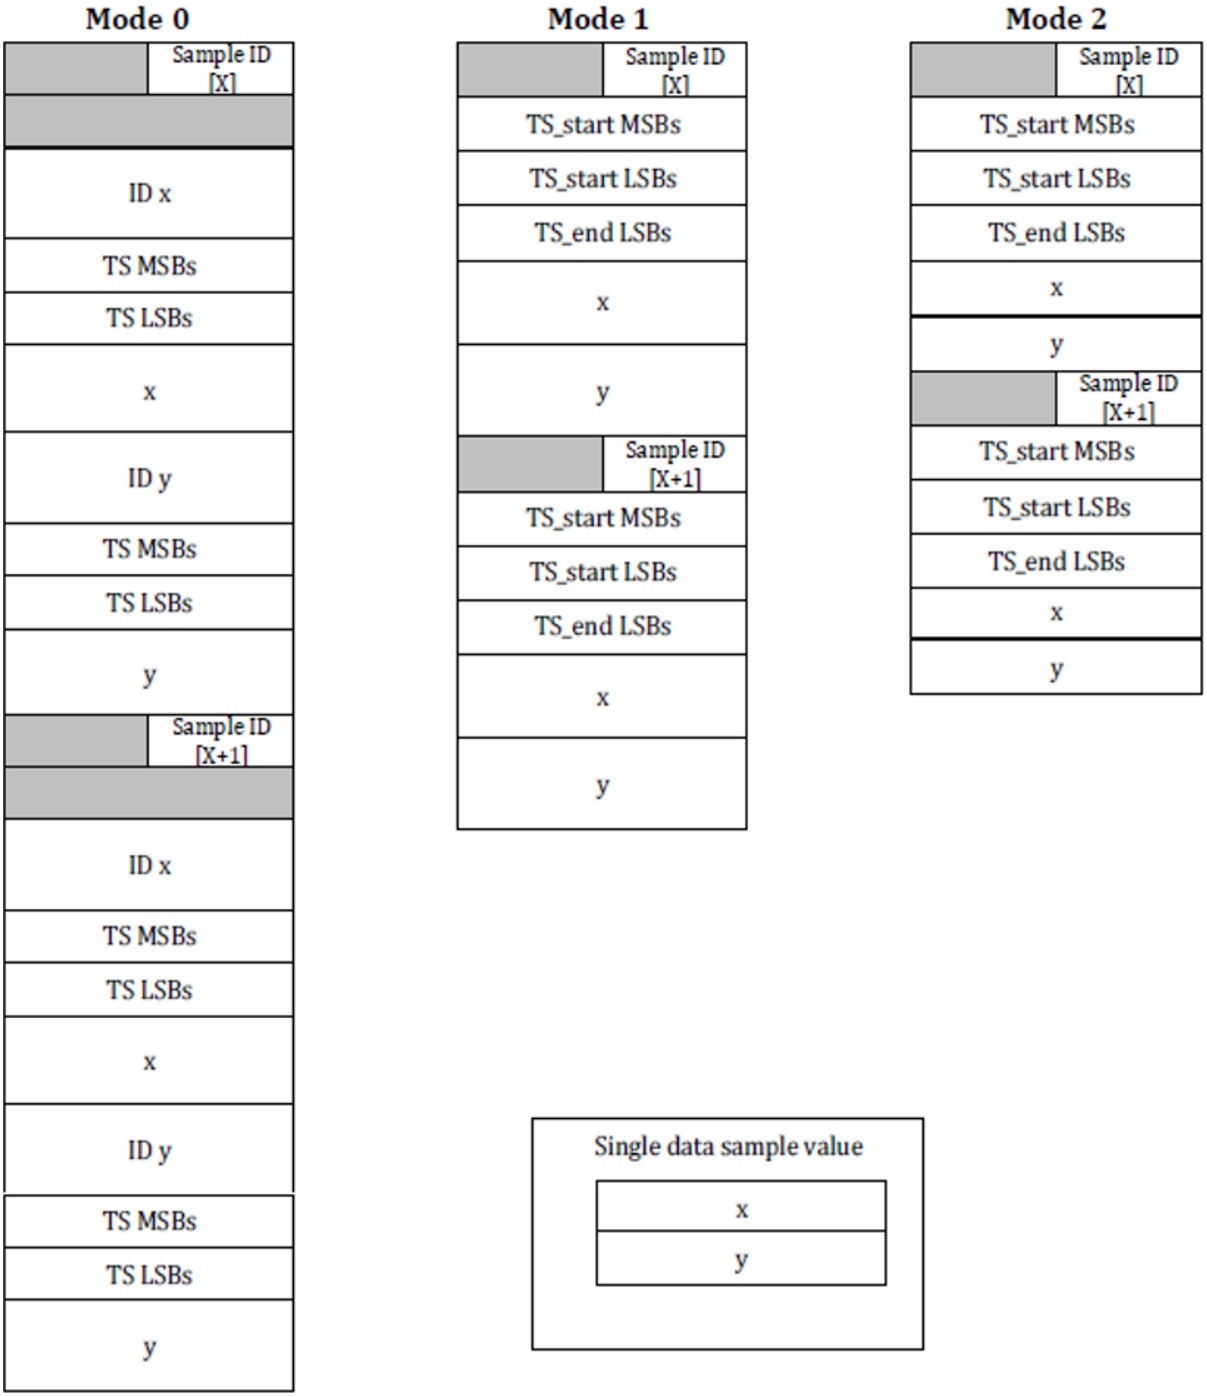
`doca_telemetry_diag` supports the following layout modes of the sampled data:

- Mode 0 – `data_id` is present in the output; data size is 64 bits; timestamp information per data
- Mode 1 – no `data_id` in the output; data size is 64 bits; timestamp information per sample (start and end)

- Mode 2 – no `data_id` in the output; data size is 32 bits; timestamp information per sample (start and end)

> ⚠ The order of the data IDs in the output is the same as the order in which the data IDs were applied
> using `doca_telemetry_diag_apply_counters_list_by_id`.

The sample layout of these modes is illustrated in the following diagrams:



5.4.18.4.5.2 Device Support

DOCA Telemetry Diagnostics requires a device to operate. For picking a device, refer to "DOCA Core Device Discovery".

As device capabilities may change (see DOCA Core Device Support), it is recommended to select your device using the following method:

- `doca_telemetry_diag_cap_is_supported`

Some devices can allow different capabilities as follows:

- The maximum number of data IDs
- The maximum number of samples that can be held by the firmware
- Support for data clear
- Support for synchronized start
- Support for different sample modes
- Support for different timestamp sources

5.4.18.4.6 Execution Phase

Once the `doca_telemetry_diag` context is started, samples can be retrieved by calling the `doca_telemetry_diag_query_counters` function.

The library only retrieves new samples without duplications and returns fewer samples than requested if there are no more new samples.

There is a slight difference in behavior between the different sampling modes:

- In case of "On demand" sampling mode, each time the `doca_telemetry_diag_query_counters` is called, a new sample is captured and retrieved.
- For "Single" and "Repetitive" sampling modes, multiple samples can be retrieved in a single call. The application defines the maximum number of samples it wishes to retrieve and supplies a buffer large enough to contain these samples.

  > The sample size can be obtained using `doca_telemetry_diag_get_sample_size`.

  > The user should limit the number of requested samples according to the `log_max_num_samples` property.

- In case of "Single" sampling mode, once sampling is terminated, the user may call `doca_telemetry_diag_restart` to restart the sampling process, overwriting the previous results.

- During the execution phase, you can dynamically adjust the sampling period using `doca_telemetry_diag_reconfig_sample_period` to change the sampling rate. Note that this function has no effect in "On demand" sampling mode. For other sampling modes, it's recommended to verify the actual sampling period using `doca_telemetry_diag_get_sample_period` after reconfiguration to ensure it matches the expected value.

5.4.18.4.7 State Machine

The following section describes the different states the `doca_telemetry_diag` context goes through, how to move between states and what is allowed in each state.

5.4.18.4.7.1 Idle

The context is Idle and has ownership over the diagnostics data registers interface.

In this state it is expected for the application to:

- Destroy the context (releases the ownership).
- Apply a configuration, moving the context to "Configured" state.

Allowed operations:

- Configuring the context according to Configurations.

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Configured	Call stop
Ready	Call stop
Running	Call stop

5.4.18.4.7.2 Configured

In this state it is expected for application to:

- Apply the list of data IDs configuration using `doca_telemetry_diag_apply_counters_list_by_id`, moving the context to "Ready" state.

Allowed operations:

- Checking if a data ID is supported using `doca_telemetry_diag_check_data_id`
- Calling stop, moving it to "Idle" state

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Successfully apply the configuration, calling `doca_telemetry_diag_apply_config`.

5.4.18.4.7.3 Ready

All the necessary configuration was applied and the context is ready to start sampling.

In this state it is expected that application:

- Start the context, moving it to "Running" state.

Allowed operations:

- Calling stop, moving it to "Idle" state.

It is possible to reach this state as follows:

Previous State	Transition Action
Configured	Successfully apply the list of counters, calling `doca_telemetry_diag_apply_counters_list_by_id`.

5.4.18.4.7.4 Running

In this state samples are generated and can be retrieved.

In this state it is expected that application:

- Query the counters.

Allowed operations:

- For "Single" sample mode, restarting the context if needed.
- Calling stop, moving it to "Idle" state

It is possible to reach this state as follows:

Previous State	Transition Action
Ready	Successfully start the context

5.4.18.4.8 Alternative Datapath Options

DOCA Telemetry Diag supports only CPU-based datapaths.

5.4.18.4.9 DOCA Telemetry Diagnostics Sample

This section describes a telemetry diagnostics sample based on the `doca_telemetry` library.

The sample illustrates the utilization of DOCA telemetry diagnostics APIs to initialize and configure the `doca_telemetry_diag` context, as well as querying and parsing diagnostic counters.

5.4.18.4.9.1 Running the Sample

1. Refer to the following documents:
    a. DOCA Installation Guide for Linux for details on how to install BlueField-related software.
    b. NVIDIA BlueField Platform Software Troubleshooting Guide for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

    ```
    cd /opt/mellanox/doca/samples/doca_telemetry/telemetry_diag
    meson /tmp/build
    ninja -C /tmp/build
    ```

    The binary `doca_telemetry_diag` is created under `/tmp/build/`.

Sample usage:

```
Usage: doca_telemetry_diag [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI device address
  -di, --data-ids                   Path to data ids JSON file
  -o, --output                      Output CSV file - default: "/tmp/out.csv"
  -rt, --sample-run-time            Total sample run time, in seconds
  -sp, --sample-period              Sample period, in nanoseconds
  -ns, --log-num-samples            Log max number of samples
  -sr, --max-samples-per-read       Max num samples per read
  -sm, --sample-mode                sample mode (0 - single, 1 - repetitive, 2 - on demand)
  -of, --output-format              output format (0 - output_format_0, 1 - output_format_1, 2 - output_format_2)
  -sym, --sync-mode                 sync mode (0 - sync_mode_no_sync, 1 - sync_mode_sync_start)
  -tss, --timestamp-source          timestamp source (0 - timestamp_source_frc, 1 - timestamp_source_rtc)
  -f, --force-ownership             Force ownership when creating context
  -e, --example-json-path           Generate an example json file with the default data_ids to the given path and
exit immediately. This file can be used as input later on. All other flags are ignored
  -rs, --reconfig-sample-period     Reconfig sample period, in nanoseconds. It means after the first sampling run
with the sample_period, if the reconfig_sample_period is non-0, before the current diag instance is stopped and
destroyed, the second sampling run will be done based on the reconfig_sample_period.
```

The sample logic includes:

1. Locating a DOCA device.
2. Initializing and configuring the `doca_telemetry_diag` instance.

3. Applying a list of data IDs to sample (either from a source JSON file or the default data IDs).
4. Starting the `doca_telemetry_diag` instance.
5. Allocating a buffer according to the sample size and amount of desired samples.
6. Querying the actual sampling period, after start.
7. Retrieving samples and writing the retrieved data to a `*.csv` file (either once or periodically).
8. If `reconfig_sample_period` is non-zero, retrieving samples and writing the sample file again based on the reconfigured sampling period.
9. Stopping the data IDs sampling.
10. Releasing all resources and destroying the context.

> ⚠ If the error message `cannot acquire ownership` is shown, please use the command option `--force-ownership` to take the ownership.

The sample can use data IDs given by the user using a JSON file. An example of the JSON file format can be created by using the `-e` flag on the sample, to export an example JSON file containing the default data IDs to a given path.

5.4.18.4.10 Visualization of Data ID's

The Ngauge tool is useful to visualise the data ID's prior to use or deployment in your application. Please see the Ngauge documentation for more information.

5.4.18.4.11 Appendix – List of Supported Data IDs

The following table lists the data IDs currently supported by DOCA:

Name	Description	Data Class	Data ID
`port_rx_bytes`	The number of received bytes on the physical port [1]	Counter	0x1020000100000XX • XX - Local port
`port_priority_rx_bytes`	The number of received bytes on the physical port and priority [1]	Counter	0x1020000200000YXX • XX - Local port • Y - Local port priority

Name	Description	Data Class	Data ID
`port_rx_packets`	The number of received packets on the physical port [1]	Counter	0x10200003000000XX • XX - Local port
`port_priority_rx_packets`	The number of received packets on the physical port and priority [1]	Counter	0x10200004000000YXX • XX - Local port • Y – local port priority
`port_rx_discard_buf_packets`	The number of received packets dropped due to lack of buffers on a physical port	Counter	0x10200005000000XX • XX - Local port
`port_priority_rx_pauses_packets`	The number of link-layer pause packets received on a physical port and priority	Counter	0x10200006000000YXX • XX - Local port • Y - Local port priority
`host_rx_buffer_discards`	The number of packets discarded due to no available data or descriptor buffers in the RX buffer, per host	Counter	0x10400001000000XX • XX - Host ID
`host_rx_transport_pass_packets`	The number of packets that pass from the RX Transport to the Scatter engine, per host	Counter	0x10800001000000XX • XX - Host ID
`host_rx_transport_out_of_buffer_packets`	The number of dropped packets due to a lack of WQE for the associated QPs/RQs (excluding hairpin QPs/RQs)	Counter	0x10800002000000XX • XX - Host ID
`host_rx_transport_out_of_buffer_hairpin_packets`	The number of dropped packets due to a lack of WQE for the associated hairpin QPs/RQs	Counter	0x10800003000000XX • XX - Host ID
`port_rx_transport_ecn_packets`	The number of RoCEv2 packets received by the notification point which were marked for experiencing the congestion (i.e., ECN bits `11` on the ingress RoCE traffic), per port	Counter	0x10800004000000XX • XX – Local port

Name	Description	Data Class	Data ID
`port_rx_transport_cnp_handled_packets`	The number of CNP received packets handled by the Reaction Point, per port	Counter	0x10800005000000XX • XX – Local port
`port_tx_transport_cnp_sent_packets`	The number of CNP packets sent by the Notification Point, per port	Counter	0x11000001000000XX • XX – Local port
`tx_transport_done_due_to_cc_deschedule_events`	The number of QP descheduled due to congestion control rate limitation	Counter	0x11000002000000
`port_tx_bytes`	The number of transmitted bytes on the physical port (excluding loopback traffic)	Counter	0x11400001000000XX • XX - Local port
`port_priority_tx_bytes`	The number of transmitted bytes on the physical port and priority (excluding loopback traffic)	Counter	0x11400002000000YXX • XX - Local port • Y - Local port priority
`port_tx_packets`	The number of transmitted packets on the physical port (excluding loopback traffic)	Counter	0x11400003000000XX • XX - Local port
`port_priority_tx_packets`	The number of transmitted packets on the physical port and priority (excluding loopback traffic)	Counter	0x11400004000000YXX • XX - Local port • Y - Local port priority
`port_priority_tx_pauses_packets`	The number of link-layer pause packets transmitted on a physical port and priority	Counter	0x11400005000000YXX • XX - Local port • Y - Local port priority
`pcie_link_inbound_bytes`	The number of bytes received from the PCIe toward the device, per PCIe link	Counter	0x11600001000ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)

Name	Description	Data Class	Data ID
`pcie_link_outbound_bytes`	The number of bytes transmitted from the device toward the PCIe, per PCIe link	Counter	0x1160000200ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_inbound_data_bytes`	The number of data bytes received from the PCIe (excluding headers) toward the device, per PCIe link	Counter	0x1160000300ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_outbound_data_bytes`	The number of data bytes transmitted from the device toward the PCI (excluding headers), per PCIe link	Counter	0x1160000400ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_write_stalled_time_no_posted_data_credits_ns`	The time period (in nanoseconds) in which the device had outbound posted write requests but stalled due to insufficient data credits per PCIe link	Counter	0x1160000500ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_write_stalled_time_no_posted_header_credits_ns`	The time period (in nanoseconds) in which the device had outbound posted write requests but stalled due to insufficient header credits per PCIe link	Counter	0x1160000600ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_read_stalled_time_no_non_posted_data_credits_ns`	The time period (in nanoseconds) in which the device had outbound non-posted read requests but stalled due to insufficient data credits per PCIe link	Counter	0x1160000700ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_read_stalled_time_no_non_posted_header_credits_ns`	The time period (in nanoseconds) in which the device had outbound non-posted read requests but stalled due to insufficient header credits per PCIe link	Counter	0x1160000800ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)

Name	Description	Data Class	Data ID
`pcie_link_read_stalled_time_no_completion_buffers_ns`	The time period (in nanoseconds) in which the device had outbound non-posted read requests but stalled due to no NIC completion buffers per PCIe link	Counter	0x1160000900ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_tclass_read_stalled_time_ordering_ns`	The time period (in nanoseconds) in which the device had outbound non-posted read requests but stalled due to PCIe ordering semantics per PCIe link and PCIe tclass	Counter	0x1160000aZZZZYYXX • XX – Node • YY – PCIe index • ZZZZ – (tclass (0 – 7) << 6) | (Depth (0 – 63))
`pcie_link_latency_total_read_ns`	The total latency (in nanoseconds) for all PCIe read from the device per PCIe link [2]	Statistic	0x1160000b00ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_latency_total_read_packets`	The total number of packets used for the `pcie_link_latency_total_read_ns` calculation	Statistic	0x1160000c00ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_latency_max_read_ns`	The maximum latency (in nanoseconds) for a single PCIe read from the device per PCIe link	Statistic	0x1160000d00ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)
`pcie_link_latency_min_read_ns`	The minimum latency (in nanoseconds) for a single PCIe read from the device per PCIe link	Statistic	0x1160000e00ZZYYXX • XX – Node • YY – PCIe index • ZZ – Depth (0 – 63)

Name	Description	Data Class	Data ID
mplhr_pcie_link_latency_read_hist_packets	The number of PCIe reads with latency in the range of the PCIe Latency Histogram bin per PCIe link. The sampled value will be the same as the MPLH corresponding bin entry "Bin" is currently 0→9 (10 bins in total)		0x1160000fZZZZYYXX • XX – Node • YY – PCIe index • ZZZZ – (Bin (0 – 31) << 6) | (Depth (0 – 63))
`global_completion_engine_rx_cqes`	Number of responder (RX) CQEs	Counter	0x10c0000100000000
`function_completion_engine_rx_cqes`	Number of RX CQEs per function	Counter	0x10c0000200000XXXX • XXXX – vhca_id
`global_completion_engine_tx_cqes`	Number of requestor (TX) CQEs	Counter	0x10c0000400000000
`function_completion_engine_tx_cqes`	Number of TX CQEs per function	Counter	0x10c0000500000XXXX • XXXX – vhca_id
`global_icmc_request`	Number of accesses to ICMC	Counter	0x1180000100000000
`global_icmc_hit`	Number of ICMC hits	Counter	0x1180000200000000
`global_icmc_miss`	Number of ICMC misses	Counter	0x1180000300000000

1. This counter includes loopback traffic and does not include packets discarded due to FCS, frame size, and similar errors.
2. Dividing this counter by `pcie_link_latency_total_read_packets` yields the average PCIe read latency of those reads.

5.4.18.5 DOCA Telemetry DPA

This guide provides instructions for building and developing applications that require telemetry data collection from NVIDIA® BlueField® and NVIDIA® ConnectX® networking platforms using the DOCA Telemetry DPA API.

> ⚠ DOCA Telemetry DPA is supported at alpha level.

5.4.18.5.1 Introduction

The DOCA Telemetry DPA library provides access to detailed telemetry data and performance statistics for the Data Path Accelerator (DPA) on supported NVIDIA networking platforms. With its API, developers can monitor and analyze DPA processes, threads, and profiling data for efficient application performance optimization.

5.4.18.5.2 Prerequisites

To use DOCA Telemetry DPA, the following prerequisites must be met:

- `fwctl` driver installed and loaded (see instructions in NVIDIA MLNX_OFED Documentation v24.07-0.6.1.0)

  To verify whether the `fwctl` driver is successfully loaded:

  ```
  $ ls /sys/class/fwctl/
  ```

  Expected output:

  ```
  fwctl0  fwctl1
  ```

  If the directory `/sys/class/fwctl` does not exist or is empty, follow these steps:

  a. Search for the `fwctl` package:

  ```
  $ apt search fwctl
  ```

  The output may indicate either `fwctl-dkms` or `fwctl-modules`.

  b. Install the appropriate package:

  ```
  $ sudo apt install fwctl-dkms
  ```

  Or:

  ```
  $ sudo apt install fwctl-modules
  ```

  c. Load the `mlx5_fwctl` module:

  ```
  $ sudo modprobe mlx5_fwctl
  ```

  d. Confirm the module is loaded:

  ```
  $ lsmod | grep fwctl
  ```

  Expected output:

```
mlx5_fwctl             20480  0
fwctl                  24576  1 mlx5_fwctl
mlx5_core            2211840  2 mlx5_fwctl,mlx5_ib
mlx_compat             20480  17
rdma_cm,ib_ipoib,mlxdevm,nvme,mlxfw,mlx5_fwctl,iw_cm,nvme_core,nvme_fabrics,ib_umad,fwctl
,ib_core,rdma_ucm,ib_uverbs,mlx5_ib,ib_cm,mlx5_core
```

- Firmware version 28.43.1000 for ConnectX-7 or 32.43.1000 for BlueField-3

5.4.18.5.3 Environment

DOCA Telemetry DPA-based applications can run on:

- Host machines – ConnectX-7 or BlueField-3 and newer
- DPU targets – BlueField-3 and newer

5.4.18.5.4 Architecture

DOCA Telemetry DPA provides comprehensive profiling data, including:

- Process and thread information – Monitor all active DPA processes and threads
- Cumulative performance counters – Track cumulative performance metrics to evaluate application behavior
- Event tracer data – Capture detailed event-based traces for in-depth analysis

To interact with a device, users must create a DOCA Telemetry DPA context using `doca_telemetry_dpa_create()`. Each context is independent of DOCA DPA contexts, meaning changes in DPA configurations are not automatically reflected in the telemetry context. A device typically corresponds to a specific port on a NIC.

⚠ Performance counters are not owned by the `doca_telemetry_dpa` context. Other active telemetry contexts could manage the same counters. Ensure only a single context is used to profile the DPA to avoid conflicts.

5.4.18.5.5 Configuration Phase

5.4.18.5.5.1 Device Support

DOCA Telemetry DPA requires a device to operate. For picking a device, refer to "DOCA Core Device Discovery".

As device capabilities may change (see DOCA Core Device Support), it is recommended to check your device using the `doca_telemetry_dpa_cap_is_supported()` method:

5.4.18.5.5.2 Output Structure Format

The user application is responsible for allocating the output structures. To that end, DOCA Telemetry DPA provides helper methods that return the structure size in bytes (see section Execution Phase for more details).

The `doca_telemetry_dpa` context supports the following layout structures for the profile data:

doca telemetry_dpa_process_info	
`dpa_process_id`	Global DPA process ID
`num_of_threads`	Number of threads in the process
`process_name`	The name of the process

doca_telemetry_dpa_thread_info	
`dpa_process_id`	Global DPA process ID
`dpa_thread_id`	Global DPA thread ID
`thread_name`	The name of the thread

doca_telemetry_dpa_cumul_info	
`dpa_process_id`	Global DPA process ID
`dpa_thread_id`	Global DPA thread ID
`time`	Total time in ticks the thread has been active
`cycles`	Total execution unit cycles the thread used
`instructions`	Total number of instructions the thread executed
`num_executions`	Total number of thread executions

doca_telemetry_dpa_event_sample	
`timestamp`	Timestamp in µsec
`cycles`	Stamp of total execution unit (EU) cycles
`instructions`	Stamp of total number of instructions of this DPA EU
`dpa_thread_id`	Global DPA thread ID
`eu_id`	Execution unit ID
`sample_id_in_eu`	Running sample ID per EU. A single `sample_id` is assigned to both schedule in and out samples.

doca_telemetry_dpa_event_sample	
`type`	Type of event sample: • `DOCA_TELEMETRY_DPA_EVENT_SAMPLE_TYPE_EMPTY_SAMPLE` • `DOCA_TELEMETRY_DPA_EVENT_SAMPLE_TYPE_SCHEDULE_IN` • `DOCA_TELEMETRY_DPA_EVENT_SAMPLE_TYPE_SCHEDULE_OUT` • `DOCA_TELEMETRY_DPA_EVENT_SAMPLE_TYPE_BUFFER_FULL`

⚠ The user can retrieve the DPA timer ticks frequency, given in kHZ, using `doca_telemetry_dpa_get_dpa_timer_freq()`. With this frequency, timer ticks can be converted to running clock using the formula: `clock_time = ticks/dpa_timer_frequency`.

5.4.18.5.5.3 Establishing the Amount of Event Tracer Samples

The user must set the maximum amount of event tracer samples to retrieve. This value can be set using `doca_telemetry_dpa_set_max_perf_event_samples()` and retrieved using `doca_telemetry_dpa_get_max_perf_event_samples()`.

5.4.18.5.5.4 Addressing All Processes and Threads

- To retrieve a unique ID to address all processes running on the DPA:

```
uint32_t all_processes_id;
doca_telemetry_dpa_get_all_process_id(&all_processes_id);
```

- To retrieve a unique ID to address all threads running on the DPA:

```
uint32_t all_threads_id;
doca_telemetry_dpa_get_all_threads_id(&all_threads_id);
```

5.4.18.5.6 Execution Phase

5.4.18.5.6.1 Retrieving Running DPA Process Information

Information about specific process or all processes running on the DPA can be retrieved using these steps:

1. Get memory size for process list allocation:

```
uint32_t size;
doca_telemetry_dpa_get_process_list_size(context, process_id, &size);
```

2. Retrieve process list:

```
doca_telemetry_dpa_read_processes_list(context, processs_id, &process_num, &process_list);
```

⚠ Ensure memory is properly allocated using the retrieved size before calling `doca_telemetry_dpa_read_processes_list()`.

5.4.18.5.6.2 Retrieving Running DPA Thread Information

Information about specific thread or all threads running on the DPA can be retrieved using these steps:

1. Get memory size for thread list allocation:

```
uint32_t size;
doca_telemetry_dpa_get_thread_list_size(context, process_id, thread_id, &size);
```

2. Retrieve thread list:

```
doca_telemetry_dpa_read_thread_list(context, process_id, thread_id, &threads_num, &thread_list);
```

⚠ If the process ID is set to address all processes, the thread ID must also be set to address all threads.

⚠ Ensure memory is properly allocated using the retrieved size before calling `doca_telemetry_dpa_read_thread_list()`.

5.4.18.5.6.3 Retrieving Cumulative Performance Profile Information Samples

Cumulative performance samples can be retrieved for specific processes and threads or for all processes and threads (see Address all processes and threads) running on the DPA using these steps:

1. Start cumulative counter/s:

```
doca_telemetry_dpa_counter_start(context, process_id, DOCA_TELEMETRY_DPA_COUNTER_TYPE_CUMULATIVE_EVENT);
```

2. Stop cumulative counter/s:

```
doca_telemetry_dpa_counter_stop(context, process_id, DOCA_TELEMETRY_DPA_COUNTER_TYPE_CUMULATIVE_EVENT);
```

3. Get memory size for cumulative samples list allocation:

```
uint32_t size;
doca_telemetry_dpa_get_cumul_samples_size(context, process_id, thread_id, &size);
```

4. Retrieve cumulative sample list:

```
doca_telemetry_dpa_read_cumul_info_list(context, process_id, thread_id, &cumul_samples_num,
&cumul_info_list);
```

The current state and type of a counter can be retrieved using `doca_telemetry_dpa_get_counter_state()` and `doca_telemetry_dpa_get_counter_type()`.

If the process ID is set to address all processes, the thread ID must also be set to address all threads.

Ensure memory is properly allocated using the retrieved size before calling `doca_telemetry_dpa_read_cumul_info_list()`.

Reset counters using `doca_telemetry_dpa_counter_restart()` to clear previous data.

5.4.18.5.6.4 Retrieving Event Tracer Profile Information Samples

Event tracer samples can be retrieved for specific processes and threads or for all processes and threads running on the DPA using these steps:

1. Start event tracer counter/s:

```
doca_telemetry_dpa_counter_start(context, all_processes_id, DOCA_TELEMETRY_DPA_COUNTER_TYPE_EVENT_TRACER);
```

2. Stop event tracer counter/s:

```
doca_telemetry_dpa_counter_stop(context, all_processes_id, DOCA_TELEMETRY_DPA_COUNTER_TYPE_EVENT_TRACER);
```

3. Get memory size for event samples list allocation:

```
uint32_t size;
doca_telemetry_dpa_get_perf_event_samples_size(context, process_id, thread_id, &size);
```

4. Retrieve event tracer sample list:

```
doca_telemetry_dpa_read_perf_event_list(context, process_id, thread_id, &perf_event_samples_num,
&event_info_list);
```

The current state and type of a counter can be retrieved using `doca_telemetry_dpa_get_counter_state()` and `doca_telemetry_dpa_get_counter_type()`.

⚠ Ensure the maximum number of samples is set before starting counters using `doca_telemetry_dpa_set_max_perf_event_samples()`.

⚠ If the process ID is set to address all processes, the thread ID must also be set to address all threads.

⚠ Ensure memory is properly allocated using the retrieved size before calling `doca_telemetry_dpa_read_perf_event_list()`.

⚠ Reset counters using `doca_telemetry_dpa_counter_restart()` before reuse.

5.4.18.5.7 State Machine

The following section describes the different states the `doca_telemetry_dpa` context goes through, how to move between states and what is allowed in each state.

5.4.18.5.7.1 Idle

The context has been created and is idle.

In this state, it is expected for the application to:

- Destroy the context
- Start the context for processing

Allowed operations:

- Configuring the context according to section "Configuration Phase"

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop

5.4.18.5.7.2 Running

In this state it is expected for the application to:

1. Stop the context.
2. Retrieve process information list
3. Retrieve thread information list.

4. Start/stop/reset counters for profiling capabilities.
5. Retrieve profile samples for cumulative performance counters.
6. Retrieve profile samples for event tracer.

Allowed operations:

- Calling stop, moving the application to "Idle" state

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Successfully start the context

> ⚠ There are currently no state restrictions on the majority of API functions.

5.4.18.5.8 Alternative Datapath Options

DOCA Telemetry DPA supports only CPU-based datapaths.

5.4.18.5.8.1 Running the Sample

1. Refer to the following documents:
   a. DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   b. NVIDIA BlueField Platform Software Troubleshooting Guide for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_telemetry/telemetry_dpa
meson /tmp/build
ninja -C /tmp/build
```

> ℹ The binary `doca_telemetry_dpa` is created under `/tmp/build/`.

Sample usage:

```
Usage: doca_telemetry_dpa [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                      Print a help synopsis
  -v, --version                   Print program version information
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>               Parse command line flags from an input json file

Program Flags:
```

```
-p, --pci-addr                  DOCA device PCI device address
-rt, --sample-run-time          Total sample run time, in miliseconds
-ct, --counter-type             Counter type, cumulus (0) or event (1)
-es, --event-samples            Set the maximum number of perf event samples to retrieve
-pi, --process-id               Specific process id to address
-ti, --thread-id                Specific thread id to address
```

The sample includes:

1. Locating and opening a DOCA device.
2. Creating a `doca_telemetry_dpa` instance.
3. Retrieval of all or one specific process
4. Retrieval of all or one specific thread
5. Starting counters for the selected profile capability
6. Retrieving the profile samples for the selected profile capability
7. Displaying the retrieve profile information.
8. Destroying the `doca_telemetry_dpa` context.

5.4.18.6 DOCA Telemetry PCC

This guide provides instructions for building and developing applications that require telemetry data collection from NVIDIA® BlueField® and NVIDIA® ConnectX® families of networking platforms.

5.4.18.6.1 Introduction

The `doca_telemetry_pcc` library provides access to algorithm information and counter statistics for any Programmable Congestion Control (PCC) implementations currently installed on NVIDIA® BlueField or ConnectX® networking platforms.

> ⚠ DOCA Telemetry PCC is supported at alpha level.

5.4.18.6.2 Prerequisites

To use DOCA Telemetry PCC, the following prerequisites must be met:

- `fwctl` driver installed and loaded (see instructions in NVIDIA MLNX_OFED Documentation v24.07-0.6.1.0)

  > ⚠ To verify whether the `fwctl` driver is successfully loaded:
  >
  > ```
  > $ ls /sys/class/fwctl/
  > ```
  >
  > Expected output:

```
fwctl0  fwctl1
```

If the directory `/sys/class/fwctl` does not exist or is empty, follow these steps:

a. Search for the `fwctl` package:

```
$ apt search fwctl
```

The output may indicate either `fwctl-dkms` or `fwctl-modules`.

b. Install the appropriate package:

```
$ sudo apt install fwctl-dkms
```

Or:

```
$ sudo apt install fwctl-modules
```

c. Load the `mlx5_fwctl` module:

```
$ sudo modprobe mlx5_fwctl
```

d. Confirm the module is loaded:

```
$ lsmod | grep fwctl
```

Expected output:

```
mlx5_fwctl             20480  0
fwctl                  24576  1 mlx5_fwctl
mlx5_core            2211840  2 mlx5_fwctl,mlx5_ib
mlx_compat             20480  17
rdma_cm,ib_ipoib,mlxdevm,nvme,mlxfw,mlx5_fwctl,iw_cm,nvme_core,nvme_fabrics,ib_umad,fwctl
,ib_core,rdma_ucm,ib_uverbs,mlx5_ib,ib_cm,mlx5_core
```

- Firmware version 28.43.1000 for ConnectX-7 or 32.43.1000 for BlueField-3

5.4.18.6.3 Environment

DOCA Telemetry-based applications can run on either the host machine (ConnectX-7 or BlueField-3 and newer) or the DPU target (BlueField-3 and newer).

5.4.18.6.4 Architecture

DOCA Telemetry PCC allows for the collection of information from any PCC images installed and actively running on a ConnectX or BlueField device.

To interact with a device, a separate `doca_telemetry_pcc` context must be created for each device. A device typically corresponds to a specific port on a NIC.

The `doca_telemetry_pcc` context operates independently of any `doca_pcc` contexts. This means that changes to the configuration of a running PCC image, such as disabling an algorithm, are not automatically reflected in the telemetry context. Implementing applications must handle these changes either by directly interacting with the PCC application or by scanning all algorithm slots to determine which are currently active.

It is assumed that a new PCC image will not be installed while a `doca_telemetry_pcc` context is active on the device.

If a complete PCC re-image is performed, a new `doca_telemetry_pcc` context must be created.

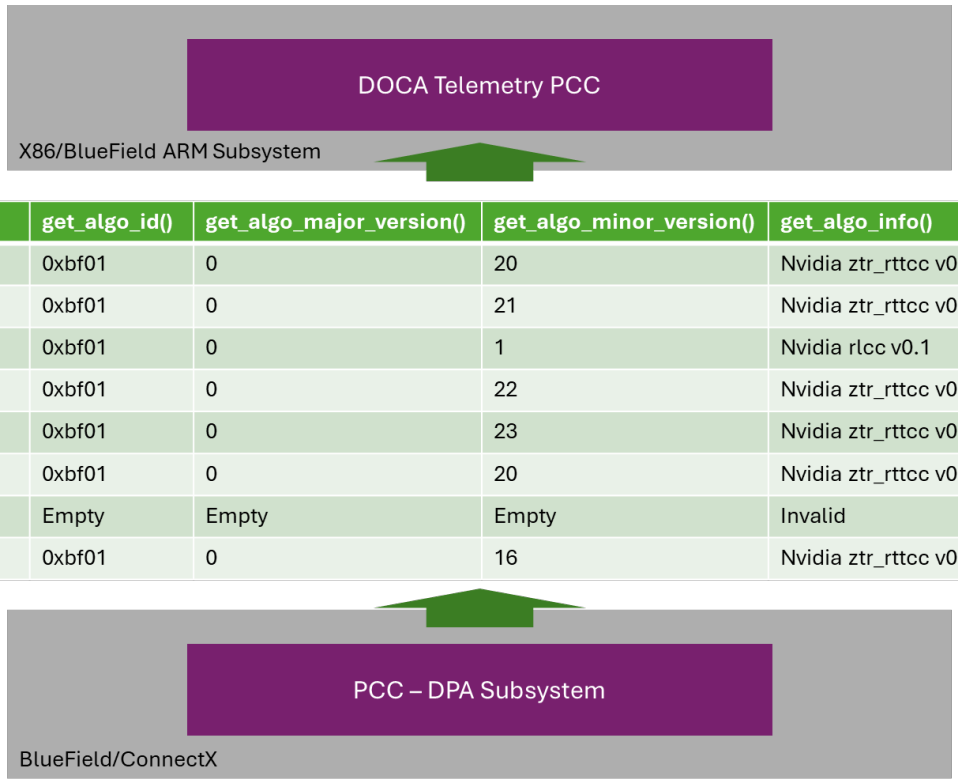
5.4.18.6.5 Schema Retrieval

5.4.18.6.5.1 Slots/Algorithms

An active PCC image running on the DPA subsystem of a device can contain multiple Congestion Control algorithms. Each algorithm is assigned to a specific "slot," with only one slot/algorithm active on the device at any given time.

The algorithms in each slot cannot be modified without re-imaging the PCC algorithm on the DPAs. While DOCA Telemetry PCC does not provide functionality to configure slots or algorithms, it enables the calling application to retrieve information about the algorithms installed in each populated slot.

For example:



Slot Index	get_algo_id()	get_algo_major_version()	get_algo_minor_version()	get_algo_info()
1	0xbf01	0	20	Nvidia ztr_rttcc v0.20
2	0xbf01	0	21	Nvidia ztr_rttcc v0.21

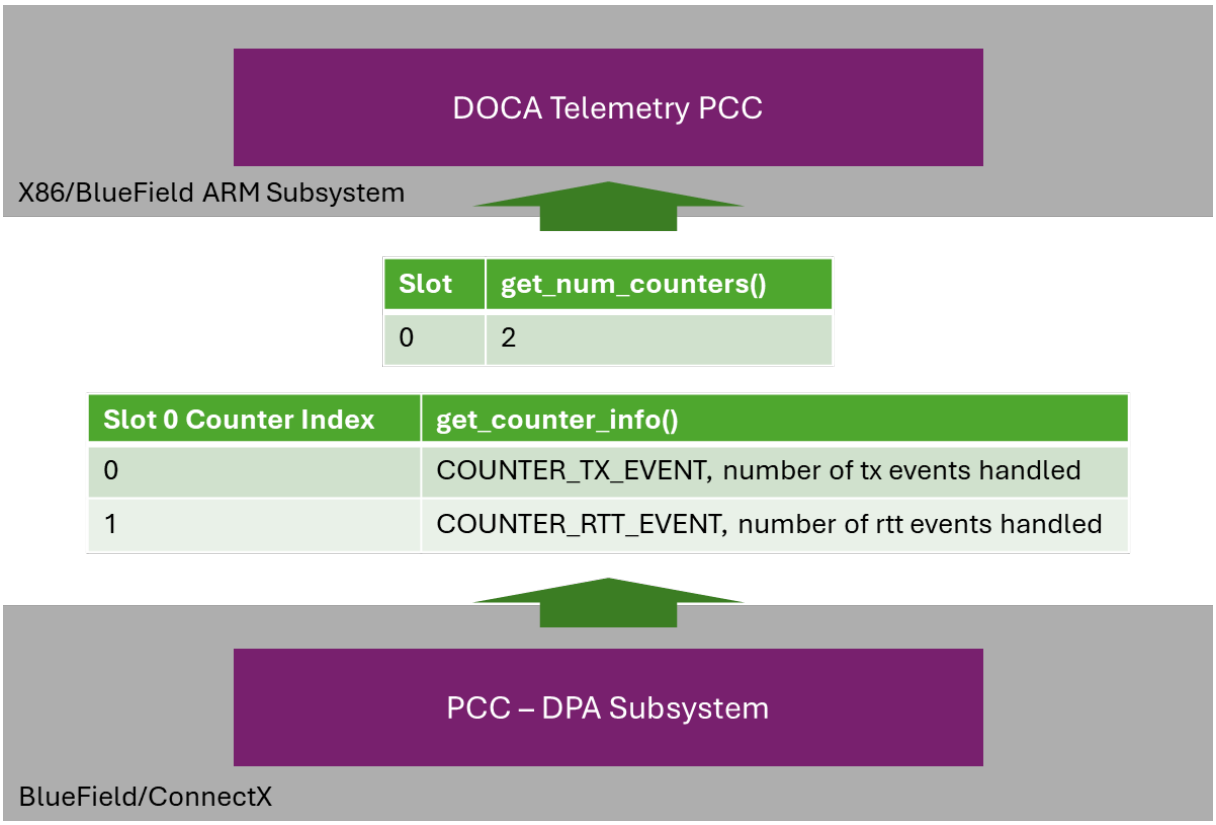
5.4.18.6.5.2 Counter Information

Similar to slots, the counter definitions for each algorithm cannot be modified without re-imaging a new PCC.

DOCA Telemetry PCC allows applications to retrieve the number of counters defined for an algorithm applied to a specific port. Each counter's definition can then be accessed using an index value, ranging from `0` to `total_counters-1`.

For example:



5.4.18.6.6 Run-time Retrieval

5.4.18.6.6.1 Status

The congestion algorithm actively running on a device at any given time is determined by the lowest enabled slot index, as multiple slots can be marked as enabled simultaneously.

The enabling or disabling of a slot can be triggered dynamically at runtime by external processes, independent of DOCA Telemetry PCC. Automatically detecting these changes falls outside the scope of a `doca_telemetry_pcc` context. It is the user's responsibility to either scan all slots periodically or interface directly with the external process to monitor changes.

In addition to enabling/disabling a slot, counters for a slot can also be enabled or disabled. Only one slot can have active counters at any given time. If counters are not active on an algorithm slot, any attempt to poll their values will result in a `DOCA_ERROR_BAD_STATE`.

The status of both the slot and its counters can be inspected using the `doca_telemetry_pcc_get_algo_enable_status` API.

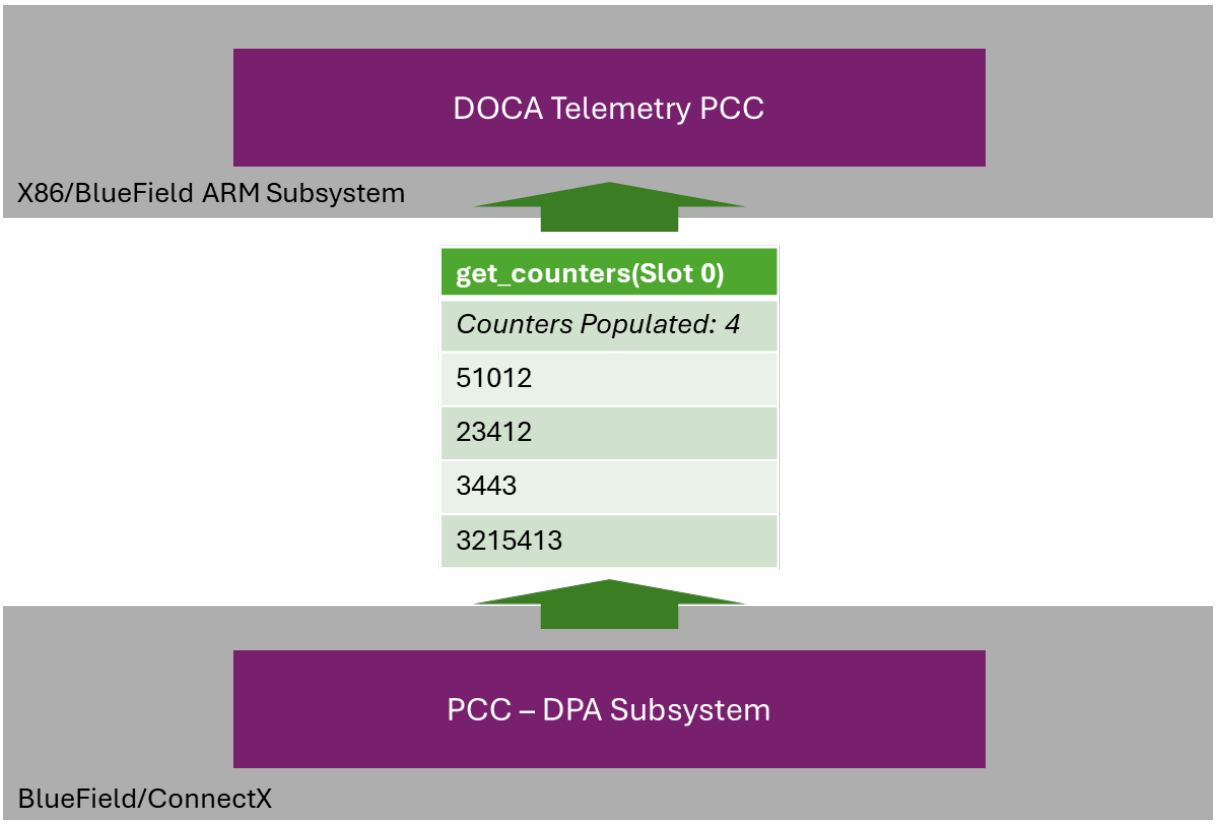
⚠ Since PCC configuration is managed outside DOCA Telemetry PCC, there is no guarantee that system conditions remain consistent between API calls. For example, `get_algo_enable_status()` may indicate that counters are enabled, but subsequent polling of those counters could fail if they were disabled between the calls.

5.4.18.6.6.2 Counters

Counter values for a slot with enabled counters can be polled using a `doca_telemetry_pcc` context associated with a specific device.

When retrieving counter values, the API returns all available counters as a block rather than individually. The counters are provided in an array of 32-bit values, along with the total number of counters populated in the array.

It is assumed that the user is familiar with what each counter index represents (refer to the "Counter Information" section for details).



DOCA Telemetry PCC provides another API function which enables the resetting of counters if so required.

5.4.18.6.7 State Machine

This section outlines the various states the `doca_telemetry_pcc` context transitions through, the methods for transitioning between these states, and the operations permitted in each state.

5.4.18.6.7.1 Idle

The context has been created and is Idle.

In this state, it is expected for the application to:

- Destroy the context.
- Start the context for processing.

Allowed operations:

- Configuring the context.

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop

5.4.18.6.7.2 Running

In this state it is expected for the application to:

- Stop the context.

Allowed operations:

- Calling stop, moving the application to "Idle" state

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Successfully start the context

There are currently no state restrictions on the majority of API functions.

5.4.18.6.8 Alternative Datapath Options

DOCA Telemetry PCC supports only CPU-based datapaths.

5.4.18.6.9 DOCA Telemetry PCC Sample

This section describes a telemetry PCC sample based on the `doca_telemetry_pcc` library. The sample illustrates the utilization of DOCA telemetry PCC APIs to initialize and configure the `doca_telemetry_pcc` context, as well as querying and parsing PCC schema and counters.

These samples are also available on GitHub.

5.4.18.6.9.1 Running the Sample

1. Refer to the following documents:
    a. DOCA Installation Guide for Linux for details on how to install BlueField-related software.
    b. NVIDIA BlueField Platform Software Troubleshooting Guide for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

    ```
    cd /opt/mellanox/doca/samples/doca_telemetry/telemetry_pcc
    meson /tmp/build
    ninja -C /tmp/build
    ```

    The binary `doca_telemetry_pcc` is created under `/tmp/build/`.

Sample usage:

```
Usage: doca_telemetry_pcc [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI device address
```

The sample includes:

1. Locating and opening a DOCA device.
2. Creating a `doca_telemetry_pcc` instance.
3. Parsing all possible slots, printing each:
    a. Algo ID
    b. Major version
    c. Minor version
    d. Description
4. Determining and displaying the current enabled status of each slot.
5. Counter values and descriptions for any slot with counters enabled.

6. Destroying the `doca_telemetry_pcc` context.

5.4.18.7 DOCA Telemetry PCI

This guide provides instructions for building and developing applications that require telemetry data collection from NVIDIA® BlueField and NVIDIA® ConnectX® families of networking platforms.

5.4.18.7.1 Introduction

The `doca_telemetry_pci` library provides access to PCIe status and performance information from BlueField or ConnectX networking platforms.

⚠ DOCA Telemetry PCI is supported at alpha level.

5.4.18.7.2 Prerequisites

To use DOCA Telemetry PCI, the following prerequisites must be met:

- `fwctl` driver installed and loaded (see instructions in NVIDIA MLNX_OFED Documentation v24.07-0.6.1.0)

  ⚠ To verify whether the `fwctl` driver is successfully loaded:

  ```
  $ ls /sys/class/fwctl/
  ```

  Expected output:

  ```
  fwctl0  fwctl1
  ```

  If the directory `/sys/class/fwctl` does not exist or is empty, follow these steps:

  a. Search for the `fwctl` package:

  ```
  $ apt search fwctl
  ```

  The output may indicate either `fwctl-dkms` or `fwctl-modules`.

  b. Install the appropriate package:

  ```
  $ sudo apt install fwctl-dkms
  ```

  Or:

```
$ sudo apt install fwctl-modules
```

c. Load the `mlx5_fwctl` module:

```
$ sudo modprobe mlx5_fwctl
```

d. Confirm the module is loaded:

```
$ lsmod | grep fwctl
```

Expected output:

```
mlx5_fwctl             20480  0
fwctl                  24576  1 mlx5_fwctl
mlx5_core            2211840  2 mlx5_fwctl,mlx5_ib
mlx_compat             20480  17
rdma_cm,ib_ipoib,mlxdevm,nvme,mlxfw,mlx5_fwctl,iw_cm,nvme_core,nvme_fabrics,ib_umad,fwctl
,ib_core,rdma_ucm,ib_uverbs,mlx5_ib,ib_cm,mlx5_core
```

- Firmware version 28.43.1000 for ConnectX-7 or 32.43.1000 for BlueField-3

5.4.18.7.3 Environment

DOCA Telemetry-based applications can run on either the host machine (ConnectX-7 or BlueField-3 and newer) or the DPU target (BlueField-3 and newer).

5.4.18.7.4 Architecture

DOCA Telemetry PCI provides insights into PCIe devices, including:

- Management information: PCIe link and speed details, power usage, function count, error detection flags, and more.
- PCIe performance counters: Data transfer rates, error rates, stall counters, L0 recovery count, and other performance metrics.
- PCIe latency histogram: Helps understand the duration of PCIe operations.

To interact with a device, typically corresponding to a specific NIC port, create a DOCA Telemetry PCI context using `doca_telemetry_pci_create()`.

5.4.18.7.5 Configuration Phase

5.4.18.7.5.1 Device Support

DOCA Telemetry PCI requires a device to operate. For picking a device, refer to "DOCA Core Device Discovery".

As device capabilities may change, it is recommended to check your device using the required set of PCIe telemetry options you desire before opening it to be confident the operations you desire and available. The set of available capability checks for DOCA Telemetry PCI are out lined below:

Functionality	Method
PCI Management Information	`doca_telemetry_pci_cap_management_info_is_supported()`
PCI Performance Counters Group 1	`doca_telemetry_pci_cap_perf_counters_1_is_supported()`
PCI Performance Counters Group 2	`doca_telemetry_pci_cap_perf_counters_2_is_supported()`
PCI Latency Histogram	`doca_telemetry_pci_cap_latency_histogram_is_supported()`

Within the structures provided during the execution phase some fields are only populated which a further sub-capability is also supported:

Functionality	Field(s)	Method
PCI Management Information	`pwr_status`, `pci_power`	`doca_telemetry_pci_cap_management_info_power_reporting_is_supported()`
	`link_peer_max_speed`	`doca_telemetry_pci_cap_management_info_link_peer_max_speed_is_supported()`
PCI Performance Counters Group 1	`tx_overflow_buffer_pkt`, `tx_overflow_buffer_marked_pkt`	`doca_telemetry_pci_cap_perf_counters_1_tx_overflow_is_supported()`
	`outbound_stalled_reads`, `outbound_stalled_writes`, `outbound_stalled_reads_events`, `outbound_stalled_writes_events`	`doca_telemetry_pci_cap_perf_counters_1_outbound_stalled_is_supported()`
	`fec_correctable_error_counter`, `fec_uncorrectable_error_counter`	`doca_telemetry_pci_cap_perf_counters_1_fec_error_is_supported()`
	`fber_magnitude`, `fber_coef`	`doca_telemetry_pci_cap_perf_counters_1_fber_is_supported()`

5.4.18.7.6 Execution Phase

5.4.18.7.6.1 Retrieving PCIe Management Information

Using a running `doca_telemetry_pci` context which supports PCIe management information the user can call `doca_telemetry_pci_read_management_info` as many times as they like to get the most recent data available with each call.

The following is a more complete example:

```
doca_error_t result;
```

```
// Check for Ability to read management info
result = doca_telemetry_pci_cap_management_info_is_supported(devinfo);
if(result != DOCA_SUCCESS)
    // Capability is not supported or an error occoured, stop

// Check any sub capabilities if you require those fields

// Create PCI telemetry
struct doca_telemetry_pci *pci_telem;
result = doca_telemetry_pci_create(dev, &pci_telem);
if(result != DOCA_SUCCESS)
    // Handle failure to create telemetry instance

// Start PCI telemetry
result = doca_telemetry_pci_start(pci_telem);
if(result != DOCA_SUCCESS)
    // Handle failure to start telemetry instance

// Read management info
struct doca_telemetry_pci_dpn dpn = {0, 0, 0};
struct doca_telemetry_pci_management_info management_info = {};

result = doca_telemetry_pci_read_management_info(pci_telem, dpn, &management_info);
if(result != DOCA_SUCCESS)
    // Handle failure to read data

// Use the data

// Cleanup
doca_telemetry_pci_stop(pci_telem);
doca_telemetry_pci_destroy(pci_telem);
```

5.4.18.7.6.2 Retrieving Performance Counters Group 1

Using a running `doca_telemetry_pci` context which supports performance counters group 1 the user can call `doca_telemetry_pci_read_perf_counters_1` as many times as they like to get the most recent data available with each call.

The following is a more complete example:

```
doca_error_t result;

// Check for Ability to read perf counters group 1
result = doca_telemetry_pci_cap_perf_counters_1_is_supported(devinfo);
if(result != DOCA_SUCCESS)
    // Capability is not supported or an error occoured, stop

// Check any sub capabilities if you require those fields

// Create PCI telemetry
struct doca_telemetry_pci *pci_telem;
result = doca_telemetry_pci_create(dev, &pci_telem);
if(result != DOCA_SUCCESS)
    // Handle failure to create telemetry instance

// Start PCI telemetry
result = doca_telemetry_pci_start(pci_telem);
if(result != DOCA_SUCCESS)
    // Handle failure to start telemetry instance

// Read perf counters group 1
struct doca_telemetry_pci_dpn dpn = {0, 0, 0};
struct doca_telemetry_pci_perf_counters_1 counters= {};

result = doca_telemetry_pci_read_perf_counters_1(pci_telem, dpn, &counters);
if(result != DOCA_SUCCESS)
    // Handle failure to read data

// Use the data

// Cleanup
doca_telemetry_pci_stop(pci_telem);
doca_telemetry_pci_destroy(pci_telem);
```

5.4.18.7.6.3 Retrieving Latency Histogram

Using a running `doca_telemetry_pci` context which supports latency histogram the user must first call `doca_telemetry_pci_get_latency_histogram_dimensions` to learn the correct dimmensions of the histogram. They can then allocate an array of histogram values and then finally they can call

`doca_telemetry_pci_read_latency_histogram` as many times as they like to get the most recent data available with each call.

The following is a more complete example:

```
doca_error_t result;

// Check for Ability to read perf counters group 2
result = doca_telemetry_pci_cap_latency_histogram_is_supported(devinfo);
if(result != DOCA_SUCCESS)
    // Capability is not supported or an error occoured, stop

// Create PCI telemetry
struct doca_telemetry_pci *pci_telem;
result = doca_telemetry_pci_create(dev, &pci_telem);
if(result != DOCA_SUCCESS)
    // Handle failure to create telemetry instance

// Start PCI telemetry
result = doca_telemetry_pci_start(pci_telem);
if(result != DOCA_SUCCESS)
    // Handle failure to start telemetry instance

// Learn the histograms dimmensions
struct doca_telemetry_pci_dpn dpn = {0, 0, 0};
uint32_t bucket_count;
uint32_t bucket_width_ns;
result = doca_telemetry_pci_get_latency_histogram_dimensions(pci_telem, dpn, &bucket_count, &bucket_width_ns);
if(result != DOCA_SUCCESS)
    // Handle failure to get histogram dimmensions

// Allocate memory to hold histogram data
uint64_t* buckets_arr = malloc(bucket_count * sizeof(uint64_t));
if( buckets_arr == NULL)
    // Handle failure to allocate memory

// Fetch histogram data
result = doca_telemetry_pci_read_latency_histogram(pci_telem, dpn, buckets_arr);
if(result != DOCA_SUCCESS)
    // Handle failure to read data

// Use the data

// Cleanup
free(buckets_arr);
doca_telemetry_pci_stop(pci_telem);
doca_telemetry_pci_destroy(pci_telem);
```

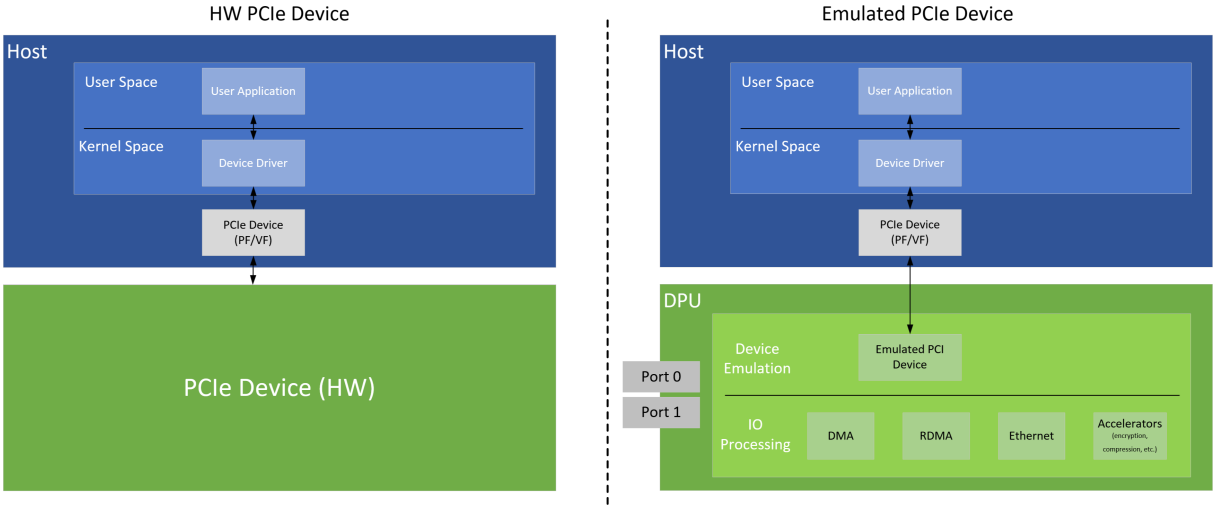
5.4.18.7.7 Alternative Datapath Options

DOCA Telemetry PCI supports only CPU-based datapaths.

5.4.19 DOCA Device Emulation

5.4.19.1 Introduction

NVIDIA® BlueField® networking platforms (DPUs or SuperNICs) provide the ability to emulate a PCIe device. The DOCA Device Emulation subsystem provides a low-level software API for users to develop PCIe devices and their controllers. These APIs include discovery, configuration, hot plugging/unplugging, management, and IO path handling. In simpler terms, the libraries enable the user to implement a hardware PCIe function using software, such that the host is not aware that the PCIe function is emulated, and all interactions from the host are routed to software on the BlueField instead of actual hardware.



The diagram shows the potential for device emulation to replace a regular PCIe function of some PCIe device.

- On the left is a conventional setup where the host is connected to a PCIe device (e.g., NVMe SSD). On the host, user applications interact with the kernel driver of that device, using some software interface, and the driver communicates with the hardware/firmware of the device.
- On the right is a setup where the PCIe device is replaced with a BlueField with an application using DOCA Device Emulation. The application can use the DOCA DevEmu PCI library to control the device, and intercept any IOs written by the host to the PCIe device. Additionally, the application can use other DOCA libraries to perform IO processing (e.g., copying data from host memory using DMA, sending RDMA/Ethernet traffic) and other acceleration libraries for encryption, compression, etc.

5.4.19.2 Known Limitations

- This library is supported at alpha level; backward compatibility is not guaranteed
- VFs are not currently supported
- Some limitations apply when creating a generic emulated function, for more details refer to DOCA DevEmu PCI Generic Limitations.
- Consult your NVIDIA representative for limitations on the emulated device's behavior

5.4.19.3 DOCA DevEmu PCI

5.4.19.3.1 Introduction

> The quality status of DOCA libraries is listed here.

DOCA DevEmu PCI is part of the DOCA Device Emulation subsystem. It provides low-level software APIs that allow management of an emulated PCIe device using the emulation capability of NVIDIA® BlueField® networking platforms.

It is a common layer for all PCIe emulation modules, such as DOCA DevEmu PCIe Generic Emulation, and DOCA DevEmu Virtio subsystem emulation.

5.4.19.3.2 Prerequisites

This library follows the architecture of a DOCA Core Context. It is recommended read the following sections beforehand:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

Generic device emulation is part of DOCA device emulation. It is recommended to read the following guides beforehand:

- DOCA Device Emulation

5.4.19.3.3 Environment

DOCA DevEmu PCI Emulation is supported only on the BlueField target. The BlueField must meet the following requirements

- DOCA version 2.7.0 or greater
- BlueField-3 firmware 32.41.1000 or higher

> Please refer to the DOCA Compatibility Policy.

The library must be run with root privileges.

Perform the following:

1. Configure the BlueField to work in DPU mode as described in BlueField Modes of Operation.

2. Enable the PCIe switch emulation capability needed for hot plugging emulated PCIe devices. This can be done by running the following command on the host or BlueField:

```
host/bf> sudo mlxconfig -d /dev/mst/mt41692_pciconf0 s PCI_SWITCH_EMULATION_ENABLE=1
```

3. Perform a BlueField system-level reset for the `mlxconfig` settings to take effect.

To support hot-plug feature, the host must have the following boot parameters:

- Intel CPU:

```
intel_iommu=on iommu=pt pci=realloc
```

- AMD CPU:

```
iommu=pt pci=realloc
```

This can be done using the following steps:

> This process may vary depending on the host OS. Users can find multiple guides online describing this process.

1. Add the boot parameters:

```
host> sudo nano /etc/default/grub
Find the variable
GRUB_CMDLINE_LINUX_DEFAULT="<existing-params>"
Add the params at the end
GRUB_CMDLINE_LINUX_DEFAULT="<existing-params> intel_iommu=on iommu=pt pci=realloc"
```

2. Update configuration.
   - For Ubuntu:

```
host> update-grub
```

   - For RHEL:

```
host> grub2-mkconfig -o /boot/grub2/grub.cfg
```

3. Perform warm boot.
4. Confirm that the parameters are in effect:

```
host> cat /proc/cmdline
<existing-params> intel_iommu=on iommu=pt pci=realloc
```

5.4.19.3.4 Architecture

The DOCA DevEmu PCI library provides 2 main software abstractions, the PCIe type, and the PCIe device. The PCIe type represents the configurations of the emulated device,

while the PCIe device represents an instance of an emulated device. Furthermore, any PCIe device instance must be associated with a single PCIe type, while PCIe type can be associated with many PCIe devices.

5.4.19.3.4.1 Pre-defined PCI Type vs. Generic PCI Type

A PCIe type object can be acquired in 2 different ways:

- Acquire a pre-defined type, using emulation libraries of existing protocols such as DOCA DevEmu Virtio FS library
- Create from scratch using the DOCA DevEmu Generic library

In case of pre-defined type, the configurability of the type is limited.

5.4.19.3.4.2 PCIe Type Name

As part of the DOCA PCIe emulation, every type has a name assigned to it. This property is not part of the PCIe specification, but rather it is a mechanism in DOCA that uniquely identifies the PCIe type.

There cannot be 2 different PCIe types with the same name, even across different processes, unless the type in the second process is configured in identical manner to the first one. Furthermore, attempting to configure the second type with same name but with slight configuration difference will fail.

5.4.19.3.4.3 Create Emulated Device

After configuring the desired DOCA Devemu PCIe type, it is possible to create an emulated device based on the configured type using `doca_devemu_pci_dev_create_rep`. This sequential process ensures that the DOCA DevEmu PCIe device is created with the specified parameters and configuration defined by the PCIe type object. Furthermore, it is possible to destroy the emulated device using `doca_devemu_pci_dev_destroy_rep`.

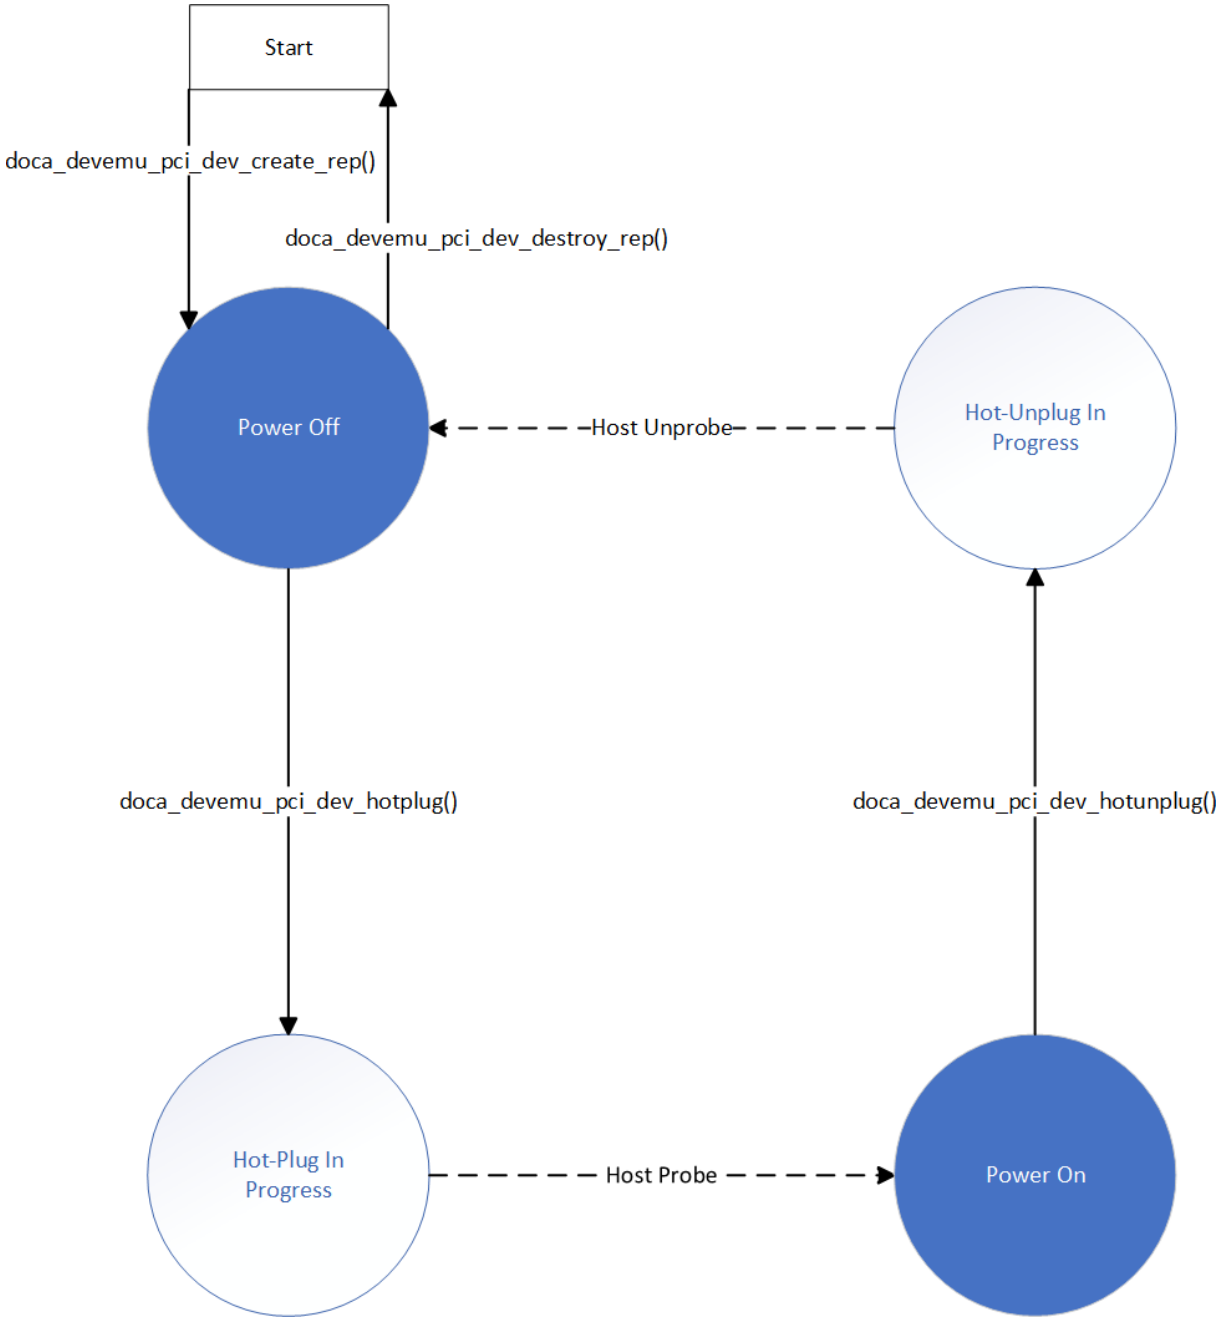
The created device representor starts in "power_off" state and is not visible to the host until hot-plug sequence is issued by the user, see Hot-plug Emulated Device. The device can then be destroyed only while in "power_off" state.

> The created emulated device may outlive the application that created it, see Objects Lifecycle and Persistency.

5.4.19.3.4.4 Hot-plug Emulated Device

Hot-plugging refers to the process of emulating the physical attachment of a PCIe device to the host PCIe subsystem after the system has been powered on and initialized. Note that some operating systems require additional settings to enable the process of hot-plugging a PCIe device. For supported systems, this feature proves particularly advantageous for systems that need to remain operational at all times while

expanding their hardware resources, such as additional storage and networking capabilities. DOCA DevEmu PCI provides software APIs that allow users to emulate this process in an asynchronous manner.



When creating a PCIe device object, if it starts in "power off" state, then the device is not yet visible to the host. It is possible then, from the BlueField, to hot-plug the device. This starts an async process of the device getting hot-plugged towards the host. Once the process completes, the emulated device transitions to "power on" and becomes visible to the host. Usually at this stage, the emulated device receives its BDF address. The hot-unplug process works in similar async manner.

Using DOCA API, the BlueField Arm can register to any changes to the hot-plug state of each emulated device using `doca_devemu_pci_dev_event_hotplug_state_change_register`.

5.4.19.3.4.5 Emulated Device Discovery

The emulated device is represented as a `doca_devinfo_rep`. It is possible to iterate through all the emulated devices as explained in DOCA Core Representor Discovery.

There are 2 ways of filtering the list of emulated devices:

- Get all emulated devices – use `DOCA_DEVINFO_REP_FILTER_EMULATED` as the filter argument in `doca_devinfo_rep_create_list`
- Get all emulated devices that belong to a certain type – `doca_devemu_pci_type_create_rep_list`

5.4.19.3.4.6 Objects Lifecycle and Persistency

This section creates distinction between firmware resources and software resources:

- Firmware resources persist until the next power cycle, and can be accessible from different processes on the BlueField Arm. Such resources are not cleared once the application exits.
- Software resources are representations of firmware resources, and are only relevant for the same thread

Using this terminology, it is possible to describe the objects as follows:

- The PCIe type object `doca_devemu_pci_type` represents a PCIe type firmware resource. The resource persists if any of the following apply:
  - There is at least 1 process holding reference to the PCIe type
  - There is at least 1 PCIe device firmware resource belonging to this type
- The emulated device representor, `doca_devinfo_rep`, represents an emulated PCIe function firmware resource:
  - `doca_devemu_pci_dev_create_rep` can be used to create such firmware resource
  - To destroy the firmware resource, `doca_devemu_pci_dev_destroy_rep` can be used
  - For static functions, the representor resource persists until configured otherwise in NVCONFIG
  - To find existing PCIe device firmware resources, use `doca_devemu_pci_type_create_rep_list`

5.4.19.3.4.7 Function-level Reset

The created emulated devices support PCIe function level reset (FLR).

Using DOCA API, the BlueField Arm can register to FLR event using `doca_devemu_pci_dev_event_flr_register`. Once the driver requests FLR, this event is triggered, calling the user provided callback.

Once FLR is detected, it is expected for the BlueField Arm to do the following:

- Destroy all resources related to the PCIe device. For information on such resources, refer to the guide of concrete PCIe type (generic/virtiofs).
- Stop the PCIe device
- Start the PCIe device again

5.4.19.3.4.8 PCIe Resources

It is possible to query the number of available PCIe emulation resources. The resources that can be queried are:

- Number of doorbells
- Number of MSI-X

These resources are globally shared across the system between all emulated devices that are created using the same `doca_dev`.

5.4.19.3.5 Device Support

DOCA PCIe Device emulation requires a device to operate. For picking a device, see DOCA Core Device Discovery.

The device emulation library is only supported for BlueField-3.

As device capabilities may change in the future (see Capability Checking), it is recommended that users choose a device using the following method:

- `doca_devemu_pci_cap_type_is_hotplug_supported` – for create and hot-plug support
- `doca_devemu_pci_cap_type_is_mgmt_supported` – for device discovery only

5.4.19.3.6 PCIe Device

5.4.19.3.6.1 Configuration Phase

To start using the DOCA DevEmu PCI Device, users must first go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context to allow retrieval of events.

Configurations

The context can be configured to match the application use case.

To find if a configuration is supported or what its min/max value is, refer to Device Support.

Mandatory Configurations

All mandatory configurations are provided during the creation of the PCIe device.

These configurations are as follows:

- A DOCA DevEmu PCIe type object
- A DOCA Device Representor, representing an emulated function with the same type as the provided PCIe object type
- A DOCA Progress Engine object

Optional Configurations

These configurations are optional. If not set, then a default value is used:

- Registering to events as described in the "Events" section. By default, the user does not receive events
- The PCIe device ID. By default, it is derived from the PCIe type.
- The PCIe vendor ID. By default, it is derived from the PCIe type.
- The PCIe subsystem ID. By default, it is derived from the PCIe type.
- The PCIe subsystem vendor ID. By default, it is derived from the PCIe type.
- The PCIe revision ID. By default, it is derived from the PCIe type.
- The PCIe class code. By default, it is derived from the PCIe type.
- The number of MSI-X vectors for MSI-X capability. By default, it is derived from the PCIe type.

5.4.19.3.6.2 Execution Phase

This section describes execution on CPU using DOCA Core Progress Engine.

Events

The DOCA DevEmu PCI device exposes asynchronous events to notify about sudden changes according to DOCA Core architecture.

Common events are described in DOCA Core Event.

Hotplug State Change

The hotplug state change event allows users to receive notifications whenever the hotplug state of the emulated device changes. See section "Hot-plug Emulated Device".

Event Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_devemu_pci_dev_event_hotplug_state_change_register`	`doca_devemu_pci_cap_type_is_hotplug_supported`

Event Trigger Condition

The event is triggered anytime an asynchronous transition happens as follows:

- `DOCA_DEVEMU_PCI_HP_STATE_PLUG_IN_PROGRESS` → `DOCA_DEVEMU_PCI_HP_STATE_POWER_ON`
- `DOCA_DEVEMU_PCI_HP_STATE_UNPLUG_IN_PROGRESS` → `DOCA_DEVEMU_PCI_HP_STATE_POWER_OFF`
- `DOCA_DEVEMU_PCI_HP_STATE_POWER_ON` → `DOCA_DEVEMU_PCI_HP_STATE_UNPLUG_IN_PROGRESS` (when initiated by the host)

Any transition initiated by user is not triggered (e.g., calling hotplug to transition from `POWER_OFF` to `PLUG_IN_PROGRESS`).

The following APIs can be used to initiate hotplug or hot-unplug transition processes:

- `doca_devemu_pci_dev_hotplug`
- `doca_devemu_pci_dev_hotunplug`

Event Output

Common output as described in DOCA Core Event.

Additionally, the internal cached hotplug state is updated and can be fetched using `doca_devemu_pci_dev_get_hotplug_state`.

Event Handling

Once the event is triggered, it means that the hotplug state has changed. The application is expected to do the following:

- Retrieve the new hotplug state using `doca_devemu_pci_dev_get_hotplug_state`

Function-level Reset

The FLR event allows users to receive notifications whenever the host initiates an FLR flow. See section "Function Level Reset".

Event Configuration

Description	API to Set the Configuration
Register to the event	`doca_devemu_pci_dev_event_flr_register`

Event Trigger Condition

The event is triggered anytime the host driver initiates an FLR flow. See section "Function Level Reset".

Event Output

Common output as described in DOCA Core Event.

Additionally, the internal cached FLR indicator is updated and can be fetched using `doca_devemu_pci_dev_is_flr`.

Event Handling

Once the event is triggered, it means that the host driver has initiated the FLR flow.

The user must handle the FLR flow by doing the following:

1. Flush all the outstanding requests back to the associated resource
2. Release all the PCIe device resources dynamically created after device start
3. Stop the PCIe device – `doca_ctx_stop`
4. Start the PCIe device again – `doca_ctx_start`
    - Call `doca_pe_progress` repeatedly until the PCIe device transitions to "running" state

For more information on starting the PCIe device again, refer to section "State Machine".

5.4.19.3.6.3 State Machine

The DOCA DevEmu PCI device object follows the context state machine as described in DOCA Core Context State Machine.

The following section describes how to transition to any state and what is allowed in each state.

Idle

In this state, it is expected that application either:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to section "Configurations"
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all resources have been destroyed
Stopping	Call progress until all resources have been destroyed

Starting

In this state, it is expected that application:

- Calls progress to allow transition to next state
- Keeps context in this state until FLR flow is complete

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after receiving FLR event (i.e., while FLR is in progress)

Running

In this state, it is expected that application:

- Calls progress to receive events
- Creates/destroys PCIe device resources

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after configuration
Starting	Call progress until FLR flow is completed

Stopping

In this state, it is expected that application:

- Destroys all emulated device resources as described in section "Function Level Reset".

Allowed operations:

- Destroying PCIe device resources

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call stop without freeing emulated device resources

5.4.19.3.7 DOCA DevEmu PCI Generic

> ⚠ This library is supported at the alpha level; backward compatibility is not guaranteed.

This guide provides instructions on building and developing applications that require emulation of a generic PCIe device.

5.4.19.3.7.1 Introduction

DOCA DevEmu PCI Generic is part of the DOCA Device Emulation subsystem. It provides low-level software APIs that allow creation of a custom PCIe device using the emulation capability of NVIDIA® BlueField®.

For example, it enables emulating an NVMe device by creating a generic emulated device, configuring its capabilities and BAR to be compliant with the NVMe spec, and operating it from the DPU as necessary.

5.4.19.3.7.2 Prerequisites

This library follows the architecture of a DOCA Core Context. It is recommended read the following sections beforehand:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

Generic device emulation is part of DOCA PCIe device emulation. It is recommended to read the following guides beforehand:

- DOCA Device Emulation
- DOCA DevEmu PCI

5.4.19.3.7.3 Environment

DOCA DevEmu PCI Generic Emulation is supported only on the BlueField target. The BlueField must meet the following requirements:

- DOCA version 2.7.0 or greater
- BlueField-3 firmware 32.41.1000 or higher

> Please refer to the DOCA Compatibility Policy.

Library must be run with root privileges.

Please refer to DOCA DevEmu PCI Environment, for further necessary configurations.

5.4.19.3.7.4 Architecture

DOCA DevEmu PCI Generic allows the creation of a generic PCI type. The PCI Type is part of the DOCA DevEmu PCI library. It is the component responsible for configuring the capabilities and bar layout of emulated devices.

The PCI Type can be considered as the template for creating emulated devices. Such that the user first configures a type, and then they can use it to create multiple emulated devices that have the same configuration.

For a more concrete example, consider that you would like to emulate an NVMe device, then you would create a type and configure its capabilities and BAR to be compliant with the NVMe spec, after that you can use the same type, to generate multiple NVMe emulated devices.

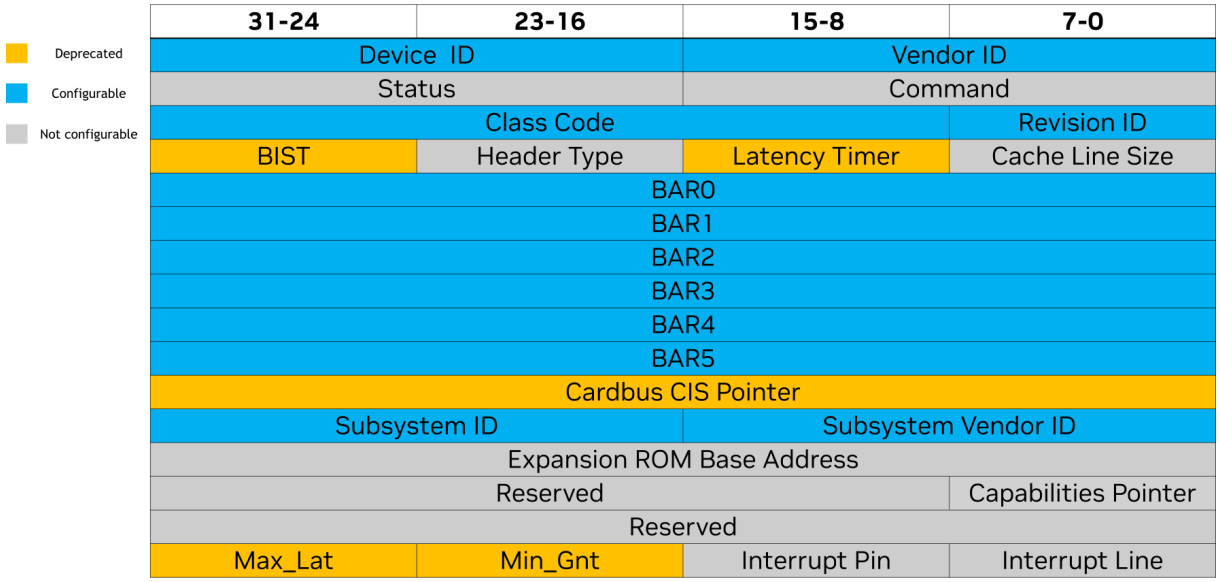
PCIe Configuration Space

The PCIe configuration space is 256 bytes long and has a header that is 64 bytes long. Each field can be referred to as a register (e.g., device ID).

Every PCIe device is required to implement the PCIe configuration space as defined in the PCIe specification.

The host can then read and/or write to registers in the PCIe configuration space. This allows the PCIe driver and the BIOS to interact with the device and perform the required setup.

It is possible to configure registers in the PCIe configuration space header as shown in the following diagram:



0x0 is the only supported header type (general device).

The following registers are read-only, and they are used to identify the device:

Register Name	Description	Example
Class Code	Defines the functionality of the device Can be further split into 3 values {class : subclass: prog IF}	0x020000 Class: 0x02 (Network Controller) Subclass: 0x00 (Ethernet Controller) Prog IF: 0x00 (N/A)
Revision ID	Unique identifier of the device revision Vendor allocates ID by itself	0x01 (Rev 01)

Vendor ID	Unique identifier of the chipset vendor Vendor allocates ID from the PCI-SIG	0x15b3 Nvidia
Device ID	Unique identifier of the chipset Vendor allocates ID by itself	0xa2dc BlueField-3 integrated ConnectX-7 network controller
Subsystem Vendor ID	Unique identifier of the card vendor Vendor allocates ID from the PCI-SIG	0x15b3 Nvidia
Subsystem ID	Unique identifier of the card Vendor allocates ID by itself	0x0051

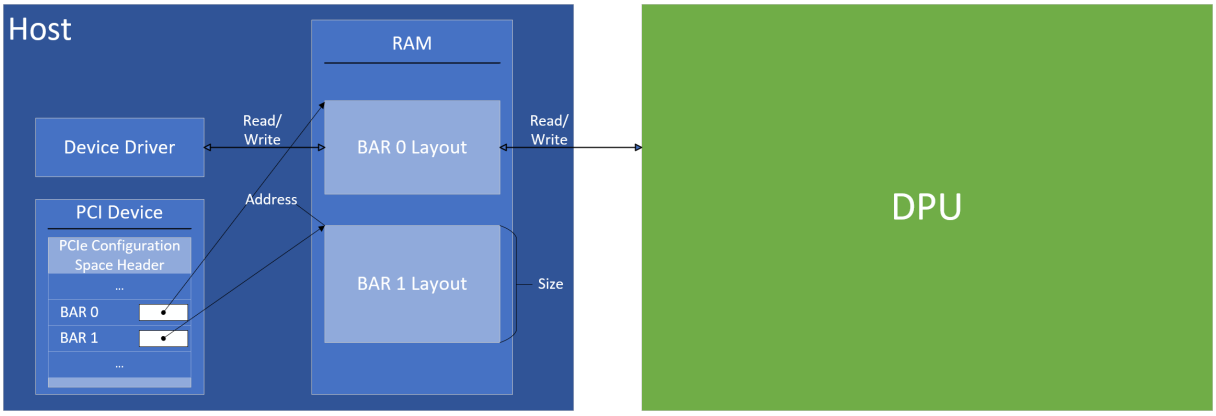
BAR

While the PCIe configuration space can be used to interact with the PCIe device, it is not enough to implement the functionality that is targeted by the device. Rather, it is only relevant for the PCIe layer.

To enable protocol-specific functionality, the device configures additional memory regions referred to as base address registers (BARs) that can be used by the host to interact with the device. Different from the PCIe configuration space, BARs are defined by the device and interactions with them is device-specific. For example, the PCIe driver interacts with an NVMe device's PCIe configuration space according to the PCIe spec, while the NVMe driver interacts with the BAR regions according to the NVMe spec.

Any read/write requests on the BAR are typically routed to the hardware, but in case of an emulated device, the requests are routed to the software.

The DOCA DevEmu PCI type library provides APIs that allow software to pick the mechanism used for routing the requests to software, while taking into consideration common design patterns utilized in existing devices.



Each PCIe device can have up to 6 BARs with varying properties. During the PCIe bus enumeration process, the PCIe device must be able to advertise information about the layout of each BAR. Based on the advertised information, the BIOS/OS then allocates a memory region for each BAR and assigns the address to the relevant BAR in the PCIe configuration space header. The driver can then use the assigned memory address to perform reads/writes to the BAR.

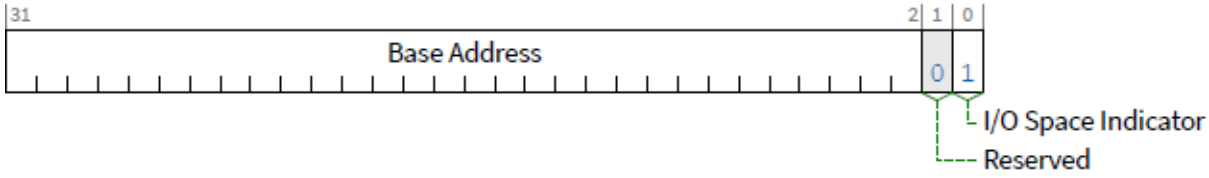
BAR Layout

The PCIe device must be able to provide information with regards to each BAR's layout.

The layout can be split into 2 types, each with their own properties as detailed in the following subsections.

I/O Mapped

According to the PCIe specification, the following represents the I/O mapped BAR:



Additionally, the BAR register is responsible for advertising the requested size during enumeration.

> The size must be a power of 2.

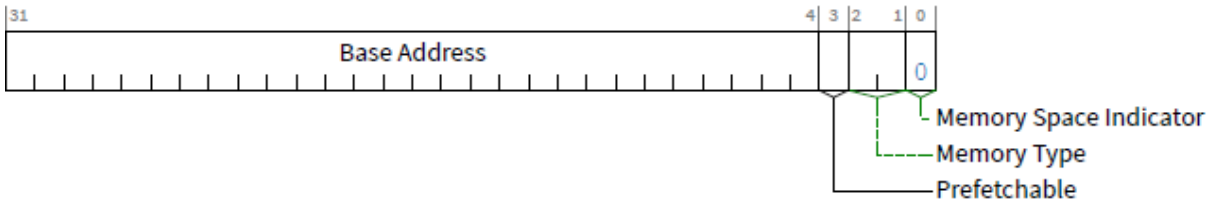
Users can use the following API to set a BAR as I/O mapped:

```
doca_devemu_pci_type_set_io_bar_conf(struct doca_devemu_pci_type *pci_type, uint8_t id, uint8_t log_sz)
```

- `id` – the BAR ID
- `log_sz` – the log of the BAR size

Memory Mapped

According to the PCIe specification, the following represents the memory mapped BAR:



Additionally, the BAR register is responsible for advertising the requested size during enumeration.

> The size must be a power of 2.

The memory mapped BAR allows a 64-bit address to be assigned. To achieve this, users must specify the bar Memory Type as 64-bit and then set the next BAR's (BAR ID + 1) size to be 0.

Setting the pre-fetchable bit indicates that reads to the BAR have no side effects.

Users can use the following API to set a BAR as memory mapped:

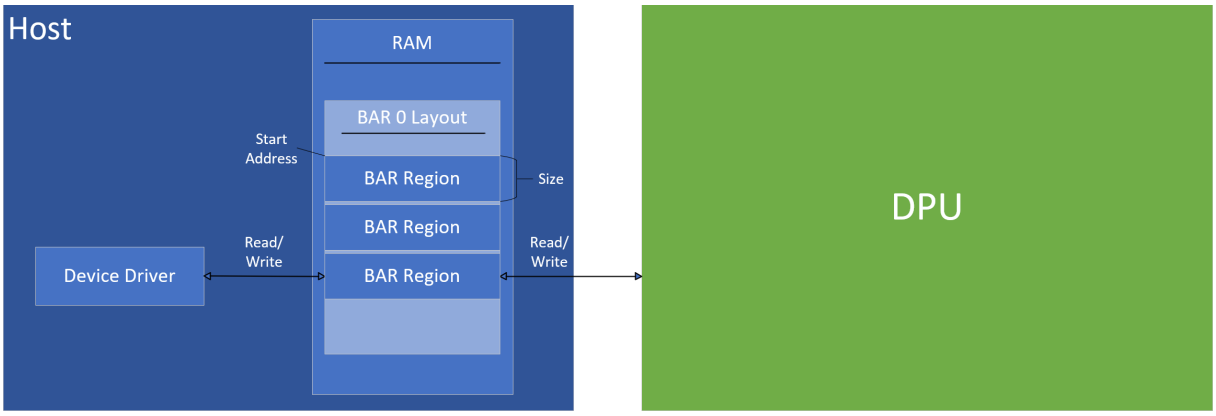
```
doca_devemu_pci_type_set_memory_bar_conf(struct doca_devemu_pci_type *pci_type, uint8_t id, uint8_t log_sz, enum
 doca_devemu_pci_bar_mem_type memory_type, uint8_t prefetchable)
```

- `id` – the BAR ID
- `log_sz` – the log of the BAR size. If set to 0, then the size is considered as 0 (instead of 1).
- `memory_type` – specifies the memory type of the BAR. If set to 64-bit, then the next BAR must have `log_sz` set to 0.
- `prefetchable` – indicates whether the BAR memory is pre-fetchable or not (a value of 1 or 0 respectively)

BAR Regions

BAR regions refer to memory regions that make up a BAR layout. This is not something that is part of the PCIe specification, rather it is a DOCA concept that allows the user to customize behavior of the BAR when interacted with by the host.

The BAR region defines the behavior when the host performs a read/write to an address within the BAR, such that every address falls in some memory region as defined by the user.



Common Configuration

All BAR regions have these configurations in common:

- `id` – the BAR ID that the region is part of
- `start_addr` – the start address of the region within the BAR layout relative to the BAR. 0 indicates the start of the BAR layout.
- `size` – the size of the BAR region

Currently, there are 4 BAR region types, defining different behavior:

- Stateful
- DB by offset
- DB by data
- MSIX table
- MSIX PBA

Generic Control Path (Stateful BAR Region)

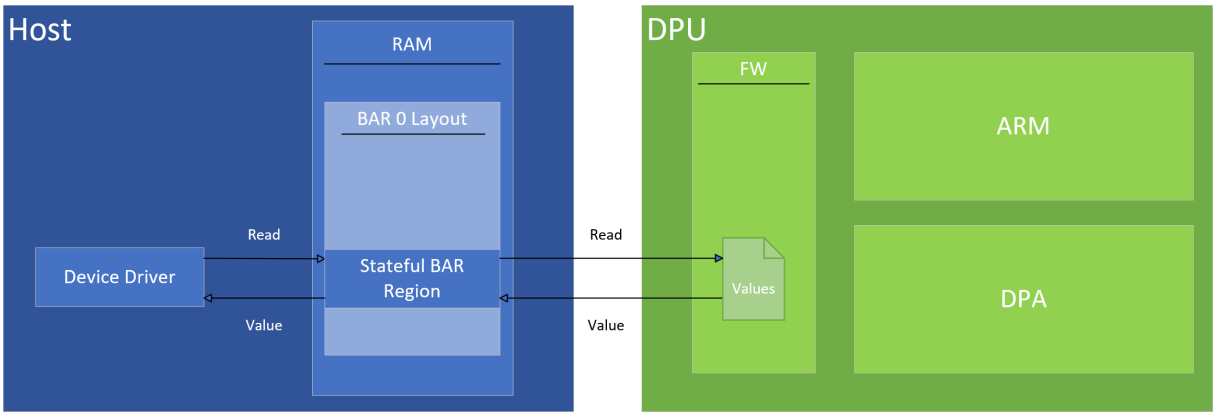
Stateful region can be used as a shared memory, such that the contents are maintained in firmware. A read from the driver returns the latest value, while a write updates the value and triggers an event to software running on the DPU.

This can be useful for communication between the driver and the device, during the control path (e.g., exposing capabilities, initialization).

Some limitations apply, please see Limitations section

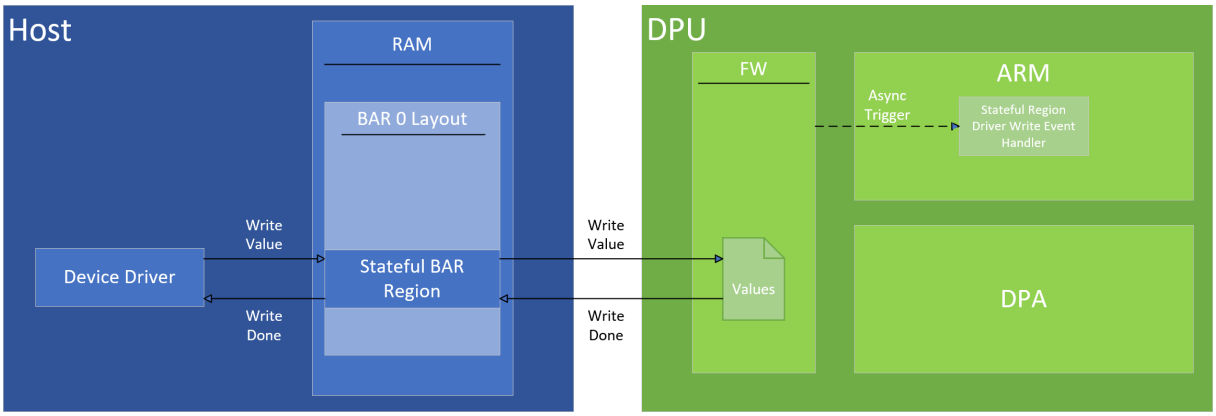
Driver Read

A read from the driver returns the latest value written to the region, whether written by the host or by the driver itself.



Driver Write

A write from the driver updates the value at the written address and notifies software running on the Arm that a write has occurred. The notification on the Arm arrives as an asynchronous event (see `doca_devemu_pci_dev_event_bar_stateful_region_driver_write`).



The event that arrives to Arm software is asynchronous such that it may arrive after the driver has completed the write.

DPU Read

The DPU can read the values of the stateful region using `doca_devemu_pci_dev_query_bar_stateful_region_values`. This returns the latest snapshot of the stateful region values. It can be particularly useful to find what was written by the driver after the "stateful region driver write event" occurs.

DPU Write

The DPU can write the values of the stateful region using `doca_devemu_pci_dev_modify_bar_stateful_region_values`. This updates the values such that subsequent reads from the driver or the DPU returns these values.

Default Values

The DPU can set default values to the stateful region. Default values come in 2 layers:

- Type default values – these values are set for all devices that have the same type. This can be set only if no device currently exists.
- Device default values – these values are set for a specific device and take effect on the next FLR cycle or the next hotplug of the device

A read of the stateful region follows the following hierarchy:

1. Return the latest value as written by the host or driver (whichever was done last).
2. Return the device default values.
3. Return the type default values.
4. Return 0.

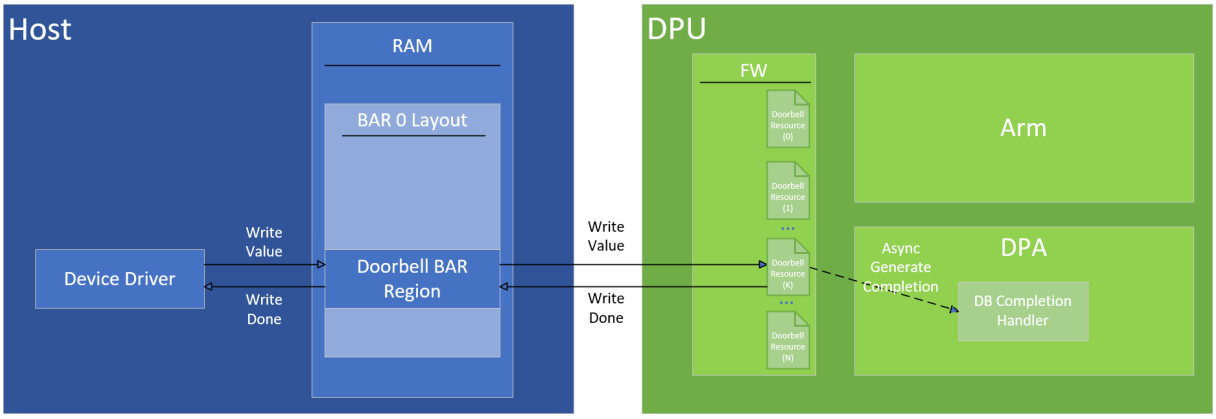
Generic Data Path (DB BAR Region)

Doorbell (DB) regions can be used to implement a consumer-producer queue between the driver and the DPU, such that a write from the driver would trigger an event on the DPU through DPA, allowing it to fetch the written value. This can be useful for communication between the driver and the device, during the data path allowing IO processing.

While DBs are not part of the PCIe specification, it is a widely used mechanism by vendors (e.g., RDMA QP, NVMe SQ, virtio VQ, etc).



The same DB region can be used to manage multiple DBs, such that each DB can be used to implement a queue.

The DPU software can utilize DB resources individually:

- Each DB resource has a unique zero-based index referred to as DB ID
- DB resource can be managed (create/destroy/modify/query) individually
- Each DB resource has a separate notification mechanism. That is, the notification on DPU is triggered for each DB separately.

Driver Write

The DB usually consists of a numeric value (e.g., `uint32_t`) representing the consumer/producer index of the queue.

When the driver writes to the DB region, the related DB resource gets updated with the written value, and a notification is sent to the DPU.

When driver writes to the DB BAR region it must adhere to the following:

- The size of the write must match the size of the DB value (e.g., `uint32_t`)
- The offset within the region must be aligned to the DB stride size or the DB size

The flow would look like the following:

- Driver performs a write of the DB value at some offset within the DB BAR region
- DPU calculates the DB ID that the write is intended for. Depending on the region type:

    - DB by offset – DPU calculates the DB ID based on the write offset relative to the DB BAR region
    - DB by data – DPU parses the written DB value and extracts the DB ID from it
- DPU updates the DB resource with the matching DB ID to the value written by the driver
- DPU sends a notification to the DPA application, informing it that the value of DB with DB ID has been updated by the driver

Driver Read

The driver should not attempt to read from the DB region. Doing so results in anomalous behavior.

BlueField Write

BlueField can update the value of each DB resource individually using `doca_devemu_pci_db_modify_value`. This produces similar side effects as though the driver updated the value using a write to the DB region.

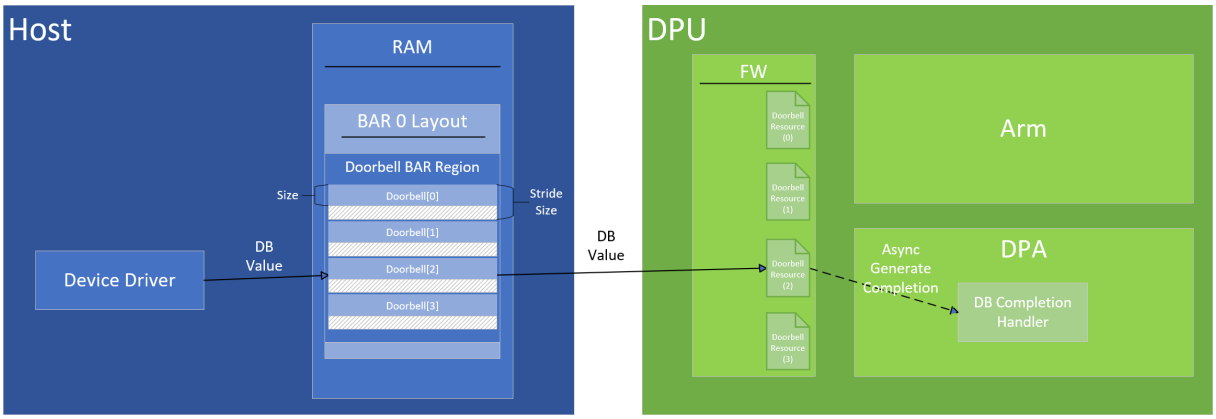
BlueField Read

BlueField can read the value of each DB resource individually using one of the following methods:

- Read the value from the BlueField Arm using `doca_devemu_pci_db_query_value`
- Read the value from the DPA using `doca_dpa_dev_devemu_pci_db_get_value`

The first option is a time-consuming operation and is only recommended for the control path. In the data path, it is recommended to use the second option only.

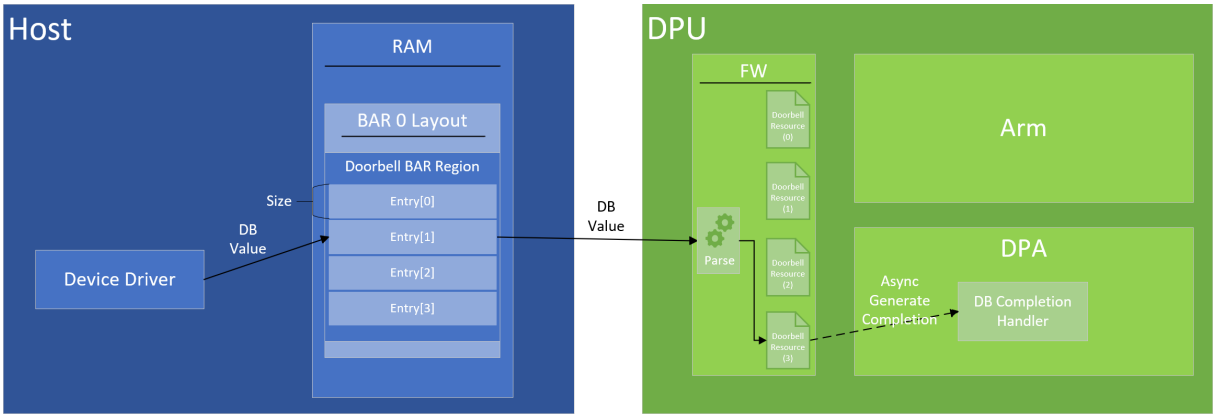
DB by Offset



The API `doca_devemu_pci_type_set_bar_db_region_by_offset_conf` can be used to set up DB by offset region. When the driver writes a DB value using this region, the DPU receives a notification for the relevant DB resource, based on the write offset, such that the DB ID is calculated as follows: `db_id` = `write_offset` / `db_stride_size`.

The area that is part of the stride but not part of the doorbell should not be used for any read/write operation, doing so will result in anomalous behavior.

DB by Data



The API `doca_devemu_pci_type_set_bar_db_region_by_data_conf` can be used to set up DB by data region. When the driver writes a DB value using this region, the DPU receives a notification for the relevant DB resource based on the written DB value, such that there is no relation between the write offset and the DB triggered. This DB region assumes that the DB ID is embedded within the DB value written by the driver. When setting up this region, the user must specify where the Most Significant Byte (MSB) and Least Significant Byte (LSB) of the DB ID are embedded in the DB value.

The DPU follows these steps to extract the DB ID from the DB value:

- Driver writes the DB value
- BlueField extracts the bytes between MSB and LSB
- DPU compares MSB index with LSB index
  - If MSB index greater than LSB index: The extracted value is interpreted as Little Endian
  - If LSB index greater than MSB index: The extracted value is interpreted as Big Endian

Example:

DB size is 4 bytes, LSB is 1, and MSB is 3.

- Driver writes value `0xCCDDEEFF` to DB region at index 0 in Little Endian
  - The value is written to memory as follows: `[0]=FF [1]=EE [2]=DD [3]=CC`
- The relevant bytes, are the following: `[1]=EE [2]=DD [3]=CC`
- Since MSB (3) is greater than LSB (1), the value is interpreted as Little Endian: `db_id = 0xCCDDEE`

MSI-X Capability (MSI-X BAR Region)

Message signaled interrupts extended (MSI-X) is commonly used by PCIe devices to send interrupts over the PCIe bus to the host driver. DOCA APIs allow users to expose the MSI-X capability as per the PCIe specification, and to later use it to send interrupts to the host driver.

To configure it, users must provide the following:

- The number of MSI-X vectors which can be done using `doca_devemu_pci_type_set_num_msix`
- Define an MSI-X table
- Define an MSI-X PBA

MSI-X Table BAR Region

As per the PCIe specification, to expose the MSI-X capability, the device must designate a memory region within its BAR as an MSI-X table region. In DOCA, this can be done using `doca_devemu_pci_type_set_bar_msix_table_region_conf`.

MSI-X PBA BAR Region

As per the PCIe specification, to expose the MSI-X capability, the device must designate a memory region within its BAR as an MSI-X pending bit array (PBA) region. In DOCA, this can be done using `doca_devemu_pci_type_set_bar_msix_pba_region_conf`.

Raising MSI-X From DPU

It is possible to raise an MSI-X for each vector individually. This can be done only using the DPA API `doca_dpa_dev_devemu_pci_msix_raise`.

DMA Memory

Some operations require accessing I/O memory that is set up by the host driver. DOCA's device emulation APIs allow users to access this memory using the DOCA mmap (see DOCA Core Memory Subsystem).

After starting the PCIe device, you can acquire an mmap that references the host memory by using `doca_devemu_pci_mmap_create`. Once this mmap is created, it must be configured with the following:

- Access permissions
- The host memory range it will reference
- The DOCA devices that are permitted to access this memory

This mmap can then be used to create `doca_buf` buffers that reference the memory on the host.

> **I/O Addresses**
>
> The addresses for these buffers are not locally accessible and cannot be dereferenced by the local CPU. They are I/O addresses as defined by the host driver.

These buffers, created from the mmap, can then be used with other DOCA libraries that accept a `doca_buf` as input. This includes:

- DOCA DMA
- DOCA RDMA
- DOCA Ethernet
- DOCA AES-GCM

Function Level Reset

FLR can be handled as described in DOCA DevEmu PCI FLR. Additionally, users must ensure that the following resources are destroyed before stopping the PCIe device:

- Doorbells created using `doca_devemu_pci_db_create_on_dpa`
- MSI-X vectors created using `doca_devemu_pci_msix_create_on_dpa`
- Memory maps created using `doca_devemu_pci_mmap_create`

Limitations

Based on explanation in "Driver Write", user can assume that DOCA DevEmu PCI Generic supports creating emulated PCI devices with the limitation that when a driver writes to a register, the value is immediately available for subsequent reads from the same register. However, this immediate availability does not ensure that any required internal actions triggered by the write have been completed. It is recommended to rely on specific different register values to confirm completion of the write action. For instance, when implementing a write-to-clear operation, e.g. writing 1 to register A to clear register B, it is advisable to poll register B until it indicates the desired state. This approach ensures that the write action has been successfully executed. If a device specification requires certain actions to be completed before exposing written values for subsequent reads, such a device cannot be emulated using the DOCA DevEmu PCI generic framework.

5.4.19.3.7.5 Device Support

DOCA PCI Device emulation requires a device to operate. For information on picking a device, see DOCA DevEmu PCI Device Support.

Some devices can allow different capabilities as follows:

- The maximum number of emulated devices
- The maximum number of different PCIe types
- The maximum number of BARs
- The maximum BAR size
- The maximum number of doorbells
- The maximum number of MSI-X vectors
- Whether adding the device to a DOCA mmap associated with a DOCA devemu PCI device is supported
- For each BAR region type, there are capabilities for:
    - Whether the region is supported

- The maximum number of regions with this type
- The start address alignment of the region
- The size alignment of the region
- The min/max size of the region

As the list of capabilities can be long, it is recommended to use the DOCA Capabilities Print Tool to get an overview of all the available capabilities.

Run the tool as root user as follows:

```
$ sudo /opt/mellanox/doca/tools/doca_caps -p <pci-address> -b devemu_pci
Example output:
PCI: 0000:03:00.0
    devemu_pci
        max_hotplug_devices                         15
        max_pci_types                               2
        mmap_add_dev_supported                      supported

```

5.4.19.3.7.6 PCI Type

Configurations

This section describes the configurations of the DOCA DevEmu PCI Type object, that can be provided before start.

To find if a configuration is supported or what its min/max value is, refer to Device Support.

Mandatory Configurations

The following are mandatory configurations and must be provided before starting the PCI type:

- A DOCA device that is an emulation manager or hotplug manager. See Device Support.

Optional Configurations

The following configurations are optional:

- The PCIe device ID
- The PCIe vendor ID
- The PCIe subsystem ID
- The PCIe subsystem vendor ID
- The PCIe revision ID
- The PCIe class code
- The number of MSI-X vectors for MSI-X capability
- One or more memory mapped BARs
- One or more I/O mapped BARs
- One or more DB region
- An MSI-X table and PBA regions
- One or more stateful regions

If these configurations are not set, then a default value is used.

5.4.19.3.7.7 PCI Device

Configuration Phase

This section describes additional configuration options, on top of the ones already described in DOCA DevEmu PCI Device Configuration Phase.

Configurations

The context can be configured to match the application's use case.

To find if a configuration is supported or what its min/max value is, refer to Device Support.

Optional Configurations

The following configurations are optional:

- Setting the stateful regions' default values – If not set, then the type default values are used. See stateful region default values for more.

Execution Phase

This section describes additional events, on top of the ones already described in DOCA DevEmu PCI Device Events.

Events

DOCA DevEmu PCI Device exposes asynchronous events to notify about changes that happen suddenly according to the DOCA Core architecture.

Common events are described in DOCA Core Event.

BAR Stateful Region Driver Write

The stateful region driver write event allows you to receive notifications whenever the host driver writes to the stateful BAR region. See section "Driver Write" for more information.

Configuration

Description	API to Set the Configuration	API to Query Support
Register to the event	`doca_devemu_pci_dev_event_bar_stateful_region_driver_write_register`	`doca_devemu_pci_cap_type_get_max_bar_stateful_regions`

If there are multiple stateful regions for the same device, then registration is done separately for each region. The details provided on registration (i.e., `bar_id` and start address) must match a region previously configured for PCIe type.

Trigger Condition

The event is triggered anytime the host driver writes to the stateful region. See section "Driver Write" for more information.

Output

Common output as described in DOCA Core Event.

Additionally, the event callback receives an event object of type `struct doca_devemu_pci_dev_event_bar_stateful_region_driver_write` which can be used to retrieve:

- The DOCA DevEmu PCI Device representing the emulated device that triggered the event – `doca_devemu_pci_dev_event_bar_stateful_region_driver_write_get_pci_dev`
- The ID of the BAR containing the stateful region – `doca_devemu_pci_dev_event_bar_stateful_region_driver_write_get_bar_id`
- The start address of the stateful region – `doca_devemu_pci_dev_event_bar_stateful_region_driver_write_get_bar_region_start_addr`

Event Handling

Once the event is triggered, it means that the host driver has written to someplace in the region.

The user must perform either of the following:

- Query the new values of the stateful region – `doca_devemu_pci_dev_query_bar_stateful_region_values`
- Modify the values of the stateful region – `doca_devemu_pci_dev_modify_bar_stateful_region_values`

It is possible also to do both. However, it is important that the memory areas that the host wrote to are either queried or overwritten with a modify operation.

> ⚠ Failure to do so results in a recurring event. For example, if the host wrote to the first half of the region, BlueField Arm only queries the second half of the region after receiving the event. Then, if the user did not handle the event, the library retriggers the event.

5.4.19.3.7.8 PCI Device DB

After the PCIe device has been created, it can be used to create DB objects, each DB object represents a DB resource identified by a DB ID. See Generic Data Path (DB BAR Region).

When creating the DB, the DB ID must be provided, this can hold different meaning for DB by offset and DB by data. The DB object can then be used to get a notification to the DPA once a driver write occurs, and to fetch the latest value using the DPA.

Configuration

Creating and Configuring DB

The flow for creating and configuring a DB should be as follows:

1. Create the DB object:

```
arm> doca_devemu_pci_db_create_on_dpa
```

2. (Optional) Query the DB value:

```
arm> doca_devemu_pci_db_query_value
```

3. (Optional) Modify the DB value:

```
arm> doca_devemu_pci_db_modify_value
```

4. Get the DB DPA handle for referencing the DB from the DPA:

```
arm> doca_devemu_pci_db_get_dpa_handle
```

5. Bind the DB to the DB completion context using the handle from the previous step:

```
dpa> doca_dpa_dev_devemu_pci_db_completion_bind_db
```

It is important to perform this step before the next one. Otherwise, the DB completion context will start receiving completions for an unbound DB.

6. Start the DB to start receiving completions on DPA:

```
arm> doca_devemu_pci_db_start
```

Once DB is started, a completion is immediately generated on the DPA.

Destroying DB

The flow for destroying a DB would look as follows:

1. Stop the DB to stop receiving completions:

```
arm> doca_devemu_pci_db_stop
```

This step ensures that no additional completions will arrive for this DB

2. Acknowledge all completions related to this DB:

```
dpa> doca_dpa_dev_devemu_pci_db_completion_ack
```

This step ensures that existing completions have been processed.

3. Unbind the DB from the DB completion context:

```
dpa> doca_dpa_dev_devemu_pci_db_completion_unbind_db
```

Make sure not to perform this step more than once.

4. Destroy the DB object:

```
arm> doca_devemu_pci_db_destroy
```

Fetching DBs on DPA

To fetch DBs on DPA, a DB completion context can be used. The DB completion context serves the following purposes:

- Notifying a DPA thread that a DB value has been updated (wakes up thread)
- Providing information about which DB has been updated

The following flow shows how to use the same DB completion context to get notified whenever any of the DBs are updated, and to find which DBs were actually updated, and finally to get the DBs' values:

1. Get DB completion element:

```
doca_dpa_dev_devemu_pci_get_db_completion
```

2. Get DB from completion:

```
doca_dpa_dev_devemu_pci_db_completion_element_get_db_properties
```

3. Store the DB (e.g., in an array).
4. Repeat steps 1-3 until there are no more completions.
5. Acknowledge the number of received completions:

```
doca_dpa_dev_devemu_pci_db_completion_ack
```

6. Request notification on DPA for the next completion:

```
doca_dpa_dev_devemu_pci_db_completion_request_notification
```

7. Go over the DBs stored in step 3 and for each DB:
    a. Request a notification for the next time the host driver writes to this DB:

```
doca_dpa_dev_devemu_pci_db_request_notification
```

    b. Get the most recent value of the DB:

```
doca_dpa_dev_devemu_pci_db_get_value
```

Query/Modify DB from Arm

It is possible to query the DB value of a particular DB using `doca_devemu_pci_db_query_value` on the Arm. Similarly, it is possible to modify the DB value using `doca_devemu_pci_db_modify_value`. When modifying the DB value, the side effects of such modification is the same as if the host driver updated the DB value.

Querying and modifying operations from the Arm are time consuming and should be used in the control path only. Fetching DBs on DPA is the recommended approach for retrieval of DB values in the data path.

5.4.19.3.7.9 PCIe Device MSI-X Vector

After the PCIe device has been created, it can be used to create MSI-X objects. Each MSI-X object represents an MSI-X vector identified by the vector index.

The MSI-X object can be used to send a notification to the host driver from the DPA.

Configuration

The MSI-X object can be created using `doca_devemu_pci_msix_create_on_dpa`. An MSI-X vector index must be provided during creation, this is a value in the range [0, `num_msix`), such that `num_msix` is the value previously set using `doca_devemu_pci_type_set_num_msix`.

Once the MSI-X object is created, `doca_devemu_pci_msix_get_dpa_handle` can be used to get a DPA handle for use within the DPA.

Raising MSI-X

The MSI-X object can be used on the DPA to raise an MSI-X vector using `doca_dpa_dev_devemu_pci_msix_raise`.

5.4.19.3.7.10 DOCA DevEmu Generic Samples

This section describes DOCA DevEmu Generic samples.

The samples illustrate how to use the DOCA DevEmu Generic API to do the following:

- List details about emulated devices with same generic type
- Create and hot-plug/hot-unplug an emulated device with a generic type
- Handle Host driver write using stateful region
- Handle Host driver write using DB region
- Raise MSI-X to the Host driver
- Perform DMA operation to copy memory buffer between the Host driver and the DPU Arm

Structure

All the samples utilize the same generic PCI type. The configurations of the type reside in `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`

The structure for some samples is as follows:

- `/opt/mellanox/doca/samples/doca_devemu/<sample directory>`
    a. `dpu`
        i. `host`
        ii. `device`
    b. `host`

Samples following this structure will have two binaries: `dpu` (1) and `host` (2), the former should be run on the BlueField and represents the controller of the emulated device, while the latter should be run on the host and represents the host driver.

For simplicity, the host (2) side is based on the VFIO driver, allowing development of a driver in user-space.

Within the `dpu` (a) directory, there is a `host` (a) and `device` (b) directories. `host` in this case refers to the BlueField Arm processor, while `device` refers to the DPA processor. Both directories are compiled into a single binary.

Running the Samples

1. Refer to the following documents:
   - DOCA Installation Guide for Linux for details on how to install BlueField-related software.
   - DOCA Troubleshooting for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_devemu/<sample_name>[/dpu or /host]
meson /tmp/build
ninja -C /tmp/build
```

> The binary `doca_<sample_name>[_dpu or _host]` is created under `/tmp/build/`.

3. Sample (e.g., `doca_devemu_pci_device_db`) usage:
   a. BlueField side (`doca_devemu_pci_device_db_dpu`):

```
Usage: doca_devemu_pci_device_db_dpu [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse all command flags from an input json file

Program Flags:
  -p, --pci-addr                    The DOCA device PCI address. Format: XXXX:XX:XX.X or XX:XX.X
  -u, --vuid                        DOCA Devemu emulated device VUID. Sample will use this device
to handle Doorbells from Host
  -r, --region-index                The index of the DB region as defined in
 devemu_pci_type_config.h. Integer
  -i, --db-id                       The DB ID of the DB. Sample will listen on DBs related to this
DB ID. Integer
```

   b. Host side (`doca_devemu_pci_device_db_host`):

```
Usage: doca_devemu_pci_device_db_host [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse all command flags from an input json file

Program Flags:
  -p, --pci-addr                    PCI address of the emulated device. Format: XXXX:XX:XX.X
  -g, --vfio-group                  VFIO group ID of the device. Integer
  -r, --region-index                The index of the DB region as defined in
 devemu_pci_type_config.h. Integer
  -d, --db-index                    The index of the Doorbell to write to. The sample will write at
byte offset (db-index * db-stride)
  -w, --db-value                    A 4B value to write to the Doorbell. Will be written in Big
Endian
```

4. For additional information per sample, use the `-h` option:

```
/tmp/build/<sample_name> -h
```

Additional sample setup:

- The BlueField samples require the emulated device to be already hot-plugged:
  - Such samples expect the VUID of the hot-plugged device (`-u, --vuid`)
  - The list sample can be used to find if any hot-plugged devices exist and what their VUID is
  - The hot-plug sample can be used to hot plug a device if no such device already exists
- The host samples require the emulated device to be already hot-plugged and that the device is bound to the VFIO driver:
  - The samples expect 2 parameters `-p` (`--pci-addr`) and `-g` (`--vfio-group`) of the emulated device as seen by the host
  - The PCI Device List sample can be used from the BlueField to find the PCIe address of the emulated device on the host
  - Once the PCIe address is found, the host can use the script `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_vfio_bind.py` to bind the VFIO driver

    ```
    $ sudo python3 /opt/mellanox/doca/samples/doca_devemu/devemu_pci_vfio_bind.py <pcie-address-of-emulated-dev>
    ```

    - The script is a python3 script which expects the PCIe address of the emulated device as a positional argument (e.g., `0000:3e:00.0`)
    - The script outputs the VFIO group ID
    - The script must be used only once after the device is hot plugged towards the host for the first time
- The hot-unplug sample requires that the device be unbound from the VFIO driver:
  - Use the script located at `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_vfio_bind.py` from the host to unbind the VFIO driver as follows:

    ```
    $ sudo python3 /opt/mellanox/doca/samples/doca_devemu/devemu_pci_vfio_bind.py <pcie-address-of-emulated-dev> --unbind
    ```

    - This python3 script expects the PCIe address of the emulated device as a positional argument (e.g., `0000:3e:00.0`) along with the `--unbind` argument

Samples

These samples are also available on GitHub.

PCI Device List

This sample illustrates how to list all emulated devices that have the generic type configured in `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.

The sample logic includes:

1. Initializing the generic PCIe type based on `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.
2. Creating a list of all emulated devices belonging to this type.
3. Iterating over the emulated devices.
4. Dumping their VUID.
5. Dumping their PCIe address as seen by the host.
6. Releasing the resources.

References:

- `/opt/mellanox/doca/samples/doca_devemu/`
  - `devemu_pci_device_list/`

    - `devemu_pci_device_list_main.c`
    - `meson.build`
  - `devemu_pci_common.h`; `devemu_pci_common.c`
  - `devemu_pci_type_config.h`

PCI Device Hot-Plug

This sample illustrates how to create and hot-plug/hot-unplug an emulated device that has the generic type configured in `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.

The sample logic includes:

1. Initializing the generic PCIe type based on `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.
2. Acquiring the emulated device representor:
   - If the user did not provide VUID as input, then creating and using a new emulated device.
   - If the user provided VUID as an input, then searching for an existing emulated device with a matching VUID and using it.

3. Creating a PCIe device context to manage the emulated device and connecting it to a progress engine (PE).
4. Registering to the PCIe device's hot-plug state change event.
5. Initializing hot-plug/hot-unplug of the device:
    a. If the user did not provide VUID as input, then initializing hot-plug flow of the device.
    b. If the user provided VUID as input, then initializing hot-unplug flow of the device.
6. Using the PE to poll for hot-plug state change event.
7. Waiting until hot-plug state transitions to expected state (power on or power off).
8. Cleaning up resources.
    - If hot-unplug was requested, then the emulated device is destroyed as well.
    - Otherwise, the emulated device persists.

    - `devemu_pci_type_config.h`

PCI Device Stateful Region

This sample illustrates how the host driver can write to a stateful region, and how the BlueField Arm can handle the write operation.

This sample consists of a host sample and BlueField sample. It is necessary to follow the additional sample setup detailed previously.

The BlueField sample logic includes:

1. Initializing the generic PCIe type based on `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.
2. Acquiring the emulated device representor that matches the provided VUID.
3. Creating a PCIe device context to manage the emulated device and connecting it to a progress engine (PE).
4. For each stateful region configured in `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`, registering to the PCIe device's stateful region write event.
5. Using the PE to poll for driver write to any of the stateful regions.
    - Every time the host driver writes to the stateful region, the handler is invoked and performs the following:
        i. Queries the values of the stateful region that the host wrote to.

ii. Logs the values of the stateful region.

- The sample polls indefinitely until the user presses [Ctrl+c] to close the sample.

6. Cleaning up resources.

The host sample logic includes:

1. Initializing the VFIO device with a matching PCIe address and VFIO group.
2. Mapping the stateful memory region from the BAR to the process address space.
3. Writing the values provided as input to the beginning of the stateful region.

  - `devemu_pci_host_common.h` ; `devemu_pci_host_common.c`
  - `devemu_pci_type_config.h`

PCI Device DB

This sample illustrates how the host driver can ring the doorbell and how the BlueField can retrieve the doorbell value. The sample also demonstrates how to handle FLR.

This sample consists of a host sample and BlueField sample. It is necessary to follow the additional sample setup detailed previously.

The BlueField sample logic includes:

- Host (BlueField Arm) logic:
  a. Initializing the generic PCIe type based on `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.
  b. Initializing DPA resources:
    i. Creating DPA instance and associating it with the DPA application.
    ii. Creating DPA thread and associating it with the DPA DB handler.
    iii. Creating DB completion context and associating it with the DPA thread.
  c. Acquiring the emulated device representor that matches the provided VUID.

d. Creating a PCIe device context to manage the emulated device and connecting it to progress engine (PE).
e. Registering to the context state changes event.
f. Registering to the PCIe device FLR event.
g. Using the PE to poll for any of the following:
    i. Every time the PCIe device context state transitions to running, the handler performs the following:
        1. Creates a DB object.
        2. Makes RPC to DPA, to initialize the DB object.
    ii. Every time the PCIe device context state transitions to stopping, the handler performs the following:
        1. Makes RPC to DPA, to un-initialize the DB object.
        2. Destroys the DB object.
    iii. Every time the host driver initializes or destroys the VFIO device, an FLR event is triggered. The FLR handler performs the following:
        1. Destroys DB object.
        2. Stops the PCIe device context.
        3. Starts the PCIe device context again.
    iv. The sample polls indefinitely until the user presses [Ctrl+c] to close the sample.

        ⚠ During this time, the DPA may start receiving DBs from the host.

h. Cleaning up resources.

- Device (BlueField DPA) logic:
    a. Initializing application RPC:
        i. Setting the global context to point to the DB completion context DPA handle.
        ii. Binding DB to the doorbell completion context.
    b. Un-initializing application RPC:
        i. Unbinding DB from the doorbell completion context.
    c. DB handler:
        i. Getting DB completion element from completion context.
        ii. Getting DB handle from the DB completion element.
        iii. Acknowledging the DB completion element.
        iv. Requesting notification from DB completion context.
        v. Requesting notification from DB.
        vi. Getting DB value from DB.

The host sample logic includes:

1. Initializing the VFIO device with its matching PCIe address and VFIO group.
2. Mapping the DB memory region from the BAR to the process address space.

3. Writing the value provided as input to the DB region at the given offset.

PCI Device MSI-X

This sample illustrates how BlueField can raise an MSI-X vector, sending a signal towards the host, and shows how the host can retrieve this signal.

This sample consists of a host sample and a BlueField sample. It is necessary to follow the additional sample setup detailed previously.

The BlueField sample logic includes:

- Host (BlueField Arm) logic:
  a. Initializing the generic PCIe type based on `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.
  b. Initializing DPA resources:
    i. Creating a DPA instance and associating it with the DPA application.
    ii. Creating a DPA thread and associating it with the DPA DB handler.
  c. Acquiring the emulated device representor that matches the provided VUID.
  d. Creating a PCIe device context to manage the emulated device and connecting it to a progress engine (PE).
  e. Creating an MSI-X vector and acquiring its DPA handle.
  f. Sending an RPC to the DPA to raise the MSI-X vector.
  g. Cleaning up resources.
- Device (BlueField DPA) logic:

a. Raising the MSI-X RPC by using the MSI-X vector handle.

The host sample logic includes:

1. Initializing the VFIO device with the matching PCIe address and VFIO group.
2. Mapping each MSI-X vector to a different FD.
3. Reading events from the FDs in a loop.
    a. Once the DPU raises MSI-X, the FD matching the MSI-X vector returns an event which is then printed to the screen.
    b. The sample polls the FDs indefinitely until the user presses [Ctrl+c] to close the sample.

    - `devemu_pci_type_config.h`

PCI Device DMA

This sample illustrates how the host driver can set up memory for DMA, then the DPU can use that memory to copy a string from the BlueField to the host and from the host to the BlueField.

This sample consists of a host sample and a BlueField sample. It is necessary to follow the additional sample setup detailed previously.

The BlueField sample logic includes:

1. Initializing the generic PCIe type based on `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.
2. Acquiring the emulated device representor that matches the provided VUID.

3. Creating a PCIe device context to manage the emulated device and connecting it to a progress engine (PE).
4. Creating a DMA context to use for copying memory across the host and BlueField.
5. Setting up an mmap representing the host driver memory buffer.
6. Setting up an mmap representing a local memory buffer.
7. Use the DMA context to copy memory from host to BlueField.
8. Use the DMA context to copy memory from BlueField to host.
9. Cleaning up resources.

The host sample logic includes:

1. Initializing the VFIO device with the matching PCIe address and VFIO group.
2. Allocating memory buffer.
3. Mapping the memory buffer to I/O memory. The BlueField can now access the memory using the I/O address through DMA.
4. Copying the string provided by user to the memory buffer.
5. Waiting for the BlueField to write to the memory buffer.
6. Un-mapping the memory buffer.
7. Cleaning up resources.

5.4.19.4 DOCA DevEmu Virtio

5.4.19.4.1 Introduction

> The quality status of DOCA libraries is listed here.

DOCA DevEmu Virtio, which is part of the DOCA Device Emulation subsystem, introduces low-level software APIs that provide building blocks for developing and manipulating virtio devices using the device emulation capability of NVIDIA® BlueField®.

This subsystem incorporates a core library that handles a common logic for various types of virtio devices, such as virtio-FS. One of its key responsibilities is managing the standard "device reset" procedure outlined in the virtio specification. This core library serves as a foundation for implementing shared functionalities across different virtio device types, ensuring consistency and efficiency in device operations and behaviors.

DOCA provides support for emulating virtio devices over the PCIe bus. The PCIe transport is commonly used for virtio devices. Configuration, discovery, and features related to PCIe (such as MSI-X and PCIe device hot plug/unplug) are managed through the DOCA DevEmu PCI APIs. This modular design enables each layer within the DOCA Device Emulation subsystem to manage its own business logic and facilitates seamless integration with the other layers, ensuring independent functionality and operation throughout the system.

This subsystem also includes device-specific libraries for various virtio device types (e.g., a library for a virtio-FS device).

From the host's perspective, there is no difference between para-virtual, DOCA-emulated, and actual hardware devices. The host uses the same virtio device drivers to operate the device under all circumstances.

5.4.19.4.2 Prerequisites

Virtio device emulation is part of the DOCA Device Emulation subsystem. It is, therefore, recommended to read the following guides beforehand:

- DOCA Device Emulation
- DOCA DevEmu PCI

5.4.19.4.3 Environment

DOCA DevEmu Virtio is supported on the BlueField target only.

The BlueField must meet the following requirements

- DOCA version 2.7.0 or greater
- BlueField-3 firmware 32.41.1000 or higher

> Please refer to the DOCA Compatibility Policy.

Library must be run with root privileges.

5.4.19.4.4 Architecture

The DOCA DevEmu Virtio core library provides the following software abstractions:

- Virtio type – extends the PCIe type, represents common/default virtio configurations of emulated virtio devices
- Virtio device – extends the PCIe device, represents an instance of an emulated virtio device
- Virtio IO context – represents a progress context which is responsible for processing virtio descriptors and their associated virtio queues

DOCA DevEmu Virtio library does not provide APIs to configure the entire BAR layout of the virtio device as this configuration is done internally. However, the library offers APIs to configure some of the registers within the common configuration structure (see Virtio Device).

5.4.19.4.4.1 Virtio Common Configuration

According to the virtio specification, the common PCIe configuration structure layout is as follows:

virtio_pci_common_cfg

```
struct virtio_pci_common_cfg {
    /* About the whole device. */
    le32 device_feature_select; /* read-write */
    le32 device_feature; /* read-only for driver */
    le32 driver_feature_select; /* read-write */
    le32 driver_feature; /* read-write */
    le16 config_msix_vector; /* read-write */
    le16 num_queues; /* read-only for driver */
    u8 device_status; /* read-write */
    u8 config_generation; /* read-only for driver */

    /* About a specific virtqueue. */
    le16 queue_select; /* read-write */
    le16 queue_size; /* read-write */
    le16 queue_msix_vector; /* read-write */
    le16 queue_enable; /* read-write */
    le16 queue_notify_off; /* read-only for driver */
    le64 queue_desc; /* read-write */
    le64 queue_driver; /* read-write */
    le64 queue_device; /* read-write */
    le16 queue_notify_data; /* read-only for driver */
    le16 queue_reset; /* read-write */
};
```

The DOCA DevEmu Virtio core library provides the ability to configure some of the listed registers using the appropriate setters.

5.4.19.4.4.2 Virtio Type

The virtio type extends the PCIe type and describes the common/default configuration of emulated virtio devices, including the common virtio configuration space registers (such as `num_queues`, `queue_size`, and others).

Virtio type is currently read-only (i.e., only getter APIs are available to retrieve information). The following methods can be used for this purpose:

- `doca_devemu_virtio_type_get_num_queues` – for getting the default initial value of the `num_queues` register for the associated virtio devices
- `doca_devemu_virtio_type_get_queue_size` – for getting the default initial value of the `queue_size` register for the associated virtio devices

- `doca_devemu_virtio_type_get_device_features_63_0` – for getting the default initial values of the `device_feature` bits (0-63) for the associated virtio devices
- `doca_devemu_virtio_type_get_config_generation` – for getting the default initial value of the `config_generation` register for the associated virtio devices

The default virtio type is extended by a virtio device's specific type (e.g., virtio-FS type) and cannot be created on demand.

5.4.19.4.4.3 Virtio Device

The virtio device extends the PCIe device. Before using the DOCA DevEmu Virtio device, it is recommended to read the guidelines of DOCA DevEmu PCI device and DOCA Core context configuration phase.

The virtio device is extended by a virtio-specific device (e.g., virtio FS device) and cannot be created on demand.

Virtio Device Configurations

The virtio device context can be configured to match the application use case and optimize the utilization of system resources.

Mandatory Configurations

The mandatory configurations are as follows:

- `doca_devemu_virtio_dev_set_num_required_running_virtio_io_ctxs` – to set the number of required running virtio IO contexts to be bound to the virtio device context. The virtio device context does not move to `running` state (according to the DOCA Core context state machine) before having this amount of running virtio IO contexts bound to it.
- `doca_devemu_virtio_dev_event_reset_register` – to register to the virtio device reset event. This configuration is mandatory

Optional Configurations

The optional configurations are as follows:

- `doca_devemu_virtio_dev_set_device_features_63_0` – to set the values of the `device_feature` bits (0-63). If not set, the default value is taken from the virtio type configuration.
- `doca_devemu_virtio_dev_set_num_queues` – to set the value of the `num_queues` register. If not set, the default value is taken from the virtio type configuration.
- `doca_devemu_virtio_dev_set_queue_size` – to set the value of the `queue_size` register for all virtio queues. If not set, the default value is taken from the virtio type configuration.

Events

DOCA DevEmu Virtio device exposes asynchronous events to notify about sudden changes, according to DOCA Core architecture.

> Common events are described in DOCA DevEmu PCI Device events and in DOCA Core Event.

Reset Event

The reset event allows users to receive notifications whenever the device reset flow is initialized by the device driver. Upon receiving this event, it is guaranteed that no further requests are routed to the user via any associated virtio IO context until the reset flow is completed.

To complete the reset flow the user must:

1. Flush all outstanding requests back to the virtio IO context associated with the request.
2. Perform one of the following:
   - Call `doca_devemu_virtio_dev_reset_complete`.
   - Follow FLR flow:
     i. `doca_ctx_stop` – stop the virtio device with its associated virtio IO contexts and wait until the device and its associated virtio IO contexts transition to `idle` state
     ii. `doca_ctx_start` – start the virtio device with its associated virtio IO contexts and wait until the device and its associated virtio IO contexts transition to `running` state

Now, the device and its associated virtio IO contexts should be fully operational again, the device is allowed to route new requests via any associated virtio IO context.

5.4.19.4.4.4 Virtio IO

The virtio IO context extends the DOCA Core context. Before using the DOCA DevEmu Virtio IO, it is recommended to read the guidelines of DOCA Core context configuration phase.

This context is associated with a single DOCA virtio device and is bound to the virtio device context upon start. The virtio IO context is a thread-unsafe object and is progressed by a single DOCA Core progress engine. Usually, users configure a single virtio IO context per BlueField core used by the application service.

The virtio IO context is responsible to route new incoming virtio requests towards the application and to complete handled requests back to the device driver. It can only route requests while in `running` state and when its associated virtio device is also in `running` state.

5.4.19.4.5 DOCA DevEmu Virtio-fs

⚠ This library is supported at alpha level; backward compatibility is not guaranteed.

5.4.19.4.5.1 Introduction

The DOCA DevEmu Virtio-fs library, part of the DOCA DevEmu Virtio subsystem, provides low-level software APIs. These APIs serve as the building blocks for developing and manipulating virtio-fs (virtio-filesystem) devices by leveraging the device emulation capabilities of NVIDIA® BlueField® DPUs.

Architecture and Library Interaction

This library is part of a modular subsystem, where each library manages its own logic:

- DOCA DevEmu PCI: Manages the PCIe transport layer, including configuration, discovery, and features like MSI-X and device hot plug/unplug.
- DOCA Virtio Common: Manages generic virtio logic, such as handling common virtio registers and the virtio device reset flow.
- DOCA DevEmu Virtio-fs: Manages the specific logic for the virtio-filesystem device.

This layered design allows for seamless integration and independent operation of each component.

Core Functionality

The DOCA DevEmu Virtio-fs library efficiently handles virtio descriptors that carry FUSE requests from the device driver. It translates these into abstract virtio-fs requests that are then routed to the user application. This process abstracts away the underlying device-specific acceleration details.

ℹ The library supports FUSE versions 7.31–7.43.

User Responsibilities

Users of this library are responsible for developing a virtio-fs controller. This controller application must:

1. Manage the underlying DOCA DevEmu Virtio-fs device.
2. Receive the abstracted DOCA Virtio-fs requests.
3. Process these requests according to the virtio-fs and FUSE specifications.
4. Translate the FUSE-based commands into the appropriate protocol for an external backend file system.

> ⚠ The backend file system itself is outside the scope of DOCA.

5.4.19.4.5.2 Prerequisites

Virtio-fs device emulation is part of DOCA DevEmu Virtio subsystem. It is, therefore, recommended to read the following guides before proceeding:

- DOCA Device Emulation
- DOCA DevEmu PCI
- DOCA DevEmu Virtio

5.4.19.4.5.3 Environment

DOCA DevEmu Virtio-fs is supported on the BlueField target only. The BlueField must meet the following requirements:

- DOCA version 2.7.0 or greater
- BlueField-3 firmware 32.41.1000 or higher

> ℹ Please refer to the DOCA Compatibility Policy.

> ⚠ Library must be run with root privileges.

Perform the following:

1. Configure BlueField to work in DPU mode as described in BlueField Modes of Operation.
2. Enable emulation by running the following on the host or DPU:

```
host/dpu> sudo mlxconfig -d /dev/mst/mt41692_pciconf0 s VIRTIO_FS_EMULATION_ENABLE=1
```

3. Configure the number of static virtio-fs physical functions and the number of MSIX for each physical function to expose. This can be done by running the following command on the DPU:

```
host/dpu> sudo mlxconfig -d /dev/mst/mt41692_pciconf0 s VIRTIO_FS_EMULATION_NUM_PF=2
VIRTIO_FS_EMULATION_NUM_MSIX=18
```

4. Perform a BlueField system reboot for the `mlxconfig` settings to take effect.

Hot-plug

Host Configuration

With a Linux environment on host OS, additional kernel boot parameters are required to support the hot-plug feature:

- For Intel machines:

```
intel_iommu=on iommu=pt pci=realloc
```

- For AMD machines:

```
iommu=pt pci=realloc
```

> ⚠ On AMD machines, hotplug may not work.

Firmware Configuration

When PCIe switch emulation is enabled, BlueField can support 1 hotplug virtio-fs function. These PCIe functions are shared among all BlueField users and applications and may hold hot-plugged devices of type NVMe, virtio-blk, virtio-fs, or other (e.g., virtio-net).

To enable PCIe switch emulation and configure one hot-plugged port, run:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PCI_SWITCH_EMULATION_ENABLE=1 PCI_SWITCH_EMULATION_NUM_PORT=2
```

`PCI_SWITCH_EMULATION_NUM_PORT` equals 1 plus the number of hot-plugged PCIe functions.

5.4.19.4.5.4 Architecture

The DOCA DevEmu Virtio-fs library provides the following main software abstractions:

- The virtio-fs type – extends the virtio type; represents common/default virtio-fs configurations of emulated virtio-fs devices
- The virtio-fs device – extends the virtio device; represents an instance of an emulated virtio-fs device
- The virtio-fs IO context – extends the virtio IO context; represents a progress context responsible for processing virtio descriptors, carrying FUSE requests, and their associated virtio queues (e.g., hiprio, request, admin, and notification queues).
- The virtio-fs request

Virtio-fs Feature Bits

According to the virtio specification, a virtio-fs device may report support for `VIRTIO_FS_F_NOTIFICATION` which indicates the ability to handle FUSE notify messages sent via the notification queue.

> ⚠ Currently, DOCA does not support reporting the `VIRTIO_FS_F_NOTIFICATION` feature to the driver.

Virtio-fs Configuration Layout

According to the virtio specification, the virtio-fs configuration structure layout is as follows:

virtio_fs_config

```
struct virtio_fs_config {
    char tag[36];
    le32 num_request_queues;
    le32 notify_buf_size;
};
```

The `tag` and `num_request_queues` fields are always available. The `notify_buf_size` field is only available when `VIRTIO_FS_F_NOTIFICATION` is set.

> ⚠ Currently, there is no support for reporting the `VIRTIO_FS_F_NOTIFICATION` feature to the driver. Therefore, `notify_buf_size` field is not available.

Virtio-fs Type

The virtio-fs type extends the virtio type and describes the common/default configuration of emulated virtio-fs devices, including some of the virtio-fs configuration space registers (e.g., `num_request_queues`).

Currently, the virtio-fs type is read-only (i.e., only getter APIs are available to retrieve information). The following method can be used for this purpose:

- `doca_devemu_vfs_type_get_num_request_queues` – to get the default initial value of the `num_request_queues` register for the associated virtio-fs devices

DOCA supports the default virtio-fs type. To retrieve the default virtio-fs type, users use the following method:

- `doca_devemu_vfs_is_default_vfs_type_supported` – check if the default DOCA Virtio-fs type is supported by the device. If supported:
  - `doca_dev_open` – open supported DOCA device
  - `doca_devemu_vfs_find_default_vfs_type_by_dev` – get the default DOCA Virtio-fs type associated with the device

Virtio-fs Device

The virtio-fs device extends the virtio device. Before using the DOCA DevEmu Virtio-fs device, it is recommended to read the guidelines of DOCA DevEmu Virtio device, DOCA DevEmu PCI device, and DOCA Core context configuration phase.

This section describes how to create, configure, and operate the virtio-fs device.

Virtio-fs Device Configurations

The virtio-fs emulated device might be in several different visibility levels from the host point of view:

- Visible/non-visible to the PCIe subsystem – If the device is visible to the PCIe subsystem, the user is not able to configure PCIe-related parameters (e.g., number of MSI-X vector, `subsystem_id`).
- Visible/non-visible to the virtio subsystem – If the device is visible to the virtio subsystem, the user is not be able to configure virtio-related parameters (e.g., number of queues, `queue_size`).

The flow for creating and configuring a virtio-fs device is as follows:

1. `doca_devemu_vfs_dev_create` – Create a new DOCA DevEmu Virtio-fs device instance.
2. `doca_devemu_vfs_dev_set_tag` – Set a unique tag for the device according to the virtio specification.
3. `doca_devemu_vfs_dev_set_num_request_queues` – Set the number of request queues for the device.
4. `doca_devemu_vfs_dev_set_vfs_req_user_data_size` – Set the user data size of the virtio-fs request. If set, a buffer with this size is allocated for each DOCA DevEmu Virtio-fs on behalf of the user.
5. Configure virtio-related parameters as described in DOCA Virtio configurations.

   > ⚠ `doca_devemu_virtio_dev_set_num_queues` should be equal to the number of request queues +1 (for the `hiprio` queue) since DOCA does not currently support the virtio-fs notification queue.

6. Configure PCIe-related parameters as described in DOCA DevEmu PCI configurations.
7. `doca_ctx_start` – Start the virtio-fs device context to finalize the configuration phase.
   - The virtio-fs device object follows the DOCA context state machine as described in DOCA Core context state machine
   - The virtio-fs device context moves to `running` state after the initial number of virtio IO contexts is bound to it and turns to `running` state, as described at DOCA DevEmu Virtio configurations

At this point, the DOCA Devemu Virtio-fs context is fully operational.

Mandatory Configurations

The following are mandatory configurations:

- `doca_devemu_vfs_dev_set_tag` – set a unique tag for the device

Optional Configurations

The optional configurations are as follows:

- `doca_devemu_vfs_dev_set_num_request_queues` – set the number of request queues for the device. If not set, the default value is taken from the virtio-fs type configuration.
- `doca_devemu_vfs_dev_set_vfs_req_user_data_size` – set the user data size of the virtio-fs request. If not set, user data size defaults to 0.

Virtio-fs Device Events

DOCA DevEmu Virtio-fs device exposes asynchronous events to notify about changes that happen out of the blue, according to the DOCA Core architecture.

Common events are described in DOCA DevEmu Virtio device events, DOCA DevEmu PCI device events and in DOCA Core event.

Virtio-fs IO

The virtio-fs IO context extends the Virtio IO Context. To start using the DOCA DevEmu Virtio-fs IO it is recommended to read the guidelines of DOCA DevEmu Virtio IO and DOCA Core context configuration phase.

This section describes how to create, configure and operate the virtio-fs IO context.

Virtio-fs IO Configurations

The flow for creating and configuring a virtio-fs IO context should be as follows:

1. `doca_devemu_vfs_io_create` – Create a new DOCA DevEmu Virtio-fs IO instance.
2. `doca_devemu_vfs_io_event_vfs_req_notice_register` – Register event handler for incoming virtio-fs requests.
3. `doca_ctx_start` – Start the virtio-fs IO context to finalize the configuration phase. The virtio-fs IO object follows the DOCA Core context state machine. The virtio-fs device context moves to `running` state after the initial number of virtio-fs IO contexts is bound to it and moves to `running` state (as described at DOCA DevEmu Virtio configurations).

Mandatory Configurations

The following are mandatory configurations:

- `doca_devemu_vfs_io_event_vfs_req_notice_register` – Register event handler for incoming virtio-fs requests is mandatory

Virtio-fs Request

The virtio-fs request object serves as an abstraction for handling requests arriving on virtio-fs queues, including high-priority, request, or notification queues. These requests are initially generated by the device driver through created virtio queues and then routed to the user via a registered event handler, which is set up using `doca_devemu_vfs_io_event_vfs_req_notice_register`, on the associated virtio IO

context. This event handler, issued by the DOCA Virtio FS library, ensures that users can receive and process virtio-fs requests effectively within their application. Once the event handler is called, the ownership of the virtio-fs request and the associated request user data move to the user. The request ownership moves back to the associated virtio IO context once it is completed by the user by calling `doca_devemu_vfs_req_complete`.

The following APIs operate a virtio-fs request:

1. `doca_devemu_vfs_req_get_datain` – Get a DOCA buffer representing the data-in of the virtio-fs request. This DOCA buffer represents the host memory for the device-readable part of the request according to the virtio specification.
2. `doca_devemu_vfs_req_get_dataout` – Get a DOCA buffer representing the data-out of the virtio-fs request. This DOCA buffer represents the host memory for the device-writable part of the request according to the virtio specification.
3. `doca_devemu_vfs_req_complete` – Complete the virtio-fs request. The associated virtio-fs IO context completes the request toward the device driver according to the virtio-fs specification.

5.4.19.4.5.5 Discovery

Emulated virtio-fs PCIe functions are represented by a `doca_devinfo_rep`. To find the suitable `doca_devinfo_rep` that is used as the input parameter for `doca_devemu_vfs_dev_create`, users should first discover the existing device representors using the below:

1. `doca_devinfo_create_list` – Get a list of all DOCA devices.
2. `doca_devemu_vfs_is_default_vfs_type_supported` – Check whether the device can manage device associated to virtio-fs type.
3. If supported:
    a. `doca_dev_open` – Get an instance of the DOCA device that can be used as virtio-fs emulation manager.
    b. `doca_devemu_vfs_find_default_vfs_type_by_dev` – Get the default virtio-fs device type.
    c. `doca_devemu_vfs_type_as_pci_type` – Cast virtio-fs type to PCIe type.
    d. `doca_devemu_pci_type_rep_list_create` – Create a list of all available representor devices for the virtio-fs type.
4. At this point, the user can choose the preferred representor device, open it using `doca_dev_rep_open`, and proceed with the flow described in section "Virtio-fs Device Configurations".

5.4.19.4.5.6 Initialization

This section describes the initialization flow of a DOCA DevEmu Virtio-fs device and one or more DOCA DevEmu Virtio-fs IO contexts (4 in this example). In this procedure, the

user sets up and prepares the environment before starting to receive control path events (from the virtio-fs device context) and IO requests (from the virtio-fs IO contexts). During initialization, the user should configure various essential components to ensure correct behavior.

The user should perform the following:

1. Choose 4 Arm cores to run the application threads on.
2. Create 4 DOCA Core progress engine (PE) objects (`pe1` , `pe2` , `pe3` , `pe4`).
3. Find the suitable representor device according to the Discovery flow or any other method.
4. Create, configure, and start a new virtio-fs device according to the virtio-fs device configuration flow. Assume `pe1` is associated with the virtio-fs device and `doca_devemu_virtio_dev_set_num_required_running_virtio_io_ctxs` is set to 4.
5. Create, configure, and start 4 new virtio-fs IO contexts according to the virtio-fs IO configuration flow. Assume `pe1` , `pe2` , `pe3` , and `pe4` are associated with each of the 4 virtio-fs IO contexts respectively.
6. At this point, the 4 virtio-fs IO contexts transition to `running` state, followed by the virtio-fs device context transitioning to `running` state.

> ⚠ During the initialization flow, it is guaranteed that no virtio/PCIe control path or IO path events are generated until the virtio-fs device has transitioned to `running` state.

5.4.19.4.5.7 Teardown

This section describes the teardown flow of DOCA DevEmu Virtio-fs device and one or more DOCA DevEmu Virtio-fs IO contexts (4 in this example). In this procedure, the user cleans all the resources allocated in the initialization flow and all the outstanding events and requests.

The user should perform the following:

1. Start the teardown flow by calling `doca_ctx_stop` . This causes the DOCA Virtio-fs device context to transition to `stopping` state. It is guaranteed that no virtio/PCIe control path events is generated during this state.
2. Call `doca_ctx_stop` for any DOCA Virtio-fs IO context. This causes the DOCA Virtio-fs IO context to transition to `stopping` state. It is guaranteed that no IO path events are generated during this state.
3. Flush all outstanding virtio-fs requests to the associated virtio-fs IO contexts by calling `doca_devemu_vfs_req_complete` . Upon completing all the requests associated with a virtio-fs IO context, the DOCA Virtio-fs IO context transitions to `idle` state.

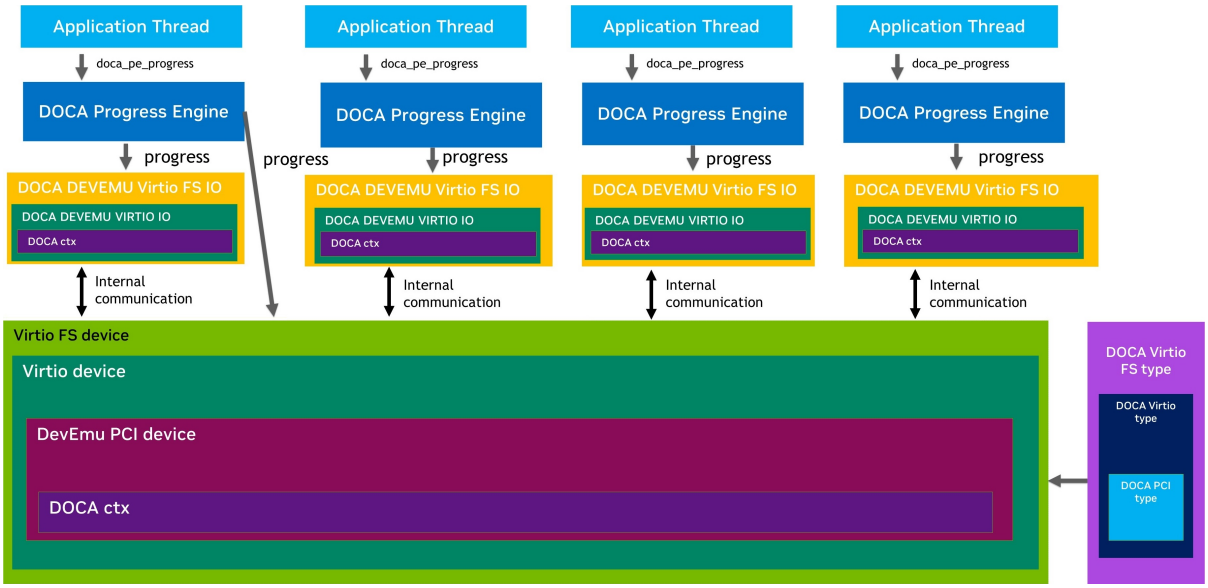
4. At this point, it is safe to destroy the virtio-fs IO context by calling `doca_devemu_vfs_io_destroy`. Destroying a virtio-fs IO context not in `idle` state will fail.
5. Once all 4 virtio-fs IO contexts associated with the virtio-fs device transition to `idle` state, the DOCA Virtio-fs device context transitions to `idle` state as well.
6. At this point, it is safe to destroy the virtio-fs device context by calling `doca_devemu_vfs_dev_destroy`. Destroying a virtio-fs device context not in `idle` state will fail.

5.4.19.4.5.8 Execution Phase

This section describes execution on BlueField Arm cores using several DOCA Core PE objects (one per core):

1. Choose 4 Arm cores to run the application threads on.
2. Create 4 DOCA Core PE objects. The application threads should periodically call `doca_pe_progress` to advance all DOCA contexts associated with the PE.
3. Create, configure, and start the DOCA Virtio-fs device.
4. Create, configure, and start 4 DOCA Virtio-fs IO contexts.

The progress of DOCA Virtio-fs objects is illustrated by the following diagram:



Control Path

The DOCA Virtio-fs device context extends the DOCA Virtio device context (which extends the DOCA PCIe device context). This means that the DOCA Virtio-fs device control path is comprised by all the object it extends (i.e., DOCA Context, DOCA DevEmu PCI device, and DOCA DevEmu Virtio device).

The following events can be triggered by a virtio-fs device context:

- DOCA context state change events as described in DOCA Core context state machine and in DOCA DevEmu PCI state machine
- DOCA DevEmu PCI FLR flow
- DOCA DevEmu Virtio reset flow

The DOCA Virtio-fs IO context extends the DOCA Virtio IO context (which extends the DOCA core context). This means that the DOCA Virtio-fs IO context control path is comprised by all the object it extends (i.e., DOCA Context and DOCA DevEmu Virtio IO).

The following events can be triggered by a Virtio-fs IO context:

- DOCA context state change events as described in DOCA Core context state machine

In addition to the control path events, the DOCA DevEmu Virtio-fs IO context also produces IO path events as described in IO path.

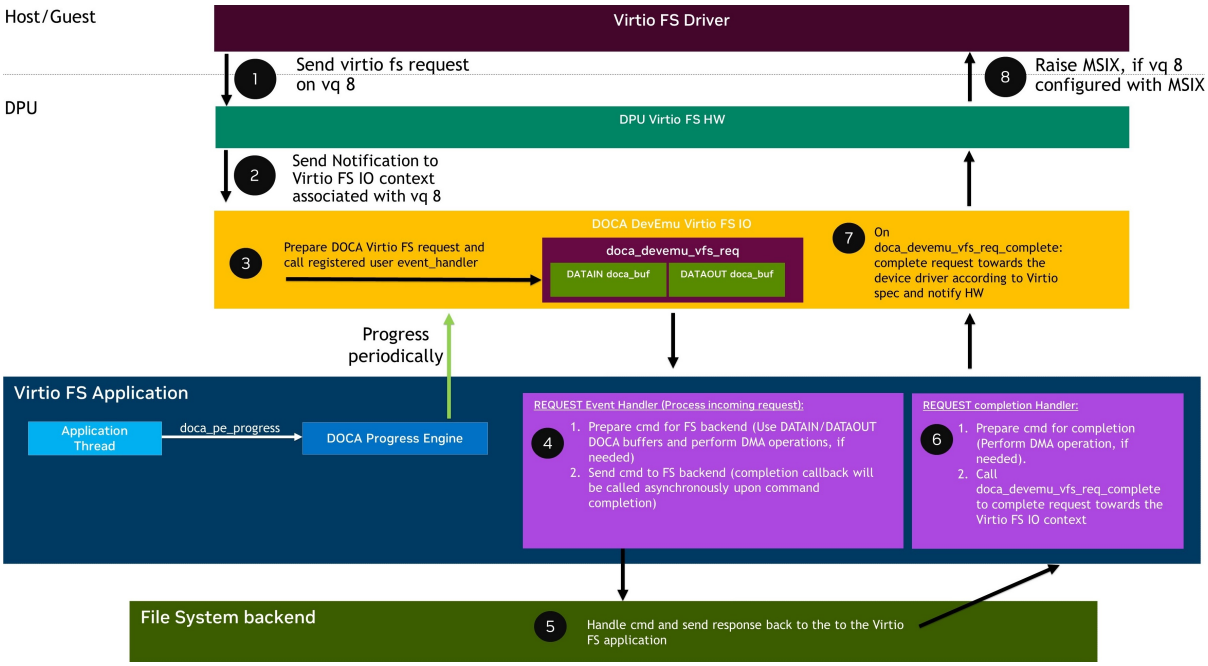
IO Path

This section describes the flow for a single virtio-fs request sent by the device driver until its completion.

It is assumed that the user properly configured an event handler for an incoming virtio-fs request as explained in section "Virtio-fs IO Configurations".

It is also assumed that the user is familiar with the virtio-fs specification and has the ability to perform DMA operations to/from the host using DOCA DMA or any other suitable method.

The DOCA virtio-fs flow is illustrated in the following diagram:



5.4.20 DOCA STA

5.4.20.1 Introduction

> The quality status of DOCA libraries is listed here.

The DOCA STA library simplifies the integration and offloading of storage target applications, such as SPDK, onto NVIDIA® BlueField®-3 and newer platforms. A storage target is any application that manages data storage access, whether from hard drives, SSDs, network-attached storage (NAS), or cloud services, and serves requests from local or remote initiators.

To enable network-based access, the NVMe-oF protocol extends the capabilities of NVMe storage across network fabrics like RoCEv1/IB RDMA and NVMeTCP. By allowing NVMe commands to execute over the network, NVMe-oF overcomes the limitations of direct-attached storage.

Applications supporting NVMe-oF are resource-intensive, requiring substantial CPU resources. To reduce CPU usage, improve latency, and conserve power, an offload solution is essential. With BlueField-3, storage target applications can leverage the data processing accelerator (DPA) to offload their operations.

DOCA STA provides a public API to manage both control-plane and data-plane operations, abstracting the complexity of communication between the offloaded target application and the hardware accelerator. This abstraction allows developers to streamline the integration process and focus on application logic.

Unlike traditional software-based storage targets that access NVMe drives over PCIe, DPA offload accelerators utilize PCIe peer-to-peer (P2P) topology to connect to NVMe drives. Special kernel configurations are required to enable this topology.

5.4.20.2 Prerequisites

To enable DPA storage target offload, a dedicated patched P2P kernel is required:

- For target applications running on the host machine, install a patched kernel that supports P2P.
  - Remove private items from linux/vfio_pci_core.h
  - Break up ioctl dispatch functions to one function per ioctl
  - Allow MMIO regions to be exported through dma-buf

    Note that the patches need to be applied manually and a custom kernel needs to be built to make it work.

- For target applications running on a BlueField machine, ensure a P2P-supported BFB is installed when the BlueField is directly attached to NVMe drives. For this you need the latest BFB with Ubuntu 22.04 (and DOCA v2.10.0).

In addition, the library makes use of existing DOCA libraries, therefore, it is recommended to read the following sections before:

- DOCA Comch
- DOCA RDMA
- DOCA DPA
- DOCA Core Device
- DOCA Core Memory Subsystem

5.4.20.3 Changes From Previous Release

N/A

5.4.20.4 Environment

DOCA STA-based applications can run either on the host machine or on the NVIDIA® BlueField-3® networking platform (DPU or SuperNIC).

When running on the BlueField platform, NVMe drives must be directly PCIe-attached, and BlueField-3 or newer is required.

5.4.20.5 Architecture

The DOCA STA library consists of two main components:

- Host side – The host-side component exposes an API for use by the target application. Using this API, the application can:
  - Initialize and configure accelerator parameters.
  - Register callbacks for data processing – Certain NVMe-oF command capsules that cannot be processed by the offload engine are forwarded to the library as "non-offloaded capsules." The application can process these capsules using registered callbacks.
  - Register callbacks for asynchronous events – The offload engine can generate notifications for events such as NVMe drive timeouts. The application can handle these events using registered callbacks.
  - Register tasks for various operations:
    - Datapath tasks – After processing non-offloaded capsules, the application can register tasks for RDMA operations, such as read, write, or send.

        - Control-path tasks – Some control operations, such as queue pair (QP) disconnection or backend destruction, may take time to complete asynchronously. The application can register tasks for these operations.
    - Device side – The device-side component consists of low-level accelerator code that implements the target offload logic, such as DPA handler code.

5.4.20.5.1 DOCA STA Contexts

DOCA STA operates with two types of DOCA contexts:

- DOCA STA context
    - Responsible for system-wide initialization and configuration.
    - Manages all target system-wide operations.
    - There should be only one instance of the DOCA STA context in the system (or virtual machine).
- DOCA STA IO context:
    - Responsible for RDMA IO operations.
    - Can exist for each system thread (e.g., per `pthread`).

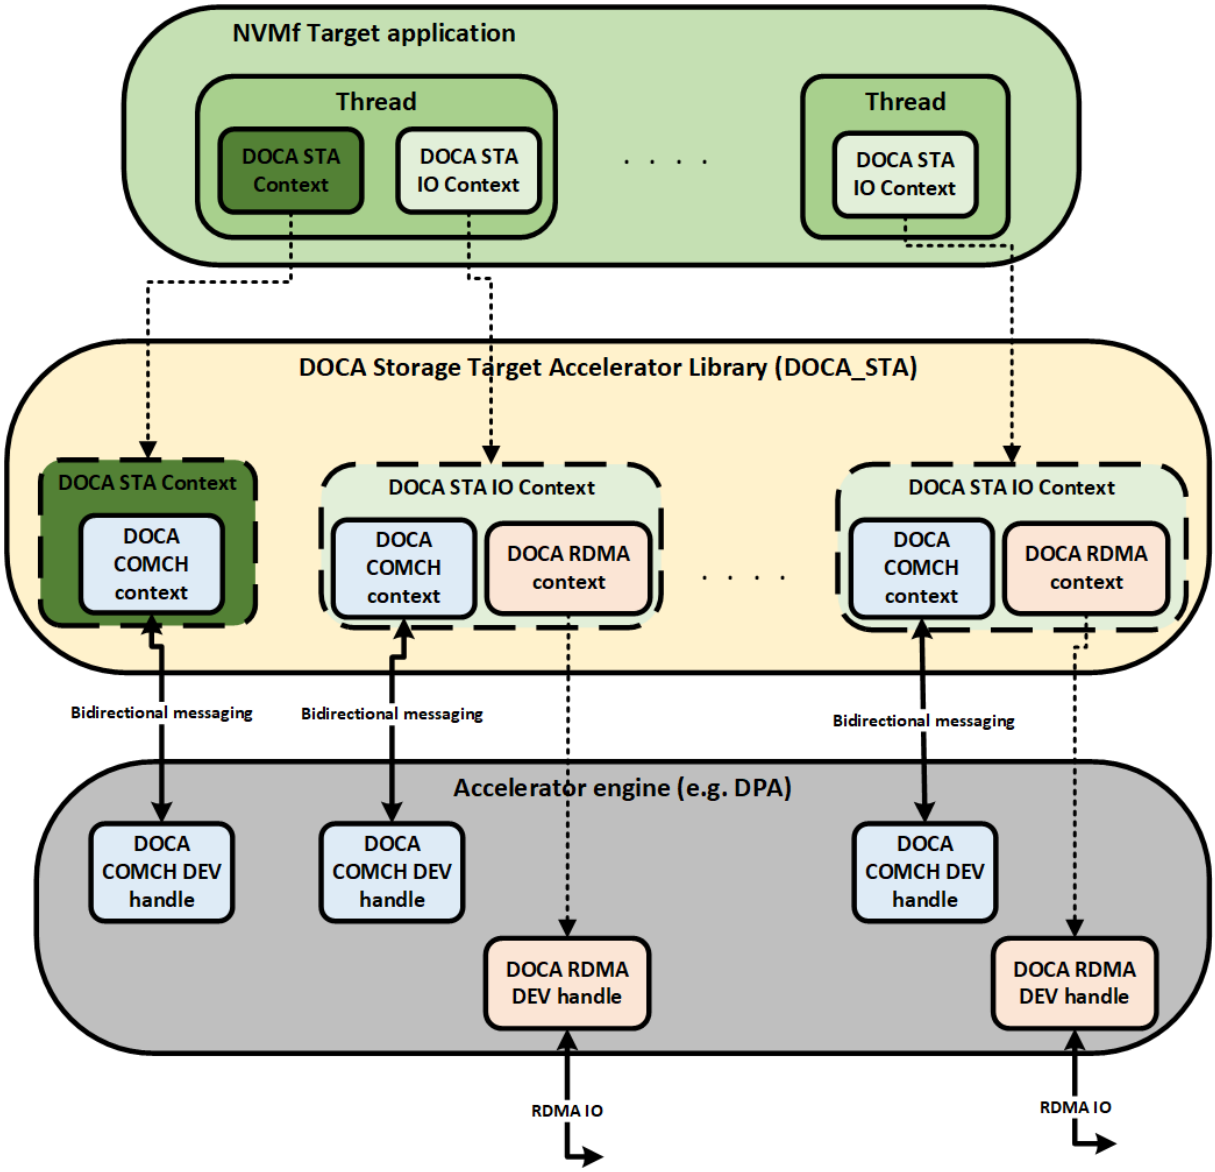
5.4.20.5.2 Key DOCA Libraries

DOCA STA relies on several other DOCA libraries for its functionality. The key libraries are:

- DOCA RDMA – Used for connecting or disconnecting queue pairs (QPs) on the accelerator datapath (e.g., DPA).
- DOCA Comch – Enables communication to and from the offload accelerator engine. For example, it facilitates posting RDMA tasks and receiving completions or handling QP disconnect tasks and their completions.

5.4.20.5.3 High-Level Connectivity

The following diagram illustrates the high-level connectivity of DOCA STA:



5.4.20.5.4 Objects

5.4.20.5.4.1 Device and Device Representor

The DOCA STA library utilizes two types of devices: a control device (PF) and one or more network devices (SF).

- Control device (PF) – This device is used to configure the DPA, such as loading the DPA-related application image.
- Network device (SF) – This device handles incoming and outgoing NVMe-oF traffic.

Applications using the DOCA STA library must select both a control device and network devices with the appropriate representors. For more information, refer to the sections on DOCA Core Device Discovery and DOCA Core Device Representor Discovery.

5.4.20.6 Configuration Phase

To begin using the DOCA STA library, users must complete a configuration phase as outlined in the DOCA Core Context Configuration Phase.

This section details the steps required to configure and initialize the DOCA STA context.

5.4.20.6.1 Configurations

The DOCA STA context must be configured to align with the application's use case.

The configuration process involves the following steps:

1. Create the DOCA STA object (main context).
2. Add network device(s).
3. Connect the DOCA STA context to the DOCA progress engine (PE).
4. Start the DOCA STA context.
5. Create the DOCA STA IO object(s) (IO context/IO threads).
6. Connect the DOCA STA IO context(s) to the DOCA PE.
7. Start the DOCA STA IO context(s).

> ⚠ The IO context(s) can only be created after the main context has been started.

The following order must be followed during the start phase:

1. Create the main context.
2. Start the main context.
3. Create IO context(s).
4. Start IO context(s).

The following order must be followed during the stop phase:

1. Stop IO context(s).
2. Stop the main context.

5.4.20.6.1.1 Create Main Context

The library relies heavily on the DPA, so the control device (PF) with STA functionality must be used to create the `doca-sta` object.

Use the `doca_sta_cap_is_supported` API to verify if the PF device supports STA functionality before proceeding.

5.4.20.6.1.2 Add Network Device

The library utilizes network device(s) (SF) to manage incoming and outgoing NVMe-oF traffic.

Before starting the `doca-sta` object, network devices (resources) must be added to it. Use the `doca_sta_add_dev` API to add network devices (SF) as needed.

5.4.20.6.1.3 Progress Engine

The Progress Engine (PE) is responsible for progressing tasks and events. Each PE is associated with one or more DOCA contexts, but a DOCA context can only be associated with a single PE.

> ⚠ It is the responsibility of the application using the library to create a dedicated PE and connect the `doca-sta` context to it.

5.4.20.6.1.4 Start Main Context

Once the `doca-sta` context is created and configured, it must be started to enable its functionality.

5.4.20.6.1.5 Create IO Context

The IO context represents the IO thread, which is responsible for initiating RDMA connectivity flows and handling "non-offload" commands.

Examples of such flows include:

- Connecting QPs
- Disconnecting QPs
- Handling non-offload commands

Non-offload commands refer to commands that the `doca-sta` library does not handle internally. These commands must be forwarded to the application layer for processing.

The IO context should be created in a similar manner to the main context.

> ⚠ The application using the library is responsible for creating a dedicated PE for each IO context and connecting the `doca-sta-io` context to this PE.

5.4.20.6.1.6 Start IO Context

Once the `doca-sta-io` context is created and configured, it must be started to enable IO-related operations.

5.4.20.7 Execution Phase

The DOCA STA library enables offloading of NVMe-oF traffic to the DPA, providing APIs to configure an NVMe-oF target application in compliance with the NVMe specification.

Before the application can begin receiving traffic from the initiator, the following steps must be completed:

1. Add subsystems.
2. Add namespaces to the subsystems.
3. Bind NVMe PCI disks to the namespaces.

> ⚠ The application is responsible for implementing the RDMA connection management service.

For additional details, refer to the `doca_sta_subsystem.h` and `doca_sta_be.h` header files.

5.4.20.7.1 RDMA Connect

Upon receiving an RDMA connection request, the application should use one of the following APIs:

- `doca_sta_io_qp_alloc` + `doca_sta_io_qp_accept`
- `doca_sta_io_qp_connect`

If the operation completes successfully, an STA QP (Queue Pair) is created, represented by an STA QP handle.

> ⚠ All communication between the application layer and QP API (and vice versa) must occur within the same IO thread (IO context) from which the QP was created.

5.4.20.7.1.1 Fabric Connect

After a connection is established, the initiator will immediately send a "Fabric Connect" (FC) command capsule.

The application is responsible for handling the FC command as part of the non-offload flow. This includes:

1. Retrieving the data/payload for the FC command (if not received as inline data).
2. Verifying the parameters inside the FC command (e.g., `host NQN`, `subsystem NQN`).
3. Completing FC processing by sending a response to the initiator.

> ⚠ All actions initiated by the application layer are asynchronous and are part of the non-offload flow. Communication between the DPA and host (DPU) is handled in this context.

For further details, refer to the `doca_sta_io_non_offload.h` header file.

5.4.20.7.2 Tasks

The DOCA STA library provides support for asynchronous tasks to handle various asynchronous flows, such as:

- Disconnecting a QP
- Removing (detaching) a namespace
- Destroying a back-end queue

The asynchronous flow is initiated by the application through the allocation of a task using the appropriate API. Once the task is allocated, the application is responsible for submitting it to trigger the desired action.

After submission, the library manages the execution and monitors the completion of the asynchronous flow. When the operation is completed, the library notifies the application by invoking a callback function.

5.4.20.7.2.1 Task Input

Common input as described in DOCA Core Task.

5.4.20.7.2.2 Task Output

Common output as described in DOCA Core Task.

5.4.20.7.2.3 Task Limitations

- The operation is not atomic
- Other limitations are described in the DOCA Core Task

5.4.20.7.2.4 Non-offload Flow Task

The application layer is responsible for processing NVMe-oF capsules within the non-offload flow.

Initially, the NVMe-oF capsule is delivered from the DPA to the host and then delegated to the application layer for processing. During this process, the application may need to perform RDMA operations to handle the capsule effectively.

> ⚠ The QP is managed by the DOCA STA library and must only be accessed through the library's API.

The following non-offload tasks can be used by the application layer to initiate RDMA operations for processing non-offload capsules:

- RDMA-READ

- RDMA-WRITE with RDMA-SEND
- RDMA-SEND

For additional details, refer to the `doca_sta_io_non_offload.h` file.

Non-offload RDMA-READ

The RDMA-READ task initiates an RDMA-READ operation. Upon completion of the operation, the library will invoke the appropriate callback function to notify the application layer of its completion.

Task Configuration

Description	API to Set the Configuration
Enable the task	`doca_sta_io_task_non_offload_set_rdma_read_conf`

Task Allocation

Description	API to Set the Configuration
Allocation the task	`doca_sta_io_task_non_offload_rdma_read_alloc_init`

Task Completion Success

After the task is completed successfully:

- The RDMA-READ operation is completed successfully

Task Completion Failure

If the task fails midway:

- The RDMA-READ operation fails

Non-offload RDMA-WRITE + RDMA-SEND

This task is responsible for initiating an RDMA-WRITE operation followed by an RDMA-SEND operation.

Upon successful completion of the operation, the library will invoke the corresponding callback function to notify the application layer about its completion.

Task Configuration

Description	API to Set the Configuration
Enable the task	`doca_sta_io_task_non_offload_set_rdma_write_send_conf`

Task Allocation

Description	API to Set the Configuration
Allocation the task	`doca_sta_io_task_non_offload_rdma_write_send_alloc_init`

Task Completion Success

After the task is completed successfully:

- The RDMA-WRITE and RDMA-SEND operation completed successfully

Task Completion Failure

If the task fails midway:

- The RDMA-WRITE and RDMA-SEND operation fails

Non-offload RDMA-SEND

This task is responsible for initiating an RDMA-SEND operation.

Upon completion, the library will invoke the appropriate callback function to notify the application layer of its successful completion.

Task Configuration

Description	API to Set the Configuration
Enable the task	`doca_sta_io_task_non_offload_set_rdma_write_send_conf`

Task Allocation

Description	API to Set the Configuration
Allocation the task	`doca_sta_io_task_non_offload_rdma_send_alloc_init`

Task Completion Success

After the task is completed successfully:

- The RDMA-SEND operation is completed successfully

Task Completion Failure

If the task fails midway:

- The RDMA-SEND operation fails

5.4.20.7.2.5 QP Disconnect Task

The QP disconnect task is responsible for initiating the asynchronous flow required to disconnect a QP. The process includes the following steps:

1. Move the QP to the error state.

2. Send a notification message from the host (DPU) to the corresponding DPA, indicating the QP disconnect request.
3. The DPA verifies that there are no pending inbound or outbound IO operations.
4. Once verification is complete, the DPA sends a response back to the host (DPU).
5. The library notifies the application about the completion of the disconnect task through a callback function.

Task Configuration

Description	API to Set the Configuration
Enable the task	`doca_sta_io_task_disconnect_set_conf`

Task Allocation

Description	API to Set the Configuration
Allocation the task	`doca_sta_io_task_disconnect_alloc_init`

Task Completion Success

After the task is completed successfully:

- The QP is disconnected and might be destroyed

Task Completion Failure

If the task fails midway:

- The QP was not disconnected

5.4.20.7.2.6 Remove Namespace Task

The remove (detach) namespace task initiates the asynchronous process for detaching a namespace. The flow includes the following steps:

1. Send a notification message from the host (DPU) to the corresponding DPA about the detach namespace request.
2. The DPA marks the namespace as no longer valid.
3. The DPA sends a response back to the host (DPU) confirming the detachment.
4. The library notifies the application about the task's completion through a callback function.

Task Configuration

Description	API to Set the Configuration
Enable the task	`doca_sta_subsystem_task_rm_ns_set_conf`

Task Allocation

Description	API to Set the Configuration
Allocation the task	`doca_sta_subsystem_task_rm_ns_alloc_init`

Task Completion Success

After the task is completed successfully:

- The namespace is removed
- Any I/O sent to the removed namespace is completed with an error

Task Completion Failure

If the task fails midway:

- The namespace is not removed

5.4.20.7.2.7 Destroy Back-end Queue Task

The destroy back-end (BE) queue task initiates the asynchronous process for destroying a back-end queue. The flow includes the following steps:

1. Send a notification message from the host (DPU) to the appropriate DPA to request the destruction of the back-end queue.
2. The DPA marks the back-end queue as destroyed.
3. Any outstanding commands in the queue are completed with an error status.
4. The DPA sends a response back to the host (DPU) confirming the destruction.
5. The library notifies the application about the task's completion through a callback function.

Task Configuration

Description	API to Set the Configuration
Enable the task	`doca_sta_be_task_destroy_queue_set_conf`

Task Allocation

Description	API to Set the Configuration
Allocation the task	`doca_sta_be_destroy_queue_task_alloc_init`

Task Completion Success

After the task is completed successfully:

- The BE queue is removed

Task Completion Failure

If the task fails midway:

- The BE queue is not removed

5.4.20.8 State Machine

The DOCA STA library follows the context state machine as described in DOCA Core Context State Machine.

The following section describes how to move states and what is allowed in each state.

5.4.20.8.1 Idle

In this state, it is expected that the application:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to the section
- Starting the context

It is possible to reach this state as follows:

Previous State	Transition Action
None	Create the context
Running	Call stop after making sure all tasks have been freed
Stopping	Call progress until all tasks are completed and freed

5.4.20.8.2 Starting

This state cannot be reached.

5.4.20.8.3 Running

In this state, it is expected that the application:

- Allocates and submits tasks
- Calls progress to complete tasks and/or receive events

Allowed operations:

- Allocating a previously configured task
- Submitting a task
- Calling stop

It is possible to reach this state as follows:

Previous State	Transition Action
Idle	Call start after the configuration

5.4.20.8.4 Stopping

In this state, it is expected that the application:

- Calls progress to complete all inflight tasks (tasks completed with failure)
- Frees any completed tasks

Allowed operations:

- Call progress

It is possible to reach this state as follows:

Previous State	Transition Action
Running	Call progress and a fatal error occurs
Running	Call stop without freeing all tasks

5.4.20.9 DOCA STA Sample Application

5.4.20.9.1 Offload Sample

This sample application demonstrates the basic usage of the DOCA STA API:

```
cd /opt/mellanox/doca/applications
meson setup /tmp/build
ninja -C /tmp/build

tmp/build/sta_offload/doca_sta_offload --doca_lib_lvl 50 --doca_app_lvl 40 --sf_dev mlx5_0
```

For a reference application utilizing the DOCA STA library, please get in touch with NVIDIA Enterprise Support.

5.4.21 DOCA Management

This guide provides instructions on how to use the DOCA Management API for developing applications for device management and configuration.

5.4.21.1 Introduction

> ⚠ The quality status of DOCA libraries is listed here.

DOCA Management provides an API to manage NVIDIA® BlueField® DPU and host devices and their associated functions (PFs, VFs, and SFs). The library offers an interface for device configuration, capability management, and direct firmware control.

Using DOCA Management, administrators and applications can dynamically configure and query device settings, enable or disable capabilities, and manage device behavior at runtime through a standardized API that communicates directly with device firmware via the Linux kernel's `fwctl` framework.

This document is intended for software developers and system administrators wishing to manage and configure DPU and host devices programmatically, control device capabilities, and integrate device management into their applications.

5.4.21.2 Prerequisites

DOCA Management library uses the Linux kernel's `fwctl` framework and as such requires the following kernel drivers:

- `fwctl.ko` – fwctl device firmware access framework
- `mlx5_fwctl.ko` – mlx5 ConnectX fwctl driver

The library also relies on DOCA Core Device for device and device representor discovery. It is recommended to read the following section before proceeding:

- DOCA Core Device

5.4.21.3 Library Changes From Previous Releases

5.4.21.3.1 Changes in 3.3.0

5.4.21.3.1.1 Added

- `doca_mgmt_icm_quota.h`

5.4.21.4 Environment

DOCA Management-based applications can run on the host machine and on the NVIDIA® BlueField® DPU. Certain configurations (e.g., configuring device capabilities) can only be performed through the device's representor, and thus must be executed where the representor resides.

5.4.21.5 Architecture

DOCA Management leverages DOCA Core Device for device and device representor discovery. The library operates through *management device contexts* and *management device representor contexts*, which correspond to DOCA devices and DOCA device representors, respectively.

The management contexts are the main objects of the library. They hold a management interface for the device and are passed to other APIs of the library to specify the device to operate on.

The library provides dedicated APIs for various configuration operations, allowing querying and setting device configuration parameters. Additionally, a generic API enables advanced users to send arbitrary configuration commands directly to the device firmware when specific abstractions are unavailable.

5.4.21.5.1 Objects

5.4.21.5.1.1 Device and Device Representor Management Context

The DOCA Management device context (`doca_mgmt_dev_ctx`) represents a management interface to a DOCA device. This context is used to perform device-level management operations. Creating the management device context requires a DOCA device, which must remain valid until the management device context is destroyed.

Similarly, the DOCA Management device representor context (`doca_mgmt_dev_rep_ctx`) represents a management interface to a DOCA device representor. This context is used to perform management operations for the device represented by the representor. Creating the management device representor context requires a DOCA Management device context (of the representor's parent device) and a DOCA device representor, which must remain valid until the management device representor context is destroyed.

The management device context and management device representor context function as handles that are passed to other DOCA Management APIs to specify the target device. Some DOCA Management APIs accept a management device context, while others accept a management device representor context.

5.4.21.5.1.2 Dedicated Management Handles

The library provides dedicated handles for specific management operations. Each handle is an opaque structure that encapsulates configuration attributes and provides APIs to both configure the handle (via setters/getters) and apply/query these attributes to or from the device (via set/get operations).

The following table lists the currently supported handles:

Handle	Description	Context	Notes
`doca_mgmt_device_caps_general`	Holds general device capabilities configuration parameters	Device representor	Configuration is done via the representor. The represented device must be uninitialized (unbound from `mlx5_core`) when setting capabilities.
`doca_mgmt_cc_global_status`	Holds congestion control global status configuration parameters	Device	Configuration applies to PFs only. Enables or disables congestion control operation for the PF and its child functions based on priority (0–7) and protocol (reaction point/notification point).
`doca_mgmt_icm_quota`	Holds ICM quota configuration parameters	Device or device representor	Interconnect Context Memory is a portion of host memory allocated exclusively for the HCA to maintain and manage its internal control objects. The amount of ICM required depends directly on the device's capabilities and the scale of resources it must support. On supported devices, the ICM Quota feature allows administrators to limit the amount of ICM a specific function is allowed to consume, query current ICM usage information, and configure these limits on both physical devices and representors.

5.4.21.6 Expected Usage Flow

The following section describes the expected usage flow of the various APIs of the DOCA Management library.

5.4.21.6.1 Device Context Creation

To start using the library, a DOCA Management device context must be created.

The following steps describe how to create a management device context:

1. Open the `doca_dev` that should be configured.
   For information about opening a DOCA device, see DOCA Core Device Discovery.
2. Create the corresponding `doca_mgmt_dev_ctx` by calling `doca_mgmt_dev_ctx_create()` with the opened `doca_dev`.
3. The created `doca_mgmt_dev_ctx` can now be used to configure the device or to create a DOCA Management device representor context for one of its representors (as explained in Device Representor Context Creation).

4. When the application finishes using the `doca_mgmt_dev_ctx`, destroy it using `doca_mgmt_dev_ctx_destroy()`. The `doca_dev` must remain valid until the `doca_mgmt_dev_ctx` is destroyed.

5.4.21.6.2 Device Representor Context Creation

Some configurations (such as configuring device capabilities) can be done only via the device representor. For this, a DOCA Management device representor context must be created.
The following steps describe how to create a management device representor context:

1. Create a `doca_mgmt_dev_ctx` for the parent device of the representor (as explained in Device Context Creation). For example, if `VF0` of `PF0` should be configured, create a `doca_mgmt_dev_ctx` for `PF0`.
2. Open the `doca_dev_rep` that should be configured. For information about opening a DOCA device representor, see DOCA Core Device Representor Discovery.
3. Create the corresponding `doca_mgmt_dev_rep_ctx` by calling `doca_mgmt_dev_rep_ctx_create()` with the created `doca_mgmt_dev_ctx` and the opened `doca_dev_rep`.
4. The created `doca_mgmt_dev_rep_ctx` can now be used to configure the device represented by the representor.
5. When the application finishes using the `doca_mgmt_dev_rep_ctx`, destroy it using `doca_mgmt_dev_rep_ctx_destroy()`. Both the `doca_dev_rep` and `doca_mgmt_dev_ctx` must remain valid until the `doca_mgmt_dev_rep_ctx` is destroyed.

5.4.21.6.3 Device Capabilities General Configuration

Configuring device capabilities is done via the device representor (`doca_mgmt_dev_rep_ctx`).

5.4.21.6.3.1 Getting General Capabilities

1. Create a `doca_mgmt_dev_rep_ctx` for the device representor that should be configured (as explained in Device Representor Context Creation).
2. Create a `doca_mgmt_device_caps_general` handle by calling `doca_mgmt_device_caps_general_create()`.

3. Query the general capabilities of the device by calling `doca_mgmt_device_caps_general_get()` with the created `doca_mgmt_dev_rep_ctx` and `doca_mgmt_device_caps_general`.
4. Get the queried attributes by calling the getters of the `doca_mgmt_device_caps_general` handle. Currently, only the *data direct* attribute is available and it can be retrieved using `doca_mgmt_device_caps_general_get_data_direct()`.
5. When the application finishes using the `doca_mgmt_device_caps_general` handle, destroy it using `doca_mgmt_device_caps_general_destroy()`.

5.4.21.6.3.2 Setting General Capabilities

⚠ To set device capabilities, the device represented by the representor must be uninitialized — i.e., unbound from the `mlx5_core` driver.

- Create a `doca_mgmt_dev_rep_ctx` for the device representor that should be configured (as explained in Device Representor Context Creation).
- Create a `doca_mgmt_device_caps_general` handle by calling `doca_mgmt_device_caps_general_create()`.
- Set the desired attributes by calling the setters of the `doca_mgmt_device_caps_general` handle. Currently, only the *data direct* attribute is available and it can be set by calling `doca_mgmt_device_caps_general_set_data_direct()` with the desired value.
- Set the general capabilities of the device by calling `doca_mgmt_device_caps_general_set()` with the created `doca_mgmt_dev_rep_ctx` and `doca_mgmt_device_caps_general`.
- When the application finishes using the `doca_mgmt_device_caps_general` handle, destroy it using `doca_mgmt_device_caps_general_destroy()`.

5.4.21.6.4 Congestion Control Global Status Configuration

Configuring the congestion control global status is done via the device (`doca_mgmt_dev_ctx`) and can be configured only for PFs.

5.4.21.6.4.1 Getting Congestion Control Global Status

1. Create a `doca_mgmt_dev_ctx` for the device that should be configured (as explained in Device Context Creation).
2. Create a `doca_mgmt_cc_global_status` handle by calling `doca_mgmt_cc_global_status_create()`.

3. Set the `priority` and `protocol` attributes to specify which congestion control entity to query.
   This is done by calling `doca_mgmt_cc_global_status_set_priority()` and `doca_mgmt_cc_global_status_set_protocol()` with the desired priority (0–7) and protocol (`RP` or `NP`).
4. Query the congestion control global status of the device by calling `doca_mgmt_cc_global_status_get()` with the created `doca_mgmt_dev_ctx` and `doca_mgmt_cc_global_status` .
5. Get the queried `enabled` attribute by calling `doca_mgmt_cc_global_status_get_enabled()` .
6. When the application finishes using the `doca_mgmt_cc_global_status` handle, destroy it using `doca_mgmt_cc_global_status_destroy()` .

5.4.21.6.4.2 Setting Congestion Control Global Status

1. Create a `doca_mgmt_dev_ctx` for the device that should be configured (as explained in Device Context Creation).
2. Create a `doca_mgmt_cc_global_status` handle by calling `doca_mgmt_cc_global_status_create()` .
3. Set the `priority` and `protocol` attributes to specify which congestion control entity to configure.
   This is done by calling `doca_mgmt_cc_global_status_set_priority()` and `doca_mgmt_cc_global_status_set_protocol()` with the desired priority (0–7) and protocol (`RP` or `NP`).
4. Set the `enabled` attribute by calling `doca_mgmt_cc_global_status_set_enabled()` with the desired value (1 to enable, 0 to disable).
5. Set the congestion control global status of the device by calling `doca_mgmt_cc_global_status_set()` with the created `doca_mgmt_dev_ctx` and `doca_mgmt_cc_global_status` .
6. When the application finishes using the `doca_mgmt_cc_global_status` handle, destroy it using `doca_mgmt_cc_global_status_destroy()` .

5.4.21.6.5 ICM Quota Configuration

ICM Quota configuration is supported on both devices and representors.

5.4.21.6.5.1 Querying ICM Quota Capabilities

Not all devices support ICM quota configuration. To check for support and discover capabilities:

1. Create a `doca_mgmt_dev_ctx` for the target device.
2. Check for support by calling `doca_mgmt_cap_icm_quota_is_supported()`.
3. If supported, retrieve the maximum quota limit using `doca_mgmt_cap_icm_quota_get_max_limit()`.

> ⚠ This returned value represents the maximum valid input for `doca_mgmt_icm_quota_set_limit()`.

> ⚠ If a device supports ICM Quota, its associated representors also support it and share the same limit.

5.4.21.6.5.2 Getting ICM Quota Configuration

To retrieve the current configuration:

1. Create a `doca_mgmt_dev_ctx` or a `doca_mgmt_dev_rep_ctx` for the device or device representor that should be configured (as explained in Device Context Creation and Device Representor Context Creation).
2. Initialize a `doca_mgmt_icm_quota` handle for the device or the device representor by calling `doca_mgmt_icm_quota_create_for_dev()` or `doca_mgmt_icm_quota_create_for_dev_rep()` with the created `doca_mgmt_dev_ctx` or `doca_mgmt_dev_rep_ctx`, respectively. The created handle will be associated with the given device or device representor and the following query will be applied to this device or device representor.
3. Query the ICM quota configuration by calling `doca_mgmt_icm_quota_query()`.
4. Use the following getters to read the results:
   - `doca_mgmt_icm_quota_get_limit()`
   - `doca_mgmt_icm_quota_get_current_allocation()`
   - `doca_mgmt_icm_quota_get_max_reached()`
5. Destroy the handle using `doca_mgmt_icm_quota_destroy()`.

5.4.21.6.5.3 Setting ICM Quota Configuration

1. Create a `doca_mgmt_dev_ctx` or a `doca_mgmt_dev_rep_ctx` for the device or device representor that should be configured (as explained in Device Context Creation and Device Representor Context Creation).

2. Initialize a `doca_mgmt_icm_quota` handle for the device or the device representor by calling `doca_mgmt_icm_quota_create_for_dev()` or `doca_mgmt_icm_quota_create_for_dev_rep()` with the created `doca_mgmt_dev_ctx` or `doca_mgmt_dev_rep_ctx`, respectively. The created handle will be associated with the given device or device representor and the following configuration will be applied to this device or device representor.
3. Set the relevant attributes to the handle:
    a. Set the quota limit using `doca_mgmt_icm_quota_set_limit()`.
    b. Reset the "max reached" counter using `doca_mgmt_icm_quota_set_reset_max_reached()`.
4. Commit the configuration by calling `doca_mgmt_icm_quota_modify()`.
5. Destroy the handle using `doca_mgmt_icm_quota_destroy()`.

5.4.21.6.6 Raw Command

For advanced use cases, the library provides a raw command API that allows sending arbitrary firmware commands directly to the device.

> ⚠ The raw command API is intended for advanced users with detailed knowledge of the device firmware interface. It is recommended to use the higher-level dedicated APIs (e.g., Congestion Control Global Status) when available.

The following steps detail how to send a raw command to a device:

1. Create a `doca_mgmt_dev_ctx` for the device that should receive the command (as explained in Device Context Creation).
2. Prepare the input payload buffer according to the specific command requirements.
3. Allocate an output payload buffer to receive the command response.
4. Call `doca_mgmt_raw_cmd()` with the following parameters:
    - The created `doca_mgmt_dev_ctx`
    - A command identifier string (for logging)
    - The command scope
    - Pointer to the input payload buffer and its size
    - Pointer to the output payload buffer and its size
5. Check the return value to verify that the command executed successfully.
6. Parse the output payload buffer according to the specific command response format.

The `command scope` parameter specifies the scope of the command being performed and must match the `fwctl` scope assigned to it by the `mlx5_fwctl` driver.

The mapping between DOCA and `fwctl` command scopes is as follows:

DOCA Management Command Scope	Corresponding fwctl Scope
`DOCA_MGMT_CMD_SCOPE_CONFIGURATION`	`FWCTL_RPC_CONFIGURATION`
`DOCA_MGMT_CMD_SCOPE_DEBUG_READ_ONLY`	`FWCTL_RPC_DEBUG_READ_ONLY`
`DOCA_MGMT_CMD_SCOPE_DEBUG_WRITE`	`FWCTL_RPC_DEBUG_WRITE`
`DOCA_MGMT_CMD_SCOPE_DEBUG_WRITE_FULL`	`FWCTL_RPC_DEBUG_WRITE_FULL`

5.4.21.7 DOCA Management Samples

This section describes DOCA Management samples based on the DOCA Management library. The samples demonstrate how to use the DOCA Management API for the following device configuration tasks:

- Configure device data direct capability.
- Configure device congestion control global status.

> All the DOCA samples described in this section are governed under the BSD-3 software license agreement.

5.4.21.7.1 Running the Samples

Refer to the following documents:

- DOCA Installation Guide for Linux for details on how to install BlueField-related software.
- NVIDIA BlueField Platform Software Troubleshooting Guide for any issue you may encounter with the installation, compilation, or execution of DOCA samples.

To build a given sample, run the following command. If you downloaded the sample from GitHub, update the path in the first line to reflect the location of the sample file:

```
cd /opt/mellanox/doca/samples/doca_mgmt/<sample_name>
meson /tmp/build
ninja -C /tmp/build
```

> The binary `doca_<sample_name>` is created under `/tmp/build/`.

Sample usage (e.g., `doca_mgmt_data_direct`):

```
Usage: doca_mgmt_data_direct [Program Commands] [DOCA Flags]

Program Commands:
  get                               Get data direct capability
  set                               Set data direct capability
```

```
DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file
```

For additional information per sample, use the `-h` option:

```
/tmp/build/doca_<sample_name> -h
/tmp/build/doca_<sample_name> get -h
/tmp/build/doca_<sample_name> set -h
```

5.4.21.7.2 Samples

The samples are also available on GitHub.

5.4.21.7.2.1 Management Data Direct

The NVIDIA® ConnectX®-8 device may expose a side DMA engine as an additional PCIe PF called the **Data Direct device**. This additional device allows access to data buffers through multiple PCIe data path interfaces. By default, the *data direct* capability is disabled for VFs and SFs and must be explicitly enabled to allow data direct usage for a specific VF or SF.

This sample demonstrates how to set and get the data direct capability for VFs and SFs using the DOCA Management library.

The sample supports two commands:

- `get` – Displays the current data direct capability state.
- `set` – Enables or disables the data direct capability.

For both commands, the device (VF or SF) to operate on must be specified.

Specifying the Device

- For VFs:
  a. Specify the VF PCIe address (e.g., `0000:08:00.2`) using the `-v` or `--vf-pci-addr` parameter.
  b. Specify the VF representor using the `-r` or `--rep` parameter in the format `pci/<parent_pf_pci_address>,pf<pfnum>vf<vfnum>`. Example for VF `0000:08:00.2`, where VF number = 0 and parent PF = `0000:08:00.0` (PF number 0):

     ```
     pci/0000:08:00.0,pf0vf0
     ```

- For SFs, specify the SF representor using the `-r` or `--rep` parameter in the format `pci/<parent_pf_pci_address>,pf<pfnum>sf<sfnum>`. Example for SF number 88 and parent PF `0000:08:00.0` (PF number 0):

```
pci/0000:08:00.0,pf0sf88
```

Set Command

The `-e` or `--enabled` parameter must be specified with `true` or `false` values to indicate whether the data direct capability should be enabled or disabled, respectively.

> ⚠ To get or set data direct, the VF or SF must have a representor, i.e., their parent PF must be in switchdev mode.

> ⚠ To set data direct, the VF or SF must be uninitialized (not bound to the `mlx5_core` driver).

> ⚠ For command-line syntax details of device and representor identifiers, refer to the DOCA Arg Parser documentation.

Example Executions

- Get *data direct* state for a VF with PCIe address `0000:08:00.2`:

```
$ /tmp/build/doca_mgmt_data_direct get --vf-pci-addr 0000:08:00.2
```

- Enable data direct for a VF (uninitialized):

```
$ /tmp/build/doca_mgmt_data_direct set --vf-pci-addr 0000:08:00.2 --enabled true
```

- Disable data direct for a VF (uninitialized):

```
$ /tmp/build/doca_mgmt_data_direct set --vf-pci-addr 0000:08:00.2 --enabled false
```

- Enable data direct using VF representor:

```
$ /tmp/build/doca_mgmt_data_direct set --rep pci/0000:08:00.0,pf0vf0 --enabled true
```

- Enable data direct for SF representor:

```
$ /tmp/build/doca_mgmt_data_direct set --rep pci/0000:08:00.0,pf0sf88 --enabled true
```

Sample Logic

- Get Data Direct:

    a. Opening the DOCA device and a DOCA device representor that were specified in the command line arguments.
    b. Creating a DOCA management device context for the DOCA device and a DOCA management device representor context for the DOCA device representor.
    c. Creating a device caps general handle.
    d. Executing get operation through the DOCA management device caps general API.
    e. Retrieving the data direct capability for the specified representor interface.
    f. Cleaning up all DOCA management and device structures.
- Set Data Direct:
    a. Opening the DOCA device that was specified in the command line arguments.
    b. Creating a DOCA management device context for the DOCA device and a DOCA management device representor context for the DOCA device representor.
    c. Creating a device caps general handle and setting data direct attribute.
    d. Executing set operation through the DOCA management device caps general API.
    e. Cleaning up all DOCA management and device structures.

Reference:

- `/opt/mellanox/doca/samples/doca_mgmt/mgmt_data_direct/mgmt_data_direct_sample.c`
- `/opt/mellanox/doca/samples/doca_mgmt/mgmt_data_direct/mgmt_data_direct_main.c`
- `/opt/mellanox/doca/samples/doca_mgmt/mgmt_data_direct/meson.build`

5.4.21.7.2.2 Management Congestion Control Global Status

This sample demonstrates how to set and get congestion control global status for different priorities and protocols (`NP` / `RP`) on a DOCA device using the DOCA Management library.

The sample logic includes two main operations:

- Get Congestion Control Global Status:
    a. Opening the DOCA device that was specified in the command line arguments.
    b. Creating a DOCA management device context for the DOCA device.
    c. Creating a congestion control global status handle and setting priority and protocol attributes.
    d. Executing get operation through the DOCA management congestion control global status API.

e. Retrieving the congestion control global status enabled attribute for the specified priority and protocol.
f. Cleaning up all DOCA management and device structures.

- Set Congestion Control Global Status:
  a. Opening the DOCA device that was specified in the command line arguments.
  b. Creating a DOCA management device context for the DOCA device.
  c. Creating a congestion control global status handle and setting priority, protocol and enabled attributes.
  d. Executing set operation through the DOCA management congestion control global status API.
  e. Cleaning up all DOCA management and device structures.

Reference:

- `/opt/mellanox/doca/samples/doca_mgmt/mgmt_cc_global_status/mgmt_cc_global_status_sample.c`
- `/opt/mellanox/doca/samples/doca_mgmt/mgmt_cc_global_status/mgmt_cc_global_status_main.c`
- `/opt/mellanox/doca/samples/doca_mgmt/mgmt_cc_global_status/meson.build`

5.4.21.7.2.3 Management ICM Quota

This sample allows getting, setting, and querying capabilities for ICM quota on a given device or device representor (PF/VF/SF), and demonstrates how to do it using DOCA management library API.

The sample supports three commands:

- `caps` – Shows the ICM quota capabilities for the device.
- `get` – Shows the current ICM quota configuration (limit, current allocation, max reached allocation).
- `set` – Sets the ICM quota limit or resets the max reached allocation counter.

For all commands, either a device or a device representor must be specified.

Specifying the Device/Device Representor

- Specify a device using the `-d` or `--device` parameter in the following format `pci/<pci_address>`. Example for a device with PCIe address `0000:08:00.0`:

```
pci/0000:08:00.0
```

- Specify a device representor using the `-r` or `--rep` parameter in the following formats:

a. VF representor format: `pci/<parent_pf_pci_address>,pf<pfnum>vf<vfnum>`. Example for a VF with VF number = 0 and parent PF = `0000:08:00.0` (PF number 0):

```
pci/0000:08:00.0,pf0vf0
```

b. SF representor format: `pci/<parent_pf_pci_address>,pf<pfnum>sf<sfnum>`. Example for a SF with SF number 88 and parent PF `0000:08:00.0` (PF number 0):

```
pci/0000:08:00.0,pf0sf88
```

For a full documentation of device and device representor formats please refer to "Syntax – Device and Device Representor" section in DOCA Arg Parser documentation.

Caps Command

Shows whether the device supports ICM quota and if so, also shows the maximum ICM qouta limit that can be set by `set` command.

Get Command

The following optional parameters can be specified to retrieve specific attributes:

- `--limit` shows the ICM quota limit that is configured for the device.
- `--cur-alloc` shows the currently allocated ICM quota of the device.
- `--max-reached` shows the maximum reached ICM quota that the device has reached so far.

If no parameters are specified, all attributes are retrieved.

Set Command

At least one of the following parameters must be specified:

- `-L` or `--limit` sets the ICM quota limit for the device (e.g., 4096, 4K, 1M, 1G, 1T, unlimited). The value must be aligned to 4K. The value must be less than or equal to the maximum ICM quota limit reported by `caps` command and less than or equal to 16TB-8KB. Value of 'unlimited' indicates no limit.
- `--reset-max-reached` resets the maximum reached ICM quota counter.

Example Executions

- Get ICM quota capabilities for a device:

```
$ /tmp/build/doca_mgmt_icm_quota caps --device pci/0000:08:00.0
```

- Get all ICM quota attributes for a device:

```
$ /tmp/build/doca_mgmt_icm_quota get --device pci/0000:08:00.0
```

- Get only the ICM quota limit for a device:

```
$ /tmp/build/doca_mgmt_icm_quota get --device pci/0000:08:00.0 --limit
```

- Set ICM quota limit to 1GB for a VF:

```
$ /tmp/build/doca_mgmt_icm_quota set --rep pci/0000:08:00.0,pf0vf0 --limit 1G
```

- Set ICM quota limit to unlimited for a device:

```
$ /tmp/build/doca_mgmt_icm_quota set --device pci/0000:08:00.0 --limit unlimited
```

- Reset the ICM quota max reached counter for a SF:

```
$ /tmp/build/doca_mgmt_icm_quota set --rep pci/0000:08:00.0,pf0sf88 --reset-max-reached
```

Sample Logic

- Get ICM Quota:
  a. Opening the DOCA device or device representor that was specified in the command line arguments.
  b. Creating a DOCA management device context for the DOCA device, and a DOCA management device representor context for the device representor.
  c. Creating an ICM quota handle.
  d. Executing get operation through the DOCA management ICM quota API.
  e. Retrieving and displaying the requested attributes (limit, current allocation, max reached).
  f. Cleaning up all DOCA management and device structures.
- Set ICM Quota:
  a. Opening the DOCA device or device representor that was specified in the command line arguments.
  b. Creating a DOCA management device context for the DOCA device, and a DOCA management device representor context for the device representor.
  c. Creating an ICM quota handle and setting the requested attributes (limit, reset max reached).
  d. Executing set operation through the DOCA management ICM quota API.
  e. Cleaning up all DOCA management and device structures.
- Get ICM Quota Capabilities:
  a. Opening the DOCA device or device representor that was specified in the command line arguments.
  b. Creating a DOCA management device context for the DOCA device or for the DOCA device representor.
  c. Checking if ICM quota is supported on the device.

d. Retrieving and displaying the maximum ICM quota limit supported by the device.
e. Cleaning up all DOCA management and device structures.

- `/opt/mellanox/doca/samples/doca_mgmt/mgmt_icm_quota/mgmt_icm_quota_main.c`
- `/opt/mellanox/doca/samples/doca_mgmt/mgmt_icm_quota/meson.build`

5.5 DOCA Utils

This section includes modules that may be used by application developers to speed up their development process.

This section contains the following pages:

- DOCA Arg Parser

5.5.1 DOCA Arg Parser

This guide provides an overview and configuration instructions for DOCA Arg Parser API.

5.5.1.1 Introduction

The DOCA Arg Parser module simplifies the creation of command-line interfaces for user-facing applications, as well as provides basic support for JSON-based configuration files. It allows developers to define and handle structured program arguments while automatically generating help and usage messages.

When a user provides invalid input, the Arg Parser outputs clear error messages along with the corresponding usage instructions, helping ensure a smooth user experience.

- The Arg Parser validates a wide range of input errors, including unsupported arguments and incorrect types.
- Upon encountering an error, the module:
  a. Prints a descriptive error message.
  b. Displays the full usage guide for the program.
  c. Exits the application with an appropriate error code.

5.5.1.2 API

For the library API reference, refer to ARGP API documentation in DOCA API References.

> ⚠ The pkg-config (`*.pc` file) for the Arg Parser library is `doca-argp`.

The following sections provide additional details about the library API.

5.5.1.2.1 doca_argp_param

The data structure contains the program flag details needed to process DOCA ARGP. These details are used to generate usage information for the flag, identify if the user passed the flag in the command line and notify the program about the flag's value.

```
struct doca_argp_param;
```

5.5.1.2.2 doca_argp_param_create

Creates a DOCA ARGP parameter instance. The user is required to update the param attributes by calling the respective setter functions and registering the param by calling `doca_argp_register_param()`.

```
doca_error_t doca_argp_param_create(struct doca_argp_param **param);
```

- `param [out]` – DOCA ARGP param structure with unset attributes

5.5.1.2.3 doca_argp_register_param

Calling this function registers the program flags in the Arg Parser database. The registration includes flag details. Those details are used to parse the input arguments and generate usage print.

> ⚠ The user must register **all** program flags before calling `doca_argp_start()`.

```
doca_error_t doca_argp_register_param(struct doca_argp_param *input_param);
```

- `input_param [in]` – program flag details

⚠ Once registered, the ownership of the parameter passes to the ARGP module, and it should no longer be accessed/used by the user.

5.5.1.2.4 doca_argp_cmd

The data structure contains the program command details needed to process DOCA ARGP. These details are used to generate usage information for the command, identify if the user passed the command in the command line, and notify the program about the selected command.

```
struct doca_argp_cmd;
```

5.5.1.2.5 doca_argp_cmd_create

Creates a DOCA ARGP command instance. The user is required to update the command attributes by calling the respective setter functions and registering the command by calling `doca_argp_register_cmd()`.

```
doca_error_t doca_argp_cmd_create(struct doca_argp_cmd **cmd);
```

- `cmd [out]` – DOCA ARGP command structure with unset attributes

5.5.1.2.6 doca_argp_cmd_register_param

Calling this function registers the program flags in the Arg Parser database as associated with the respective command. The registration includes flag details which are used to parse the input arguments and generate usage print.

```
doca_error_t doca_argp_cmd_register_param(struct doca_argp_cmd *cmd, struct doca_argp_param *input_param);
```

- `cmd [in]` – program cmd
- `input_param [in]` – program flag details

⚠ Once registered, the ownership of the parameter passes to the ARGP module, and it should no longer be accessed/used by the user.

5.5.1.2.7 doca_argp_cmd_register_cmd

Calling this function registers the program cmd as a sub-command to the respective associated command. The registration includes cmd details which are used to parse the input arguments and generate usage print.

```
doca_error_t doca_argp_cmd_register_cmd(struct doca_argp_cmd *cmd, struct doca_argp_cmd *input_cmd);
```

- `cmd [in]` – program cmd
- `input_cmd [in]` – program cmd details (sub-command)

Once registered, the ownership of the sub-command passes to the ARGP module, and it should no longer be accessed/used by the user.

5.5.1.2.8 doca_argp_register_cmd

Calling this function registers the program command in the Arg Parser database. The registration includes command details which are used to parse the input arguments and generate usage print.

The user must register all program commands before calling `doca_argp_start()`.

```
doca_error_t doca_argp_register_cmd(struct doca_argp_cmd *input_cmd);
```

- `input_cmd [in]` – program command details

Once registered, the ownership of the command passes to the ARGP module, and it should no longer be accessed/used by the user.

5.5.1.2.9 doca_argp_set_dpdk_program

Marks the programs as a DPDK program. Once ARGP is finished with the parsing, DPDK (EAL) flags are forwarded to the program by calling the given callback function.

```
void doca_argp_set_dpdk_program(dpdk_callback callback);
```

- `callback [in]` - callback function to handle DPDK (EAL) flags.

⚠ Due to a current limitation, programs that support several commands cannot be marked as "DPDK Programs".

5.5.1.2.10 doca_argp_init

This function initializes the ARGP module and must be the first function called when using this module. Initialization includes the basic information about the program and about the user's context as will later be used during the parsing of the command-line.

```
doca_error_t doca_argp_init(const char *program_name, void *program_config);
```

- `program_name [in]` – program name as will be used in the help printout
- `program_config [in]` – pointer to the user's configuration struct (if there is one)

5.5.1.2.11 doca_argp_start

The `doca_argp_start()` function initiates the parsing and classification of command-line arguments. It maps user-provided arguments to their corresponding user-defined parameters and, if present, transfers DPDK EAL flags back to the program by invoking the registered callback.

```
doca_error_t doca_argp_start(int argc, char **argv);
```

- `argc [in]` – the number of input arguments
- `argv [in]` – the array of input strings representing the command-line arguments

5.5.1.2.12 doca_argp_destroy

Cleans up all the resources used by the module. Should be invoked upon program termination following a successful invocation of `doca_argp_init()`.

```
doca_error_t doca_argp_destroy(void);
```

5.5.1.3 JSON Syntax

DOCA Arg Parser has built-in support for basic JSON configuration files, which is activated when using the `j` / `json` CLI flags.

Important nodes:

- The key names in the JSON file are the **long** flag names as were registered on DOCA Arg Parser's API.
- A flag can be passed to **both** CLI and JSON file, in which case the CLI value will override that found in the provided JSON file.

5.5.1.4 DOCA General Flags

The following table lists the supported DOCA general flags:

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

5.5.1.5 DOCA Program Flags

The flags for each program can be found in the document dedicated to that program, including instructions on how to run it using the command-line interface.

5.5.1.6 DOCA Program Commands

While simple programs might only use a single command with some program flags, DOCA ARGP supports the registration of a command tree so as to provide support for more advanced programs. Using this mechanism, program flags could be associated directly with their respective commands, allowing the user to access them only when needed.

When existing, the commands for each program can be found in the document dedicated to that program, including instructions on how to run it.

5.5.1.6.1 Detailed Example of Program Commands

Assuming there is a dummy program named `doca_test` with the following commands and parameters:

- Command – `info` – Show extended information about a given category
  - Command – `devices` – Show information about all devices, across all PCIe addresses
    - Parameter – `--pci-address` – Limit the command to the provided PCIe address (optional)
- Command – `ping` – Ping a given remote network address
  - Parameter – `--network-address` – Target network address for the ping (mandatory)
  - Parameter – `--payload-length` – Length of the payload for the ping command (optional; default is 100 bytes)
- Parameter – `--output` – Output file to save the log messages into (optional; inherited)

Optional invocations:

- Show information about all devices:

```
doca_test info devices
```

- Show information about all devices under a specific PCIe address and store output to `/tmp/log.txt`:

```
doca_test info devices --pci-address 00:03:00.0 --output /tmp/log.txt
```

- Ping a remote machine at `8.8.8.8` and store output to `/tmp/log.txt`:

```
doca_test ping --network-address 8.8.8.8 --output /tmp/log.txt
```

> The `--output` parameter is inherited. That is, it is registered once and serves all commands at the relevant command level, including all their sub-commands (`info` , `info devices` , `ping`).

5.5.1.7 Syntax – Device and Device Representor

In addition to the primitive built-in types supported by DOCA Argp, the module also provides support for the following advanced argument types:

- DOCA Device – `DOCA_ARGP_TYPE_DEVICE`
- DOCA Device Representor – `DOCA_ARGP_TYPE_DEVICE_REP`

Support for these advanced types includes the following logic:

1. Parsing the string-based identifier provided via the command line.
2. Locating the requested device or representor based on the parsed identifier.
3. Passing the resolved device object to the user's callback using the appropriate context type:
   - Device: `struct doca_argp_device_ctx`
   - Device Representor: `struct doca_argp_device_rep_ctx`

The accepted syntax for these types is composed of several identifier categories, each of which is detailed in the sections below.

> To view a list of currently available devices and representors, it is recommended to use the DOCA Caps utility:
>
> - `--list-devs` – Lists all available DOCA devices
> - `--list-rep-devs` – Lists all available DOCA representors
>
> The output from this tool provides the necessary information to construct valid identifiers for all supported categories described in the following subsections.

5.5.1.7.1 JSON Syntax

The JSON syntax for the devices and representors is as follows.:

```
"device-flag": {
    "type": "pci",
    "identifier": "08:00.0",
}
...
"device-rep-flag": {
    "type": "pci",
    "identifier": "08:00.0,pf0vf1",
    "devargs": "dv_flow_en=2",
}
```

The example above uses "device-flag" as the long flag name for the device type parameter, and "device-rep-flag" as the long name for the device representor type parameter.

> ⚠ The "devargs" subkey is supported by both device and device representor types and is **optional**.

5.5.1.7.2 PCIe Identifiers

5.5.1.7.2.1 Devices

- Syntax:

```
pci/<PCI device identifier>[,<device args>]
```

- Examples:
  - `pci/08:00.0`
  - `pci/0000:03:00.1,dv_flow_en=2`

This identifier category is used to identify devices based on their PCIe device identifiers, following the standard Bus-Device-Function (BDF) notation.

5.5.1.7.2.2 Representors

- Syntax:

```
pci/<PCI device identifier>,<representor identifiers>[,<device args>]
```

- Examples:
  - `pci/08:00.0,pf0vf1` - The representor of the second VF (indices start from 0) under PF0, and associated to device with PCI address of `08:00.0`
  - `pci/0000:03:00.0,c1pf[0-1]vf[2-3,6]sf2,dv_flow_en=2` - Multiple representors under the respective PF0 and PF1, associated with the host (controller) with index 1:
    - VF2
    - VF3,
    - VF6
    - SF2

      > ⚠ If PF1 is to be used as a representor under PF0 as the eswitch manager, the above representors string is **not** enough, and an **additional** argument should be passed so to indicate PF1 as a representor. For example: `pci/08:00.1`

> ⚠ If only a single representor is expected by the program, it is the developer's responsibility to ensure that the user did not pass multiple representors.

- `pci/03:00.0,pf0vf-1` - The host representor of PF0
- `pci/03:00.0` - The uplink representor of the device with the given PCI address.

Aside from the exceptions for the host and uplink representors, the syntax follows the scheme `pci/BDF,c#pf#vf#sf#`, where:

- `c#` – *(Optional)* Specifies the host/controller index
- `pf#` – *(Mandatory)* Specifies the index or indices of the relevant PFs
- `vf#` – *(Optional)* Specifies the index or indices of the relevant VFs
- `sf#` – *(Optional)* Specifies the index or indices of the relevant SFs

Each identifier may be expressed as:

- A single numeric value (e.g., `3`)
- A set of values or ranges (e.g., `[2,4-8]`), allowing for compact specification of multiple instances.

5.5.1.7.3 InfiniBand (IB) Identifiers

5.5.1.7.3.1 Devices

- Syntax:

```
ib/<IB-device-identifier>[,<device args>]
```

- Examples:
  - `ib/mlx5_3`
  - `ib/mlx5_4,dv_flow_en=2`

This identifier category is used to identify devices based on their InfiniBand device name.

5.5.1.7.3.2 Representors

- Syntax:

```
ib/<IB-device-identifier>:<port identifier>[,<device args>]
```

- Examples:
  - `ib/mlx5_0:2`

- `ib/mlx5_1:3,dv_flow_en=2`

Since representors are identified by their port association within the scope of a given InfiniBand (IB) device, this identifier format includes both the IB device name and the associated port number.

5.5.1.7.4 Network Interface Names

- Syntax:

```
ifname/<interface-name>[,<device args>]
```

- Examples:
  - `ifname/eth2`
  - `ifname/eth3,dv_flow_en=2`

This identifier category supports all device and representor types and identifies them based on their network interface name.

5.5.1.7.5 Network Interface Indices

- Syntax:

```
ifindex/<interface-index>[,<device args>]
```

- Examples:
  - `ifindex/3`
  - `ifindex/4,dv_flow_en=2`

This identifier category supports all device and representor types and identifies them based on their network interface index.

5.5.1.7.6 Auxiliary Device Indices

- Syntax:

```
aux/<aux-device-index>[,<device args>]
```

- Examples:
  - `aux/3`
  - `aux/4,dv_flow_en=2`

This identifier category is primarily intended for identifying SFs, which are defined as auxiliary devices in PCIe terminology.

The auxiliary device syntax applies only to actual devices; it is not applicable to representor devices, as representors do not have an associated auxiliary index.

5.6 DOCA Drivers

This section describes underlying drivers included in DOCA and includes the following pages:

- DOCA UCX
- MLX Drivers

5.6.1 DOCA UCX

This guide provides instructions for developing applications on top of the UCX library.

5.6.1.1 Introduction

Unified Communication X (UCX) is an optimized point-to-point communication framework.

UCX exposes a set of abstract communication primitives that utilize the best available hardware resources and offloads, such as active messages, tagged send/receive, remote memory read/write, atomic operations, and various synchronization routines. The supported hardware types include RDMA (InfiniBand and RoCE), TCP, GPUs, and shared memory.

UCX facilitates rapid development by providing a high-level API, masking the low-level details, while maintaining high-performance and scalability.

UCX implements best practices for transfer of messages of all sizes, based on the accumulated experience gained from applications running on the world's largest datacenters and supercomputers.

5.6.1.2 Prerequisites

UCX runtime libraries are installed as part of the DOCA installation.

UCX is used the same way from the host and the DPU side.

Any active network device available on the system might be used by UCX, including network devices that might be unreachable to the remote peer.

If one of the destinations is not reachable via a certain network device (e.g., a BlueField cannot reach another BlueField via `tmfifo_net0`), UCX communication may fail.

To resolve this, use the UCX environment variable `UCX_NET_DEVICES` to specify which devices UCX can use. For example:

```
export UCX_NET_DEVICES=enp3s0f0s0,enp3s0f1s0
```

Or:

```
env UCX_NET_DEVICES=enp3s0f0s0,enp3s0f1s0 <UCX-program>
```

Using the command `show_gids` on the BlueField one can obtain the mlx device name and the port of an SF. Then that can be used to limit the UCX network interfaces and allow IB. For example:

```
dpu> show_gids
DEV     PORT    INDEX   GID                                     IPv4            VER  DEV
---     ----    -----   ---                                     ------------    ---  ---
mlx5_2  1       0       fe80:0000:0000:0000:0052:72ff:fe63:1651                 v2   enp3s0f0s0
mlx5_3  1       0       fe80:0000:0000:0000:0032:6bff:fe13:f13a                 v2   enp3s0f1s0
dpu> env UCX_NET_DEVICES=mlx5_2:1,mlx5_3:1 <UCX-program>
```

When RDMACM is not available, it is also required to list the Ethernet devices in `UCX_NET_DEVICES` configuration, so they could be used for TCP-based connection establishment. For example:

```
dpu> env UCX_NET_DEVICES=enp3s0f0s0,enp3s0f1s0,mlx5_2:1,mlx5_3:1 <UCX-program>
```

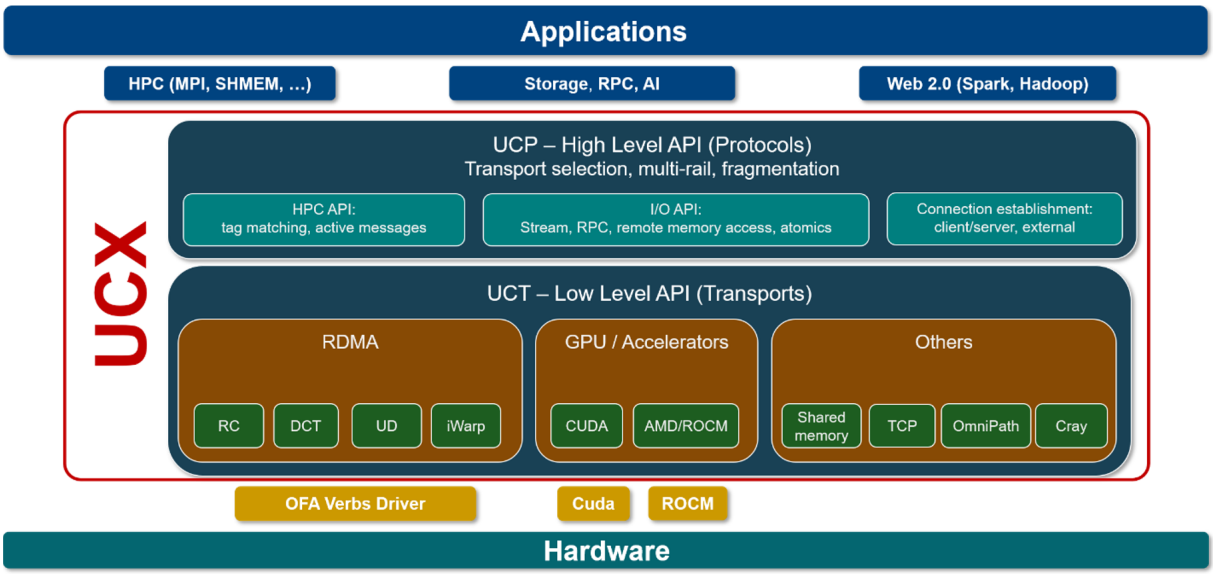
5.6.1.3 Architecture

The following image describes the software layers of UCX middleware.

On the upper layer, various applications that utilize high-speed communications are built on top of the UCX high-level API (UCP).

UCP layer implements the business logic to utilize, combine, and manipulate different transports to achieve the best possible performance for different use cases. This logic decides which transports must be used for each message, which types of basic hardware communication primitives to use, how to fragment messages, etc.

UCT, the transport API, is a hardware abstraction layer that brings different types of communication devices to a common denominator. There are multiple communication primitives defined by UCT API, but each transport service may implement only some of them—preferably the ones that are natively supported by the underlying hardware. UCT users (e.g., UCP) are expected to handle the missing communication primitives defined by UCT API but not implemented by a transport service.



5.6.1.3.1 UCP Objects

This section describes the high-level communication objects that are used by most applications written on top of UCX.

5.6.1.3.1.1 UCP Context (ucp_context_h)

The context is the top-level object and it defines the scope of all other UCX objects. It is possible to create multiple contexts in the same process to have a complete separation of hardware and memory resources.

5.6.1.3.1.2 UCP Worker (ucp_worker_h)

The worker represents a communication state and its associated network resources. It is responsible for sending and processing incoming messages and handling all network-related events. All point-to-point connections are created in the scope of a particular worker.

A worker object can be defined to support usage from multiple threads. However, due to lock contention, the performance is better when a given worker is used most of the time from one thread.

The worker progresses communications either by active polling, waiting for asynchronous events, or a combination of both.

5.6.1.3.1.3 UCP Endpoint (ucp_ep_h)

The endpoint represents a connection from a local worker to a remote worker. That remote worker may be created in any place that is reachable by one of the communication networks supported by UCT layer. That could be, for example, on a different host in the fabric, the same host, on the DPU, or even in the same process.

5.6.1.3.1.4 UCP Listener (ucp_listener_h)

The listener binds to a network port number on the underlying operating system, and dispatches incoming connection requests. The incoming connection request can be used to create a matching endpoint on the server (passive) side or rejected and released.

5.6.1.3.1.5 UCP Request (ucp_request_h)

The request object is created by one of the non-blocking communications primitives in a case where the operation could not be completed immediately in-place. The application is expected to check the request for completion, either by testing it directly, or by associating a custom callback with the request.

5.6.1.4 API

This section describes the main UCX APIs for high-speed communications. For the full reference, refer to UCX API specification.

UCX exposes two kinds of API: the high-level UCP API and the low-level UCT (transport) API. For most applications, it is recommended to use only the UCP API, since it relieves much of the burden of handling each transport's capabilities, limitations, and performance traits.

Many of the APIs accept a structure pointer with a `field_mask` as an argument. This method is used to provide backward ABI/API compatibility: If new function arguments are introduced, they are added as new fields in the struct, so the function signature does not change. In addition, `field_mask` specifies which struct fields are valid from the caller's (user application) perspective. UCX only accesses the fields enabled by this bitmask and uses default values for the remaining struct fields.

Some APIs require passing user-defined callbacks as a method to get notifications about specific events. Unless otherwise specified, such callbacks are called from the context of the `ucp_worker_progress()` call (detailed below), and are expected to complete quickly or defer some of their tasks to another thread (to avoid timeouts and starvation of processing from other network events).

> ⚠ The pkg-config (`*.pc` file) for the UCX library is named `ucx`.

The following sections provide additional details about the library API.

5.6.1.4.1 ucs_status_t

An `enum` type that holds all UCX error codes.

5.6.1.4.2 ucp_init

```
ucs_status_t ucp_init(const ucp_params_t *params, const ucp_config_t *config, ucp_context_h *context_p)
```

- `params [in]` – points to a structure with optional parameters. All fields are optional except `features`, which must be set.
- `config [in]` – optional, can be NULL for default behavior. Configuration can be obtained by calling `ucp_config_read()`.

  > ⚠ The supported configuration options can change between UCX versions. The full list can be obtained by running the `ucx_info` CLI tool: `ucx_info -c -f`

- `context_p [out]` – a pointer to a location in memory for the created UCP context

The function returns an error code as defined by `ucs_status_t`.

This function creates a new UCP top-level context and returns it by value in the `context_p` argument.

5.6.1.4.3 ucp_cleanup

```
void ucp_cleanup(ucp_context_h context_p)
```

- `context_p [in]` – a UCP context instance

This function destroys a previously created context. Prior to calling this function, any other resources created on this context (e.g., workers or endpoints) must be destroyed.

5.6.1.4.4 ucp_worker_create

```
ucs_status_t ucp_worker_create(ucp_context_h context, const ucp_worker_params_t *params, ucp_worker_h *worker_p)
```

- `context [in]` – an existing UCP context
- `params [in]` – points to a structure with configuration parameters. All fields are optional. Commonly, only the field `thread_mode` is used.

  Possible `thread_mode` values are as follows:

  - `UCS_THREAD_MODE_SINGLE` – only one specific thread (typically, the one that created the worker) is used to access the worker and its associated endpoints.

- `UCS_THREAD_MODE_SERIALIZED` – multiple threads can access the worker and its associated endpoints, but only one at a time. This implies an exclusion mechanism (e.g., locking) implemented in the application. Sometimes, more expensive bus flushing instructions are needed with serialized mode, compared to single thread mode.
- `UCS_THREAD_MODE_MULTI` – multiple threads can access the worker at any given time. UCX takes care of the locking internally. As of version 1.12, it is implemented as a global lock on the worker.

- `worker_p [out]` – a pointer to a location in memory for the created worker

The function returns an error code as defined by `ucs_status_t`.

This function creates a new UCP worker on a previously created context and returns it by value in the `worker_p` argument.

When `ucp_worker_create()` succeeds, the caller is still expected to check the actual thread mode the worker was created with by calling `ucp_worker_query()` API, and take the necessary actions (for example, report an error or fallback) if the returned thread mode is not as expected to be.

5.6.1.4.5 ucp_worker_destroy

```
void ucp_worker_destroy(ucp_worker_h worker)
```

- `context_p [in]` – an UCP worker instance

This function destroys a previously created worker. Prior to calling this function, all associated endpoints and listeners must be destroyed.

Destroying the worker may cause communication errors on any remote peer that has an open endpoint to this worker. These errors are handled according to that endpoint's error handling configuration (detailed in section `ucp_ep_create`).

5.6.1.4.6 ucp_listener_create

```
ucs_status_t ucp_listener_create(ucp_worker_h worker, const ucp_listener_params_t *params, ucp_listener_h
*listener_p)
```

- `worker [in]` – an existing UCP worker
- `params [in]` – points to a structure with configuration parameters. The fields `sockaddr` and `conn_handler` are mandatory, but the rest of the fields are optional.

- `sockaddr` – specifies IPv4/IPv6 address to listen for connections. The semantics are similar to the built-in bind() function. `INADDR_ANY/INADDR6_ANY` can be used to listen on all network interfaces. If the port number is set to 0, a random unused port is selected. The actual port number can be obtained by calling the `ucp_listener_query()` API.
- `conn_handler` – a callback for handling incoming connection requests along with an associated user-defined argument. The callback type is defined as:

  ```
  void (*ucp_listener_conn_callback_t) (ucp_conn_request_h conn_request, void *arg)
  ```

  Whenever a remote endpoint is created through this listener, this callback is called on the listener side with a new `conn_request` object representing the incoming connection, and the user-defined argument `arg` that is passed to `ucp_listener_create()`.
  The callback is expected to process this connection request by either creating an endpoint for it (pass `conn_request` as a parameter to `ucp_ep_create`, including on a different worker), or rejecting and destroying it (call `ucp_listener_reject`). This does not have to happen immediately. The callback may put the connection request on an internal application queue and process it later.
- `listener_p [out]` – a pointer to a location in memory for the created listener

The function returns an error code as defined by `ucs_status_t`.

This function creates a new listener object to accept incoming connections on a specific network port, and returns it by value in the `listener_p` argument.

5.6.1.4.7 ucp_listener_destroy

```
void ucp_listener_destroy(ucp_listener_h listener_p)
```

- `listener_p [in]` – a listener instance

This function destroys a previously created listener. Prior to calling this function, any connection requests that were reported by `conn_handler` are expected to be processed. Pending connection requests that have not been reported to the application yet, or new connection requests that arrive after this function is called, are rejected.

5.6.1.4.8 ucp_ep_create

```
ucs_status_t ucp_ep_create(ucp_worker_h worker, const ucp_ep_params_t *params, ucp_ep_h *ep_p)
```

- `worker [in]` – an existing UCP worker
- `params [in]` – Points to a structure with configuration parameters. A creation mode field must be set. Other fields are optional. Commonly used fields are described in the following subsections.
- `ep_p [in]` – a pointer to a location in memory for the created endpoint

The function returns an error code as defined by `ucs_status_t`.

This function creates a new connection to a remote peer and returns it by value in the `ep_p` parameter. The new endpoint can be used for communication immediately after it is created, though some operations may be queued internally and sent after the underlying connection is established.

5.6.1.4.8.1 Create Modes (ucp_ep_params_t)

There are three ways the endpoint can be created:

- Client connects to a remote listener
  In this case, the `sockaddr` field specifies the remote IPv4/IPv6 address and port number. The `flags` field must be enabled and must include the `UCP_EP_PARAMS_FLAGS_CLIENT_SERVER` flag. Optionally, from UCX version 1.13 on, the `local_sockaddr` field may be used to specify a local source device address to bind to.
- Server creates an endpoint due to an incoming connection request
  In this case, the `conn_request` field must be set to this connection request. Such endpoint can optionally be created on a different worker, not the same one this connection request was accepted on.
- Create an endpoint to a specific worker address
  In this case, the field `address` must be set to point to a remote worker's address. That address (and its length) must be obtained on the remote side by calling `ucp_worker_query()` and sent using an application-defined method (e.g., TCP socket, or other existing communication mechanism). The internal structure of the address is opaque and may change in different versions.

5.6.1.4.8.2 User-Defined Error Handling (ucp_ep_params_t)

By default, unexpected errors on the connection (e.g., network disconnection or aborted remote process) generate a fatal failure. To enable graceful error handing, several parameters must be set during endpoint creation:

- The `err_mode` field must be set to `UCP_ERR_HANDLING_MODE_PEER`. This guarantees that send requests are always completed (successfully or error). Otherwise, network errors are considered fatal and abort the application without giving it a chance to perform cleanup or fallback flows.

- `The err_handler.cb` field must be set to a user-defined callback which is called if a connection error occurs. The error handler is defined as follows:

```
void (*ucp_err_handler_cb_t)(void *arg, ucp_ep_h ep, ucs_status_t status)
```

  The callback parameters are the user-defined argument (passed in `user_data`), the endpoint handle on which the error happened, and the error code.
  After this callback, no more communications should be done on the endpoint. The application is expected to close the endpoint.
- The `user_data` field must be set to a user-defined argument passed to the `err_handler` callback

5.6.1.4.9 ucs_status_ptr_t

```
typedef void* ucs_status_ptr_t;
```

This function is commonly used as a return value for non-blocking operations.

The return value of `ucs_status_ptr_t` combines a status code and a request pointer which may be one of the following:

- A NULL pointer indicating that the operation has completed successfully in-place. The user-provided callback, if there is one, is not called.
- An error status, that can be detected by the `UCS_PTR_IS_ERR(status)` macro and extracted by `UCS_PTR_STATUS(status)`.
- Otherwise, the status is a request pointer which can also be detected by the `UCS_PTR_IS_PTR(status)` macro. This means that the communication operation has started (or was queued) but not yet completed. The completion is reported by calling the user-provided callback (in `ucp_request_param_t`) or through an explicit check on the request status by calling `ucp_request_check_status()`.

5.6.1.4.10 ucp_ep_close_nbx

```
ucs_status_ptr_t ucp_ep_close_nbx(ucp_ep_h ep, const ucp_request_param_t *param)
```

- `ep [in]` – an existing UCP endpoint
- `param [in]` – points to a structure that defines how the closing operation is performed. The `flags` field of the `param` structure specifies which method to use to close the endpoint:

- `UCP_EP_CLOSE_MODE_FORCE` – close the endpoint immediately without attempting to flush outstanding operation. Some requests already completed on the transport level may complete successfully, others may be completed with an error status. In the latter case, it is not known whether they have reached the destination process or completed there.
  Closing an endpoint this way is equivalent to calling `close()` on a TCP socket and can generate a connection error on the remote side. Therefore, to use this mode, both the local and remote endpoints must be created with the `err_mode` parameter set to `UCP_ERR_HANDLING_MODE_PEER`.
- `UCP_EP_CLOSE_MODE_FLUSH` – synchronize with the remote peer and flush outstanding operations. Some operations may be canceled and complete with the status `UCS_ERR_CANCELED`. However, it is guaranteed that they did not complete on the remote peer as well.

The function returns a status pointer to check the operation's status. `NULL` means success.

This function starts the process of closing a previously created endpoint. The function is non-blocking, and the returned value is a status pointer used to indicate when the endpoint is fully destroyed. For more information, refer to section Communications.

5.6.1.4.11 ucp_request_param_t

```
struct ucp_request_param_t {
    uint32_t op_attr_mask;
    uint32_t flags;
    union ucp_request_param_t cb;
    void *user_data;
    ucp_datatype_t datatype;
    /* Some other fields that are rarely used */
    …
}
```

- `op_attr_mask [in]` – mask of enabled fields and several control flags.
- `flags [in]` – operation-specific flags. Each API method defines its own set of flags for this field.
- `cb [in]` – callback for when the operation is completed.
- `user_data [in]` – user-defined argument passed to the completion callback.
- `datatype [in]` – may be used to specify a custom data layout for the data buffer (not `user_data`) that is provided to the communication API. If this parameter is not set, the data buffer is treated as a contiguous byte buffer.

The fields of `ucp_request_param_t` specify several common attributes and flags that are used to control how the communications request is allocated and completed. This is aimed to optimize different use-cases.

5.6.1.4.12 ucp_worker_progress

```
unsigned ucp_worker_progress(ucp_worker_h worker)
```

- `worker [in]` – an existing UCP worker

The function returns a non-zero value if any communication has been progressed. Otherwise, it returns zero.

This function progresses outstanding communications on the worker. This includes polling hardware and shared memory queues, calling callbacks, pushing pending operations to the network devices, advancing the state of complex protocols, progressing connection establishment process, and more.

Though some transports, such as RDMA, offload do much of the heavy lifting, the initiation and completion of communication operations still must be performed explicitly by the process. UCX does not spawn additional progress threads. Instead, it is expected that the upper-layer application spawns its own progress thread, as needed, to call `ucp_worker_progress()`.

This function cannot be used from inside a callback.

5.6.1.4.13 ucp_am_send_nbx

```
ucs_status_ptr_t ucp_am_send_nbx(ucp_ep_h ep, unsigned id, const void *header,
                  size_t header_length, const void *buffer,
                  size_t count, const ucp_request_param_t *param)
```

- `ep [in]` – connection to send the active message on. Previously returned from `ucp_ep_create()`.
- `id [in]` – active message identifier. This is an arbitrary 16-bit integer value defined by the application and used to select the active message callback to call on the receiver side. This allows handling different types of messages by different callback functions.
- `header [in]` – pointer to a user-defined header for an active message
- `header_length [in]` – length of the header to send. Usually, the header is small and, in any case, it should be no larger than the `max_am_header` worker attribute, as returned from `ucp_worker_query()`. The header size could vary depending on the available transports and is usually expected to be at least 256 bytes.
- `buffer [in]` – pointer to the active message payload
- `count [in]` – number of elements in the payload buffer. By default, each element is a single byte, so this is the byte-length of the buffer. Other data layouts, such as IO vector (IOV) list, could be specified by `param->datatype`.

- `param [in]` – additional parameters controlling request completion semantics. The relevant field is only `flags` and it can be set to a combination of the following flags:
  - `UCP_AM_SEND_FLAG_REPLY` – force passing `reply_ep` to the callback on the receiver side. This can increase the internal header size and add some overhead.
  - `UCP_AM_SEND_FLAG_EAGER` – force using eager protocol (details below).
  - `UCP_AM_SEND_FLAG_RNDV` – force using rendezvous protocol (details below). The active message can be sent either by the eager or rendezvous protocol. Eager protocol means the data buffer is available on the receiver immediately during the callback, while the rendezvous protocol requires fetching the data using an additional call to `ucp_am_recv_data_nbx()`, allowing it to be placed directly to an application-selected buffer. By default, smaller messages are sent via eager protocol, and larger messages use rendezvous protocol. This can be overridden using `UCP_AM_SEND_FLAG_EAGER` or `UCP_AM_SEND_FLAG_RNDV`.

> ⚠ `UCP_AM_SEND_FLAG_EAGER` and `UCP_AM_SEND_FLAG_RNDV` are mutually exclusive.

The function returns a status pointer to check the operation's status. `NULL` means success.

This function initiates sending of an active message from the initiator side. As a result, a designated callback (registered by `ucp_worker_set_am_recv_handler`) is called on the receiver side to handle this message. The function is non-blocking, so if the send operation is not completed immediately, a request handle is retuned.

5.6.1.4.14 ucp_worker_set_am_recv_handler

```
ucs_status_t ucp_worker_set_am_recv_handler(ucp_worker_h worker, const ucp_am_handler_param_t *param)
```

- `worker [in]` – an existing UCP worker.
- `param [in]` – set callback configurations. See more below.

The function returns a non-zero value if any communication has been progressed. Otherwise, it returns zero.

This function registers a callback for processing active messages on the given worker.

The following are the mandatory fields to set in `param`:

- `id` – active message identifier to bind with the registered callback. Callback is invoked when receiving incoming messages with the same ID.

- `arg` – a user-defined argument to pass to the active message callback.
- `cb` – a user-defined callback to invoke when an active message arrives. The callback is defined as:

```
ucs_status_t (*ucp_am_recv_callback_t)(void *arg, const void *header,
                                       size_t header_length, void *data,
                                       size_t length,
                                       const ucp_am_recv_param_t *param)
```

The following are the parameters passed from UCX to the callback:

- `arg` – the same user-defined argument passed to `ucp_worker_set_am_recv_handler`.
- `header` – points to the active message header as defined by the sender side while sending the active message. The header should be consumed by the callback since it is not valid after the callback returns.
- `header_length` – valid size of the buffer pointer by `header`.
- `data` – pointer to the data or an opaque handle that can be used to fetch the data according to the `UCP_AM_RECV_ATTR_FLAG_RNDV` flag in the field `param->recv_attr`. When flag is on, this is an opaque handle.
- `length` – length of the active message data (even if the data argument is an opaque handle and not the actual data).
- `param` – pointer to additional parameters of the incoming message. The relevant fields are:
  - `recv_attr` – flags providing more information about the incoming message.
  - `reply_ep` – if `UCP_AM_RECV_ATTR_FIELD_REPLY_EP` is set in `recv_attr`, then this field holds a handle to an endpoint that can be used to send replies to the active message sender.

The callback is expected to return `UCS_OK` if the message data has been consumed or if `UCP_AM_RECV_ATTR_FLAG_RNDV` is set in `recv_attr`. Otherwise, the if `UCP_AM_RECV_ATTR_FLAG_DATA` is set in `recv_attr`, the callback is allowed to keep the data for later processing (by adding it to an internal application queue, for example). In this case, the callback should return `UCS_INPROGRESS` as indication that the data should persist.

When a message arrives with `UCP_AM_RECV_ATTR_FLAG_RNDV` flag, the function `ucp_am_recv_data_nbx` must be used to fetch the data from the sender.

5.6.1.4.15 ucp_am_recv_data_nbx

```
ucs_status_ptr_t ucp_am_recv_data_nbx(ucp_worker_h worker, void *data_desc,
                                      void *buffer, size_t count,
                                  const ucp_request_param_t *param)
```

- `worker [in]` – UCP worker object to use for initiating the receive operation.

  ⚠ The connection handle (endpoint) is not needed.

- `data_desc [in]` – handle for the data to receive. Obtained from the `data` argument for the active message callback.
- `buffer [in]` – receive buffer for the incoming data.
- `count [in]` – number of elements in the payload buffer. By default, each element is a single byte, so this is the byte-length of the buffer. Other data layouts, such as the IOV list, may be specified by `param->datatype`.
- `param [in]` – additional parameters that control request allocation and completion reporting. No specific flags are needed for this function.

The function returns a status pointer to check the operation's status. `NULL` means success.

This function is used for rendezvous active messages. The function initiates the process of fetching data from the sender side into an application-defined receive buffer. It is expected to be used when an active message callback is called with the `UCP_AM_RECV_ATTR_FLAG_RNDV` flag set in `params->recv_attr` field.

5.6.1.5 UCX Best Practices

5.6.1.5.1 Initialization

An application using UCX will usually create one global context (`ucp_context_h`) then create one or more workers (`ucp_worker_h`). Each worker consumes some memory for send/receive buffers, so it is not recommended to create too many workers. The rule of thumb is that the number of workers should be roughly tied to the number of CPU cores/threads.

The mapping of workers to threads is defined by the application's use case, for example:

- A single-threaded application does not need more than one worker
- A simple implementation of a multi-threaded application can create one or more workers in multi-threaded mode. These workers can be used by any thread.
- A multi-threaded application with a strong affinity between the thread and CPU core can create a dedicated worker per thread. These workers can be created in a single-threaded mode.
- Applications with many threads can implement a pool of workers and use one randomly or assign some to threads temporarily.

> ⚠ If there are multiple workers, each of them needs to create its own set of endpoints, since every endpoint connects a specific pair of workers.

To initiate communications, the application should create endpoints (`ucp_ep_h`) connected to the remote peers. There are two main methods to create an endpoint: Either by connecting directly to a remote worker's address, or by creating a listener object (`ucp_listener_h`) and connecting to remote IP address and port. These methods are described in more detail in the `ucp_ep_create()` section.

5.6.1.5.2 Communications

After initializing the UCP context, worker, and endpoints, the application can start using the endpoint for communications. Usually, endpoints are associated with application-level object that represents a connection.

Most communication operations follow a similar pattern: A non-blocking function (with `_nbx` suffix) receives a pointer to the `ucp_request_param_t` structure and returns `ucs_status_ptr_t` . Using a struct pointer allows extending the operations and while maintaining backward compatibility.

There are several types of communication methods supported by UCP intended for different kinds of applications. The recommended method for most applications is active messages which mean that the initiator can send arbitrary data to the responder, and the responder invokes a callback that can access this data.

5.6.2 MLX Drivers

> ⚠ It is recommended to enable the "above 4G decoding" BIOS setting for features that require a large amount of PCIe resources (e.g., SR-IOV with numerous VFs, PCIe Emulated Switch, Large BAR Requests).

The chapter contains the following sections:

- InfiniBand Network
- Ethernet Network
- DPU
- Storage Protocols
- Virtualization
- Resiliency
- Docker Containers
- HPC-X

- Fast Driver Unload

5.6.2.1 InfiniBand Network

The chapter contains the following sections:

- InfiniBand Interface
- NVIDIA SM
- InfiniBand QoS
- IP Over InfiniBand
- Advanced Transport
- Optimized Memory Access
- NVIDIA PeerDirect
- CPU Overhead Distribution
- Out-of-order Data Placement
- IB Router
- MAD Congestion Control

5.6.2.1.1 InfiniBand Interface

5.6.2.1.1.1 Port Type Management

For information on port type management of ConnectX-4 and above adapter cards, please refer to Port Type Management Configuration section.

5.6.2.1.1.2 RDMA Counters

- RDMA counters are available only through sysfs located under:
  - `# /sys/class/infiniband/<device>/ports/*/hw_counters/`
  - `# /sys/class/infiniband/<device>/ports/*/counters`

For mlx5 port and RDMA counters, refer to the Understanding mlx5 Linux Counters Community post.

5.6.2.1.2 NVIDIA SM

NVIDIA SM is an InfiniBand compliant Subnet Manager (SM). It is provided as a fixed flow executable called "opensm", accompanied by a testing application called osmtest. NVIDIA SM implements an InfiniBand compliant SM according to the InfiniBand Architecture Specification chapters: Management Model, Subnet Management, and Subnet Administration.

5.6.2.1.2.1 OpenSM Application

OpenSM is an InfiniBand compliant Subnet Manager and Subnet Administrator that runs on top of the NVIDIA OFED stack. OpenSM performs the InfiniBand specification's required tasks for initializing InfiniBand hardware. One SM must be running for each InfiniBand subnet.
OpenSM defaults were designed to meet the common case usage on clusters with up to a few hundred nodes. Thus, in this default mode, OpenSM will scan the IB fabric, initialize it, and sweep occasionally for changes.
OpenSM attaches to a specific IB port on the local machine and configures only the fabric connected to it. (If the local machine has other IB ports, OpenSM will ignore the fabrics connected to those other ports). If no port is specified, opensm will select the first "best" available port. opensm can also present the available ports and prompt for a port number to attach to.

By default, the OpenSM run is logged to `/var/log/opensm.log`. All errors reported in this log file should be treated as indicators of IB fabric health issues. (Note that when a fatal and non-recoverable error occurs, OpenSM will exit). opensm.log should include the message "SUBNET UP" if OpenSM was able to set up the subnet correctly.

Syntax:

```
opensm [OPTIONS]
```

For the complete list of OpenSM options, please run:

```
opensm --help / -h / -?
```

Environment Variables

The following environment variables control OpenSM behavior:

- OSM_TMP_DIR - controls the directory in which the temporary files generated by OpenSM are created. These files are: opensm-subnet.lst, opensm.fdbs, and opensm.mcfdbs. By default, this directory is /var/log.
- OSM_CACHE_DIR - opensm stores certain data to the disk such that subsequent runs are consistent. The default directory used is /var/cache/opensm. The following file is included in it:
  `guid2lid` – stores the LID range assigned to each GUID

Signaling

When OpenSM receives a HUP signal, it starts a new heavy sweep as if a trap has been received or a topology change has been found.
Also, SIGUSR1 can be used to trigger a reopen of /var/log/opensm.log for logrotate purposes.

Running OpenSM as Daemon

OpenSM can also run as daemon. To run OpenSM in this mode, enter:

```
host1# service opensmd start
```

5.6.2.1.2.2 osmtest

osmtest is a test program for validating the InfiniBand Subnet Manager and Subnet Administrator. osmtest provides a test suite for opensm. It can create an inventory file of all available nodes, ports, and PathRecords, including all their fields. It can also verify the existing inventory with all the object fields and matches it to a pre-saved one. osmtest has the following test flows:

- Multicast Compliancy test
- Event Forwarding test
- Service Record registration test
- RMPP stress test
- Small SA Queries stress test

For further information, please refer to the tool's man page.

5.6.2.1.2.3 Partitions

OpenSM enables the configuration of partitions (PKeys) in an InfiniBand fabric. By default, OpenSM searches for the partitions configuration file under the name /etc/opensm/partitions.conf. To change this filename, you can use opensm with the '--Pconfig' or '-P' flags.

The default partition is created by OpenSM unconditionally, even when a partition configuration file does not exist or cannot be accessed.

The default partition has a P_Key value of 0x7fff. The port out of which runs OpenSM is assigned full membership in the default partition. All other end-ports are assigned partial membership.

- Adding a new partition to the partition.conf file, does not require SM restart, but signalling SM process via a HUP signal (e.g pkill -HUP opensm).
- The default partition cannot be removed.

Adjustments to the Port GUIDs, including additions, removals, or membership alterations (denoted as "<PortGUID>=[full|limited|both]" in the "Partition Definition") can be applied with a HUP signal to the Subnet Manager process (e.g pkill -HUP opensm).

Performing changes in the ipoib_bc_flags (ipoib/sl/scope/rate/mtu) and mgroup flags of an existing partition requires a restart of the Subnet Manager to take effect.

File Format

Line content followed after '#' character is comment and ignored by parser.

General File Format

```
<Partition Definition>:\[<newline>\]<Partition Properties>
```

- <Partition Definition>:

```
[PartitionName][=PKey][,indx0][,ipoib_bc_flags][,defmember=full|limited]
```

Where:

`PartitionName`	String, `will be used with logging. When omitted empty string will be used.`
`PKey`	`P_Key value for this partition. Only low 15 bits will be used. When omitted will be auto-generated.`
`indx0`	`Indicates that this pkey should be inserted in block 0 index 0.`
`ipoib_bc_flags`	`Used to indicate/specify IPoIB capability of this partition.`
`defmember=full|limited|both`	`Specifies default membership for port GUID list. Default is limited.`

ipoib_bc_flags are:

`ipoib`	`Indicates that this partition may be used for IPoIB, as a result the IPoIB broadcast group will be created with the flags given, if any.`
`rate=<val>`	`Specifies rate for this IPoIB MC group (default is 3 (10GBps))`
`mtu=<val>`	`Specifies MTU for this IPoIB MC group (default is 4 (2048))`
`sl=<val>`	`Specifies SL for this IPoIB MC group (default is 0)`
`scope=<val>`	`Specifies scope for this IPoIB MC group (default is 2 (link local))`

- <Partition Properties>:

```
\[<Port list>|<MCast Group>\]* | <Port list>
```

- <Port List>:

```
<Port Specifier>[,<Port Specifier>]
```

  - <Port Specifier>:

```
<PortGUID>[=[full|limited|both]]
```

Where:

`PortGUID`	GUID of partition member EndPort. Hexadecimal numbers should start from 0x, decimal numbers are accepted too.
`full, limited`	Indicates full and/or limited membership for this both port. When omitted (or unrecognized) limited membership is assumed. Both indicate full and limited membership for this port.

  - <MCast Group>:

```
mgid=gid[,mgroup_flag]*<newline>
```

Where:

`mgid=gid`	gid specified is verified to be a Multicast address IP groups are verified to match the rate and mtu of the broadcast group. The P_Key bits of the mgid for IP groups are verified to either match the P_Key specified in by "Partition Definition" or if they are 0x0000 the P_Key will be copied into those bits.	
`mgroup_flag`	`rate=<val>`	Specifies rate for this MC group (default is 3 (10GBps))
	`mtu=<val>`	Specifies MTU for this MC group (default is 4 (2048))
	`sl=<val>`	Specifies SL for this MC group (default is 0)
	`scope=<val>`	Specifies scope for this MC group (default is 2 (link local)). Multiple scope settings are permitted for a partition. ⚠ This overwrites the scope nibble of the specified mgid. Furthermore specifying multiple scope settings will result in multiple MC groups being created.
	`qkey=<val>`	Specifies the Q_Key for this MC group (default: 0x0b1b for IP groups, 0 for other groups)
	`tclass=<val>`	Specifies tclass for this MC group (default is 0)

`FlowLabel=<val>`	Specifies FlowLabel for this MC group (default is 0)

Note that values for rate, MTU, and scope should be specified as defined in the IBTA specification (for example, mtu=4 for 2048). To use 4K MTU, edit that entry to "mtu=5" (5 indicates 4K MTU to that specific partition).

PortGUIDs list:

```
PortGUID    GUID of partition member EndPort. Hexadecimal numbers should start from 0x, decimal numbers are
accepted too.
full or limited indicates full or limited membership for this port. When omitted (or unrecognized) limited
membership is assumed.
```

There are some useful keywords for PortGUID definition:

- 'ALL_CAS' means all Channel Adapter end ports in this subnet
- 'ALL_VCAS' means all virtual end ports in the subnet
- 'ALL_SWITCHES' means all Switch end ports in this subnet
- 'ALL_ROUTERS' means all Router end ports in this subnet
- 'SELF' means subnet manager's port. An empty list means that there are no ports in this partition

Notes:

- White space is permitted between delimiters ('=', ',','.',';').
- PartitionName does not need to be unique, PKey does need to be unique. If PKey is repeated then those partition configurations will be merged and the first PartitionName will be used (see the next note).
- It is possible to split partition configuration in more than one definition, but then PKey should be explicitly specified (otherwise different PKey values will be generated for those definitions).

Examples:

```
Default=0x7fff : ALL, SELF=full ;
Default=0x7fff : ALL, ALL_SWITCHES=full, SELF=full ;

NewPartition , ipoib : 0x123456=full, 0x3456789034=limi, 0x2134af2306 ;

YetAnotherOne = 0x300 : SELF=full ;
YetAnotherOne = 0x300 : ALL=limited ;

ShareIO = 0x80 , defmember=full : 0x123451, 0x123452;
# 0x123453, 0x123454 will be limited
ShareIO = 0x80 : 0x123453, 0x123454, 0x123455=full;
# 0x123456, 0x123457 will be limited
ShareIO = 0x80 : defmember=limited : 0x123456, 0x123457, 0x123458=full;
ShareIO = 0x80 , defmember=full : 0x123459, 0x12345a;
ShareIO = 0x80 , defmember=full : 0x12345b, 0x12345c=limited, 0x12345d;

# multicast groups added to default
Default=0x7fff,ipoib:
mgid=ff12:401b::0707,sl=1 # random IPv4 group
mgid=ff12:601b::16 # MLDv2-capable routers
mgid=ff12:401b::16 # IGMP
mgid=ff12:601b::2 # All routers
mgid=ff12::1,sl=1,Q_Key=0xDEADBEEF,rate=3,mtu=2 # random group
ALL=full;
```

The following rule is equivalent to how OpenSM used to run prior to the partition manager:

```
Default=0x7fff,ipoib:ALL=full;
```

5.6.2.1.2.4 Effect of Topology Changes

If a link is added or removed, OpenSM may not recalculate the routes that do not have to change. A route has to change if the port is no longer UP or no longer the MinHop. When routing changes are performed, the same algorithm for balancing the routes is invoked.
In the case of using the file-based routing, any topology changes are currently ignored. The 'file' routing engine just loads the LFTs from the file specified, with no reaction to real topology. Obviously, this will not be able to recheck LIDs (by GUID) for disconnected nodes, and LFTs for non-existent switches will be skipped. Multicast is not affected by 'file' routing engine (this uses min hop tables).

5.6.2.1.2.5 Routing Algorithms

OpenSM offers the following routing engines:

1. Min Hop Algorithm
   Based on the minimum hops to each node where the path length is optimized.
2. UPDN Algorithm
   Based on the minimum hops to each node, but it is constrained to ranking rules. This algorithm should be chosen if the subnet is not a pure Fat Tree, and a deadlock may occur due to a loop in the subnet.
3. Fat-tree Routing Algorithm
   This algorithm optimizes routing for a congestion-free "shift" communication pattern. It should be chosen if a subnet is a symmetrical Fat Tree of various types, not just a K-ary-N-Tree: non-constant K, not fully staffed, and for any CBB ratio. Similar to UPDN, Fat Tree routing is constrained to ranking rules.
4. DOR Routing Algorithm
   Based on the Min Hop algorithm, but avoids port equalization except for redundant links between the same two switches. This provides deadlock free routes for hypercubes when the fabric is cabled as a hypercube and for meshes when cabled as a mesh.
5. Torus-2QoS Routing Algorithm
   Based on the DOR Unicast routing algorithm specialized for 2D/3D torus topologies. Torus- 2QoS provides deadlock-free routing while supporting two quality of service (QoS) levels. Additionally, it can route around multiple failed fabric links or a single failed fabric switch without introducing deadlocks, and without changing path SL values granted before the failure.
6. Routing Chains
   Allows routing configuration of different parts of a single InfiniBand subnet by

different routing engines. In the current release, minhop/updn/ftree/dor/torus-2QoS/pqft can be combined.

⚠ Please note that LASH Routing Algorithm is not supported.

MINHOP/UPDN/DOR routing algorithms are comprised of two stages:

1. MinHop matrix calculation. How many hops are required to get from each port to each LID. The algorithm to fill these tables is different if you run standard (min hop) or Up/Down. For standard routing, a "relaxation" algorithm is used to propagate min hop from every destination LID through neighbor switches. For Up/Down routing, a BFS from every target is used. The BFS tracks link direction (up or down) and avoid steps that will perform up after a down step was used.
2. Once MinHop matrices exist, each switch is visited and for each target LID a decision is made as to what port should be used to get to that LID. This step is common to standard and Up/Down routing. Each port has a counter counting the number of target LIDs going through it. When there are multiple alternative ports with same MinHop to a LID, the one with less previously assigned ports is selected.
   If LMC > 0, more checks are added. Within each group of LIDs assigned to same target port:
   a. Use only ports which have same MinHop
   b. First prefer the ones that go to different systemImageGuid (then the previous LID of the same LMC group)
   c. If none, prefer those which go through another NodeGuid
   d. Fall back to the number of paths method (if all go to same node).

Min Hop Algorithm

The Min Hop algorithm is invoked by default if no routing algorithm is specified. It can also be invoked by specifying '-R minhop'.
The Min Hop algorithm is divided into two stages: computation of min-hop tables on every switch and LFT output port assignment. Link subscription is also equalized with the ability to override based on port GUID. The latter is supplied by:

```
-i <equalize-ignore-guids-file>
-ignore-guids <equalize-ignore-guids-file>
```

This option provides the means to define a set of ports (by GUIDs) that will be ignored by the link load equalization algorithm.

LMC awareness routes based on a (remote) system or on a switch basis.

UPDN Algorithm

The UPDN algorithm is designed to prevent deadlocks from occurring in loops of the subnet. A loop-deadlock is a situation in which it is no longer possible to send data

between any two hosts connected through the loop. As such, the UPDN routing algorithm should be sent if the subnet is not a pure Fat Tree, and one of its loops may experience a deadlock (due, for example, to high pressure).
The UPDN algorithm is based on the following main stages:

1. Auto-detect root nodes - based on the CA hop length from any switch in the subnet, a statistical histogram is built for each switch (hop num vs the number of occurrences). If the histogram reflects a specific column (higher than others) for a certain node, then it is marked as a root node. Since the algorithm is statistical, it may not find any root nodes. The list of the root nodes found by this auto-detect stage is used by the ranking process stage.

   ⚠ The user can override the node list manually.

   ⚠ If this stage cannot find any root nodes, and the user did not specify a GUID list file, OpenSM defaults back to the Min Hop routing algorithm.

2. Ranking process - All root switch nodes (found in stage 1) are assigned a rank of 0. Using the BFS algorithm, the rest of the switch nodes in the subnet are ranked incrementally. This ranking aids in the process of enforcing rules that ensure loop-free paths.
3. Min Hop Table setting - after ranking is done, a BFS algorithm is run from each (CA or switch) node in the subnet. During the BFS process, the FDB table of each switch node traversed by BFS is updated, in reference to the starting node, based on the ranking rules and GUID values.

At the end of the process, the updated FDB tables ensure loop-free paths through the subnet.

UPDN Algorithm Usage

Activation through OpenSM:

- Use '-R updn' option (instead of old '-u') to activate the UPDN algorithm.
- Use '-a <root_guid_file>' for adding an UPDN GUID file that contains the root nodes for ranking. If the `-a' option is not used, OpenSM uses its auto-detect root nodes algorithm.

Notes on the GUID list file:

- A valid GUID file specifies one GUID in each line. Lines with an invalid format will be discarded
- The user should specify the root switch GUIDs

Fat-tree Routing Algorithm

The fat-tree algorithm optimizes routing for "shift" communication pattern. It should be chosen if a subnet is a symmetrical or almost symmetrical fat-tree of various types. It

supports not just K- ary-N-Trees, by handling for non-constant K, cases where not all leafs (CAs) are present, any Constant Bisectional Ratio (CBB)ratio. As in UPDN, fat-tree also prevents credit-loop-dead- locks.

If the root GUID file is not provided ('a' or '-root_guid_file' options), the topology has to be pure fat-tree that complies with the following rules:

- Tree rank should be between two and eight (inclusively)
- Switches of the same rank should have the same number of UP-going port groups, unless they are root switches, in which case the shouldn't have UP-going ports at all.
  Note: Ports that are connected to the same remote switch are referenced as 'port group'.
- Switches of the same rank should have the same number of DOWN-going port groups, unless they are leaf switches.
- Switches of the same rank should have the same number of ports in each UP-going port group.
- Switches of the same rank should have the same number of ports in each DOWN-going port group.
- All the CAs have to be at the same tree level (rank).

If the root GUID file is provided, the topology does not have to be pure fat-tree, and it should only comply with the following rules:

- Tree rank should be between two and eight (inclusively)
- All the Compute Nodes have to be at the same tree level (rank). Note that non-compute node CAs are allowed here to be at different tree ranks.
  Note: List of compute nodes (CNs) can be specified using '-u' or '--cn_guid_file' OpenSM options.

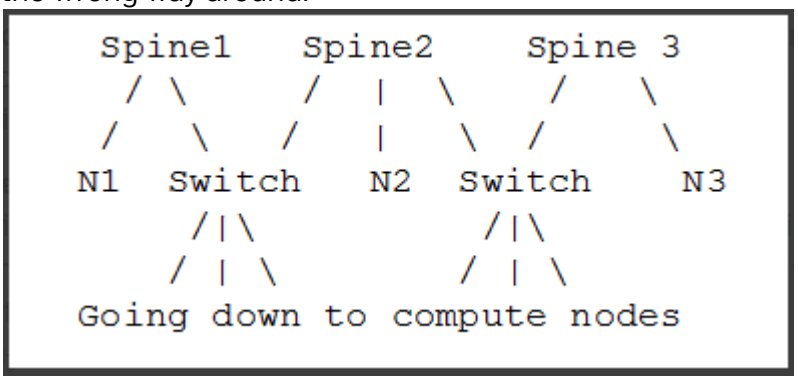
Topologies that do not comply cause a fallback to min-hop routing. Note that this can also occur on link failures which cause the topology to no longer be a "pure" fat-tree. Note that although fat-tree algorithm supports trees with non-integer CBB ratio, the routing will not be as balanced as in case of integer CBB ratio. In addition to this, although the algorithm allows leaf switches to have any number of CAs, the closer the tree is to be fully populated, the more effective the "shift" communication pattern will be. In general, even if the root list is provided, the closer the topology to a pure and symmetrical fat-tree, the more optimal the routing will be.

The algorithm also dumps the compute node ordering file (opensm-ftree-ca-order.dump) in the same directory where the OpenSM log resides. This ordering file provides the CN order that may be used to create efficient communication pattern, that will match the routing tables.

Routing between non-CN Nodes

The use of the io_guid_file option allows non-CN nodes to be located on different levels in the fat tree. In such case, it is not guaranteed that the Fat Tree algorithm will route between two non-CN nodes. In the scheme below, N1, N2 , and N3 are non-CN nodes.

Although all the CN have routes to and from them, there will not necessarily be a route between N1,N2 and N3. Such routes would require to use at least one of the switches the wrong way around.



To solve this problem, a list of non-CN nodes can be specified by \'-G\' or \'--io_guid_file\' option. These nodes will be allowed to use switches the wrong way around a specific number of times (specified by \'-H\' or \'--max_reverse_hops\'. With the proper max_reverse_hops and io_guid_file values, you can ensure full connectivity in the Fat Tree. In the scheme above, with a max_reverse_hop of 1, routes will be instantiated between N1<->N2 and N2<->N3. With a max_reverse_hops value of 2, N1,N2 and N3 will all have routes between them.

> ⚠ Using max_reverse_hops creates routes that use the switch in a counter-stream way. This option should never be used to connect nodes with high bandwidth traffic between them! It should only be used to allow connectivity for HA purposes or similar. Also having routes the other way around can cause credit loops.

Activation through OpenSM

Use '-R ftree' option to activate the fat-tree algorithm.

> ⚠ LMC > 0 is not supported by fat-tree routing. If this is specified, the default routing algorithm is invoked instead.

DOR Routing Algorithm

The Dimension Order Routing algorithm is based on the Min Hop algorithm and so uses shortest paths. Instead of spreading traffic out across different paths with the same shortest distance, it chooses among the available shortest paths based on an ordering of dimensions. Each port must be consistently cabled to represent a hypercube dimension or a mesh dimension. Paths are grown from a destination back to a source using the lowest dimension (port) of available paths at each step. This provides the ordering necessary to avoid deadlock. When there are multiple links between any two switches, they still represent only one dimension and traffic is balanced across them unless port equalization is turned off. In the case of hypercubes, the same port must be used throughout the fabric to represent the hypercube dimension and match on both

ends of the cable. In the case of meshes, the dimension should consistently use the same pair of ports, one port on one end of the cable, and the other port on the other end, continuing along the mesh dimension.
Use '-R dor' option to activate the DOR algorithm.

Torus-2QoS Routing Algorithm

Torus-2QoS is a routing algorithm designed for large-scale 2D/3D torus fabrics. The torus-2QoS routing engine can provide the following functionality on a 2D/3D torus:

- Free of credit loops routing
- Two levels of QoS, assuming switches support 8 data VLs
- Ability to route around a single failed switch, and/or multiple failed links, without:
    - introducing credit loops
    - changing path SL values
- Very short run times, with good scaling properties as fabric size increases

Unicast Routing

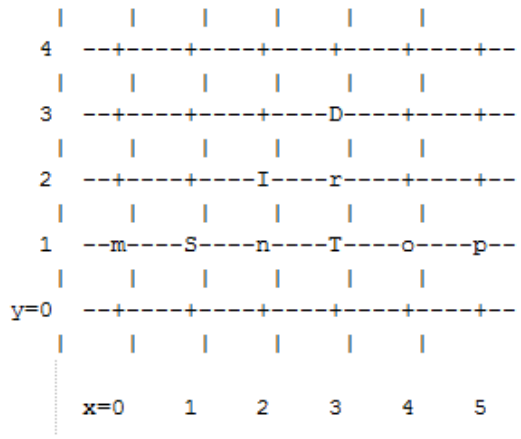
Torus-2 QoS is a DOR-based algorithm that avoids deadlocks that would otherwise occur in a torus using the concept of a dateline for each torus dimension. It encodes into a path SL which datelines the path crosses as follows:

```
sl = 0;
for (d = 0; d < torus_dimensions; d++)
/* path_crosses_dateline(d) returns 0 or 1 */
sl |= path_crosses_dateline(d) << d;
```

For a 3D torus, that leaves one SL bit free, which torus-2 QoS uses to implement two QoS levels. Torus-2 QoS also makes use of the output port dependence of switch SL2VL maps to encode into one VL bit the information encoded in three SL bits. It computes in which torus coordinate direc- tion each inter-switch link "points", and writes SL2VL maps for such ports as follows:

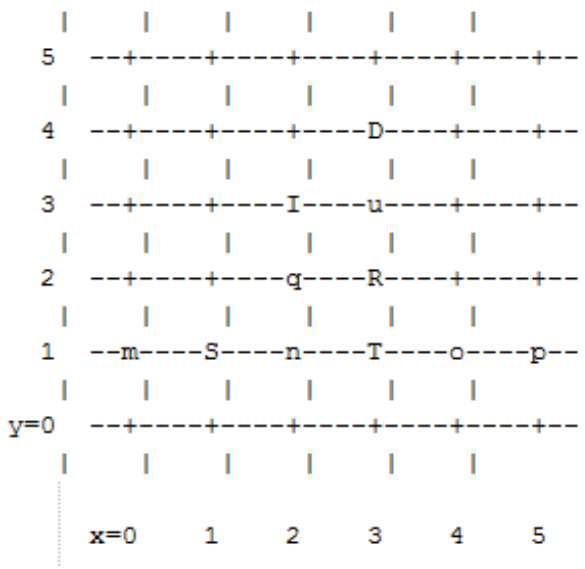
```
for (sl = 0; sl < 16; sl ++)
/* cdir(port) reports which torus coordinate direction a switch port
* "points" in, and returns 0, 1, or 2 */
sl2vl(iport,oport,sl) = 0x1 & (sl >> cdir(oport));
```

Thus, on a pristine 3D torus, i.e., in the absence of failed fabric switches, torus-2 QoS consumes 8 SL values (SL bits 0-2) and 2 VL values (VL bit 0) per QoS level to provide deadlock-free routing on a 3D torus. Torus-2 QoS routes around link failure by "taking the long way around" any 1D ring interrupted by a link failure. For example, consider the 2D 6x5 torus below, where switches are denoted by [+a-zA-Z]:

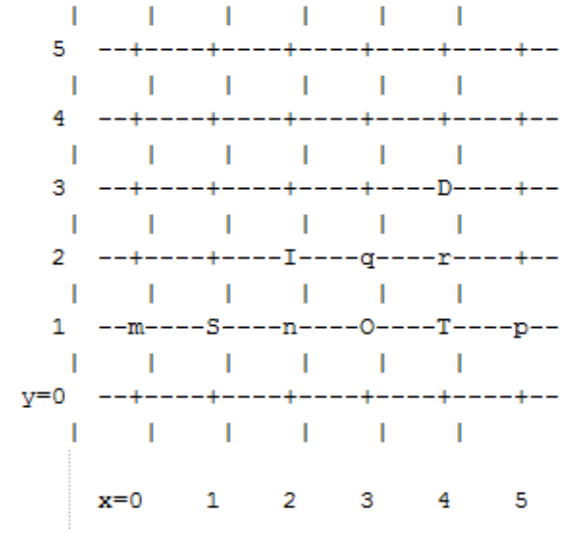


For a pristine fabric the path from S to D would be S-n-T-r-D. In the event that either link S-n or n-T has failed, torus-2QoS would use the path S-m-p-o-T-r-D.
Note that it can do this without changing the path SL value; once the 1D ring m-S-n-T-o-p-m has been broken by failure, path segments using it cannot contribute to deadlock, and the x-direction dateline (between, say, x=5 and x=0) can be ignored for path segments on that ring. One result of this is that torus-2QoS can route around many simultaneous link failures, as long as no 1D ring is broken into disjoint segments. For example, if links n-T and T-o have both failed, that ring has been broken into two disjoint segments, T and o-p-m-S-n. Torus-2QoS checks for such issues, reports if they are found, and refuses to route such fabrics.
Note that in the case where there are multiple parallel links between a pair of switches, torus-2QoS will allocate routes across such links in a round-robin fashion, based on ports at the path destination switch that are active and not used for inter-switch links. Should a link that is one of several such parallel links fail, routes are redistributed across the remaining links. When the last of such a set of parallel links fails, traffic is rerouted as described above.
Handling a failed switch under DOR requires introducing into a path at least one turn that would be otherwise "illegal", i.e. not allowed by DOR rules. Torus-2QoS will introduce such a turn as close as possible to the failed switch in order to route around it. n the above example, suppose switch T has failed, and consider the path from S to D. Torus-2QoS will produce the path S-n-I-r-D, rather than the S-n-T-r-D path for a pristine torus, by introducing an early turn at n. Normal DOR rules will cause traffic arriving at switch I to be forwarded to switch r; for traffic arriving from I due to the "early" turn at n, this will generate an "illegal" turn at I.
Torus-2QoS will also use the input port dependence of SL2VL maps to set VL bit 1 (which would be otherwise unused) for y-x, z-x, and z-y turns, i.e., those turns that are illegal under DOR. This causes the first hop after any such turn to use a separate set of VL values, and prevents deadlock in the presence of a single failed switch. For any given path, only the hops after a turn that is illegal under DOR can contribute to a credit loop that leads to deadlock. So in the example above with failed switch T, the location of the illegal turn at I in the path from S to D requires that any credit loop caused by that turn must encircle the failed switch at T. Thus the second and later hops after the illegal turn

at I (i.e., hop r-D) cannot contribute to a credit loop because they cannot be used to construct a loop encircling T. The hop I-r uses a separate VL, so it cannot contribute to a credit loop encircling T. Extending this argument shows that in addition to being capable of routing around a single switch failure without introducing deadlock, torus-2QoS can also route around multiple failed switches on the condition they are adjacent in the last dimension routed by DOR. For example, consider the following case on a 6x6 2D torus:



Suppose switches T and R have failed, and consider the path from S to D. Torus-2QoS will generate the path S-n-q-I-u-D, with an illegal turn at switch I, and with hop I-u using a VL with bit 1 set. As a further example, consider a case that torus-2QoS cannot route without deadlock: two failed switches adjacent in a dimension that is not the last dimension routed by DOR; here the failed switches are O and T:

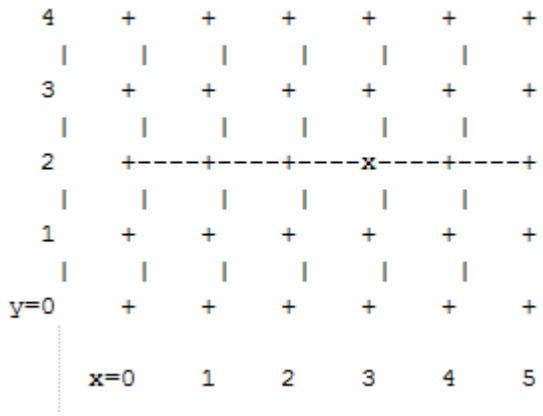


In a pristine fabric, torus-2QoS would generate the path from S to D as S-n-O-T-r-D. With failed switches O and T, torus-2QoS will generate the path S-n-I-q-r-D, with an illegal turn at switch I, and with hop I-q using a VL with bit 1 set. In contrast to the

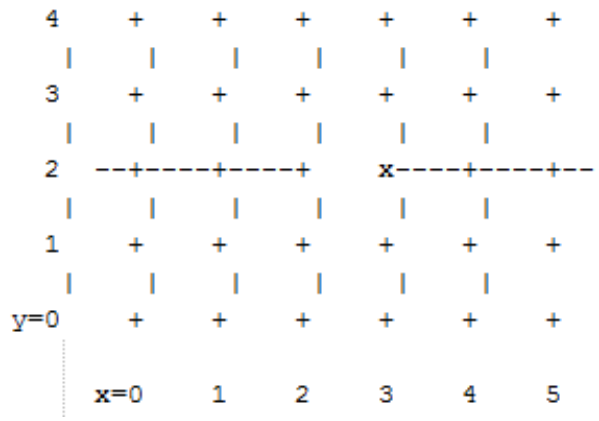
earlier examples, the second hop after the illegal turn, q-r, can be used to construct a credit loop encircling the failed switches.

Multicast Routing

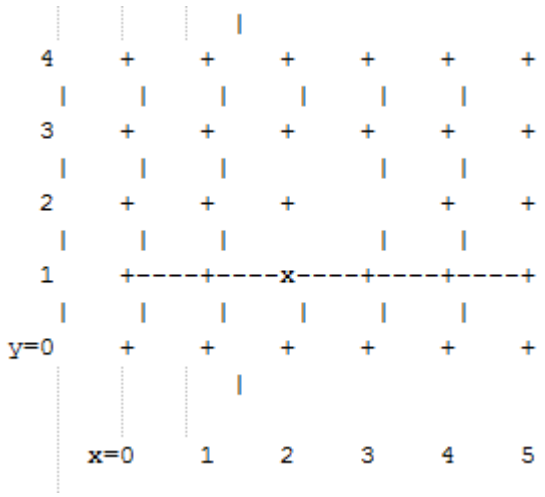
Since torus-2QoS uses all four available SL bits, and the three data VL bits that are typically available in current switches, there is no way to use SL/VL values to separate multicast traffic from unicast traffic. Thus, torus-2QoS must generate multicast routing such that credit loops cannot arise from a combination of multicast and unicast path segments. It turns out that it is possible to construct spanning trees for multicast routing that have that property. For the 2D 6x5 torus
example above, here is the full-fabric spanning tree that torus-2QoS will construct, where "x" is the root switch and each "+" is a non-root switch:



For multicast traffic routed from root to tip, every turn in the above spanning tree is a legal DOR turn. For traffic routed from tip to root, and some traffic routed through the root, turns are not legal DOR turns. However, to construct a credit loop, the union of multicast routing on this spanning tree with DOR unicast routing can only provide 3 of the 4 turns needed for the loop. In addition, if none of the above spanning tree branches crosses a dateline used for unicast credit loop avoidance on a torus, and if multicast traffic is confined to SL 0 or SL 8 (recall that torus-2QoS uses SL bit 3 to differentiate QoS level), then multicast traffic also cannot contribute to the "ring" credit loops that are otherwise possible in a torus. Torus-2QoS uses these ideas to create a master spanning tree. Every multicast group spanning tree will be constructed as a subset of the master tree, with the same root as the master tree. Such multicast group spanning trees will in general not be optimal for groups which are a subset of the full fabric. However, this compromise must be made to enable support for two QoS levels on a torus while preventing credit loops. In the presence of link or switch failures that result in a fabric for which torus-2QoS can generate credit-loop-free unicast routes, it is also possible to generate a master spanning tree for multicast that retains the required properties. For example, consider that same 2D 6x5 torus, with the link from (2,2) to (3,2) failed. Torus-2QoS will generate the following master spanning tree:



Two things are notable about this master spanning tree. First, assuming the x dateline was between x=5 and x=0, this spanning tree has a branch that crosses the dateline. However, just as for unicast, crossing a dateline on a 1D ring (here, the ring for y=2) that is broken by a failure cannot contribute to a torus credit loop. Second, this spanning tree is no longer optimal even for multicast groups that encompass the entire fabric. That, unfortunately, is a compromise that must be made to retain the other desirable properties of torus-2QoS routing. In the event that a single switch fails, torus-2QoS will generate a master spanning tree that has no "extra" turns by appropriately selecting a root switch. In the 2D 6x5 torus example, assume now that the switch at (3,2) (i.e., the root for a pristine fabric), fails. Torus-2QoS will generate the following master spanning tree for that case:



Assuming the dateline was between y=4 and y=0, this spanning tree has a branch that crosses a dateline. However, this cannot contribute to credit loops as it occurs on a 1D ring (the ring for x=3) that is broken by failure, as in the above example.

Torus Topology Discovery

The algorithm used by torus-2QoS to construct the torus topology from the undirected graph representing the fabric requires that the radix of each dimension be configured via torus-2QoS.conf. It also requires that the torus topology be "seeded"; for a 3D torus this requires configuring four switches that define the three coordinate directions of the torus. Given this starting information, the algorithm is to examine the cube formed

by the eight switch locations bounded by the corners (x,y,z) and (x+1,y+1,z+1). Based on switches already placed into the torus topology at some of these locations, the algorithm examines 4-loops of inter-switch links to find the one that is consistent with a face of the cube of switch locations and adds its switches to the discovered topology in the correct locations.
Because the algorithm is based on examining the topology of 4-loops of links, a torus with one or more radix-4 dimensions requires extra initial seed configuration. See torus-2QoS.conf(5) for details. Torus-2QoS will detect and report when it has an insufficient configuration for a torus with radix-4 dimensions.
In the event the torus is significantly degraded, i.e., there are many missing switches or links, it may happen that torus-2QoS is unable to place into the torus some switches and/or links that were discovered in the fabric, and will generate a warning in that case. A similar condition occurs if torus-2QoS is misconfigured, i.e., the radix of a torus dimension as configured does not match the radix of that torus dimension as wired, and many switches/links in the fabric will not be placed into the torus.

Quality Of Service Configuration

OpenSM will not program switches and channel adapters with SL2VL maps or VL arbitration configuration unless it is invoked with -Q. Since torus-2QoS depends on such functionality for correct operation, always invoke OpenSM with -Q when torus-2QoS is in the list of routing engines. Any quality of service configuration method supported by OpenSM will work with torus-2QoS, subject to the following limitations and considerations. For all routing engines supported by OpenSM except torus-2QoS, there is a one-to-one correspondence between QoS level and SL. Torus-2QoS can only support two quality of service levels, so only the high-order bit of any SL value used for unicast QoS configuration will be honored by torus-2QoS. For multicast QoS configuration, only SL values 0 and 8 should be used with torus-2QoS.
Since SL to VL map configuration must be under the complete control of torus-2QoS, any configuration via qos_sl2vl, qos_swe_sl2vl, etc., must and will be ignored, and a warning will be generated. Torus-2QoS uses VL values 0-3 to implement one of its supported QoS levels, and VL values 4-7 to implement the other. Hard-to-diagnose application issues may arise if traffic is not delivered fairly across each of these two VL ranges. Torus-2QoS will detect and warn if VL arbitration is configured unfairly across VLs in the range 0-3, and also in the range 4-7. Note that the default OpenSM VL arbitration configuration does not meet this constraint, so all torus-2QoS users should configure VL arbitration via qos_vlarb_high, qos_vlarb_low, etc.

Operational Considerations

Any routing algorithm for a torus IB fabric must employ path SL values to avoid credit loops. As a result, all applications run over such fabrics must perform a path record query to obtain the correct path SL for connection setup. Applications that use rdma_cm for connection setup will automatically meet this requirement.
If a change in fabric topology causes changes in path SL values required to route without credit loops, in general, all applications would need to repath to avoid message deadlock. Since torus- 2QoS has the ability to reroute after a single switch failure without changing path SL values, repathing by running applications is not required when

the fabric is routed with torus-2QoS.
Torus-2QoS can provide unchanging path SL values in the presence of subnet manager failover provided that all OpenSM instances have the same idea of dateline location. See torus- 2QoS.conf(5) for details. Torus-2QoS will detect configurations of failed switches and links that prevent routing that is free of credit loops and will log warnings and refuse to route. If "no_fall- back" was configured in the list of OpenSM routing engines, then no other routing engine will attempt to route the fabric. In that case, all paths that do not transit the failed components will continue to work, and the subset of paths that are still operational will continue to remain free of credit loops. OpenSM will continue to attempt to route the fabric after every sweep interval and after any change (such as a link up) in the fabric topology. When the fabric components are repaired, full functionality will be restored. In the event OpenSM was configured to allow some other engine to route the fabric if torus-2QoS fails, then credit loops and message deadlock are likely if torus-2QoS had previously routed the fabric successfully. Even if the other engine is capable of routing a torus without credit loops, applications that built connections with path SL values granted under torus-2QoS will likely experience message deadlock under routing generated by a different engine, unless they repath. To verify that a torus fabric is routed free of credit loops, use `ibdmchk` to analyze data collected via ibdiagnet `-`vlr.

Torus-2QoS Configuration File Syntax

The file torus-2QoS.conf contains configuration information that is specific to the OpenSM routing engine torus-2QoS. Blank lines and lines where the first non-whitespace character is "#" are ignored. A token is any contiguous group of non-whitespace characters. Any tokens on a line following the recognized configuration tokens described below are ignored.

```
[torus|mesh] x_radix[m|M|t|T] y_radix[m|M|t|T] z_radix[m|M|t|T]
```

Either torus or mesh must be the first keyword in the configuration and sets the topology that torus-2QoS will try to construct. A 2D topology can be configured by specifying one of x_radix, y_radix, or z_radix as 1. An individual dimension can be configured as mesh (open) or torus (looped) by suffixing its radix specification with one of m, M, t, or T. Thus, "mesh 3T 4 5" and "torus 3 4M 5M" both specify the same topology.
Note that although torus-2QoS can route mesh fabrics, its ability to route around failed components is severely compromised on such fabrics. A failed fabric components very likely to cause a disjoint ring; see UNICAST ROUTING in torus-2QoS(8).

```
xp_link sw0_GUID sw1_GUID
yp_link sw0_GUID sw1_GUID
zp_link sw0_GUID sw1_GUID
xm_link sw0_GUID sw1_GUID
ym_link sw0_GUID sw1_GUID
zm_link sw0_GUID sw1_GUID
```

These keywords are used to seed the torus/mesh topology. For example, "xp_link 0x2000 0x2001" specifies that a link from the switch with node GUID 0x2000 to the switch with node GUID 0x2001 would point in the positive x direction, while "xm_link

0x2000 0x2001" specifies that a link from the switch with node GUID 0x2000 to the switch with node GUID 0x2001 would point in the negative x direction. All the link keywords for a given seed must specify the same "from" switch.
In general, it is not necessary to configure both the positive and negative directions for a given coordinate; either is sufficient. However, the algorithm used for topology discovery needs extra information for torus dimensions of radix four (see TOPOLOGY DISCOVERY in torus-2QoS(8)). For such cases, both the positive and negative coordinate directions must be specified.
Based on the topology specified via the torus/mesh keyword, torus-2QoS will detect and log when it has insufficient seed configuration.

```
GUIDx_dateline position
y_dateline position
z_dateline position
```

In order for torus-2QoS to provide the guarantee that path SL values do not change under any conditions for which it can still route the fabric, its idea of dateline position must not change relative to physical switch locations. The dateline keywords provide the means to configure such behavior.

The dateline for a torus dimension is always between the switch with coordinate 0 and the switch with coordinate radix-1 for that dimension. By default, the common switch in a torus seed is taken as the origin of the coordinate system used to describe switch location. The position parameter for a dateline keyword moves the origin (and hence the dateline) the specified amount relative to the common switch in a torus seed.

```
next_seed
```

If any of the switches used to specify a seed were to fail torus-2QoS would be unable to complete topology discovery successfully. The next_seed keyword specifies that the following link and dateline keywords apply to a new seed specification.

For maximum resiliency, no seed specification should share a switch with any other seed specification. Multiple seed specifications should use dateline configuration to ensure that torus-2QoS can grant path SL values that are constant, regardless of which seed was used to initiate topology discovery.

- portgroup_max_ports max_ports - This keyword specifies the maximum number of parallel inter-switch links, and also the maximum number of host ports per switch, that torus-2QoS can accommodate. The default value is 16. Torus-2QoS will log an error message during topology discovery if this parameter needs to be increased. If this keyword appears multiple times, the last instance prevails.
- port_order p1 p2 p3 ... - This keyword specifies the order in which CA ports on a destination switch are visited when computing routes. When the fabric contains switches connected with multiple parallel links, routes are distributed in a round-robin fashion across such links, and so changing the order that CA ports are visited changes the distribution of routes across such links. This may be advantageous for some specific traffic patterns.

The default is to visit CA ports in increasing port order on destination switches. Duplicate values in the list will be ignored.

Example:

```
# Look for a 2D (since x radix is one) 4x5 torus.
torus 1 4 5
# y is radix-4 torus dimension, need both
# ym_link and yp_link configuration.
yp_link 0x200000 0x200005 # sw @ y=0,z=0 -> sw @ y=1,z=0
ym_link 0x200000 0x20000f # sw @ y=0,z=0 -> sw @ y=3,z=0
# z is not radix-4 torus dimension, only need one of
# zm_link or zp_link configuration.
zp_link 0x200000 0x200001 # sw @ y=0,z=0 -> sw @ y=0,z=1
next_seed
yp_link 0x20000b 0x200010 # sw @ y=2,z=1 -> sw @ y=3,z=1
ym_link 0x20000b 0x200006 # sw @ y=2,z=1 -> sw @ y=1,z=1
zp_link 0x20000b 0x20000c # sw @ y=2,z=1 -> sw @ y=2,z=2
y_dateline -2 # Move the dateline for this seed
z_dateline -1 # back to its original position.
# If OpenSM failover is configured, for maximum resiliency
# one instance should run on a host attached to a switch
# from the first seed, and another instance should run
# on a host attached to a switch from the second seed.
# Both instances should use this torus-2QoS.conf to ensure
# path SL values do not change in the event of SM failover.
# port_order defines the order on which the ports would be
# chosen for routing.
port_order 7 10 8 11 9 12 25 28 26 29 27 30
```

Routing Chains

The routing chains feature is offering a solution that enables one to configure different parts of the fabric and define a different routing engine to route each of them. The routings are done in a sequence (hence the name "chains") and any node in the fabric that is configured in more than one part is left with the routing updated by the last routing engine it was a part of.

Configuring Routing Chains

To configure routing chains:

1. Define the port groups.
2. Define topologies based on previously defined port groups.
3. Define configuration files for each routing engine.
4. Define routing engine chains over previously defined topologies and configuration files.

Defining Port Groups

The basic idea behind the port groups is the ability to divide the fabric into sub-groups and give each group an identifier that can be used to relate to all nodes in this group. The port groups is a separate feature from the routing chains but is a mandatory prerequisite for it. In addition, it is used to define the participants in each of the routing algorithms.

Defining a Port Group Policy File

In order to define a port group policy file, set the parameter 'pgrp_policy_file' in the OpenSM configuration file.
pgrp_policy_file /etc/opensm/conf/port_groups_policy_file

Configuring a Port Group Policy

The port groups policy file details the port groups in the fabric. The policy file should be composed of one or more paragraphs that define a group. Each paragraph should begin with the line 'port-group' and end with the line 'end-port-group'.
For example:

```
port-group
…port group qualifiers…
end-port-group
```

Port Group Qualifiers

> ⚠ Unlike the port group's beginning and end which do not require a colon, all qualifiers must end with a colon (':'). Also - a colon is a predefined mark that must not be used inside qualifier values. The inclusion of a colon in the name or the use of a port group will result in the policy's failure.

Rule Qualifier

Parameter	Description	Example
`name`	Each group must have a name. Without a name qualifier, the policy fails.	`name: grp1`
`use`	'use' is an optional qualifier that one can define in order to describe the usage of this port group (if undefined, an empty string is used as a default).	`use: first port group`

There are several qualifiers used to describe a rule that determines which ports will be added to the group. Each port group may include one or more rules out of the rules described in the below table (at least one rule must be defined for each port group).

Parameter	Description	Example
`guid list`	Comma separated list of GUIDs to include in the group. If no specific physical ports were configured, all physical ports of the guid are chosen. However, for each guid, one can detail specific physical ports to be included in the group. This can be done using the following syntax: • Specify a specific port in a guid to be chosen port-guid: 0x283@3 • Specify a specific list of ports in a guid to be chosen port-guid: 0x286@1/5/7 • Specify a specific range of ports in a guid to be chosen port-guid: 0x289@2-5 • Specify a list of specific ports and ports ranges in a guid to be chosen port-guid: 0x289@2-5/7/9-13/18 • Complex rule port-guid: 0x283@5-8/12/14, 0x286, 0x289/6/ 8/12	`port-guid: 0x283, 0x286, 0x289`
`port guid range`	It is possible to configure a range of guids to be chosen to the group. However, while using the range qualifier, it is impossible to detail specific physical ports. Note: A list of ranges cannot be specified. The below example is invalid and will cause the policy to fail: port-guid-range: 0x283-0x289, 0x290- 0x295	`port-guid-range: 0x283-0x289`

Parameter	Description	Example
`port name`	One can configure a list of hostnames as a rule. Hosts with a node description that is built out of these hostnames will be chosen. Since the node description contains the network card index as well, one might also specify a network card index and a physical port to be chosen. For example, the given configuration will cause only physical port 2 of a host with the node description 'kuku HCA-1' to be chosen. port and hca_idx parameters are optional. If the port is unspecified, all physical ports are chosen. If hca_idx is unspecified, all card numbers are chosen. Specifying a hostname is mandatory. One can configure a list of hostname/ port/hca_idx sets in the same qualifier as follows: port-name: hostname=kuku; port=2; hca_idx=1 , hostname=host1; port=3, hostname=host2 Note: port-name qualifier is not relevant for switches, but for HCA's only.	`port-name: host-name=kuku; port=2; hca_idx=1`
`port regexp`	One can define a regular expression so that only nodes with a matching node description will be chosen to the group. Note: This example shows how to choose nodes which their node description starts with 'SW'.	`port-regexp: SW`
	It is possible to specify one physical port to be chosen for matching nodes (there is no option to define a list or a range of ports). The given example will cause only nodes that match physical port 3 to be added to the group.	`port-regexp: SW:3`
`union rule`	It is possible to define a rule that unites two different port groups. This means that all ports from both groups will be included in the united group.	`union-rule: grp1, grp2`
`subtract rule`	One can define a rule that subtracts one port group from another. The given rule, for example, will cause all the ports which are a part of grp1, but not included in grp2, to be chosen. In subtraction (unlike union), the order does matter, since the purpose is to subtract the second group from the first one. There is no option to define more than two groups for union/subtraction. However, one can unite/subtract groups which are a union or a subtraction themselves, as shown in the port groups policy file example.	`subtract-rule: grp1, grp2`

Predefined Port Groups

There are 3 predefined, automatically created port groups that are available for use, yet cannot be defined in the policy file (if a group in the policy is configured with the name of one of these predefined groups, the policy fails) -

- ALL - a group that includes all nodes in the fabric
- ALL_SWITCHES - a group that includes all switches in the fabric
- ALL_CAS - a group that includes all HCAs in the fabric
- ALL_ROUTERS - a group that includes all routers in the fabric (supported in OpenSM starting from v4.9.0)

Port Groups Policy Examples

```
port-group
name: grp3
use: Subtract of groups grp1 and grp2
subtract-rule: grp1, grp2
end-port-group

port-group
name: grp1
```

```
port-guid: 0x281, 0x282, 0x283
end-port-group

port-group
name: grp2
port-guid-range: 0x282-0x286
port-name: hostname=server1 port=1
end-port-group

port-group
name: grp4
port-name: hostname=kika port=1 hca_idx=1
end-port-group

port-group
name: grp3
union-rule: grp3, grp4
end-port-group
```

Defining a Topologies Policy File

In order to define a topology policy file, set the parameter 'topo_policy_file' in the OpenSM configuration file.

```
topo_policy_file /etc/opensm/conf/topo_policy_file.cfg
```

Configuring a Topology Policy

The topologies policy file details a list of topologies. The policy file should be composed of one or more paragraphs which define a topology. Each paragraph should begin with the line 'topol- ogy' and end with the line 'end-topology'.
For example:

```
topology
…topology qualifiers…
end-topology
```

Topology Qualifiers

> ⚠ Unlike topology and end-topology which do not require a colon, all qualifiers must end with a colon (':'). Also - a colon is a predefined mark that must not be used inside qualifier values. An inclusion of a column in the qualifier values will result in the policy's failure.

All topology qualifiers are mandatory. Absence of any of the below qualifiers will cause the policy parsing to fail.

Parameter	Description	Example
`id`	Topology ID. Legal Values – any positive value. Must be unique.	`id: 1`
`sw-grp`	Name of the port group that includes all switches and switch ports to be used in this topology.	`sw-grp: ys_switches`
`hca-grp`	Name of the port group that includes all HCA's to be used in this topology.	`hca-grp: ys_hosts`

Configuration File per Routing Engine

Each engine in the routing chain can be provided by its own configuration file. Routing engine configuration file is the fraction of parameters defined in the main OpenSM configuration file.
Some rules should be applied when defining a particular configuration file for a routing engine:

- Parameters that are not specified in specific routing engine configuration file are inherited from the main OpenSM configuration file.
- The following configuration parameters are taking effect only in the main OpenSM configuration file:
  - qos and qos_* settings like (vl_arb, sl2vl, etc.)
  - lmc
  - routing_engine

Defining a Routing Chain Policy File

In order to define a port group policy file, set the parameter 'rch_policy_file' in the OpenSM configuration file.

```
rch_policy_file /etc/opensm/conf/chains_policy_file
```

First Routing Engine in the Chain

The first unicast engine in a routing chain must include all switches and HCAs in the fabric (topology id must be 0). The path-bit parameter value is path-bit 0 and it cannot be changed.

Configuring a Routing Chains Policy

The routing chains policy file details the routing engines (and their fallback engines) used for the fabric's routing. The policy file should be composed of one or more paragraphs which defines an
engine (or a fallback engine). Each paragraph should begin with the line 'unicast-step' and end with the line 'end-unicast-step'.
For example:

```
unicast-step
…routing engine qualifiers…
end-unicast-step
```

Routing Engine Qualifiers

Unlike unicast-step and end-unicast-step which do not require a colon, all qualifiers must end with a colon (':'). Also - a colon is a predefined mark that must not be used inside qualifier values. An inclusion of a colon in the qualifier values will result in the policy's failure.

Parameter	Description	Example
`id`	'id' is mandatory. Without an ID qualifier for each engine, the policy fails. • Legal values – size_t value (0 is illegal). • The engines in the policy chain are set according to an ascending id order, so it is highly crucial to verify that the id that is given to the engines match the order in which you would like the engines to be set.	`is: 1`
`engine`	This is a mandatory qualifier that describes the routing algorithm used within this unicast step. Currently, on the first phase of routing chains, legal values are minhop/ftree/updn.	`engine: minhop`
`use`	This is an optional qualifier that enables one to describe the usage of this unicast step. If undefined, an empty string is used as a default.	`use: ftree routing for for yellow stone nodes`
`config`	This is an optional qualifier that enables one to define a separate OpenSM config file for a specific unicast step. If undefined, all parameters are taken from main OpenSM configuration file.	`config: /etc/config/opensm2.cfg`
`topology`	Define the topology that this engine uses. • Legal value – id of an existing topology that is defined in topologies policy (or zero that represents the entire fabric and not a specific topology). • Default value – If unspecified, a routing engine will relate to the entire fabric (as if topology zero was defined). • Notice: The first routing engine (the engine with the lowest id) MUST be configured with topology: 0 (entire fabric) or else, the routing chain parser will fail.	`topology: 1`
`fallback-to`	This is an optional qualifier that enables one to define the current unicast step as a fallback to another unicast step. This can be done by defining the id of the unicast step that this step is a fallback to. • If undefined, the current unicast step is not a fallback. • If the value of this qualifier is a non-existent engine id, this step will be ignored. • A fallback step is meaningless if the step it is a fallback to did not fail. • It is impossible to define a fallback to a fall- back step (such definition will be ignored)	`-`
`path-bit`	This is an optional qualifier that enables one to define a specific lid offset to be used by the current unicast step. Setting lmc > 0 in main OpenSM configuration file is a prerequisite for assigning specific path-bit for the routing engine. Default value is 0 (if path-bit is not specified)	`Path-bit: 1`

Dump Files per Routing Engine

Each routing engine on the chain will dump its own data files if the appropriate log_flags is set (for instance 0x43).

The files that are dumped by each engine are:

- opensm-lid-matrix.dump
- opensm-lfts.dump
- opensm.fdbs

- opensm-subnet.lst

These files should contain the relevant data for each engine topology.

> ⚠ sl2vl and mcfdbs files are dumped only once for the entire fabric and NOT by every routing engine.

- Each engine concatenates its ID and routing algorithm name in its dump files names, as follows:
  - opensm-lid-matrix.2.minhop.dump
  - opensm.fdbs.3.ftree
  - opensm-subnet.4.updn.lst
- In case that a fallback routing engine is used, both the routing engine that failed and the fallback engine that replaces it, dump their data.
  If, for example, engine 2 runs ftree and it has a fallback engine with 3 as its id that runs minhop, one should expect to find 2 sets of dump files, one for each engine:
  - opensm-lid-matrix.2.ftree.dump
  - opensm-lid-matrix.3.minhop.dump
  - opensm.fdbs.2.ftree
  - opensm.fdbs.3.munhop

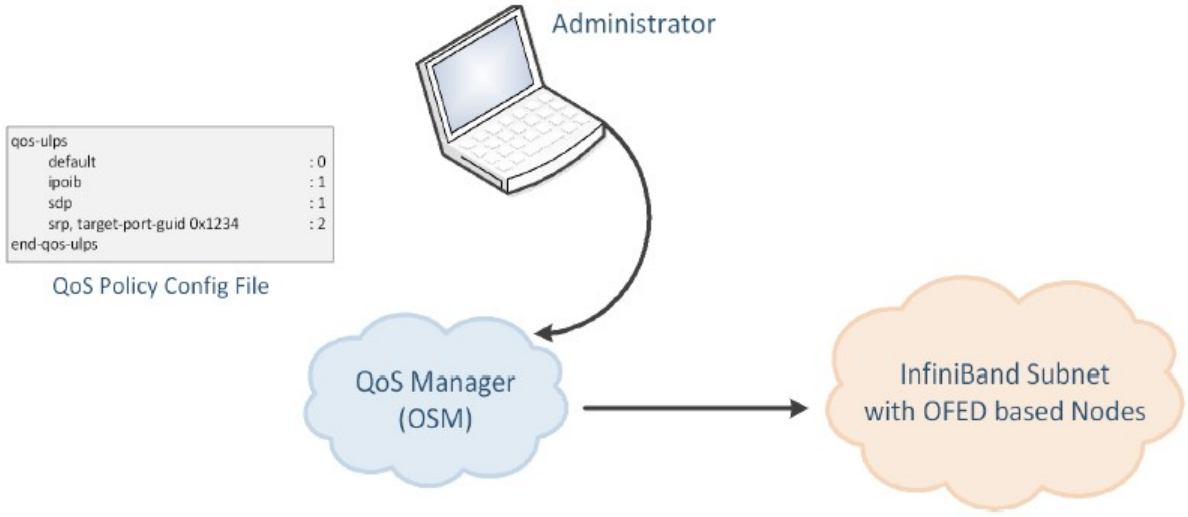
5.6.2.1.2.6 Unicast Routing Cache

Unicast routing cache prevents routing recalculation (which is a heavy task in a large cluster) when no topology change was detected during the heavy sweep, or when the topology change does not require new routing calculation (for example, when one or more CAs/RTRs/leaf switches going down, or one or more of these nodes coming back after being down).

5.6.2.1.2.7 Quality of Service Management in OpenSM

When Quality of Service (QoS) in OpenSM is enabled (using the '-Q' or '--qos' flags), OpenSM looks for a QoS Policy file. During fabric initialization and at every heavy sweep, OpenSM parses the QoS policy file, applies its settings to the discovered fabric elements, and enforces the provided policy on client requests. The overall flow for such requests is as follows:

- The request is matched against the defined matching rules such that the QoS Level definition is found
- Given the QoS Level, a path(s) search is performed with the given restrictions imposed by that level



There are two ways to define QoS policy:

- Advanced – the advanced policy file syntax provides the administrator various ways to match a PathRecord/MultiPathRecord (PR/MPR) request, and to enforce various QoS constraints on the requested PR/MPR
- Simple – the simple policy file syntax enables the administrator to match PR/MPR requests by various ULPs and applications running on top of these ULPs

Advanced QoS Policy File

The QoS policy file has the following sections:

1. Port Groups (denoted by port-groups) - this section defines zero or more port groups that can be referred later by matching rules (see below). Port group lists ports by:
   - Port GUID
   - Port name, which is a combination of NodeDescription and IB port number
   - PKey, which means that all the ports in the subnet that belong to partition with a given PKey belong to this port group
   - Partition name, which means that all the ports in the subnet that belong to partition with a given name belong to this port group
   - Node type, where possible node types are: CA, SWITCH, ROUTER, ALL, and SELF (SM's port).

2. QoS Setup (denoted by qos-setup) - this section describes how to set up SL2VL and VL Arbitration tables on various nodes in the fabric. However, this is not supported in OFED. SL2VL and VLArb tables should be configured in the OpenSM options file (default location - /var/cache/opensm/opensm.opts).

3. QoS Levels (denoted by qos-levels) - each QoS Level defines Service Level (SL) and a few optional fields:
   - MTU limit

- Rate limit
- PKey
- Packet lifetime

When path(s) search is performed, it is done with regards to restriction that these QoS Level parameters impose. One QoS level that is mandatory to define is a DEFAULT QoS level. It is applied to a PR/MPR query that does not match any existing match rule. Similar to any other QoS Level, it can also be explicitly referred by any match rule.

- QoS Matching Rules (denoted by qos-match-rules) - each PathRecord/ MultiPathRecord query that OpenSM receives is matched against the set of matching rules. Rules are scanned in order of appearance in the QoS policy file such as the first match takes precedence.
  Each rule has a name of QoS level that will be applied to the matching query. A default QoS level is applied to a query that did not match any rule.
  Queries can be matched by:
  - Source port group (whether a source port is a member of a specified group)
  - Destination port group (same as above, only for destination port)
  - PKey
  - QoS class
  - Service ID

  To match a certain matching rule, PR/MPR query has to match ALL the rule's criteria. However, not all the fields of the PR/MPR query have to appear in the matching rule.
  For instance, if the rule has a single criterion - Service ID, it will match any query that has this Service ID, disregarding rest of the query fields. However, if a certain query has only Service ID (which means that this is the only bit in the PR/MPR component mask that is on), it will not match any rule that has other matching criteria besides Service ID.

Simple QoS Policy Definition

Simple QoS policy definition comprises of a single section denoted by qos-ulps. Similar to the advanced QoS policy, it has a list of match rules and their QoS Level, but in this case a match rule has only one criterion - its goal is to match a certain ULP (or a certain application on top of this ULP) PR/MPR request, and QoS Level has only one constraint - Service Level (SL).
The simple policy section may appear in the policy file in combine with the advanced policy, or as a stand-alone policy definition. See more details and list of match rule criteria below.

Policy File Syntax Guidelines

- Leading and trailing blanks, as well as empty lines, are ignored, so the indentation in the example is just for better readability.

- Comments are started with the pound sign (#) and terminated by EOL.
- Any keyword should be the first non-blank in the line, unless it's a comment.
- Keywords that denote section/subsection start have matching closing keywords.
- Having a QoS Level named "DEFAULT" is a must - it is applied to PR/MPR requests that did not match any of the matching rules.
- Any section/subsection of the policy file is optional.

Examples of Advanced Policy Files

As mentioned earlier, any section of the policy file is optional, and the only mandatory part of the policy file is a default QoS Level.
Here is an example of the shortest policy file:

```
qos-levels
    qos-level
        name: DEFAULT
        sl: 0
    end-qos-level
end-qos-levels
```

Port groups section is missing because there are no match rules, which means that port groups are not referred anywhere, and there is no need defining them. And since this policy file doesn't have any matching rules, PR/MPR query will not match any rule, and OpenSM will enforce default QoS level. Essentially, the above example is equivalent to not having a QoS policy file at all.

The following example shows all the possible options and keywords in the policy file and their syntax:

```
#
# See the comments in the following example.
# They explain different keywords and their meaning.
#
port-groups

    port-group # using port GUIDs
        name: Storage
        # "use" is just a description that is used for logging
        #  Other than that, it is just a comment
        use: SRP Targets
        port-guid: 0x10000000000001, 0x10000000000005-0x1000000000FFFA
        port-guid: 0x1000000000FFFF
    end-port-group

    port-group
        name: Virtual Servers
        # The syntax of the port name is as follows:
        #   "node_description/Pnum".
        # node_description is compared to the NodeDescription of the node,
        # and "Pnum" is a port number on that node.
        port-name: "vs1 HCA-1/P1, vs2 HCA-1/P1"
    end-port-group

    # using partitions defined in the partition policy
    port-group
        name: Partitions
        partition: Part1
        pkey: 0x1234
    end-port-group

    # using node types: CA, ROUTER, SWITCH, SELF (for node that runs SM)
    # or ALL (for all the nodes in the subnet)
    port-group
        name: CAs and SM
        node-type: CA, SELF
    end-port-group

end-port-groups

qos-setup
    # This section of the policy file describes how to set up SL2VL and VL
    # Arbitration tables on various nodes in the fabric.
    # However, this is not supported in OFED - the section is parsed
    # and ignored. SL2VL and VLArb tables should be configured in the
    # OpenSM options file (by default - /var/cache/opensm/opensm.opts).
end-qos-setup
```

```
qos-levels

    # Having a QoS Level named "DEFAULT" is a must - it is applied to
    # PR/MPR requests that didn't match any of the matching rules.
    qos-level
        name: DEFAULT
        use: default QoS Level
        sl: 0
    end-qos-level

    # the whole set: SL, MTU-Limit, Rate-Limit, PKey, Packet Lifetime
    qos-level
        name: WholeSet
        sl: 1
        mtu-limit: 4
        rate-limit: 5
        pkey: 0x1234
        packet-life: 8
    end-qos-level

end-qos-levels

# Match rules are scanned in order of their appearance in the policy file.
# First matched rule takes precedence.
qos-match-rules

    # matching by single criteria: QoS class
    qos-match-rule
        use: by QoS class
        qos-class: 7-9,11
        # Name of qos-level to apply to the matching PR/MPR
        qos-level-name: WholeSet
    end-qos-match-rule

    # show matching by destination group and service id
    qos-match-rule
        use: Storage targets
        destination: Storage
        service-id: 0x10000000000001, 0x10000000000008-0x10000000000FFF
        qos-level-name: WholeSet
    end-qos-match-rule

    qos-match-rule
        source: Storage
        use: match by source group only
        qos-level-name: DEFAULT
    end-qos-match-rule
    qos-match-rule
        use: match by all parameters
        qos-class: 7-9,11
        source: Virtual Servers
        destination: Storage
        service-id: 0x0000000000010000-0x000000000001FFFF
        pkey: 0x0F00-0x0FFF
        qos-level-name: WholeSet
    end-qos-match-rule
end-qos-match-rules
```

Simple QoS Policy - Details and Examples

Simple QoS policy match rules are tailored for matching ULPs (or some application on top of a ULP) PR/MPR requests. This section has a list of per-ULP (or per-application) match rules and the SL that should be enforced on the matched PR/MPR query.
Match rules include:

- Default match rule that is applied to PR/MPR query that didn't match any of the other match rules
- IPoIB with a default PKey
- IPoIB with a specific PKey
- Any ULP/application with a specific Service ID in the PR/MPR query
- Any ULP/application with a specific PKey in the PR/MPR query
- Any ULP/application with a specific target IB port GUID in the PR/MPR query

Since any section of the policy file is optional, as long as basic rules of the file are kept (such as no referring to nonexistent port group, having default QoS Level, etc), the simple policy section (qos-ulps) can serve as a complete QoS policy file.
The shortest policy file in this case would be as follows:

```
qos-ulps
```

```
    default   : 0 #default SL
end-qos-ulps
```

It is equivalent to the previous example of the shortest policy file, and it is also equivalent to not having policy file at all. Below is an example of simple QoS policy with all the possible keywords:

```
qos-ulps
default                 :0 # default SL
sdp, port-num 30000     :0 # SL for application running on
                           # top of SDP when a destination
                           # TCP/IPport is 30000
sdp, port-num 10000-20000     : 0
sdp                     :1 # default SL for any other
                           # application running on top of SDP
rds                     :2 # SL for RDS traffic
ipoib, pkey 0x0001      :0 # SL for IPoIB on partition with
                           # pkey 0x0001
ipoib                   :4 # default IPoIB partition,
                           # pkey=0x7FFF
any, service-id 0x6234:6 # match any PR/MPR query with a
                           # specific Service ID
any, pkey 0x0ABC        :6 # match any PR/MPR query with a
                           # specific PKey
srp, target-port-guid 0x1234  : 5 # SRP when SRP Target is located
                           # on a specified IB port GUID
any, target-port-guid 0x0ABC-0xFFFFF : 6 # match any PR/MPR query
                           # with a specific target port GUID
end-qos-ulps
```

Similar to the advanced policy definition, matching of PR/MPR queries is done in order of appearance in the QoS policy file such as the first match takes precedence, except for the "default" rule, which is applied only if the query didn't match any other rule. All other sections of the QoS policy file take precedence over the qos-ulps section. That is, if a policy file has both qos-match-rules and qos-ulps sections, then any query is matched first against the rules in the qos-match-rules section, and only if there was no match, the query is matched against the rules in qos-ulps section.

Note that some of these match rules may overlap, so in order to use the simple QoS definition effectively, it is important to understand how each of the ULPs is matched.

IPoIB

IPoIB query is matched by PKey or by destination GID, in which case this is the GID of the multicast group that OpenSM creates for each IPoIB partition.
Default PKey for IPoIB partition is 0x7fff, so the following three match rules are equivalent:

```
ipoib:<SL>ipoib, pkey 0x7fff : <SL>
any, pkey 0x7fff : <SL>
```

SRP

Service ID for SRP varies from storage vendor to vendor, thus SRP query is matched by the target IB port GUID. The following two match rules are equivalent:

```
srp, target-port-guid 0x1234 : <SL>
any, target-port-guid 0x1234 : <SL>
```

Note that any of the above ULPs might contain target port GUID in the PR query, so in order for these queries not to be recognized by the QoS manager as SRP, the SRP match

rule (or any match rule that refers to the target port GUID only) should be placed at the end of the qos-ulps match rules.

MPI

SL for MPI is manually configured by an MPI admin. OpenSM is not forcing any SL on the MPI traffic, which explains why it is the only ULP that did not appear in the qos-ulps section.

SL2VL Mapping and VL Arbitration

OpenSM cached options file has a set of QoS related configuration parameters, that are used to configure SL2VL mapping and VL arbitration on IB ports. These parameters are:

- Max VLs: the maximum number of VLs that will be on the subnet
- High limit: the limit of High Priority component of VL Arbitration table (IBA 7.6.9)
- VLArb low table: Low priority VL Arbitration table (IBA 7.6.9) template
- VLArb high table: High priority VL Arbitration table (IBA 7.6.9) template
- SL2VL: SL2VL Mapping table (IBA 7.6.6) template. It is a list of VLs corresponding to SLs 0-15 (Note that VL15 used here means drop this SL).

There are separate QoS configuration parameters sets for various target types: CAs, routers, switch external ports, and switch's enhanced port 0. The names of such parameters are prefixed by "qos_<type>_" string. Here is a full list of the currently supported sets:

- qos_ca_ —QoS configuration parameters set for CAs.
- qos_rtr_ —parameters set for routers.
- qos_sw0_ —parameters set for switches' port 0.
- qos_swe_ —parameters set for switches' external ports.

Here's the example of typical default values for CAs and switches' external ports (hard-coded in OpenSM initialization):

```
qos_ca_max_vls 15
qos_ca_high_limit 0
qos_ca_vlarb_high 0:4,1:0,2:0,3:0,4:0,5:0,6:0,7:0,8:0,9:0,10:0,11:0,12:0,13:0,14:0
qos_ca_vlarb_low 0:0,1:4,2:4,3:4,4:4,5:4,6:4,7:4,8:4,9:4,10:4,11:4,12:4,13:4,14:4
qos_ca_sl2vl 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,7
qos_swe_max_vls 15
qos_swe_high_limit 0
qos_swe_vlarb_high 0:4,1:0,2:0,3:0,4:0,5:0,6:0,7:0,8:0,9:0,10:0,11:0,12:0,13:0,14:0
qos_swe_vlarb_low 0:0,1:4,2:4,3:4,4:4,5:4,6:4,7:4,8:4,9:4,10:4,11:4,12:4,13:4,14:4
qos_swe_sl2vl 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,7
```

VL arbitration tables (both high and low) are lists of VL/Weight pairs. Each list entry contains a VL number (values from 0-14), and a weighting value (values 0-255), indicating the number of 64 byte units (credits) which may be transmitted from that VL when its turn in the arbitration occurs. A weight of 0 indicates that this entry should be skipped. If a list entry is programmed for VL15 or for a VL that is not supported or is not currently configured by the port, the port may either skip that entry or send from any supported VL for that entry.
Note, that the same VLs may be listed multiple times in the High or Low priority arbitration tables, and, further, it can be listed in both tables. The limit of high-priority

VLArb table (qos_<type>_high_limit) indicates the number of high-priority packets that can be transmitted without an opportunity to send a low-priority packet. Specifically, the number of bytes that can be sent is high_limit times 4K bytes.

A high_limit value of 255 indicates that the byte limit is unbounded.

> ⚠ If the 255 value is used, the low priority VLs may be starved.

A value of 0 indicates that only a single packet from the high-priority table may be sent before an opportunity is given to the low-priority table.

Keep in mind that ports usually transmit packets of size equal to MTU. For instance, for 4KB MTU a single packet will require 64 credits, so in order to achieve effective VL arbitration for packets of 4KB MTU, the weighting values for each VL should be multiples of 64.

Below is an example of SL2VL and VL Arbitration configuration on subnet:

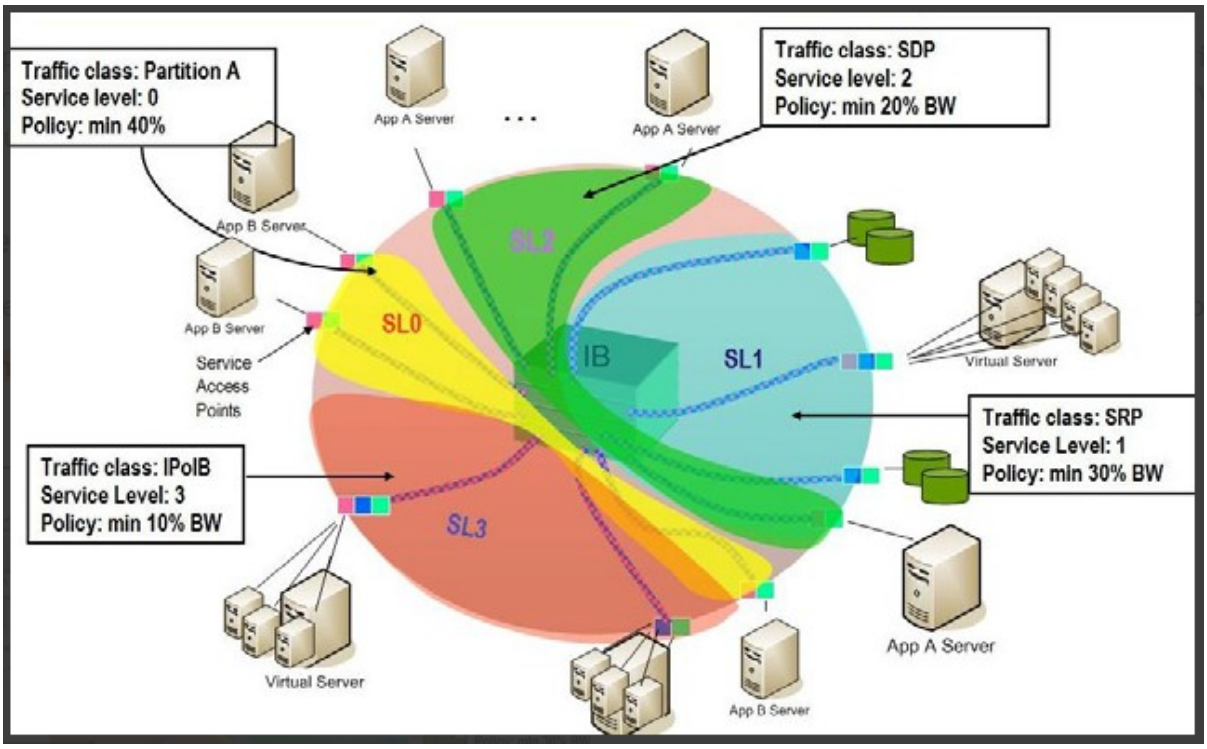
```
qos_ca_max_vls 15
qos_ca_high_limit 6
qos_ca_vlarb_high 0:4
qos_ca_vlarb_low 0:0,1:64,2:128,3:192,4:0,5:64,6:64,7:64
qos_ca_sl2vl 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,7
qos_swe_max_vls 15
qos_swe_high_limit 6
qos_swe_vlarb_high 0:4
qos_swe_vlarb_low 0:0,1:64,2:128,3:192,4:0,5:64,6:64,7:64
qos_swe_sl2vl 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,7
```

In this example, there are 8 VLs configured on subnet: VL0 to VL7. VL0 is defined as a high priority VL, and it is limited to 6 x 4KB = 24KB in a single transmission burst. Such configuration would suilt VL that needs low latency and uses small MTU when transmitting packets. Rest of VLs are defined as low priority VLs with different weights, while VL4 is effectively turned off.

Deployment Example

The figure below shows an example of an InfiniBand subnet that has been configured by a QoS manager to provide different service levels for various ULPs.

QoS Deployment on InfiniBand Subnet Example



QoS Configuration Examples

The following are examples of QoS configuration for different cluster deployments. Each example provides the QoS level assignment and their administration via OpenSM configuration files.

Typical HPC Example: MPI and Lustre

Assignment of QoS Levels

- MPI
  - Separate from I/O load
  - Min BW of 70%
- Storage Control (Lustre MDS)
  - Low latency
- Storage Data (Lustre OST)
  - Min BW 30%

Administration

- MPI is assigned an SL via the command line
  `host1# mpirun -sl 0`
- OpenSM QoS policy file

```
qos-ulps
   default                                    :0 # default SL (for MPI)
   any, target-port-guid OST1,OST2,OST3,OST4  :1 # SL for Lustre OST
   any, target-port-guid MDS1,MDS2            :2 # SL for Lustre MDS
```

```
end-qos-ulps
```

Note: In this policy file example, replace OST* and MDS* with the real port GUIDs.

- OpenSM options file

```
qos_max_vls 8
qos_high_limit 0
qos_vlarb_high 2:1
qos_vlarb_low 0:96,1:224
qos_sl2vl 0,1,2,3,4,5,6,7,15,15,15,15,15,15,15,15
```

EDC SOA (2-tier): IPoIB and SRP

The following is an example of QoS configuration for a typical enterprise data center (EDC) with service oriented architecture (SOA), with IPoIB carrying all application traffic and SRP used for storage.

QoS Levels

- Application traffic
  - IPoIB (UD and CM) and SDP
  - Isolated from storage
  - Min BW of 50%
- SRP
  - Min BW 50%
  - Bottleneck at storage nodes

Administration

- OpenSM QoS policy file

```
qos-ulps
   default                                 :0
   ipoib                                   :1
   sdp                                     :1
   srp, target-port-guid SRPT1,SRPT2,SRPT3     :2
end-qos-ulps
```

Note: In this policy file example, replace SRPT* with the real SRP Target port GUIDs.

- OpenSM options file

```
qos_max_vls 8
qos_high_limit 0
qos_vlarb_high 1:32,2:32
qos_vlarb_low 0:1,
qos_sl2vl 0,1,2,3,4,5,6,7,15,15,15,15,15,15,15,15
```

EDC (3-tier): IPoIB, RDS, SRP

The following is an example of QoS configuration for an enterprise data center (EDC), with IPoIB carrying all application traffic, RDS for database traffic, and SRP used for storage.

QoS Levels

- Management traffic (ssh)
    - IPoIB management VLAN (partition A)
    - Min BW 10%
- Application traffic
    - IPoIB application VLAN (partition B)
    - Isolated from storage and database
    - Min BW of 30%
- Database Cluster traffic
    - RDS
    - Min BW of 30%
- SRP
    - Min BW 30%
    - Bottleneck at storage nodes

Administration

- OpenSM QoS policy file

```
qos-ulps
   default                                  :0
   ipoib, pkey 0x8001                       :1
   ipoib, pkey 0x8002                       :2
   rds                                      :3
   srp, target-port-guid SRPT1, SRPT2, SRPT3   :4
end-qos-ulps
```

Note: In the following policy file example, replace SRPT* with the real SRP Initiator port GUIDs.

- OpenSM options file

```
qos_max_vls 8
qos_high_limit 0
qos_vlarb_high 1:32,2:96,3:96,4:96
qos_vlarb_low 0:1
qos_sl2vl 0,1,2,3,4,5,6,7,15,15,15,15,15,15,15,15
```

- Partition configuration file

```
Default=0x7fff,ipoib : ALL=full;PartA=0x8001, sl=1, ipoib : ALL=full;
```

Enhanced QoS

Enhanced QoS provides a higher resolution of QoS at the service level (SL). Users can configure rate limit values per SL for physical ports, virtual ports, and port groups, using enhanced_qos_policy_file configuration parameter.
Valid values of this parameter:

- Full path to the policy file through which Enhanced QoS Manager is configured
- "null" - to disable the Enhanced QoS Manager (default value)

To enable Enhanced QoS Manager, QoS must be enabled in OpenSM.

Enhanced QoS Policy File

The policy file is comprised of three sections:

- BW_NAMES: Used to define bandwidth setting and name (currently, rate limit is the only setting). Bandwidth names can be used in BW_RULES and VPORT_BW_RULES sections.
  Bandwidth names are defined using the syntax:
  `<name> = <rate limit in 1Mbps units>`
  Example: `My_bandwidth = 50`
- BW_RULES: Used to define the rules that map the bandwidth setting to a specific SL of a specific GUID.
  Bandwidth rules are defined using the syntax:
  `<guid>|<port group name> = <sl id>:<bandwidth name>, <sl id>:<bandwidth name>…`
  Examples:
  `0x2c90000000025 = 5:My_bandwidth, 7:My_bandwidth`
  `Port_grp1 = 3:My_bandwidth, 9:My_bandwidth`
- VPORT_BW_RULES: Used to define the rules that map the bandwidth setting to a specific SL of a specific virtual port GUID.
  Bandwidth rules are defined using the syntax:
  `<guid>= <sl id>:<bandwidth name>, <sl id>:<bandwidth name>…`
  Examples:
  `0x2c90000000026= 5:My_bandwidth, 7:My_bandwidth`

Special Keywords

- Keyword “all” allows setting a rate limit of all SLs to some BW for a specific physical or virtual port. It is possible to combine “all” with specific SL rate limits.
  Example:
  `0x2c90000000025 = all:BW1,SL3:BW2`
  In this case, SL3 will be assigned BW2 rate limit, while the rest of SLs get BW1 rate limit.
- "default" is a well-known name which can be used to define a default rule used for any GUID with no defined rule.
  If no default rule is defined, any GUID without a specific rule will be configured with unlimited rate limit for all SLs.
  Keyword “all” is also applicable to the default rule. Default rule is local to each section.

Special Subnet Manager Configuration Options

New SM configuration option enhanced_qos_vport0_unlimit_default_rl was added to opensm.conf.

The possible values for this configuration option are:

- TRUE: For specific virtual port0 GUID, SLs not mentioned in bandwidth rule will be set to unlimited bandwidth (0) regardless of the default rule of the VPORT_BW_RULES section.
  Virtual port0 GUIDs not mentioned in VPORT_BW_SECTION will be set to unlimited BW on all SLs.
- FALSE: The GUID of virtual port0 is treated as any other virtual port in VPORT_BW_SECTION.
  SM should be signaled by HUP once the option is changed.

Default: TRUE

Notes

- When rate limit is set to 0, it means that the bandwidth is unlimited.
- Any unspecified SL in a rule will be set to 0 (unlimited) rate limit automatically if no default rule is specified.
- Failure to complete policy file parsing leads to an undefined behavior. User must confirm no relevant error messages in SM log in order to ensure Enhanced QoS Manager is configured properly.
- A file with only 'BW_NAMES' and 'BW_RULES' keywords configures the network with an unlimited rate limit.
- HCA physical port GUID can be specified in BW_RULES and VPORT_BW_RULES sections.
- In BW_RULES section, the rate limit assigned to a specific SL will limit the total BW that can be sent through the PF on a given SL.
- In VPORT_BW_RULES section, the rate limit assigned to a specific SL will limit only the traffic sent from the IB interface corresponding to the physical port GUID (virtual port0 IB interface). The traffic sent from other virtual IB interfaces will not be limited if no specific rules are defined.

Policy File Example

All physical ports in the fabric are with a rate limit of 50Mbps on SL1, except for GUID 0x2c90000000025, which is configured with rate limit of 25Mbps on SL1. In this example, the traffic on SLs (other than SL1) is unlimited.
All virtual ports in the fabric (except virtual port0 of all physical ports) will be rate-limited to 15Mbps for all SLs because of the default rule of VPORT_BW_RULES section.
Virtual port GUID 0x2c90000000026 is configured with a rate limit of 10Mbps on SL3. The rest of the SLs on this virtual port will get a rate limit of 15 Mbps because of the default rule of VPORT_BW_RULES section.

```
------------------------------------------------------------------------
BW_NAMES
```

```
bw1 = 50
bw2 = 25
bw3 = 15
bw4 = 10

BW_RULES
default= 1:bw1
0x2c90000000025= 1:bw2

VPORT_BW_RULES
default= all:bw3
0x2c90000000026= 3:bw4

------------------------------------------------------------------------
```

5.6.2.1.2.8 Adaptive Routing Manager and Self-Healing Networking

Adaptive Routing Manager supports advanced InfiniBand features; Adaptive Routing (AR) and Self-Healing Networking.

For information on how to set up AR and Self-Healing Networking, please refer to HowTo Configure Adaptive Routing and Self-Healing Networking Community post.

DOS MAD Prevention

DOS MAD prevention is achieved by assigning a threshold for each agent's RX. Agent's RX threshold provides a protection mechanism to the host memory by limiting the agents' RX with a threshold. Incoming MADs above the threshold are dropped and are not queued to the agent's RX.

To enable DOS MAD Prevention:

1. Go to /etc/modprobe.d/mlnx.conf.
2. Add to the file the option below.

```
ib_umad enable_rx_threshold 1
```

The threshold value can be controlled from the user-space via libibumad.

To change the value, use the following API:

```
int umad_update_threshold(int fd, int threshold);

@fd: file descriptor, agent's RX associated to this fd.
@threshold: new threshold value
```

5.6.2.1.2.9 IB Router Support in OpenSM

In order to enable the IB router in OpenSM, the following parameters should be configured:

IB Router Parameters for OpenSM

Parameter	Description	Default Value
`rtr_pr_flow_label`	Defines whether the SM should create alias GUIDs required for router support for each port. Defines flow label value to use in response for path records related to the router.	0 (Disabled)
rtr_pr_tclass	Defines TClass value to use in response for path records related to the router	0

Parameter	Description	Default Value
rtr_pr_sl	Defines sl value to use in response for path records related to router.	0
rtr_p_mtu	Defines MTU value to use in response for path records related to the router.	4 (IB_MTU_LEN_2048)
rtr_pr_rate	Defines rate value to use in response for path records related to the router.	16 (IB_PATH_RECORD_RATE_100_GBS)

5.6.2.1.2.10 OpenSM Activity Report

OpenSM can produce an activity report in a form of a dump file which details the different activities done in the SM. Activities are divided into subjects. The OpenSM Supported Activities table below specifies the different activities currently supported in the SM activity report.
Reporting of each subject can be enabled individually using the configuration parameter `activity_report_subjects`:

- Valid values:
  Comma separated list of subjects to dump. The current supported subjects are:
  - "mc" - activity IDs 1, 2 and 8
  - "prtn" - activity IDs 3, 4, and 5
  - "virt" - activity IDs 6 and 7
  - "routing" - activity IDs 8-12

  Two predefined values can be configured as well:
  - "all" - dump all subjects
  - "none" - disable the feature by dumping none of the subjects
- Default value: "none"

OpenSM Supported Activities

ACtivity ID	Activity Name	Additional Fields	Comments	Description
1	mcm_member	• MLid • MGid • Port Guid • Join State	Join state: 1 - Join -1 - Leave	Member joined/ left MC group
2	mcg_change	• MLid • MGid • Change	Change: 0 - Create 1 - Delete	MC group created/deleted
3	prtn_guid_add	• Port Guid • PKey • Block index • Pkey Index		Guid added to partition
4	prtn_create	-PKey • Prtn Name		Partition created

ACtivity ID	Activity Name	Additional Fields	Comments	Description
5	prtn_delete	• PKey • Delete Reason	Delete Reason: 0 - empty prtn 1 - duplicate prtn 2 - sm shutdown	Partition deleted
6	port_virt_discover	• Port Guid • Top Index		Port virtualization discovered
7	vport_state_change	• Port Guid • VPort Guid • VPort Index • VNode Guid • VPort State	VPort State: 1 - Down 2 - Init 3 - ARMED 4 - Active	Vport state changed
8	mcg_tree_calc	mlid		MCast group tree calculated
9	routing_succeed	routing engine name		Routing done successfully
10	routing_failed	routing engine name		Routing failed
11	ucast_cache_invali-dated			ucast cache invalidated
12	ucast_cache_rout-ing_done			ucast cache routing done

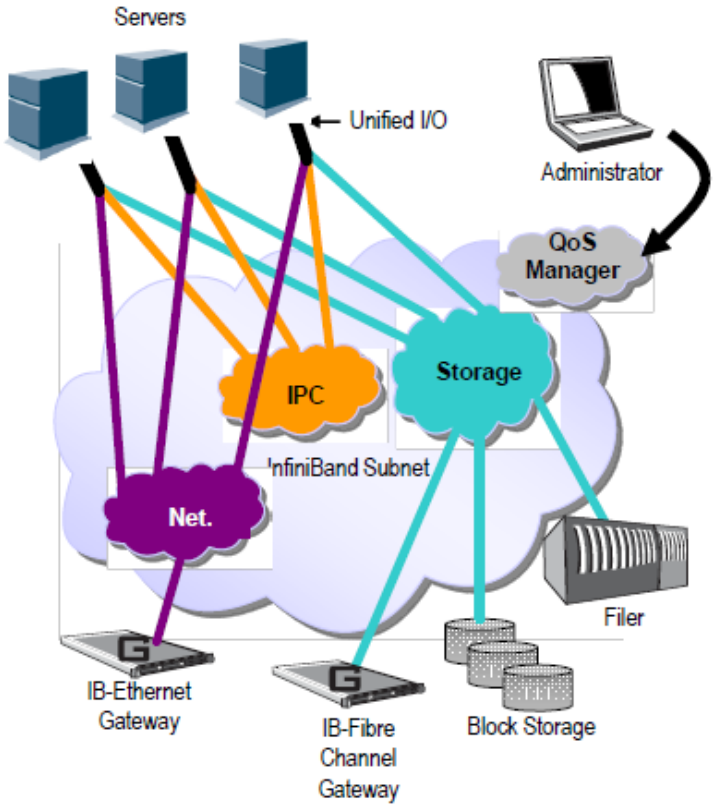
5.6.2.1.2.11 Offsweep Balancing

When working with minhop/dor/updn, subnet manager can re-balance routing during idle time (between sweeps).

- offsweep_balancing_enabled - enables/disables the feature. Examples:
  - offsweep_balancing_enabled = TRUE
  - offsweep_balancing_enabled = FALSE (default)
- offsweep_balancing_window - defines window of seconds to wait after sweep before starting the re-balance process. Applicable only if offsweep_balancing_enabled=TRUE. Example: offsweep_balancing_window = 180 (default)

5.6.2.1.3 InfiniBand QoS

Quality of service (QoS) requirements stem from the realization of I/O consolidation over an IB network. As multiple applications and ULPs share the same fabric, a means is needed to control their use of network resources.



The basic need is to differentiate the service levels provided to different traffic flows, such that a policy can be enforced and can control each flow utilization of fabric resources.

The InfiniBand Architecture Specification defines several hardware features and management interfaces for supporting QoS:

Up to 15 Virtual Lanes (VL) carry traffic in a non-blocking manner

- Arbitration between traffic of different VLs is performed by a two-priority-level weighted round robin arbiter. The arbiter is programmable with a sequence of (VL, weight) pairs and a maximal number of high priority credits to be processed before low priority is served
- Packets carry class of service marking in the range 0 to 15 in their header SL field
- Each switch can map the incoming packet by its SL to a particular output VL, based on a programmable table VL=SL-to-VL-MAP (in-port, out-port, SL)
- The Subnet Administrator controls the parameters of each communication flow by providing them as a response to Path Record (PR) or Multi-path Record (MPR) queries

DiffServ architecture (IETF RFC 2474 & 2475) is widely used in highly dynamic fabrics. The following subsections provide the functional definition of the various software elements that enable a DiffServ-like architecture over the NVIDIA OFED software stack.

5.6.2.1.3.1 QoS Architecture

QoS functionality is split between the SM/SA, CMA and the various ULPs. We take the "chronology approach" to describe how the overall system works.

1. The network manager (human) provides a set of rules (policy) that define how the network is being configured and how its resources are split to different QoS-Levels. The policy also define how to decide which QoS-Level each application or ULP or service use.
2. The SM analyzes the provided policy to see if it is realizable and performs the necessary fab- ric setup. Part of this policy defines the default QoS-Level of each partition. The SA is enhanced to match the requested Source, Destination, QoS-Class, Service-ID, PKey against the policy, so clients (ULPs, programs) can obtain a policy enforced QoS. The SM may also set up partitions with appropriate IPoIB broadcast group. This broadcast group carries its QoS attributes: SL, MTU, RATE, and Packet Lifetime.
3. IPoIB is being setup. IPoIB uses the SL, MTU, RATE and Packet Lifetime available on the multicast group which forms the broadcast group of this partition.
4. MPI which provides non IB based connection management should be configured to run using hard coded SLs. It uses these SLs for every QP being opened.
5. ULPs that use CM interface (like SRP) have their own pre-assigned Service-ID and use it while obtaining `PathRecord` / `MultiPathRecord` (PR/MPR) for establishing connections. The SA receiving the PR/MPR matches it against the policy and returns the appropriate PR/MPR including SL, MTU, RATE and Lifetime.
6. ULPs and programs (e.g. SDP) use CMA to establish RC connection provide the CMA the target IP and port number. ULPs might also provide QoS-Class. The CMA then creates Service-ID for the ULP and passes this ID and optional QoS-Class in the PR/MPR request. The resulting PR/MPR is used for configuring the connection QP.

`PathRecord` and Multi Path Record Enhancement for QoS:

As mentioned above, the `PathRecord` and `MultiPathRecord` attributes are enhanced to carry the Service-ID which is a 64bit value. A new field QoS-Class is also provided.

A new capability bit describes the SM QoS support in the SA class port info. This approach provides an easy migration path for existing access layer and ULPs by not introducing new set of PR/MPR attributes.

5.6.2.1.3.2 Supported Policy

The QoS policy, which is specified in a stand-alone file, is divided into the following four subsections:

Port Group

A set of CAs, Routers or Switches that share the same settings. A port group might be a partition defined by the partition manager policy, list of GUIDs, or list of port names based on `NodeDescription`.

Fabric Setup

Defines how the SL2VL and VLArb tables should be set up.

> ⚠ In OFED this part of the policy is ignored. SL2VL and VLArb tables should be configured in the OpenSM options file (opensm.opts).

QoS-Levels Definition

This section defines the possible sets of parameters for QoS that a client might be mapped to. Each set holds SL and optionally: Max MTU, Max Rate, Packet Lifetime and Path Bits.

> ⚠ Path Bits are not implemented in OFED.

Matching Rules

A list of rules that match an incoming PR/MPR request to a QoS-Level. The rules are processed in order such as the first match is applied. Each rule is built out of a set of match expressions which should all match for the rule to apply. The matching expressions are defined for the following fields:

- SRC and DST to lists of port groups
- Service-ID to a list of Service-ID values or ranges
- QoS-Class to a list of QoS-Class values or ranges

5.6.2.1.3.3 CMA Features

The CMA interface supports Service-ID through the notion of port space as a prefix to the port number, which is part of the sockaddr provided to `rdma_resolve_add()`. The CMA also allows the ULP (like SDP) to propagate a request for a specific QoS-Class. The CMA uses the provided QoS-Class and Service-ID in the sent PR/MPR.

IPoIB

IPoIB queries the SA for its broadcast group information and uses the SL, MTU, RATE and Packet Lifetime available on the multicast group which forms this broadcast group.

SRP

The current SRP implementation uses its own CM callbacks (not CMA). So SRP fills in the Service-ID in the PR/MPR by itself and use that information in setting up the QP.

SRP Service-ID is defined by the SRP target I/O Controller (it also complies with IBTA Service- ID rules). The Service-ID is reported by the I/O Controller in the

`ServiceEntries` DMA attribute and should be used in the PR/MPR if the SA reports its ability to handle QoS PR/MPRs.

5.6.2.1.4 IP Over InfiniBand

5.6.2.1.4.1 Upper Layer Protocol (ULP)

The IP over IB (IPoIB) ULP driver is a network interface implementation over InfiniBand. IPoIB encapsulates IP datagrams over an InfiniBand Datagram transport service. The IPoIB driver, ib_ipoib, exploits the following capabilities:

- VLAN simulation over an InfiniBand network via child interfaces
- High availability (HA) via Bonding
- Varies MTU values:
    - up to 4k in Datagram mode
- Uses any ConnectX® IB ports (one or two)
- Inserts IP/UDP/TCP checksum on outgoing packets
- Calculates checksum on received packets
- Support net device TSO through ConnectX® LSO capability to defragment large data- grams to MTU quantas.

IPoIB also supports the following software based enhancements:

- Giant Receive Offload
- NAPI
- Ethtool support

5.6.2.1.4.2 Enhanced IPoIB

Enhanced IPoIB feature enables offloading ULP basic capabilities to a lower vendor specific driver, in order to optimize IPoIB data path. This will allow IPoIB to support multiple stateless offloads, such as RSS/TSS, and better utilize the features supported, enabling IPoIB datagram to reach peak performance in both bandwidth and latency.

Enhanced IPoIB supports/performs the following:

- Stateless offloads (RSS, TSS)
- Multi queues
- Interrupt moderation
- Multi partitions optimizations
- Sharing send/receive Work Queues
- Vendor specific optimizations
- UD mode only

5.6.2.1.4.3 Port Configuration

The physical port MTU (indicates the port capability) default value is 4k, whereas the IPoIB port MTU ("logical" MTU) default value is 2k as it is set by the OpenSM.
To change the IPoIB MTU to 4k, edit the OpenSM partition file in the section of IPoIB setting as follow:

```
Default=0xffff, ipoib, mtu=5 : ALL=full;
```

Where:

- `mtu=5` indicates that all IPoIB ports in the fabric are using 4k MTU, (`mtu=4` indicates 2k MTU)

5.6.2.1.4.4 IPoIB Configuration

Unless you have run the installation script mlnxofedinstall with the flag '-n', then IPoIB has not been configured by the installation. The configuration of IPoIB requires assigning an IP address and a subnet mask to each HCA port, like any other network adapter card (i.e., you need to prepare a file called ifcfg-ib<n> for each port). The first port on the first HCA in the host is called interface ib0, the second port is called ib1, and so on.

IPoIB configuration can be based on DHCP or on a static configuration that you need to supply (see below). You can also apply a manual configuration that persists only until the next reboot or driver restart (see below).

IPoIB Configuration Based on DHCP

Setting an IPoIB interface configuration based on DHCP is performed similarly to the configuration of Ethernet interfaces. In other words, you need to make sure that IPoIB configuration files include the following line:

- For RedHat:

  ```
  BOOTPROTO=dhcp
  ```

- For SLES:

  ```
  BOOTPROTO='dchp'
  ```

  ⚠ If IPoIB configuration files are included, `ifcfg-ib<n>` files will be installed under:
  - `/etc/sysconfig/network-scripts/` on a RedHat machine
  - `/etc/sysconfig/network/` on a SuSE machine.

> ⚠ A patch for DHCP may be required for supporting IPoIB. For further information, please see the REAME file available under the `docs/dhcp/` directory.

> ⚠ Red Hat Enterprise Linux 7 supports assigning static IP addresses to InfiniBand IPoIB interfaces. However, as these interfaces do not have a normal hardware Ethernet address, a different method of specifying a unique identifier for the IPoIB interface must be used. The standard is to use the option dhcp-client-identifier= construct to specify the IPoIB interface's dhcp-client-identifier field. The DHCP server host construct supports at most one hardware Ethernet and one dhcp-client-identifier entry per host stanza. However, there may be more than one fixed-address entry and the DHCP server will automatically respond with an address that is appropriate for the network that the DHCP request was received on.

Standard DHCP fields holding MAC addresses are not large enough to contain an IPoIB hardware address. To overcome this problem, DHCP over InfiniBand messages convey a client identifier field used to identify the DHCP session. This client identifier field can be used to associate an IP address with a client identifier value, such that the DHCP server will grant the same IP address to any client that conveys this client identifier.

The length of the client identifier field is not fixed in the specification. For the *NVIDIA OFED for Linux* package, it is recommended to have IPoIB use the same format that FlexBoot uses for this client identifier.

DHCP Server

In order for the DHCP server to provide configuration records for clients, an appropriate configuration file needs to be created. By default, the DHCP server looks for a configuration file called `dhcpd.conf` under `/etc`. You can either edit this file or create a new one and provide its full path to the DHCP server using the -cf flag (See a file example at docs/dhcpd.conf).
The DHCP server must run on a machine which has loaded the IPoIB module. To run the DHCP server from the command line, enter:

```
dhcpd <IB network interface name> -d
```

Example:

```
host1# dhcpd ib0 -d
```

DHCP Client (Optional)

⚠ A DHCP client can be used if you need to prepare a diskless machine with an IB driver.

In order to use a DHCP client identifier, you need to first create a configuration file that defines the DHCP client identifier.

Then run the DHCP client with this file using the following command:

```
dhclient -cf <client conf file> <IB network interface name>
```

Example of a configuration file for the ConnectX (PCI Device ID 26428), called `dhclient.conf`:

```
The value indicates a hexadecimal number interface "ib1" {
send dhcp-client-identifier
ff:00:00:00:00:02:00:00:02:c9:00:00:02:c9:03:00:00:10:39;
}
```

Example of a configuration file for InfiniHost III Ex (PCI Device ID 25218), called `dhclient.conf`:

```
The value indicates a hexadecimal number interface "ib1" {
send dhcp-client-identifier
20:00:55:04:01:fe:80:00:00:00:00:00:00:02:c9:02:00:23:13:92;
}
```

➤ To use the configuration file, run:

```
host1# dhclient -cf dhclient.conf ib1
```

Static IPoIB Configuration

If you wish to use an IPoIB configuration that is not based on DHCP, you need to supply the installation script with a configuration file (using the '-n' option) containing the full IP configuration. The IPoIB configuration file can specify either or both of the following data for an IPoIB interface:

- A static IPoIB configuration
- An IPoIB configuration based on an Ethernet configuration
  See your Linux distribution documentation for additional information about configuring IP addresses.

The following code lines are an excerpt from a sample IPoIB configuration file:

```
# Static settings; all values provided by this file
IPADDR_ib0=10.4.3.175
NETMASK_ib0=255.255.0.0
NETWORK_ib0=10.4.0.0
BROADCAST_ib0=10.4.255.255
ONBOOT_ib0=1
# Based on eth0; each '*' will be replaced with a corresponding octet
# from eth0.
LAN_INTERFACE_ib0=eth0
IPADDR_ib0=10.4.'*'.'*'
NETMASK_ib0=255.255.0.0
NETWORK_ib0=10.4.0.0
```

```
BROADCAST_ib0=10.4.255.255
ONBOOT_ib0=1
# Based on the first eth<n> interface that is found (for n=0,1,...);
# each '*' will be replaced with a corresponding octet from eth<n>.
LAN_INTERFACE_ib0=
IPADDR_ib0=10.4.'*'.'*'
NETMASK_ib0=255.255.0.0
NETWORK_ib0=10.4.0.0
BROADCAST_ib0=10.4.255.255
ONBOOT_ib0=1
```

Manually Configuring IPoIB

> ⚠ This manual configuration persists only until the next reboot or driver restart.

To manually configure IPoIB for the default IB partition (VLAN), perform the following steps:

1. Configure the interface by entering the ifconfig command with the following items:
   - The appropriate IB interface (ib0, ib1, etc.)
   - The IP address that you want to assign to the interface
   - The netmask keyword
   - The subnet mask that you want to assign to the interface

   The following example shows how to configure an IB interface:

   ```
   host1$ ifconfig ib0 10.4.3.175 netmask 255.255.0.0
   ```

2. (Optional) Verify the configuration by entering the ifconfig command with the appropriate interface identifier `ib#` argument.

   The following example shows how to verify the configuration:

   ```
   host1$ ifconfig ib0
   b0  Link encap:UNSPEC  HWaddr 80-00-04-04-FE-80-00-00-00-00-00-00-00-00-00-00
   inet addr:10.4.3.175  Bcast:10.4.255.255  Mask:255.255.0.0
   UP BROADCAST MULTICAST  MTU:65520  Metric:1
   RX packets:0 errors:0 dropped:0 overruns:0 frame:0
   TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
   collisions:0 txqueuelen:128
   RX bytes:0 (0.0 b)  TX bytes:0 (0.0 b)
   ```

3. Repeat the first two steps on the remaining interface(s).

5.6.2.1.4.5 Sub-interfaces

You can create sub-interfaces for a primary IPoIB interface to provide traffic isolation. Each such sub-interface (also called a child interface) has a different IP and network addresses from the primary (parent) interface. The default Partition Key (PKey), ff:ff, applies to the primary (parent) interface.
This section describes how to:

- Create a subinterface
- Remove a subinterface

Creating a Subinterface

In the following procedure, ib0 is used as an example of an IB sub-interface.

➢ To create a child interface (sub-interface), follow this procedure:

1. Decide on the PKey to be used in the subnet (valid values can be 0 or any 16-bit unsigned value). The actual PKey used is a 16-bit number with the most significant bit set. For example, a value of 1 will give a PKey with the value 0x8001.
2. Create a child interface by running:

   ```
   host1$ echo <PKey> > /sys/class/net/<IB subinterface>/create_child
   ```

   Example:

   ```
   host1$ echo 1 > /sys/class/net/ib0/create_child
   ```

   This will create the interface ib0.8001.
3. Verify the configuration of this interface by running:

   ```
   host1$ ifconfig <subinterface>.<subinterface PKey>
   ```

   Using the example of the previous step:

   ```
   host1$ ifconfig ib0.8001
   ib0.8001  Link encap:UNSPEC  HWaddr 80-00-00-4A-FE-80-00-00-00-00-00-00-00-00-00-00
   BROADCAST MULTICAST  MTU:2044  Metric:1
   RX packets:0 errors:0 dropped:0 overruns:0 frame:0
   TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
   collisions:0 txqueuelen:128
   RX bytes:0 (0.0 b)  TX bytes:0 (0.0 b)
   ```
4. As can be seen, the interface does not have IP or network addresses. To configure those, you should follow the manual configuration procedure described in "Manually Configuring IPoIB" section above.
5. To be able to use this interface, a configuration of the Subnet Manager is needed so that the PKey chosen, which defines a broadcast address, be recognized.

Removing a Subinterface

➢ To remove a child interface (subinterface), run:

```
echo <subinterface PKey> /sys/class/net/<ib_interface>/delete_child
```

Using the example of the second step from the previous chapter:

```
echo 0x8001 > /sys/class/net/ib0/delete_child
```

Note that when deleting the interface you must use the PKey value with the most significant bit set (e.g., 0x8000 in the example above).

5.6.2.1.4.6 Verifying IPoIB Functionality

➢ To verify your configuration and IPoIB functionality are successful, perform the following steps:

1. Verify the IPoIB functionality by using the `ifconfig` command.
   The following example shows how two IB nodes are used to verify IPoIB functionality. In the following example, IB node 1 is at 10.4.3.175, and IB node 2 is at 10.4.3.176:

```
host1# ifconfig ib0 10.4.3.175 netmask 255.255.0.0
host2# ifconfig ib0 10.4.3.176 netmask 255.255.0.0
```

2. Enter the ping command from 10.4.3.175 to 10.4.3.176.
3. The following example shows how to enter the ping command:

```
host1# ping -c 5 10.4.3.176
PING 10.4.3.176 (10.4.3.176) 56(84) bytes of data.
64 bytes from 10.4.3.176: icmp_seq=0 ttl=64 time=0.079 ms
64 bytes from 10.4.3.176: icmp_seq=1 ttl=64 time=0.044 ms
64 bytes from 10.4.3.176: icmp_seq=2 ttl=64 time=0.055 ms
64 bytes from 10.4.3.176: icmp_seq=3 ttl=64 time=0.049 ms
64 bytes from 10.4.3.176: icmp_seq=4 ttl=64 time=0.065 ms
--- 10.4.3.176 ping statistics ---
5 packets transmitted, 5 received, 0% packet loss, time 3999ms rtt min/avg/max/mdev = 0.044/0.058/0.079/
0.014 ms, pipe 2
```

5.6.2.1.4.7 Bonding IPoIB

To create an interface configuration script for the ibX and bondX interfaces, you should use the standard syntax (depending on your OS).

Bonding of IPoIB interfaces is accomplished in the same manner as would bonding of Ethernet interfaces: via the Linux Bonding Driver.

- Network Script files for IPoIB slaves are named after the IPoIB interfaces (e.g: ifcfg- ib0)
- The only meaningful bonding policy in IPoIB is HA (bonding mode number 1, or active-backup)
- Bonding parameter "fail_over_mac" is meaningless in IPoIB interfaces, hence, the only supported value is the default: 0

For a persistent bonding IPoIB Network configuration, use the same Linux Network Scripts semantics, with the following exceptions/ additions:

- In the bonding master configuration file (e.g: ifcfg-bond0), in addition to Linux bonding semantics, use the following parameter: MTU=65520

  > ⚠ For IPoIB slaves, use MTU=2044. If you do not set the correct MTU or do not set MTU at all, performance of the interface might decrease.

- In the bonding slave configuration file (e.g: ifcfg-ib0), use the same Linux Network Scripts semantics. In particular: DEVICE=ib0
- In the bonding slave configuration file (e.g: ifcfg-ib0.8003), the line TYPE=InfiniBand is necessary when using bonding over devices configured with partitions (`p_key`)
- For RHEL, add the following lines in `/etc/modprobe.b/bond.conf` :

```
alias bond0 bonding
```

- For SLES users:
  It is necessary to update the `MANDATORY_DEVICES` environment variable in `/etc/sysconfig/network/config` with the names of the IPoIB slave devices (e.g. ib0, ib1, etc.). Otherwise, bonding master may be created before IPoIB slave interfaces at boot time.
  It is possible to have multiple IPoIB bonding masters and a mix of IPoIB bonding master and Ethernet bonding master. However, It is NOT possible to mix Ethernet and IPoIB slaves under the same bonding master.

⚠ Restarting openibd does no keep the bonding configuration via Network Scripts. You have to restart the network service in order to bring up the bonding master. After the configuration is saved, restart the network service by running: /etc/init.d/network restart.

5.6.2.1.4.8 Dynamic PKey Change

Dynamic PKey change means the PKey can be changed (add/removed) in the SM database and the interface that is attached to that PKey is updated immediately without the need to restart the driver.
If the PKey is already configured in the port by the SM, the child-interface can be used immediately. If not, the interface will be ready to use only when SM adds the relevant PKey value to the port after the creation of the child interface. No additional configuration is required once the child-interface is created.

5.6.2.1.4.9 Precision Time Protocol (PTP) over IPoIB

This feature allows for accurate synchronization between the distributed entities over the network. The synchronization is based on symmetric Round Trip Time (RTT) between the master and slave devices.

This feature is enabled by default, and is also supported over PKey interfaces.

For more on the PTP feature, refer to Running Linux PTP with ConnectX-4/ConnectX-5/ConnectX-6 Community post.

5.6.2.1.4.10 One Pulse Per Second (1PPS) over IPoIB

1PPS is a time synchronization feature that allows the adapter to be able to send or receive 1 pulse per second on a dedicated pin on the adapter card using an SMA connector (SubMiniature version A). Only one pin is supported and could be configured as 1PPS in or 1PPS out.

5.6.2.1.5 Advanced Transport

5.6.2.1.5.1 Atomic Operations in mlx5 Driver

The mlx5 driver supports atomic operations; however, due to potential endianness mismatches between requester and responder systems, specific configuration is required to ensure correct behavior.

To enable atomic operations in environments where such an endianness contradiction may exist, the application must explicitly configure the Queue Pair (QP) during creation.

Use the `ibv_create_qp()` function and set the following flag in the `create_flags` field:

```
IBV_QP_CREATE_ATOMIC_BE_REPLY
```

This flag ensures that the QP is configured to handle big-endian formatted atomic replies, allowing atomic operations to complete correctly across systems with differing byte orders.

5.6.2.1.5.2 XRC - eXtended Reliable Connected Transport Service for InfiniBand

XRC (eXtended Reliable Connected transport) is an InfiniBand transport type designed to improve scalability in large-scale deployments by reducing the number of required QPs and associated memory resources. It enables more efficient *all-to-all* process connectivity, particularly in environments with many multicore end-nodes.

By decoupling the send and receive sides of a QP, XRC significantly reduces memory usage and improves resource management, making it ideal for large clusters.

For detailed technical background, refer to "Annex A14 Supplement to InfiniBand Architecture Specification Volume 1.2.1".

API Usage

A new set of verbs APIs has been introduced to support XRC in user-space applications. While the legacy XRC API is still supported in both binary and source form, it is deprecated. Developers are strongly encouraged to use the new API.

Key Verbs for XRC:

- `ibv_open_xrcd()` / `ibv_close_xrcd()` – Open and close XRC domain objects
- `ibv_create_srq_ex()` – Create an SRQ with extended attributes
- `ibv_get_srq_num()` – Retrieve SRQ number
- `ibv_create_qp_ex()` – Create a QP with extended attributes (including XRC target/source)
- `ibv_open_qp()` – Open an existing QP from a remote XRC domain

For basic testing and example usage of the XRC transport, refer to the `ibv_xsrq_pingpong` utility. It provides a working reference for integrating XRC into user applications.

For complete documentation of each API function and its options, consult the corresponding man pages.

5.6.2.1.5.3 Dynamically Connected Transport

Dynamically Connected Transport (DCT) is an advanced RDMA transport service designed to improve scalability and efficiency in environments with sparse or dynamic communication patterns. It allows Reliable Connection (RC)-type QPs to dynamically connect and disconnect from remote nodes as needed, rather than maintaining persistent connections.

This on-demand connection model reduces system-wide resource usage and enhances performance by:

- Minimizing the total number of QPs required.
- Lowering the memory footprint.
- Reducing connection setup overhead.
- Improving on-chip cache utilization.

As a result, DCT is particularly beneficial for large-scale or highly dynamic deployments where traditional RC QP scaling becomes a bottleneck.

⚠ DCT is supported only by the mlx5 driver.

⚠
- NVIDIA® ConnectX®-4 devices support DCT v0.
- NVIDIA® ConnectX®-5 and later devices support DCT v1.

DCT v0 and DCT v1 are not interoperable. Ensure all participating nodes are using the same DCT version to maintain compatibility.

5.6.2.1.5.4 MPI Tag Matching and Rendezvous Offloads

⚠ Supported in NVIDIA® ConnectX®-5 and above adapter cards.

MPI Tag Matching and Rendezvous Offloads is a technology developed by NVIDIA to offload the processing of MPI (Message Passing Interface) communications from the host CPU to the network adapter. This offload mechanism is designed to optimize message matching and reduce memory overhead in high-performance computing environments.

By leveraging this feature:

- MPI messages are delivered directly to the user's buffer with zero-copy semantics, eliminating the need for intermediate memory copies.
- Rendezvous protocol progress is handled entirely by the network adapter, without host CPU intervention.
- The CPU is freed to continue executing application-level computation while the adapter concurrently manages data transfers.

This offload model significantly improves performance and scalability for MPI-based applications by overlapping computation with communication and reducing CPU load.

For more information, refer to the community post Understanding MPI Tag Matching and Rendezvous Offloads (ConnectX-5).

5.6.2.1.6 Optimized Memory Access

5.6.2.1.6.1 Memory Region Re-registration

Memory region re-registration allows the user to change attributes of the memory region. The user may change the PD, access flags or the address and length of the memory region. Memory region supports contagious pages allocation. Consequently, it de-registers memory region followed by register memory region. Where possible, resources are reused instead of de-allocated and reallocated.

Example:

```
int ibv_rereg_mr(struct ibv_mr *mr, int flags, struct ibv_pd *pd, void *addr, size_t length, uint64_t access,
struct ibv_rereg_mr_attr *attr);
```

@mr:	The memory region to modify.
@flags:	A bit-mask used to indicate which of the following properties of the memory region are being modified. Flags should be one of: `IBV_REREG_MR_CHANGE_TRANSLATION` /* Change translation (location and length) */ `IBV_REREG_MR_CHANGE_PD` /* Change protection domain*/ `IBV_REREG_MR_CHANGE_ACCESS` /* Change access flags*/
@pd:	If `IBV_REREG_MR_CHANGE_PD` is set in flags, this field specifies the new protection domain to associated with the memory region, otherwise, this parameter is ignored.
@addr:	If `IBV_REREG_MR_CHANGE_TRANSLATION` is set in flags, this field specifies the start of the virtual address to use in the new translation, otherwise, this parameter is ignored.
@length:	If `IBV_REREG_MR_CHANGE_TRANSLATION` is set in flags, this field specifies the length of the virtual address to use in the new translation, otherwise, this parameter is ignored.

@access:	If `IBV_REREG_MR_CHANGE_ACCESS` is set in flags, this field specifies the new memory access rights, otherwise, this parameter is ignored. Could be one of the following:
	`IBV_ACCESS_LOCAL_WRITE`
	`IBV_ACCESS_REMOTE_WRITE`
	`IBV_ACCESS_REMOTE_READ`
	`IBV_ACCESS_ALLOCATE_MR` /* Let the library allocate the memory for the user, tries to get contiguous pages */

@attr:	Future extensions

`ibv_rereg_mr` returns 0 on success, or the value of an errno on failure (which indicates the error reason). In case of an error, the MR is in undefined state. The user needs to call `ibv_dereg_mr` in order to release it.

Please note that if the MR (Memory Region) is created as a Shared MR and a translation is requested, after the call, the MR is no longer a shared MR. Moreover, Re-registration of MRs that uses NVIDIA PeerDirect™ technology are not supported.

5.6.2.1.6.2 Memory Window

Memory Window allows the application to have a more flexible control over remote access to its memory. It is available only on physical functions/native machines The two types of Memory Windows supported are: type 1 and type 2B.
Memory Windows are intended for situations where the application wants to:

- Grant and revoke remote access rights to a registered region in a dynamic fashion with less of a performance penalty
- Grant different remote access rights to different remote agents and/or grant those rights over different ranges within registered region

For further information, please refer to the InfiniBand specification document.

Memory Windows API cannot co-work with peer memory clients (PeerDirect).

Query Capabilities

Memory Windows are available if and only the hardware supports it. To verify whether Memory Windows are available, run `ibv_query_device`.

For example:

```
struct ibv_device_attr device_attr = {.comp_mask = IBV_DEVICE_ATTR_RESERVED - 1};
ibv_query_device(context, & device_attr);
if (device_attr.exp_device_cap_flags & IBV_DEVICE_MEM_WINDOW ||
                  device_attr.exp_device_cap_flags & IBV_DEVICE_MW_TYPE_2B) {
/* Memory window is supported */
```

Memory Window Allocation

Allocating memory window is done by calling the `ibv_alloc_mw` verb.

```
type_mw = IBV_MW_TYPE_2/ IBV_MW_TYPE_1
mw = ibv_alloc_mw(pd, type_mw);
```

Binding Memory Windows

After being allocated, memory window should be bound to a registered memory region. Memory Region should have been registered using the IBV_ACCESS_MW_BIND access flag.

For further information on how to bind memory windows, please see rdma-core man page.

Invalidating Memory Window

Before rebinding Memory Window type 2, it must be invalidated using `ibv_post_send`; see here.

Deallocating Memory Window

Deallocating memory window is done using the ibv_dealloc_mw verb.

```
ibv_dealloc_mw(mw);
```

5.6.2.1.6.3 User-Mode Memory Registration (UMR)

User-mode Memory Registration (UMR) is a fast registration mode which uses send queue. The UMR support enables the usage of RDMA operations and scatters the data at the remote side through the definition of appropriate memory keys on the remote side.
UMR enables the user to:

- Create indirect memory keys from previously registered memory regions, including creation of KLM's from previous KLM's. There are not data alignment or length restrictions associated with the memory regions used to define the new KLM's.
- Create memory regions, which support the definition of regular non-contiguous memory regions.

5.6.2.1.6.4 On-Demand-Paging (ODP)

On-Demand-Paging (ODP) is a technique to alleviate much of the shortcomings of memory registration. Applications no longer need to pin down the underlying physical pages of the address space, and track the validity of the mappings. Rather, the HCA requests the latest translations from the OS when pages are not present, and the OS invalidates translations which are no longer valid due to either non-present pages or mapping changes. ODP does not support contiguous pages.
ODP can be further divided into 2 subclasses: Explicit and Implicit ODP.

- Explicit ODP
  In Explicit ODP, applications still register memory buffers for communication, but this operation is used to define access control for IO rather than pin-down the

pages. ODP Memory Region (MR) does not need to have valid mappings at registration time.

- Implicit ODP
  In Implicit ODP, applications are provided with a special memory key that represents their complete address space. This all IO accesses referencing this key (subject to the access rights associated with the key) does not need to register any virtual address range.

Query Capabilities

On-Demand Paging is available if both the hardware and the kernel support it. To verify whether ODP is supported, run `ibv_query_device`.

For further information, please refer to the `ibv_query_device` manual page.

Registering ODP Explicit and Implicit MR

ODP Explicit MR is registered after allocating the necessary resources (e.g. PD, buffer), while ODP implicit MR registration provides an implicit lkey that represents the complete address space.

For further information, please refer to the `ibv_reg_mr` manual page.

De-registering ODP MR

ODP MR is deregistered the same way a regular MR is deregistered:

```
ibv_dereg_mr(mr);
```

Advice MR Verb

The driver can pre-fetch a given range of pages and map them for access from the HCA. The advice MR verb is applicable for ODP MRs only.
For further information, please refer to the `ibv_advise_mr` manual page.

ODP Statistics

To aid in debugging and performance measurements and tuning, ODP support includes an extensive set of statistics.

For further information, please refer to rdma-statistics manual page.

5.6.2.1.6.5 Inline-Receive

The HCA may write received data to the Receive CQE. Inline-Receive saves PCIe Read transaction since the HCA does not need to read the scatter list. Therefore, it improves performance in case of short receive-messages.

On poll CQ, the driver copies the received data from CQE to the user's buffers.

Inline-Receive is enabled by default and is transparent to the user application. To disable it globally, set `MLX5_SCATTER_TO_CQE` environment variable to the value of 0. Otherwise, disable it on a specific QP using `mlx5dv_create_qp()` with `MLX5DV_QP_CREATE_DISABLE_SCATTER_TO_CQE`.

For further information, please refer to the manual page of `mlx5dv_create_qp()`.

5.6.2.1.7 NVIDIA PeerDirect

NVIDIA PeerDirect™ enables direct memory access between InfiniBand (IB) Core and peer memory clients (e.g., GPU cards) through a dedicated API. This allows RDMA-based applications (over InfiniBand or RoCE) to leverage the computing power of peer devices and the RDMA interconnect simultaneously—without copying data between peer-to-peer (P2P) devices.

A common use case is GPUDirect RDMA, which utilizes PeerDirect for efficient GPU communication.

For a detailed description of the API, refer to `docs/readme_and_user_manual/PEER_MEMORY_API.txt` in the MLNX_OFED installation package.

5.6.2.1.7.1 PeerDirect Async

The PeerDirect Async subsystem allows hardware peer devices (such as GPUs or dedicated accelerator cards) to control the HCA (Host Channel Adapter) directly for critical-path operations, reducing CPU involvement. This is achieved through a set of verb calls and data structures that provide the application with an abstract representation of operation sequences meant to be executed by the peer device.

5.6.2.1.7.2 Relaxed Ordering (RSYNC)

This feature is only supported on ConnectX-5 adapter cards and above.

In GPU systems that utilize relaxed memory ordering, an RSYNC callback is used to ensure memory consistency. This callback is registered and implemented via an external module provided by the system vendor. Once the module is loaded, it registers the callback with MLNX_OFED, which will then use it to maintain proper memory operation ordering.

5.6.2.1.8 CPU Overhead Distribution

When creating a Completion Queue (CQ) using the `ibv_create_cq()` API, the `comp_vector` argument determines the assignment of the CQ to an Event Queue (EQ).

If `comp_vector` is set to `0` and the CPU core executing the verb is not core 0, the driver automatically assigns the CQ to the completion EQ with the fewest CQs currently reporting to it. This strategy helps balance CPU overhead by distributing CQs across available completion EQs.

To explicitly assign a CQ to a specific EQ, set the desired EQ index in the `comp_vector` argument.

5.6.2.1.9 Out-of-order Data Placement

⚠ This feature is only supported on:

- NVIDIA® ConnectX®-5 adapters and above
- RC and XRC QPs
- DC transport
