Component	Minimum Version
Ubuntu OS	24.04
DOCA BFB Bundle	3.2.0+
DOCA Networking	3.2.0+
Firmware	32.47.1000+

Firmware is included in the BFB bundle available on the NVIDIA DevZone. Use `bfb-install` to install the bundle. For example:

Example of BFB installation

```
bfb-install --bfb bf-bundle-x.x.x-x_x.x_ubuntu-24.04_prod.bfb --rshim rshim0
```

SuperNIC:

Component	Minimum Version
Ubuntu OS	24.04
DOCA Networking	3.2.0+
Firmware	82.47.0000+

Firmware can be found on the NVIDIA DevZone.

Helpful resources:

- DOCA Installation Guide for Linux
- Set Up DPU Management Access and Update BlueField-Bundle

8.10.6.2.4 Firmware Settings

The following firmware configuration is required and applied by the `dpl_system_setup.sh` script documented at DPL Container Deployment:

```
FLEX_PARSER_PROFILE_ENABLE=4
PROG_PARSE_GRAPH=true
SRIOV_EN=1  # Required only if using VFs
```

To enable multi-port eSwitch mode, also set:

```
LAG_RESOURCE_ALLOCATION=1
```

8.10.6.3 Supported Port Forwarding

The following table lists the possible ingress and egress ports for a given packet that is processed by a BlueField pipeline (DPU mode) / SuperNIC pipeline:

Ingress Port	Egress Port			
	Wire Port P0	`pf0hpf`	`pf0vf_n`	`pf0vf_m`
Wire port P0	Allowed	Allowed	Allowed	Allowed
`pf0hpf`	Allowed	Disabled	Allowed	Allowed
`pf0vf_n`	Allowed	Allowed	Disabled	Allowed
`pf0vf_m`	Allowed	Allowed	Allowed	Disabled

All forwarding combinations supported for SR-IOV VFs are also supported for scalable functions (SFs).

8.10.6.4 Deploying the DPL Runtime Service

8.10.6.4.1 Prerequisites

- BlueField must be in DPU Mode.
- SR-IOV or SFs must be enabled and created on the host.
- DOCA must be installed on the host and BlueField.
- Ensure `doca-rt-service` configuration files are available. Refer to DPL Service Configuration for details.

8.10.6.4.2 Installation

Refer to the DPL Container Deployment for detailed steps on deploying the DPL Runtime Service container.

8.10.6.5 DPL Dev Container

The `dpl-dev` container provides essential developer tools for compiling, loading, and debugging DPL programs, including:

- DPL Compiler
- Nspect CLI
- Admin CLI
- DPL Debugger
- Runtime Controller SDK

> Refer to the DPL Installation Guide for installation instructions.

8.10.6.6 Proceeding with DPL

Once the `dpl-rt-service` is running and the `dpl-dev` container is installed, you can:

1. Compile your DPL programs. Refer to Compiling DPL Applications.
2. Load the compiled program into the runtime. Refer to Loading DPL Applications.
3. (Optional) Use DOCA Pipeline Language Developer Tools for debugging and verification.

8.10.6.7 Implementing Your Own P4Runtime Controller

Advanced users may implement their own controller to communicate with the DPL Runtime via P4Runtime 1.3.0 over gRPC (TCP port `9559`).

Resources:

- Protobuf definitions available at `p4lang/p4runtime` GitHub
- Local Path (container): `/opt/mellanox/third_party/dpl_rt_service/p4runtime/`
- Toolchain: Use standard `gRPC` + `protobuf` toolchains (e.g., IN C++)

8.10.6.8 DPL Container Deployment

8.10.6.8.1 Introduction

The DPL Runtime Service supports Bluefield devices (DPU mode) and ConnectX-9 (Host mode).

> ⚠ There are few differences when preparing the system for running the DPL Runtime Service on DPU mode (BlueField) vs Host mode (ConnectX-9), these differences are outlined in the sections below where applicable.

8.10.6.8.2 BlueField Preparations

This section is specific to DPU mode when running on BlueField devices.

8.10.6.8.2.1 Setting BlueField to DPU Mode

BlueField must run in DPU mode to use the DPL Runtime Service. For details on how to change modes, see: BlueField Modes of Operation.

8.10.6.8.2.2 Determining Your BlueField Variant

Your BlueField may be installed in a host server or it may be a standalone server.

If your BlueField is a standalone server, ignore the parts that mention the host server or SR-IOV. You may still use Scalable Functions (SFs) if your BlueField is a standalone server.

8.10.6.8.2.3 Setting Up DPU Management Access and Updating BlueField-Bundle

These pages provide detailed information about DPU management access, software installation, and updates:

- Host-side Interface Configuration
- BF-Bundle Installation and Upgrade
- NVIDIA DOCA Downloads

> ⚠ Systems with a host server typically use RShim (i.e., the `tmfifo_net0` interface). Standalone systems must use the OOB interface option for management access.

8.10.6.8.3 Device Configuration

8.10.6.8.3.1 Changing the eSwitch to switchdev mode

> Do this before creating SR-IOV Virtual functions. In case Virtual Functions already exist for the interface, remove them before trying to change the mode.

The DPL Runtime Service can only start if the eSwitch is in switchdev mode. If it's not, an error will be logged on startup and the process will exit.

If the platform is Bluefield in DPU mode, run this command in the DPU shell, otherwise, (e.g. ConnectX-9), use the host shell.
Your Bluefield DPU may be pre-configured in switchdev mode after the bfb installation. If this is the case, this step may be unnecessary.

Find the PCI address of the interface that you'd like to use with the DPL Runtime Service and use the following command (replace the pci/<addr> part with correct values)

Example

```
sudo devlink dev eswitch set pci/0000:03:00.0 mode switchdev
```

Here are a few options for commands that may help you find your PCI address:

- `lspci -D`
- `mst status -v`
- `ip -d link`
- `ethtool -i <interface name>`

> `devlink` settings are not persistent across reboots.

8.10.6.8.3.2 Enabling Multiport eSwitch Mode (Optional)

> This step is optional and depends on your DPL program and setup needs.

Multiport eSwitch mode allows for traffic forwarding between multiple physical ports and their VFs/SFs (e.g., between `p0` and `p1`).

Before enabling this mode:

1. Ensure `LAG_RESOURCE_ALLOCATION` is enabled in firmware:

Example

```
sudo mlxconfig -d 0000:03:00.0 s LAG_RESOURCE_ALLOCATION=1
```

Refer to the Using mlxconfig guide for more information.

2. After reboot or firmware reset, enable `esw_multiport` mode:

Example

```
sudo devlink dev param set pci/0000:03:00.0 name esw_multiport value 1 cmode runtime
```

`devlink` settings are not persistent across reboots.

8.10.6.8.3.3 Creating SR-IOV Virtual Functions

To use SR-IOV, first create Virtual Functions (VFs) on the host server:

Example

```
sudo -s  # enter sudo shell
echo 4 > /sys/class/net/eth2/device/sriov_numvfs
exit     # exit sudo shell
```

Entering a sudo shell is necessary because `sudo` only applies to the `echo` command, and not the redirection (`>`), which would otherwise result in "Permission denied."

This example creates 4 VFs under Physical Function `eth2` . Adjust the number as needed.

If a PF already has VFs and you'd like to change the number, first set it to `0` before applying the new value.

8.10.6.8.3.4 Creating Scalable Functions (Optional)

This step is optional and depends on your DPL program and setup needs.

For more information, see the BlueField Scalable Function User Guide, TODO: CX9.

If you create SFs, refer to their representors in the configuration file.

8.10.6.8.4 Installing the DPL Runtime Service

8.10.6.8.4.1 Downloading Container Resources from NGC

Start by downloading and installing the ngc-cli tools.
For example:

- For DPU mode, download the ARM ngc-cli tool:

  Example

  ```
  wget --content-disposition https://api.ngc.nvidia.com/v2/resources/nvidia/ngc-apps/ngc_cli/versions/4.5.2/files/ngccli_arm64.zip -O ngccli_arm64.zip
  unzip ngccli_arm64.zip
  ```

- For Host mode, download the appropriate ngc-cli tool for your system architecture:

  Example for x86_64

  ```
  wget --content-disposition https://api.ngc.nvidia.com/v2/resources/nvidia/ngc-apps/ngc_cli/versions/4.5.2/files/ngccli_linux.zip -O ngccli_linux.zip
  unzip ngccli_linux.zip
  ```

Once the ngc-cli tool has been downloaded, use it to download the latest dpl_rt_service resources:

```
./ngc-cli/ngc registry resource download-version "nvidia/doca/dpl_rt_service"
```

This creates a directory in the format `dpl_rt_service_v**a.b.c**-doca**x.y.z**`. Where `a.b.c` is the DPL Runtime Service version number, and `x.y.z` is the DOCA version number.
For example: `dpl_rt_service_v1.2.0-doca3.1.0`.

> You can find available versions at NGC Catalog.

> Each release includes a `kubelet.d` YAML file that is used by the `dpl_rt_service_ctl.sh` script for retrieving the correct container image for either DPU or Host mode.

8.10.6.8.4.2 Running the Preparation Script

Run the `dpl_system_setup.sh` script to configure the system:

- For DPU mode:

```
cd dpl_rt_service_va.b.c-docax.y.z
chmod +x ./scripts/dpl_system_setup.sh
sudo ./scripts/dpl_system_setup.sh
sudo systemctl restart kubelet.service
sudo systemctl restart containerd.service
```

> For DPU mode, restarting `kubelet` and `containerd` is required whenever `hugepages` configuration changes for the changes to take effect.

- For Host mode, specify the ConnectX device(s) that should be configured for DPL use using the `--dev` option (this option can be repeated):

```
cd dpl_rt_service_va.b.c-docax.y.z
chmod +x ./scripts/dpl_system_setup.sh
sudo ./scripts/dpl_system_setup.sh --dev 0000:08:00.0
```

The `dpl_system_setup.sh` script will perform the following:

- Configures `mlxconfig` values:
  - `FLEX_PARSER_PROFILE_ENABLE=4`
  - `PROG_PARSE_GRAPH=true`
  - `SRIOV_EN=1`
- Enables SR-IOV
- Sets up initial DPL Runtime Service configuration folder at `/etc/dpl_rt_service/`
- Configures hugepages

> Please note that the `dpl_system_setup.sh` script takes optional arguments to control the hugepages.
>
> For DPU mode, if you set it larger than 4GB of hugepages, you also have to modify `dpl_rt_service.yaml` with a higher limit for `spec->resources->limits->hugepages-2Mi`

8.10.6.8.4.3 Editing the Configuration Files

Create device(s) configuration file based on the provided template config file.
See DPL Service Configuration for details.

For example:

Example

```
sudo cp /etc/dpl_rt_service/devices.d/NAME.conf.template /etc/dpl_rt_service/devices.d/1000.conf
# Then update /etc/dpl_rt_service/devices.d/1000.conf as needed.
sudo vim /etc/dpl_rt_service/devices.d/1000.conf
```

You must create at least one device configuration file.
Otherwise, the DPL Runtime Service Container will not be able to start.

8.10.6.8.4.4 Firewall configuration to open gRPC server ports

The DPL Runtime Service has a couple of gRPC servers, each listening on a dedicated TCP port, supporting a corresponding DPL Developer tool.

It is critical to make sure that these ports are accessible from the system(s) where you plan to run the DPL Developer tools.
Those tools will connect to the DPL Runtime Service using the corresponding tool's gRPC server TCP port.

The needed ports are configurable (see `server_tcp_port` settings at DPL Service Configuration). By default they have the following values:

gRPC server	TCP Port
P4 Runtime	9559
DPL Admin	9600
DPL Nspect/Debugger	9560

Example for allowing the ports on RHEL-9

```
sudo firewall-cmd --permanent --add-port=9559/tcp
sudo firewall-cmd --permanent --add-port=9600/tcp
sudo firewall-cmd --permanent --add-port=9560/tcp
sudo firewall-cmd --reload

# List Configurations to confirm ports were allowed.
sudo firewall-cmd --list-all
```

8.10.6.8.4.5 Starting the DPL Runtime Service Container

Once your configuration files are ready, use the `dpl_rt_service_ctl.sh` script to start the container:

Before running the script for the first time, user must grant it execution rights:

```
sudo chmod +x ./scripts/dpl_rt_service_ctl.sh
```

```
sudo ./scripts/dpl_rt_service_ctl.sh --start
```

For DPU mode, the script will copy the YAML file into the `/etc/kubelet.d/` directory, which will trigger automatic creation and start of DPL RT Service Pod and container.

For Host mode, the script will start a Docker container named `dpl-rt-service`.

Allow a few minutes for the container to start. To monitor status:

- For DPU mode:
  - Check logs:

    ```
    sudo journalctl -u kubelet --since -5m
    ```

  - List images:

    ```
    sudo crictl images
    ```

  - List pods:

    ```
    sudo crictl pods
    ```

- For Host mode:
  - Check logs:

    ```
    sudo docker logs dpl-rt-service
    ```

  - List images:

    ```
    sudo docker images
    ```

- View runtime logs:

  ```
  /var/log/doca/dpl_rt_service/dpl_rtd.log
  ```

If the container fails to start due to configuration errors, then the log file at /var/log/doca/dpl_rt_service/dpl_rtd.log might be empty or missing the relevant error logs.
In such case, you can view logs with the relevant errors using the relevant tool:

For DPU:

```
sudo crictl logs $(sudo crictl ps -a | grep dpl-rt-service | awk '{print $1}')
```

For Host:

```
sudo docker logs dpl-rt-service
```

8.10.6.8.4.6 Stopping the DPL Runtime Service Container

Stop the container by using the `dpl_rt_service_ctl.sh` script:

```
sudo ./scripts/dpl_rt_service_ctl.sh --stop
```

> For DPU mode, the script will remove the YAML file from the `/etc/kubelet.d/` directory.
>
> For Host mode, the script will stop the Docker container named `dpl-rt-service`.

To confirm the pod is gone (this might take a few seconds to complete):

```
# For DPU:
sudo crictl pods | grep dpl-rt-service

# For Host:
sudo docker ps | grep dpl-rt-service
```

8.10.6.8.4.7 Restarting the DPL Runtime Service After Configuration Changes

Once the DPL Runtime Service container is up and running, any change to any file under the `/etc/dpl_rt_service/` configuration folder requires restarting the container in order for the new changes to take effect.

Perform the following steps to restart the container:

1. Stop the container.

   ```
   sudo ./scripts/dpl_rt_service_ctl.sh --stop
   ```

2. Wait for the container to stop.
3. Start the container:

   ```
   sudo ./scripts/dpl_rt_service_ctl.sh --start
   ```

8.10.6.8.4.8 End-to-End Installation Steps

⚠ Replace device IDs and filenames as appropriate for your setup.

DPU Example

```
# Download NGC CLI tool:
wget --content-disposition https://api.ngc.nvidia.com/v2/resources/nvidia/ngc-apps/ngc_cli/versions/4.5.2/files/
ngccli_arm64.zip -O ngccli_arm64.zip
unzip ngccli_arm64.zip

# Download the DPL Runtime Service Resources bundle:
./ngc-cli/ngc registry resource download-version "nvidia/doca/dpl_rt_service"

# Prepare DPU and restart services:
cd dpl_rt_service_va.b.c-docax.y.z
chmod +x ./scripts/dpl_system_setup.sh
sudo ./scripts/dpl_system_setup.sh
sudo systemctl restart kubelet.service
sudo systemctl restart containerd.service

# Create a device configuration file with relevant interfaces info:
sudo cp /etc/dpl_rt_service/devices.d/NAME.conf.template /etc/dpl_rt_service/devices.d/1000.conf
sudo vim /etc/dpl_rt_service/devices.d/1000.conf

# Launch the Pod and container:
sudo ./scripts/dpl_rt_service_ctl.sh --start
```

Host Example

```
# Download NGC CLI tool:
wget --content-disposition https://api.ngc.nvidia.com/v2/resources/nvidia/ngc-apps/ngc_cli/versions/4.5.2/files/
ngccli_linux.zip -O ngccli_linux.zip
unzip ngccli_linux.zip

# Download the DPL Runtime Service Resources bundle:
./ngc-cli/ngc registry resource download-version "nvidia/doca/dpl_rt_service"

# Prepare DPU and restart services:
cd dpl_rt_service_va.b.c-docax.y.z
chmod +x ./scripts/dpl_system_setup.sh
sudo ./scripts/dpl_system_setup.sh --dev 0000:08:00.0

# Create a device configuration file with relevant interfaces info:
sudo cp /etc/dpl_rt_service/devices.d/NAME.conf.template /etc/dpl_rt_service/devices.d/1000.conf
sudo vim /etc/dpl_rt_service/devices.d/1000.conf

# Launch the Docker container:
sudo ./scripts/dpl_rt_service_ctl.sh --start
```

8.10.6.8.5 Troubleshooting

For additional troubleshooting steps and deeper explanations, refer to BlueField Container Deployment Guide.

Checkpoint	Command
View recent kubelet logs (DPU only)	`sudo journalctl -u kubelet --since -5m`
View logs of the `dpl-rt-service` container Helpful if `/var/log/doca/dpl_rt_service/dpl_rtd.log` is missing or incomplete	For DPU: `sudo crictl logs $(sudo crictl ps -a | grep dpl-rt-service | awk '{print $1}')` For Host: `sudo docker logs dpl-rt-service`
List pulled container images	For DPU: `sudo crictl images` For Host: `sudo docker images`

Checkpoint	Command
List all created pods (DPU only)	`sudo crictl pods`
List running containers	For DPU: `sudo crictl ps` For Host: `sudo docker ps`
View DPL service logs	`/var/log/doca/dpl_rt_service/dpl_rtd.log`

Make sure the following conditions are met before or during deployment:

- VFs were created before deploying the container (if using SR-IOV)
- All required configuration files exist under `/etc/dpl_rt_service/`, are correctly named, and include valid device IDs
- Network interface names and MTU settings match the physical and virtual network topology
- Firmware is up to date and matches DOCA compatibility requirements
- For DPU mode, BlueField is operating in the correct mode (DPU mode) using `sudo mlxconfig -d <pci-device> q`

8.10.6.9 DPL Service Configuration

8.10.6.9.1 Introduction

The DPL Runtime Service utilizes three distinct types of configuration files. These files adhere to a simplified INI-style format, which supports repeated sections (e.g., `[INTERFACE]`) and uses `#` for comments rather than `;`.

The available configuration files are as follows:

- DPL Device Configuration: Located at `/etc/dpl_rt_service/devices.d/<device-id>.conf`.
- Service Daemon Configuration: Located at `/etc/dpl_rt_service/dpl_rt.conf`.
- System Configuration: Located at `/etc/dpl_rt_service/system.conf`.

The `dpl_dpu_setup.sh` script installs default (recommended) daemon and system configuration files. However, users must create their own DPL Device configuration file based on the provided template, which is also installed by the setup script.

Any changes made to files within the `/etc/dpl_rt_service/` directory require a restart of the DPL Runtime Service Container to take effect. Please refer to the section "Restarting the DPL Runtime Service After Configuration Changes" for instructions.

8.10.6.9.2 DPL Device Configuration

Path: `/etc/dpl_rt_service/devices.d/<device-id>.conf` (e.g., `/etc/dpl_rt_service/devices.d/1000.conf`).

This file defines the device, its interfaces, and the mapping to DPL Port IDs used in DPL programs. A configuration template is available at `/etc/dpl_rt_service/devices.d/NAME.conf.template`.

> ⚠ When using SFs or SR-IOV VFs, ensure the configuration references their representor interfaces, not the SF/VF interfaces themselves.

8.10.6.9.2.1 DPL Port ID Mapping

Each physical or virtual interface is assigned a logical DPL Port ID (`dpl_logical_port_id`). Consistency between the DPL program and this configuration is mandatory.

Supported interface types include:

- Uplink netdev interface (e.g., `p0`).
- PF representor (e.g., `pf0hpf`).
- VF representor (e.g., `pf0vf0`).
- SF representor (e.g., `en3f0pf0sf1`).

Unless multiport eswitch is enabled, all listed interfaces must belong to the same uplink port.

8.10.6.9.2.2 DPL Port ID Rules

The following rules apply to `dpl_device_id` and `dpl_logical_port_id` values:

Condition	Requirement
Reserved value	`UINT32_MAX`
DPL Device ID	Must be a positive integer
DPL Interface ID	Integer between `0` and `UINT32_MAX`
Uplink ports per config	Exactly one (unless multiport eswitch is enabled)

8.10.6.9.2.3 Example DPL Device Configuration File

The following is an example of a valid device configuration file.

```
# [DEVICE] section: Must appear only once.
[DEVICE]
# The DPL Device ID used by the controller to manage tables.
```

```
dpl_device_id=1000
# Cache counter timeout to decrease HW accesses.
dpl_counter_cache_timeout=0
# Counter polling interval for idle-timeout (in seconds).
idle_timeout_polling_interval=2
# Polling interval for TCP state objects from HW (in milliseconds).
tcp_state_polling_interval_msec=200

# [P4_RT_CONTROLLER] section: Must appear only once.
[P4_RT_CONTROLLER]
# DPL Port ID for traffic originating from the controller.
p4_controller_port_id=9876

# [INTERFACE] section: Repeated for each DPL Port (network interface).
[INTERFACE]
interface=p0
dpl_logical_port_id=0
mtu=1514
# mac=00:00:00:00:00:00

[INTERFACE]
interface=pf0hpf
dpl_logical_port_id=65535
mtu=1514

[INTERFACE]
interface=pf0vf0
dpl_logical_port_id=1
mtu=1514
```

8.10.6.9.2.4 Section DEVICE

This section defines the attributes of the DPL Device, which consists of multiple ports and supports DPL program loading. It must appear exactly once per device `.conf` file.

- `dpl_device_id` The Device ID used by controller applications to identify the target device for connection and program management.
- `dpl_counter_cache_timeout` This parameter reduces hardware accesses for counter reads. When the cache expires, a hardware access occurs upon the next request. Note that enabling this may result in the retrieval of outdated counter values.
- `idle_timeout_polling_interval` Sets the polling interval (in seconds) for reading entry counters from hardware and identifying stale entries (those with no traffic for a period exceeding the defined threshold). This interval affects both Entry Timeout and Delayed Counter Statistics. Larger values impact the accuracy of timeout notifications and the refresh rate of counter statistics.
- `tcp_state_polling_interval_msec` Defines the interval (in milliseconds) for reading TCP state objects from the hardware.

8.10.6.9.2.5 Section P4_RT_CONTROLLER

This section configures communication with P4 Controllers.

`p4_controller_port_id` P4 controller applications can send packets ("Packet Out") to the DPL Runtime Service via RPC messages. These packets are assigned a port ID equal to `p4_controller_port_id`. A DPL programmer can identify traffic originating from a P4 Controller by comparing `std_meta.ingress_port` to this value.

8.10.6.9.2.6 Section INTERFACE

This section defines the attributes of a port belonging to the device. This section may be repeated for multiple interfaces.

- `interface`: The net-device interface name on the system.
- `dpl_logical_port_id`: The ID used to reference the port in DPL programs and table updates. It is used for matching ingress traffic and directing egress traffic. Programmers can verify the source port by comparing `std_meta.ingress_port` to this value.
- `mtu`: Defines the Ethernet frame size (MTU).

  Currently, this field is ignored.
- `mac`: Defines the MAC address.

  Currently, this field is ignored.

8.10.6.9.3 Service Daemon Configuration

Path: `/etc/dpl_rt_service/dpl_rt.conf`.

This file configures core behaviors for the DPL Runtime Service, including logging and gRPC server binding addresses.

8.10.6.9.3.1 Section LOGGING

- `log_file_path`: Defines the path to the `dpl_rtd` log file.
- `log_level`: Sets the default log level upon startup. Supported values (case-insensitive) include: `DISABLE`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, `DEBUG`, and `TRACE`.

  Log levels can be changed dynamically via the DPL Admin client but will not persist across restarts unless updated in this file.

8.10.6.9.3.2 RPC Server Sections

The daemon supports three distinct gRPC servers:

1. `[P4RT_RPC_SERVER]`: Listens for P4Runtime client connections. A sample open-source client is included in the DPL Dev container.
2. `[DPL_ADMIN_RPC_SERVER]`: Listens for `dpl_admin` tool connections.
3. `[DPL_NSPECT_RPC_SERVER]`: Listens for DPL Debugger tool connections.

Common gRPC Server Parameters

The following parameters apply to all three server sections:

- `server_address` : The TCP binding address. Use `[::]` (IPv6 ANY) to allow connections from all interfaces (including IPv4), or specify a specific IP address.
- `server_tcp_port` : The TCP binding port. If a non-default port is configured, client applications must specify this port when connecting.

TLS Authentication

TLS authentication can be enabled independently for each server. To enable TLS, the following mutually inclusive parameters must be added to the relevant server section:

- `server_cert` : Path to the `server.crt` file.
- `ca_cert` : Path to the `ca.crt` file.
- `server_key` : Path to the `server.key` file.

8.10.6.9.3.3 Section DPL_PACKET_IO

- `enabled` : When set to `true` , initializes the Packet IO infrastructure. This is required for P4 Controller Packet IO, the "Add Entry" feature (from DPL programs), and DPL Debugger tools.
- `dpdk_log_level` : Sets the DPDK log level for Packet IO operations (e.g., `*:debug`). Refer to the DPDK Logging Guide for details.

8.10.6.9.3.4 Section DPL_SHM

- `enabled` : When set to `true` , initializes the Shared Memory (SHM) infrastructure, required for controller applications utilizing the DPL Runtime Controller SDK.

8.10.6.9.3.5 Example Service Daemon Configuration File

```
# Example of a possible DPL RT Service GENERAL configuration file

[LOGGING]
# Path to the dpl_rtd log file.
log_file_path=/var/log/doca/dpl_rt_service/dpl_rtd.log
# Log level for the DPL RT Service.
# Possible log_level values (case insensitive):
# DISABLE
# CRITICAL
# ERROR
# WARNING
# INFO
# DEBUG
# TRACE
log_level=INFO

[P4RT_RPC_SERVER]
server_address=[::]    # IPv6 "ANY" allows IPv4 connections
server_tcp_port=9559
## If you would like to enable TLS authentication for the gRPC server connections, uncomment the following line and
provided the required info:
#server_cert=/path/to/server.crt
#ca_cert=/path/to/ca.crt
#server_key=/path/to/server.key

[DPL_ADMIN_RPC_SERVER]
server_address=[::]    # IPv6 "ANY" allows IPv4 connections
server_tcp_port=9600
## If you would like to enable TLS authentication for the gRPC server connections, uncomment the following line and
provided the required info:
#server_cert=/path/to/server.crt
#ca_cert=/path/to/ca.crt
#server_key=/path/to/server.key

[DPL_NSPECT_RPC_SERVER]
server_address=[::]    # IPv6 "ANY" allows IPv4 connections
server_tcp_port=9560
```

```
## If you would like to enable TLS authentication for the gRPC server connections, uncomment the following line and
provided the required info:
#server_cert=/path/to/server.crt
#ca_cert=/path/to/ca.crt
#server_key=/path/to/server.key

[DPL_PACKET_IO]
# Enable Packet IO processing.
enabled=true
# DPDK --log-level value to be used when working with Packet IO.
# Uncomment and set the desired log level, for example *:debug for high Debug level logs.
# See more details and possible values at https://doc.dpdk.org/guides/prog_guide/log_lib.html
#dpdk_log_level=*:debug

[DPL_SHM]
# Enable Shared Memory (SHM) infrastructure for High Update Rate tables support using dpl-rt-controller SDK.
enabled=true
```

8.10.6.9.4 System Configuration

Path: `/etc/dpl_rt_service/system.conf`.

This file handles hardware interaction tuning for the DPL Runtime Service.

8.10.6.9.4.1 Section LOGICAL_CORES

- `packet_io_lcores`: Specifies the logical CPU core for Packet IO processing. Do not use lcore 0.
- `rule_insertion_lcores`: Specifies the logical CPU core for rule insertions/deletions. Do not use lcore 0.

> ⚠ This core must be different from cores used by any controller application utilizing the DPL Runtime Controller SDK.

8.10.6.9.4.2 Section HAL

This section configures Hardware Steering (HWS) settings.

> ⛔ Do not modify settings in this section unless instructed by NVIDIA Support. These settings directly impact performance characteristics such as rule update rates and latency.

- `queue_size`: HWS queue size.
- `queues_num`: Number of HWS queues for rule insertions/deletions.
- `burst_size`: Burst size for HWS rule insertions/deletions.

8.10.6.9.4.3 Example System Configuration File

```
[LOGICAL_CORES]
# Logical CPU core for processing Packet IO (do not use lcore 0).
packet_io_lcores=1
# Logical CPU core for processing rule insertions/deletions (do not use lcore 0).
rule_insertion_lcores=2

[HAL]
queue_size=1024
queues_num=1
```

```
burst_size=32
```

8.10.7 DPL Development Container

The DPL Development Container is designed for developers building data path applications using the DOCA Pipeline Language (DPL) — NVIDIA's P4-derived language for programmable networking pipelines. DPL is supported on NVIDIA® BlueField® platforms, including DPUs and SuperNICs operating in DPU mode.

To help you get started and build effectively with DPL, refer to the following key resources:

- DPL Target Architecture – Explains the architecture that DPL programs run on, including the hardware building blocks and capabilities of BlueField
- P4 Language Support in DPL – Details which features from the P4-16 language are supported or modified within DPL
- DPL Installation Guide – Provides instructions on how to install and set up the DPL Development container
- Compiling DOCA Applications – Describes how to compile DPL source files into binary artifacts, with explanations of available compiler options
- Loading DOCA Applications – Walks through how to deploy compiled DPL binaries to BlueField hardware
- Sample DPL Applications – Offers reference programs and examples that demonstrate practical use cases and patterns for DPL development
- Inspecting DPL Programs – A step-by-step guide to use the DPL Nspect, a CLI tool used for both inspecting DPL loaded programs state (like tables, entries, keys etc.), and recording a debug session (to be used by the DPL Debugger).
- Debugging DPL Programs – A step-by-step guide to use the DPL Debugger, a GUI tool which allows both offline and runtime debugging.
- DPL Program Metrics – Explains the estimated resource usage and performance-impacting processing paths for a compiled DPL program's implementation in BlueField hardware
- DPL Performance User Guide - Guidelines and discussion for how to write performant DPL applications.

If you are new to DPL, start with the target architecture and sample applications to build context before diving into compilation or runtime deployment.

8.10.7.1 DOCA Target Architecture

This page introduces the NVIDIA DPL Model for NVIDIA® BlueField®-3 networking platforms (DPUs or SuperNICs).

8.10.7.1.1 Introduction

The DOCA Target Architecture is a fundamental concept in P4 programming, serving as a specification that defines:

- Programmable components (e.g., parsers, ingress control flows)
- Interfaces between hardware and the P4 software layer

This specification serves as a formal contract between the P4 program and the target hardware, ensuring compatibility and efficient utilization of the hardware's data plane capabilities.

For each hardware platform, NVIDIA provides:

- A P4-based compiler tailored to NVIDIA architecture
- A DPL hardware-specific architecture definition

This page focuses on the DPL DOCA Target Architecture, providing a detailed guide on:

- Programming BlueField-3 DPUs for customized packet processing and forwarding
- Utilizing NVIDIA's DPL compiler to interact with various interfaces and ports on BlueField devices
- Considerations for Target Architectures for future BlueField generations

> ⚠ While different Target Architectures may share similarities, they are generally vendor-specific and are not designed for cross-vendor portability.

8.10.7.1.2 ConnectX-9 Target Architecture

The default DOCA target architecture described in this document applies to the BlueField-3 DPU. The NVIDIA® ConnectX®-9 Target Architecture extends the DPL DOCA Target Architecture to ConnectX-9 SuperNIC adapters, in addition to BlueField®-3 DPUs. ConnectX-9 is optimized for AI/ML and high-scale networking workloads, operating in Host mode. DPL programs targeting ConnectX-9 use a distinct target string in the compilation flow:

- `doca-bf3` – BlueField-3 DPU
- `doca-cx9` – ConnectX-9

Unless otherwise noted, P4-level semantics (parser model, extern behavior, table semantics) are compatible between BlueField-3 and ConnectX-9. Differences are primarily in scale and in the availability of additional Extern object types. These differences will be noted in the documentation below with `CX-9 feature`.

8.10.7.1.3 Annotations

Annotations in the P4 programming language serve as a mechanism to attach metadata, compiler hints, and documentation to program entities without altering the core packet processing logic. They are similar to “attributes” in other programming languages. DPL specific annotations always begin with @nv_. The compiler expects these annotations to be associated with specific DPL entities. If placed on unsupported entities, the annotation is ignored and a compiler warning may be produced. For unrecognized/undocumented annotations (for example, from another target architecture), the annotation is silently ignored. The following is a list of supported DPL annotations, with further details under the specific feature:

DPL Annotation	Purpose
@nv_extract	Specifies a parser extraction point
@nv_transition	Defines a parser state transition
@nv_transition_from	Specifies which parser state to transition from
@nv_header_data_fields	Provides values for each header field in encapsulation templates
@nv_controller_metadata	Marks a struct as packet-in or packet-out controller metadata
@nv_high_entropy_bits	Specifies which bits of a match key had high entropy (for hash optimizations)
@nv_modifiable	Marks an action parameter as atomically modifiable at runtime

The following core P4 annotations are supported:

Annotation	Purpose
@name("...")	Assigns a control-plane visible name to an entity
@optional	Parameter is optional
@pkginfo(key=value)	Package metadata to be included in the p4info
@brief("...")	Short description
@description("...")	Long description

8.10.7.1.4 DOCA Pipeline Model

The DOCA pipeline model encompasses a set of control stages that are supported by the hardware. Each top-level object within this model is designed to receive a specific set of parameters:

8.10.7.1.4.1 Parser

The parser processes incoming packets by extracting header information.

- Operates without access to metadata during parsing
- Focuses exclusively on the packet's content and structure

Syntax:

```
parser NvDocaParser<HEADERS>(
    packet_in packet,
    out HEADERS headers);
```

8.10.7.1.4.2 Control Stage

The control stage processes metadata and applies user logic to modify packet behavior.

It manages three distinct types of metadata:

- Standard Metadata (read-only) – Provides packet-related information obtained from earlier processing stages (e.g., parser, crypto engine)
- User Metadata (read-write) – Stores application-specific variables that allow for custom processing logic
- Packet Out Metadata (read-write) – Carries additional information from the SDN controller to the DOCA pipeline when sending packets to the data plane

Syntax:

```
control NvDocaMainControl<HEADERS, USER_META, PKT_OUT_META>(
    inout HEADERS headers,
    in nv_standard_metadata_t std_meta,
    inout USER_META user_meta,
    inout PKT_OUT_META pkt_out_meta
);
```

BlueField hardware supports in-line packet modification and reparsing, eliminating the need for a separate deparser control stage. This simplifies pipeline design and removes the need for packet recirculation.

8.10.7.1.4.3 Main Package (Entry Point)

The main package acts as the entry point of every P4 program for DOCA Target Architecture.

It consists of:

- A parser (`NvDocaParser`)
- A control stage (`NvDocaMainControl`)

Syntax:

```
package NvDocaPipeline<HEADERS, USER_META, PKT_OUT_META>(
    NvDocaParser<HEADERS> parse,
    NvDocaMainControl<HEADERS, USER_META, PKT_OUT_META> main
);
```

Packet modifications are applied immediately and do not require explicit deparser logic.

8.10.7.1.5 DOCA Core Library

The DOCA Core Library provides a foundational set of common types and metadata structures used within the DOCA Target Architecture. These types and constants are defined in `doca_core.p4` and are commonly used across various DOCA Target Architecture interfaces, such as extern functions.

8.10.7.1.5.1 Typedefs

The following typedefs define commonly used header fields and standard metadata fields:

```
typedef bit<32> nv_logical_port_t;
typedef bit<48> nv_mac_addr_t;
typedef bit<32> nv_ipv4_addr_t;
typedef bit<128> nv_ipv6_addr_t;
typedef bit<32> nv_tunnel_id_t;
typedef bit<12> nv_vlan_id_t;
typedef bit<24> nv_vxlan_id_t;
typedef bit<20> nv_mpls_label_t;
typedef bit<8> nv_debug_cookie_t;
```

8.10.7.1.5.2 Constants

The following DOCA Target Architecture-specific constants define standard metadata key fields:

```
const bit<2> L2_TYPE_UNICAST   = 2w0;
const bit<2> L2_TYPE_MULTICAST = 2w1;
const bit<2> L2_TYPE_BROADCAST = 2w2;

const bit<2> L3_TYPE_NONE   = 2w0;
const bit<2> L3_TYPE_IPV4   = 2w1;
const bit<2> L3_TYPE_IPV6   = 2w2;

const bit<2> L4_TYPE_NONE   = 2w0;
const bit<2> L4_TYPE_TCP    = 2w1;
const bit<2> L4_TYPE_UDP    = 2w2;
const bit<2> L4_TYPE_IPSEC  = 2w3;

const bit<4> L4_TYPE_EXT_NONE  = 4w0;
const bit<4> L4_TYPE_EXT_TCP   = 4w1;
const bit<4> L4_TYPE_EXT_UDP   = 4w2;
const bit<4> L4_TYPE_EXT_ICMP  = 4w3;

const bit<2> VLAN_TYPE_NONE  = 2w0;
const bit<2> VLAN_TYPE_SVLAN = 2w1;
const bit<2> VLAN_TYPE_CVLAN = 2w2;

const bit<2> ENCAP_TYPE_NONE      = 2w0;
const bit<2> ENCAP_TYPE_L2_TUNNEL = 2w1;
const bit<2> ENCAP_TYPE_L3_TUNNEL = 2w2;
const bit<2> ENCAP_TYPE_ROCE      = 2w3;

const bit<2> IPSEC_TYPE_NONE     = 2w0;
const bit<2> IPSEC_TYPE_OVER_IP  = 2w1;
const bit<2> IPSEC_TYPE_OVER_UDP = 2w2;

const bit<8> IPSEC_SYNDROME_OK  = 8w0;
const bit<8> PSP_SYNDROME_OK    = 8w0;
```

These values are used for interpreting type codes within standard metadata.

8.10.7.1.5.3 Defines

The following macros define industry-standard values for various RFC protocol fields (e.g., Ethertype, IP protocol numbers).

- IP Protocol Numbers

```
#define NV_IPV6_HBH_OPTION   0x00  /* IPv6 Hop-by-Hop option */
#define NV_ICMP_PROTOCOL     0x01  /* ICMP */
#define NV_IPV4_PROTOCOL     0x04  /* IPv4-over-IPv4 encapsulation */
#define NV_TCP_PROTOCOL      0x06  /* TCP */
#define NV_UDP_PROTOCOL      0x11  /* UDP */
#define NV_IPV6_PROTOCOL     0x29  /* IPv6-over-IPv6 encapsulation */
#define NV_GRE_PROTOCOL      0x2F  /* Generic Routing Encapsulation (GRE) */
#define NV_ESP_PROTOCOL      0x32  /* IPsec ESP */
#define NV_AH_PROTOCOL       0x33  /* IPsec AH */
#define NV_ICMP6_PROTOCOL    0x3A  /* ICMPv6 */
#define NV_SCTP_PROTOCOL     0x84  /* SCTP */
#define NV_ROCE_PROTOCOL     0xFE  /* RoCE v1.5 */
```

- EtherType Values

```
#define NV_TYPE_VLAN_CTAG    0x8100
#define NV_TYPE_VLAN_STAG    0x88A8
#define NV_TYPE_IPV4         0x0800
#define NV_TYPE_IPV6         0x86DD
#define NV_TYPE_ARP          0x0806
#define NV_TYPE_CONTROL      0x0808
#define NV_TYPE_MPLS         0x8847
#define NV_TYPE_MPLS_MC      0x8848
#define NV_TYPE_PTP          0x88F7
#define NV_TYPE_FCOE         0x8906
#define NV_TYPE_ROCE         0x8915  /* v1 */
#define NV_TYPE_MAC          0x6558  /* Transparent Ethernet Bridge for Generic Routing Encapsulation */
```

- UDP Port Numbers

```
#define NV_ROCE_PORT         4791   /* v2 bth */
#define NV_VXLAN_PORT        4789
#define NV_VXLAN_GPE_PORT    4790
#define NV_GENEVE_PORT       6081
#define NV_MPLS_TUNNEL_PORT  6635
#define NV_IPSEC_NAT_PORT    4500
#define NV_PTP_EVENT_PORT    319
#define NV_PTP_GEN_PORT      320
#define NV_IPV4_OPTION_MRI   31
#define NV_GTP_U_PORT        2152
#define NV_PSP_PORT          1000
#define NV_GUE_PORT          666
```

- Tunnel encapsulation protocol numbers

```
/* VXLAN GPE protocols */
#define NV_VXLAN_GPE_IPV4    0x01
#define NV_VXLAN_GPE_IPV6    0x02
#define NV_VXLAN_GPE_MAC     0x03
#define NV_VXLAN_GPE_NSH     0x04   /* RFC8300 */

/* PSP protocols */
#define NV_PSP_IPV4          0x04
#define NV_PSP_IPV6          0x29
#define NV_PSP_TCP           0x06
#define NV_PSP_UDP           0x11
```

These values help interpret standard protocol fields within BlueField's packet processing pipeline.

8.10.7.1.5.4 Metadata

The standard metadata (`struct nv_standard_metadata_t`) for the DOCA Target Architecture are found in `doca_metadata.p4` . The members of the standard metadata struct are all read only, and are separated into 4 logical categories:

- Pipeline metadata, information set by hardware units before the programmable part of the BlueField pipeline
- Outer packet header metadata, information set by the hardware parser for the outer packet

- Inner packet header metadata, information set by the hardware parser for the inner packet (if present)
- Union packet fields (packet fields which share the same memory location)

8.10.7.1.5.5 User Metadata

The DPL programmer can create and use their own metadata struct in the DOCA Target Architecture. The type can be `bit<>` or a struct, limited in size by the number of internal registers on the device. For convenience, the Target Architecture defines `nv_empty_metadata_t` which the user optionally use in the main package declaration if no metadata is needed.

8.10.7.1.6 DOCA Packet Parser

In the DOCA Target Architecture, headers represent the various packet protocol formats that are recognized by the parser. Once these headers are identified, the fields within the packet become candidates for further processing. They can be matched against entries in a match-action table, where they may be altered based on user-defined actions. The DOCA Target Architecture comes equipped with a default hardware-integrated parser that can understand a range of protocols standardized by the Internet Engineering Task Force (IETF). To accommodate custom requirements, architecture allows for the integration of user-defined ("flex") headers. These flex headers are seamlessly incorporated into the pre-existing parser graph, extending its capabilities to recognize and process additional protocol formats as specified by the user. This flexibility enables developers to tailor the data plane processing to specific applications and protocols beyond the standard set, and future-proofs the developer's investment in the hardware.

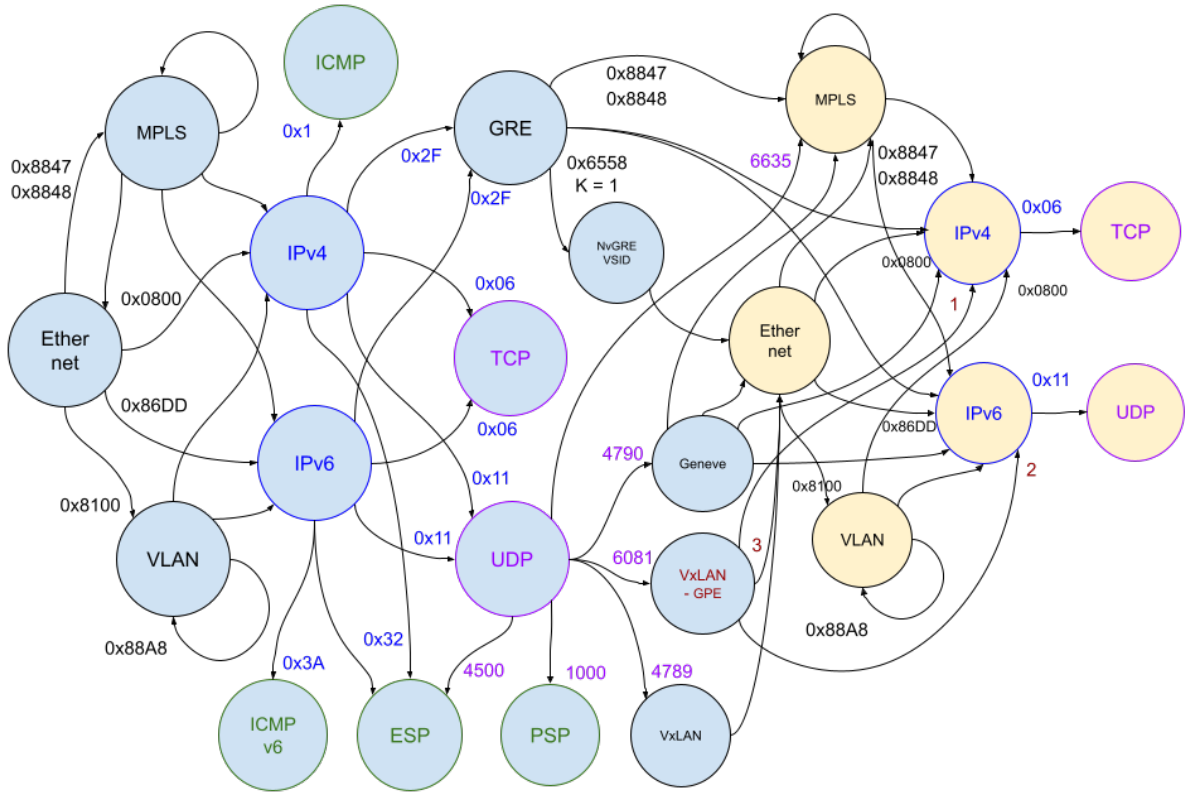
This section on the DPL Packet Parser focuses on BlueField-3 devices and higher. NVIDIA's BlueField architecture combines native and flexible parsing capabilities, allowing the user to enhance the hardware's packet parsing engine with custom protocol headers. This integration is seamless, utilizing built-in parsing for standardized headers.

8.10.7.1.6.1 Flex Parser Configuration

Flex nodes are user-configurable within the DOCA parser, covering elements including the next protocol field, fixed length headers, and calculations for variable header sizes. Arcs link flex nodes and feature properties such as the `is_tunnel` flag, transition value, source node, and destination node. Configurations that are not supported will trigger a compile-time error. Packet fields are extracted from the flex node to the hardware's sampler registers, facilitating the use of fields as match keys and enabling header modification actions.

8.10.7.1.6.2 Use Cases

Examples of custom flex headers include TCP options, SRv6, GTP-U, RTP, SCTP, GUE, eCPRI, GENEVE options, and proprietary tunnels. The hybrid architecture ensures smooth integration of user-defined protocols with the fixed parser graph. Below is an illustration of the default fixed parser for BlueField-3:



The DPL compiler enables the user to effectively utilize the P4 language to program packet parsers, taking full advantage of its native and flexible parsing capabilities to meet a variety of network processing needs. The remainder of this section describes the features of the BlueField-3 parser.

8.10.7.1.6.3 Native Parse Graph and Headers

BlueField's parser supports a hybrid architecture that incorporates both predefined (fixed) headers and standard transitions between headers as defined by the Internet Engineering Task Force (IETF). These transitions are determined based on the "next header type" field present within each protocol. For a comprehensive understanding of these transitions and the supported protocols, users are encouraged to refer to IANA Service Names and Port Numbers for a comprehensive list of protocol identifiers supported by the BlueField parser:

- Service Names and Port Numbers – IANA Service Names and Port Numbers

- IEEE 802 Numbers – IANA IEEE 802 Numbers
- Protocol Numbers – IANA Protocol Numbers

These resources provide detailed information on the various service names, port numbers, IEEE standards, and protocol numbers that are recognized and supported by BlueField's parser, facilitating a broad range of packet processing applications. The following table describes the native header and transition support in the DOCA Target Architecture:

Header Type	Next Protocol Field	Field Size (bits)	Fixed IETF Transitions	Flex Transition
MAC w VLAN	Ether Type	16	IPv4 (0x0800), IPv6 (0x86DD), MPLS UC (0x8847), MPLS MC (0x8848), VLAN (0x8100), SVLAN (0x88A8)	From, outer, inner
IPv4	Protocol	8	UDP (0x11), TCP (0x6), GRE(0x2F), ICMP(0x1), IPSec AH (0x33), IPSec ESP (0x32), IPv4 encap (0x4)	To, outer, inner
IPv6	Protocol	8	HOPOPT (0x0), UDP (0x11), TCP (0x6),GRE(0x2F), ICMP(0x3A), IPSec AH (0x33), IPSec ESP (0x32), IPv6-Route (0x2B), , IPv6 encap (0x29), IPv6-Frag(0x2C), IPv6-NoNxt (0x3B), IPv6-DestOpts (0x3c)	To, outer, inner
IP	Protocol	8	UDP, TCP, GRE, ICMP, IPSec AH, IPSec ESP	From, outer, inner (both IPv4 and IPv6)
UDP	Destination port	16	VXLAN (4789 + 3 additional custom ports) VXLAN-GPE (4790) GENEVE (6081) MPLS over UDP (6635) IPSEC ESP over UDP (4500) PSP(1000 + 2 additional custom ports)	To, from, outer, inner
TCP	Destination port	16	None	To, from, outer, inner
ICMP	None	N/A	None	Not supported - cannot transition to or from
GRE	Ether Type	16	IPv4 (0x0800), IPv6 (0x86DD) MPLS over GRE (0x8847, 0x8848)	To, from, outer
NVGRE (GRE)	Ether Type	16	Inner MAC (0x6558)	To, from, outer
NVGRE Options	Key present	1	Key present true	Cannot transition to or from
VXLAN	None	N/A	Inner MAC (fixed)	From, outer
VXLAN-GPE	Next Protocol	8	Reserved (0x00), IPv4 (0x01), IPv6 (0x02), Ethernet (0x03), NSH (0x04)	From, outer
GENEVE	Ether Type	16	Inner MAC (0x6558), IPv4 (0x0800), IPv6 (0x86DD), MPLS (0x8847, 0x8848)	From, outer
MPLS	Lookahead	4	IPv4, IPv6	To, from, outer

Header Type	Next Protocol Field	Field Size (bits)	Fixed IETF Transitions	Flex Transition
IPSEC ESP	Next Header	8	Not supported	From, outer
PSP	Next Header	8	Tunnel: IPv4 (4), IPv6 (41) Transport: TCP (6), UDP (17)	To, from, outer

Note that L3 control plane headers ARP (0x0806), MAC control (0x8808), LLDP (0x88CC), PTP (0x88F7) are recognized and steered to a special QP by hardware that are parsed but not matchable in the steering pipeline. Users should create a custom header if matching is required.

8.10.7.1.6.4 Using Default Native Parser

The DOCA Target Architecture defines a default native parser. The user need only include `doca_parser.p4` and reference `nv_fixed_parser` in the DPL package declaration to use the built-in hardware parser. The program should then use the native headers structure, `nv_headers_t`.

8.10.7.1.6.5 Reparsing Capability

A distinctive feature of DPL, setting it apart from other P4 hardware architectures, is its ability to perform reparsing as needed, even midway through the processing pipeline. This flexibility allows for dynamic adjustments to packet processing based on intermediate outcomes during the pipeline's execution. Unlike RMT-based P4 Target Architectures, there are no strict pipeline stages, as the pipeline runs to completion. This means:

- Tables may be applied multiple times, saving scale by not requiring the duplication of tables and their entries at different points in the pipeline.
- Packets do not need to be resubmitted to the pipeline after packet modification (e.g., for encapsulation or decapsulation actions). The push and pop header extern functions also control the reparsing behavior, along with a specific extern to force a reparse.
- Looping in the pipeline is permitted.

This capability greatly improves the user experience by allowing the DPL developer to focus on a logical view of the pipeline behavior, rather than dealing recirculation logic and saving state in metadata.

8.10.7.1.6.6 Defining a Custom Parser

The P4-16 language does not provide a method to extend a pre-existing, target architecture defined parser. Hence the DPL compiler maintains an internal representation of the default parser (based on a "read only" `doca_parser.p4` source file), and allows headers to be added or removed. In this case, header removal may be

implicit, based on excluding a fixed header from the DOCA parser definition. There are 3 steps to defining a custom parser that will be used in conjunction with the native parser:

1. Define the custom header.
2. Add the header to a headers struct.
3. Define the state in a custom parser in the program.

Custom Headers and Headers Struct

A macro, `NV_FIXED_HEADERS`, is provided that references all the headers that the fixed parser can extract. This definition may be used directly as the body of type `headers_t`, or added to, for example:

```
#include <doca_parser.p4>
header custom_header_t {
    bit<16> x;
}
struct custom_headers_t
{
    NV_FIXED_HEADERS
    custom_header_t custom;
}
```

The DPL programmer is expected to use `NV_FIXED_HEADERS` as the basis of their `headers_t` definition. Failure to do so may result in unexpected behavior, for example:

- Headers/fields that are never extracted at runtime even if extracted by parser states
- Use of flex extractions for every single referenced header field
- Compilation errors

Custom Parser States

A macro, `NV_FIXED_PARSER`, is provided which describes the fixed parser. This definition may be used directly as the body of a parser, or extended by writing additional states, and linking them using the `@nv_transition_from` annotation:

```
parser my_parser(packet_in packet, out custom_headers_t headers)
{
    NV_FIXED_PARSER(packet, headers)

    @nv_transition_from("nv_parse_ethernet", 0x1234)
    state parse_custom {
        packet.extract(headers.custom);
        transition select(headers.custom.x) {
            1: nv_parse_ipv4;
            2: nv_parse_ipv6;
            default: accept;
        }
    }
}
```

The DPL programmer is expected to use `NV_FIXED_HEADERS` as the basis of their parser definition. The macro must take the same variable name use for packet_in and headers used in the parser control definition. Failure to do so may result in unexpected behavior, for example:

- Use of hardware flex parser resources for every parser state, even where hardware fixed parser resources could have been used.
- Definitions of states with names matching states in `NV_FIXED_PARSER` being ignored, and their fixed definition used instead.
- Compilation errors.

Finally, the custom parser should be instantiated in the main DPL package:

```
NvDocaPipeline(
    my_parser(),
    my_main_control()
) main;
```

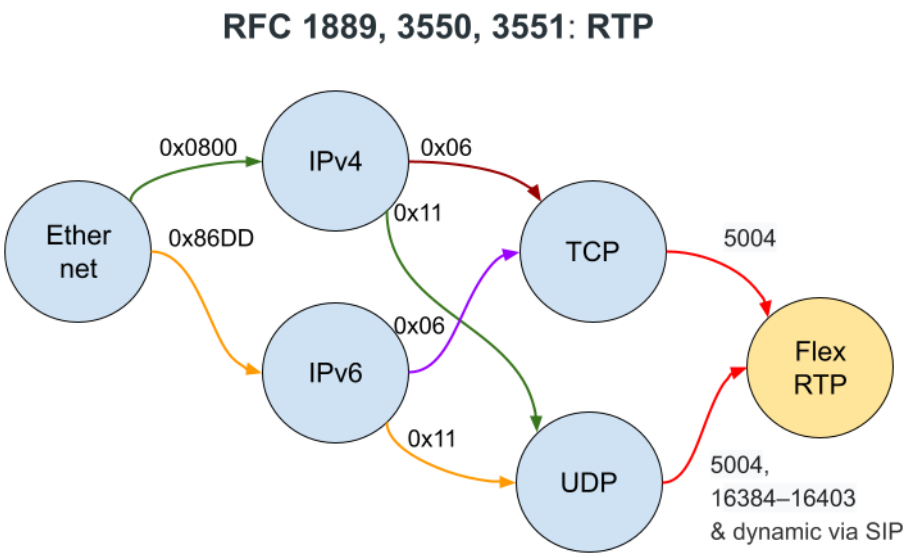
8.10.7.1.6.7 Specifying Transitions to Flex Headers

To extend the native parser with flex headers, the DOCA Target Architecture utilizes a combination of macros and DPL annotations to instruct the compiler how to stitch in the customized headers into an existing parse graph.

To create an unconditional transition from a source state, the parser state must be preceded by an `@nv_transition_from` annotation with 1 argument: the source state name. If the parser contains multiple state definitions with an `@nv_transition_from` annotation with the same source state, a single state will be selected (in an undefined manner) to be the target state of the transition. Put another way, each `@nv_transition_from` annotation from a given source state annotation may be considered to override any earlier (in an undefined order) transition destination for that source state.

To create a conditional transition based on the source state's transition field, the parser state must be preceded by an `@nv_transition_from` annotation with 2 arguments: the source state name and transition value. Transitions of this type are prepended to the source state's list of transitions and thus are guaranteed to override any transitions defined by `NV_FIXED_PARSER` in an undefined order. Entries with identical transition values will override each other but may generate warnings due to unreachability.

The following diagram shows an example of extending the native parser to support the RTP protocol:



In the native parser, as an optimization, the user can specify a transition from both IPv4 and IPv6 headers to a flex header using a special 2 argument annotation of the format:

```
@nv_transition_from("nv_parse_ipv6, nv_parse_ipv4", 0x1234)
```

Where 0x1234 is an example of the custom IP protocol value for some user defined L4 protocol.

8.10.7.1.6.8 Specifying Transitions to Fixed Headers

In a limited number of cases, transitions from fixed headers can be configured. This uses a different annotation, `@nv_transition` , and is always used to annotate the top level parser object. For example, it is a common requirement to add nonstandard transitions from UDP to VxLAN:

```
@nv_transition("nv_parse_udp", "nv_parse_vxlan", 1234)
@nv_transition("nv_parse_udp", "nv_parse_vxlan", 1235)
@nv_transition("nv_parse_udp", "nv_parse_vxlan", 1236)
parser custom_parser(
    packet_in packet,
    out nv_headers_t headers
) {
    NV_FIXED_PARSER(packet, headers)
}
```

where the first parameter specifies the parser node to transition "from", and the second parameter specifies the parser node to transition "to". Note that the annotation `@nv_transition` can be used instead of `@nv_transition_from` for connecting headers.

8.10.7.1.6.9 Defining TLV Parsing for Headers with Optional Data

The DOCA Target Architecture allows the user to define protocol headers that have TLVs as sub headers. Note that a custom base "parent" header must be supplied in order to

create custom TLVs. It is not supported to create custom TLVs for native headers. For example, the user can define a GENEVE header as follows:

```
header geneve_t {
    bit<2> ver;
    bit<6> opt_len;
    bit<1> o;
    bit<1> c;
    bit<6> reserved;
    bit<16> protocol_type;
    bit<24> vni;
    bit<8> reserved56;
};
```

And then define a struct for the base GENEVE option fields (TYPE and LENGTH) along with a customized VALUE data.

```
// Struct so it can be a field within other headers
struct geneve_option_t {
    bit<24> option_class;
    bit<8> option_type;
    bit<3> reserved24;
    bit<5> length;
};

header geneve_option_int_md_t {
    geneve_option_t base;
    bit<4> ver;
    bit<1> d;
    bit<1> e;
    bit<1> m;
    bit<12> reserved7;
    bit<5> hop_ml;
    bit<8> remaining_hop_count;
    // etc.
};
```

Next, the user must add the custom headers to the struct of headers and connect them in the parser. Both the base option struct and the newly defined headers must be present in the headers struct so that there is a reference to these types in the parser.

```
struct app_headers {
    NV_FIXED_HEADERS
    geneve_t custom_geneve;
    geneve_option_t geneve_opt;
    geneve_option_int_md_t geneve_opt_int_md;
};
```

The DOCA Target Architecture uses an `NvOptionsParser` extern object to define TLV options, since the P4 language itself does not provide a native way to define TLV parsing. An instance of the `NvOptionsParser` must be created in the parser, at the outermost scope, with the following parameters:

- `options_length_field` - the name of the field in the parent header (as a string) that holds the total length of the options. If the total options length is fixed (i.e., not specified in the header's data), then this field should be omitted.
- `options_length_shift` - the value by which the parser should apply a shift (i.e. multiply by power of 2) to the value of the option length field. If the length value is fixed or does not need to be shifted, then this field should be omitted.
- `options_length_add` - the constant to which the parser should add to the value option length field after shifting. If the length value does not need an addend, then this field should be omitted. If the total options length is fixed, then this field must specify the fixed length of the TLV options.

- `option_layout header_type` - the user defined P4 struct that holds the TLV field layout of the option header
- `option_length_field` - the name of the field in the base option struct (as a string) that holds the length of the options. If the options length is fixed (i.e., not specified in the base options struct), then this field should be omitted.
- `option_length_shift` - the value by which the parser should apply a shift (i.e. multiply by power of 2) to the option length field. If the length value is fixed or does not need to be shifted, then this field should be omitted.
- `option_length_add` - the constant to which the parser should add to the option length field. If the length value does not need an addend, then this field should be omitted. If the options length is fixed, then this field must specify the fixed length of the TLV options.
- `options` - a list of tuples, where the first value is the TYPE, and the second value is the name of the child header defined by the user

```
parser geneve_parser(
    packet_in packet,
    out app_headers headers
) {
    NvOptionParser<bit<24>, _>(
        "opt_len",           // options_length_field
        2,                   // options_length_shift
        0,                   // options_length_add
        "geneve_option_t",   // option_layout_header_type
        "length",            // option_length_field
        0,                   // option_length_shift
        4,                   // option_length_add
        "option_class_type", // option_type_field
        // options data
        (list<tuple<bit<24>, _>>){
            {24w0x010301, "headers.geneve_opt_int_md"}
            // list of additional options ...
        }
    ) geneveOptions;

    NV_FIXED_PARSER(packet, headers)

    @nv_transition_from("nv_parse_udp", 6082)
    state parse_custom_geneve {
        packet.extract(headers.custom_geneve);
        geneveOptions.parseOptions(packet, headers);
        transition accept;
    }
}
```

8.10.7.1.6.10 Restrictions and Unsupported Parser Features

DOCA parser features that either differ from the $P4_{16}$ specification, are restricted in the DOCA Target Architecture or are unsupported are listed below.

Unsupported Features

These features are not supported by the DOCA Target Architecture in comparison to the $P4_{16}$ specification. Utilizing these features will result in compilation errors.

- Variable Declarations and Extern Instantiations: Parsers and parser states cannot contain any variable declarations or extern instantiations other than `NvOptionsParser`.
- Lookahead and Advance: Programmable lookahead and advance functionalities are not supported.

- Parser Value Sets: Parser value sets for setting transition values from runtime data are not supported.
- State Declarations: States may not contain any declaration, or any statement besides extract, transition statements and calls to `NvOptionsParser` methods.
- Expressions: Conditionals and assignments are not supported.

Restricted Behavior

The following points highlight how the DOCA Target Architecture implementation of DPL parser features differs from the standard $P4_{16}$ specification.

- Reserved State Names: Parser state names beginning with `nv_*` are reserved by the DOCA Target Architecture. Custom states using this reserved prefix will be ignored.
- State and Header Coupling: Each state must extract exactly one header, and they are considered to be coupled in a 1:1 fashion.
- Fixed-Size Header Extraction: The extracted header must be fixed-size, known at compile-time, and defined in the P4 header type definition. I.e., `p.extract(headers.xxx)` is allowed, but `p.extract(headers.xxx, someLength)` is not.
- Transition Statements: Besides terminal pre-defined states (`accept` , `reject`), states must transition to another state using a transition statement, which may be unconditional or conditional.
- Transition Select: Transition select statements are limited to using a single field from the header the state extracts or a constant. Lists of expressions, constants, operators, references to declarations other than a field in the header the state extracts, and any other expression not explicitly allowed are disallowed.
- Default Case in Transition Select: Every transition select statement must have a default case, transitioning to the accept state.
- Extract Before Transition: A state's `extract` statement must precede its transition statement.
- Empty Accept and Reject States: The `accept` and `reject` states must be completely empty.
- Loops in Parser Graph: Loops are not allowed in the DPL program's parser graph. Each path through the parser must be acyclic.

Hybrid Parser Behavior

These restrictions and behaviors apply to the unique hybrid fixed/flex parser model supported by the DOCA Target Architecture.

- Start state of `nv_parse_ethernet` – The start state cannot be changed or overwritten.
- Redefining states – States may not be redefined. This includes no possibility of applying `@nv_transition_from` to the body of any fixed state.

- `NV_FIXED_PARSER` and `NV_FIXED_HEADERS` – States part of `NV_FIXED_PARSER` extract the pre-defined fixed header, irrespective of the state body. States not part of `NV_FIXED_PARSER` must extract headers not part of `NV_FIXED_HEADERS`.
- Fixed-to-fixed transitions – It is not possible to disable any fixed->fixed transition. These may be overridden to transition to a custom state by applying an `@nv_transition_from` annotation to the destination state.
- MPLSoUDP stops parsing at the inner MAC header if the pseudo-wire Control Word is set to 0. Additional inner packet fields will not be parsed.

8.10.7.1.7 DOCA Extern Functions

Extern functions serve as a mechanism for exposing DPL target specific functionality that may be beyond a standard P4 model.

Note that many of these externs mutate the packet, for which the HEADERS are a part of the extern signature.

8.10.7.1.7.1 nv_drop

Terminal extern function that stops packet processing and drops the packet.

Signature:

```
extern void nv_drop();
```

8.10.7.1.7.2 nv_send_to_port

Terminal extern function that stops packet processing and sends the packet to the specified port.

Signature:

```
extern void nv_send_to_port(in nv_logical_port_t port);
```

Parameters:

- `port[in]`: This parameter specifies the logical port to which the packet will be sent.

8.10.7.1.7.3 nv_send_to_controller

Terminal extern function that forwards packet metadata to a P4Runtime controller

Signature:

```
extern void nv_send_to_controller<PACKET_META>(in PACKET_META pkt_in_meta);
```

Parameters:

- `pkt_in_meta[in]` : The metadata accompanying the packet being sent to the controller for processing. Maximum of 32 bits of metadata.

8.10.7.1.7.4 nv_set_l2_ethertype

Extern function that sets the last extracted etherType field. The hardware only maintains the last etherType when parsing an L2 header with multiple VLAN tags.

Signature:

```
extern void nv_set_l2_ethertype<HEADERS>(inout HEADERS headers, in bit<16> last_ether_type);
```

Parameters:

- `headers[in/out]` : packet headers struct
- `last_ether_type[in]` : ethertype value to set

8.10.7.1.7.5 nv_set_ip_dscp

Extern function that sets the DSCP value in the IP header. Applies to both IPv4/IPv6 portion of the traffic class field.

Signature:

```
extern void nv_set_ip_dscp<HEADERS>(inout HEADERS headers, in bit<6> dscp_value);
```

Parameters:

- `headers[in/out]` : packet headers struct
- `dscp_value[in]` : DSCP value to set

8.10.7.1.7.6 nv_set_ip_ecn

Extern function that sets the ECN value in the IP header. Applies to both IPv4/IPv6 portion of the traffic class field.

Signature:

```
extern void nv_set_ip_ecn<HEADERS>(inout HEADERS headers, in bit<2> ecn_value);
```

Parameters:

- `headers` [in/out]: packet headers struct
- `ecn_value` [in]: ECN value to set

8.10.7.1.7.7 nv_set_ip_protocol

Extern function that sets the IP protocol value in an IP header. Applies to both IPv4 protocol field and IPv6 next header field.

Signature:

```
extern void nv_set_ip_protocol<HEADERS>(inout HEADERS headers, in bit<8> protocol);
```

Parameters:

- `headers` [in/out]: packet headers struct
- `protocol` [in]: IP protocol value to set

8.10.7.1.7.8 nv_set_l4_src_port

Extern function that sets the L4 source port value in the TCP/UDP header.

Signature:

```
extern void nv_set_l4_src_port<HEADERS>(inout HEADERS headers, in bit<16> src_port);
```

Parameters:

- `headers` [in/out]: packet headers struct
- `src_port` [in]: L4 port value to set

8.10.7.1.7.9 nv_set_l4_dst_port

Extern function that sets the L4 destination port value the TCP/UDP header.

Signature:

```
extern void nv_set_l4_dst_port<HEADERS>(inout HEADERS headers, in bit<16> dst_port);
```

Parameters:

- `headers` [in/out]: packet headers struct
- `dst_port` [in]: L4 port value to set

8.10.7.1.7.10 nv_l2_decap

Extern function that performs L2 decapsulation on the packet headers (i.e., removing Ethernet/VLAN/tunnel headers). The encapsulated inner packet must begin with a valid L2 Ethernet header. The packet will be reparsed at the end of this action.

Signature:

```
void nv_l2_decap<HEADERS>(inout HEADERS headers)
```

Parameters:

- `headers` [in/out]: packet headers struct that will be decapsulated.

8.10.7.1.7.11 nv_l3_decap

Extern function that performs Layer 3 decapsulation on the packet headers; i.e. removing ethernet/VLAN/tunnel headers. A new L2 header will be prepended with specified data. The encapsulated inner packet must begin with a valid L3 header. The packet will be reparsed at the end of this action.

```
void nv_l3_decap<HEADERS>(inout HEADERS headers, nv_mac_addr_t dst_mac, nv_mac_addr_t src_mac, bit<16>
l3_ether_type, @optional nv_vlan_id_t vid)
```

Parameters:

- `headers` [inout]: The packet headers that will be decapsulated from.
- `dst_mac` [in]: The destination MAC address in the Ethernet frame.
- `src_mac` [in]: The source MAC address in the Ethernet frame.
- `l3_ether_type` [in]: The EtherType value in the Ethernet frame
- `vid` [in]: Optional VLAN ID.

8.10.7.1.7.12 nv_push_vlan

Extern function that inserts a VLAN header immediately after the L2 header.

```
void nv_push_vlan<HEADERS>(inout HEADERS headers, in NvVlanTagId tpid, in bit<3> pcp, in bit dei, in nv_vlan_id_t
vid);
```

Parameters:

- `headers` [inout]: The packet headers that the VLAN will be pushed to.
- `tpid` [in]: Tag Protocol Identifier. SVLAN = 0x88a8, CVLAN = 0x8100.
- `pcp` [in]: Priority Code Point.
- `dei` [in]: Drop Eligible Indicator (formerly CFI).
- `vid` [in]: VLAN Identifier.

8.10.7.1.7.13 nv_pop_vlan

Extern function that removes the outermost VLAN header, immediately after the L2 header.

```
void nv_pop_vlan<HEADERS>(inout HEADERS headers);
```

Parameters:

- `headers` [inout]: The packet headers that the VLAN will be popped from.

8.10.7.1.7.14 nv_push_headers

Extern function that inserts one or more headers (native or custom) to the packet, starting at the specified anchor point.

```
void nv_push_headers<HEADERS, NV_HEADER_DATA_TEMPLATE, VALUES, NV_ANCHOR>(
    inout HEADERS headers,
    NV_HEADER_DATA_TEMPLATE data,
    in VALUES values,
    NV_ANCHOR anchor,
    bit<7> word_offset = 7w0,
    bool do_updates = true,
    bool do_reparse = true
);
```

The following anchor points are allowed:

```
enum NvAnchor {
    PACKET_START,
    L2_START_OF_HEADER,
    VLAN_1ST_START_OF_HEADER,
    VLAN_2ND_START_OF_HEADER,
    MPLS_START_OF_HEADER,
    IP_START_OF_HEADER,
    L4_START_OF_HEADER,
    ESP_START_OF_HEADER,
    TUNNEL_START_OF_HEADER,
    INNER_L2_START_OF_HEADER,
    INNER_VLAN_1ST_START_OF_HEADER,
    INNER_VLAN_2ND_START_OF_HEADER,
    INNER_MPLS_START_OF_HEADER,
    INNER_IP_START_OF_HEADER,
    INNER_L4_START_OF_HEADER,
    PSP_START_OF_HEADER,
    PSP_PAYLOAD_START,
    BTH_HEADER_START_OF_HEADER,
};
```

Parameters:

- `headers` [in/out]: The packet headers to which the additional headers are to be pushed.
- `data` [in]: The NvHeaderDataTemplate object that specifies the list of headers and the header values. See also `NvHeaderDataTemplate` annotation.
- `values` [in]: A list expression whose length matches the number of header fields marked "variable" in the `NvHeaderDataTemplate` object's annotation. The order of the header fields determines which value a field corresponds to (e.g., 3rd header field marked "variable" will be set to the 3rd value in the list). Each value is required to be runtime constant (i.e., it may either be an integer value or an action parameter value). Named parameters are not supported in the list expression.
- `anchor` [in]: An enum specifying the location in the packet where the header insertion should start. The user must separately verify the existence of the header (using isValid), otherwise the behavior is undefined.
- `word_offset` [in]: The offset from the anchor point, in words, where the header insertion should start.
- `do_updates` [in]: If true, then perform IP header field updates (e.g., checksum, length) once the push is completed (e.g., for encapsulations).
- `do_reparse` [in]: If true, then perform a packet reparse once the push is completed.

Limitations:

Only the following combinations of anchors, offsets, and packet updates are validated:

Start Anchor	Offset (bytes)	Do Update
`PACKET_START`	0	true
`PACKET_START`	0	false
`PACKET_START`	12	false
`L4_START_OF_HEADER`	0	true
`IP_START_OF_HEADER`	0	false
`IP_START_OF_HEADER`	20	false
`IP_START_OF_HEADER`	40	false
`ESP_START_OF_HEADER`	0	false

Use of parameters beyond the limitations specified above is considered experimental and is provided *as-is* for testing purposes only. This usage is known to contain defects and may result in unpredictable behavior, including—but not limited to—packet corruption, data loss, or network instability. Deploying such features in production environments is strictly discouraged. These capabilities should be used only in isolated, non-critical test environments with appropriate safeguards in place to prevent potential disruptions to network operations.

8.10.7.1.7.15 nv_pop_header_words

Extern function that removes data from a packet, starting at the specific anchor point.

```
void nv_pop_header_words<HEADERS, NV_ANCHOR>(
    inout HEADERS headers,
    NV_ANCHOR anchor,
    bit<6> num_words,
    bit<7> word_offset = 7w0,
    bool do_reparse = true
);
```

Parameters:

- `headers` [in/out]: The packet headers to which the header data is to be removed.
- `anchor` [in]: An enum specifying the location in the packet where the header data removal should start. The user must separately verify the existence of the header (using isValid), otherwise the behavior is undefined.
- `num_words` [in]: The amount of packet data to remove, in words.
- `word_offset` [in]: The offset from the anchor point, in words, where the header removal should start.

- `do_reparse` [in]: If true, then perform a packet reparse once the removal is completed.

Limitations:

Only the following anchors listed below are validated.

Start Anchor
`PACKET_START`
`VLAN_1ST_START_OF_HEADER`
`IP_START_OF_HEADER`
`L4_START_OF_HEADER`
`ESP_START_OF_HEADER`

Use of parameters beyond the limitations specified above is considered experimental and is provided *as-is* for testing purposes only. This usage is known to contain defects and may result in unpredictable behavior, including—but not limited to—packet corruption, data loss, or network instability. Deploying such features in production environments is strictly discouraged. These capabilities should be used only in isolated, non-critical test environments with appropriate safeguards in place to prevent potential disruptions to network operations.

8.10.7.1.7.16 nv_pop_headers

Extern function that removes data from a packet, beginning at the specified start anchor point and stopping at the specified end anchor point.

```
void nv_pop_headers<HEADERS, NV_ANCHOR_START, NV_ANCHOR_END>(
    inout HEADERS headers,
    NV_ANCHOR_START start_anchor,
    NV_ANCHOR_END end_anchor,
    bool do_updates = true,
    bool do_reparse = true
);
```

Parameters:

- `headers` [in/out]: The packet headers to which the header data is to be removed.
- `start_anchor` [in]: An enum specifying the location in the packet where the header data removal should start. The user must separately verify the existence of the header (using isValid), otherwise the behavior is undefined.
- `end_anchor` [in]: An enum specifying the location in the packet where the header data removal should stop. The user must separately verify the existence of the header (using isValid), otherwise the behavior is undefined.
- `do_updates` [in]: If true, then perform IP header field updates (e.g., checksum, length) once the pop is completed (e.g., for decapsulations).

- `do_reparse` [in]: If true, then perform a packet reparse once the pop is completed.

Limitations:

Only the exact combinations of start anchor, end anchor and packet updates (e.g., due to decapsulation) are validated.

Start Anchor	End Anchor	Do Update
`PACKET_START`	`INNER_L2_START_OF_HEADER`	Yes
`PACKET_START`	`INNER_IP_START_OF_HEADER`	Yes
`PACKET_START`	`PACKET_START`	Yes
`PACKET_START`	`IP_START_OF_HEADER`	No
`IP_START_OF_HEADER`	`L4_START_OF_HEADER`	No
`IP_START_OF_HEADER`	`IP_START_OF_HEADER`	Yes
`L4_START_OF_HEADER`	`PSP_PAYLOAD_START`	Yes
`PSP_START_OF_HEADER`	`PSP_PAYLOAD_START`	No
`PACKET_START`	`PSP_PAYLOAD_START`	Yes

Use of parameters beyond the limitations specified above is considered experimental and is provided *as-is* for testing purposes only. This usage is known to contain defects and may result in unpredictable behavior, including—but not limited to—packet corruption, data loss, or network instability. Deploying such features in production environments is strictly discouraged. These capabilities should be used only in isolated, non-critical test environments with appropriate safeguards in place to prevent potential disruptions to network operations.

8.10.7.1.7.17 nv_force_reparse

This extern is used in conjunction with `nv_push_headers`, `nv_pop_header_words`, and `nv_pop_headers`. Its purpose is to trigger a packet reparse after header modifications. When performing a series of header modifications with the `do_parse` flag `false`, it may be necessary to commit the final changes and have the packet reparsed. Certain fields such as standard checksums and length fields may be recalculated. However, triggering a reparse mid-modification may leave the packet in an indeterminate state.

Signature:

```
extern void nv_force_reparse<HEADERS>(inout HEADERS headers);
```

Parameters:

- `headers` [in/out]: The packet headers that will be reparsed

8.10.7.1.7.18 nv_set_vxlan_v4_underlay

Description:

Extern function that encapsulates the packet with an ethernet frame (optionally VLAN tagged), an ipv4 header and a VXLAN header.

Signature:

```
void nv_set_vxlan_v4_underlay<HEADERS>(inout HEADERS headers, in nv_mac_addr_t dst_mac, in nv_mac_addr_t src_mac,
in nv_ipv4_addr_t sip, in nv_ipv4_addr_t dip, in nv_vxlan_id_t vni, @optional in nv_vlan_id_t vid)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a VXLAN underlay.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `sip` [in]: Source IPv4 address.
- `dip` [in]: Destination IPv4 address.
- `vni` [in]: VXLAN Network Identifier.
- `vid` [in]: Optional VLAN ID

8.10.7.1.7.19 nv_set_vxlan_v6_underlay

Description:
Extern function that encapsulates the packet with an ethernet frame (optionally VLAN tagged), an IPv6 header, and a VXLAN header.

Signature:

```
void nv_set_vxlan_v6_underlay<HEADERS>(inout HEADERS headers, in nv_mac_addr_t dst_mac, in nv_mac_addr_t src_mac,
in nv_ipv6_addr_t sip, in nv_ipv6_addr_t dip, in nv_vxlan_id_t vni, @optional in nv_vlan_id_t vid)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a VXLAN underlay.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `sip` [in]: Source IPv6 address.
- `dip` [in]: Destination IPv6 address.
- `vni` [in]: VXLAN Network Identifier.
- `vid` [in]: Optional VLAN ID.

8.10.7.1.7.20 nv_set_gre_v4_underlay

Description:
Extern function that configures GRE IPV4 underlay encapsulation, with an optional VLAN tag and optional GRE key.

Signature:

```
void nv_set_gre_v4_underlay<HEADERS>(inout HEADERS headers, in nv_mac_addr_t dst_mac, in nv_mac_addr_t src_mac, in
nv_ipv4_addr_t sip, in nv_ipv4_addr_t dip, in NvInnerProtocolType proto_type, @optional in nv_vlan_id_t vid,
@optional in bit<32> key)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a GRE underlay.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `sip` [in]: Source IPv4 address.
- `dip` [in]: Destination IPv4 address.
- `proto_type` [in]: Protocol type for the inner payload.
- `vid` [in]: Optional VLAN ID.
- `key` [in]: Optional GRE key.

8.10.7.1.7.21 nv_set_gre_v6_underlay

Description:
Extern function that configures GRE IPV6 underlay encapsulation, with an optional VLAN tag and optional GRE key.

Signature:

```
void nv_set_gre_v6_underlay<HEADERS>(inout HEADERS headers, in nv_mac_addr_t dst_mac, in nv_mac_addr_t src_mac, in
nv_ipv6_addr_t sip, in nv_ipv6_addr_t dip, in NvInnerProtocolType proto_type, @optional in nv_vlan_id_t vid,
@optional in bit<32> key)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a GRE underlay.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `sip` [in]: Source IPv6 address.
- `dip` [in]: Destination IPv6 address.
- `proto_type` [in]: Protocol type for the inner payload.
- `vid` [in]: Optional VLAN ID.
- `key` [in]: Optional GRE key.

8.10.7.1.7.22 nv_set_geneve_v4_underlay

Description:
Extern function that configures GENEVE IPV4 underlay encapsulation with optional VLAN tagging and an optional GENEVE option with 32 bits of data.

Signature:

```
void nv_set_geneve_v4_underlay<HEADERS>(inout HEADERS headers, in nv_mac_addr_t dst_mac, in nv_mac_addr_t src_mac,
in nv_ipv4_addr_t src_ip, in nv_ipv4_addr_t dst_ip, in bit<6> opt_fields_len, in bit<1> oam, in bit<1> critical, in
NvInnerProtocolType proto_type, in bit<24> vni, @optional in nv_vlan_id_t vid, @optional in bit<16> opt_class,
@optional in bit<8> opt_type, @optional in bit<5> opt_len, @optional in bit<32> opt_data)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a GENEVE underlay.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `src_ip` [in]: Source IPv4 address.
- `dst_ip` [in]: Destination IPv4 address.
- `opt_fields_len` [in]: Length of the options field in 4-byte units (must be set to 0 if no options are set)
- `oam` [in]: OAM flag.
- `critical` [in]: Critical options flag.
- `proto_type` [in]: Protocol type for the inner payload.
- `vni` [in]: Virtual Network Identifier.
- `vid` [in]: Optional VLAN ID.
- `opt_class` [in]: Optional GENEVE option class.
- `opt_type` [in]: Optional GENEVE option type.
- `opt_len` [in]: Optional GENEVE option length in 4-byte units. (must be 1 if set)
- `opt_data` [in]: Optional GENEVE option data.

8.10.7.1.7.23 nv_set_geneve_v6_underlay

Description:
Extern function that configures GENEVE IPV6 underlay encapsulation with optional VLAN tagging and an optional GENEVE option with 32 bits of data.

Signature:

```
void nv_set_geneve_v6_underlay<HEADERS>(inout HEADERS headers, in nv_mac_addr_t dst_mac, in nv_mac_addr_t src_mac,
in nv_ipv6_addr_t src_ip, in nv_ipv6_addr_t dst_ip, in bit<6> opt_fields_len, in bit<1> oam, in bit<1> critical, in
NvInnerProtocolType proto_type, in bit<24> vni, @optional in nv_vlan_id_t vid, @optional in bit<16> opt_class,
@optional in bit<8> opt_type, @optional in bit<5> opt_len, @optional in bit<32> opt_data)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a GENEVE underlay.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `src_ip` [in]: Source IPv6 address.
- `dst_ip` [in]: Destination IPv6 address.
- `opt_fields_len` [in]: Length of the options field in 4-byte units (must be set to 0 if no options are set, otherwise must be set to 2)
- `oam` [in]: OAM flag.
- `critical` [in]: Critical options flag.
- `proto_type` [in]: Protocol type for the inner payload.
- `vni` [in]: Virtual Network Identifier.
- `vid` [in]: Optional VLAN ID.
- `opt_class` [in]: Optional GENEVE option class.
- `opt_type` [in]: Optional GENEVE option type.
- `opt_len` [in]: Optional GENEVE option length in 4-byte units. (must be 1 if set)
- `opt_data` [in]: Optional GENEVE option data.

8.10.7.1.7.24 nv_set_l2tunnel_underlay

Description:
Extern function that configures custom underlay followed by an L2 encapsulation of the original packet. It is optional, but recommended, that the new tunnel encapsulation be parsable by the DPL parser. For more details see the section on NvHeaderDataTemplate.

Signature:

```
void nv_set_l2tunnel_underlay<HEADERS, NV_HEADER_DATA_TEMPLATE, VALUES>(
    inout HEADERS headers,
    NV_HEADER_DATA_TEMPLATE tunnel,
    in VALUES values)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated.
- `tunnel` [in]: The `NvHeaderDataTemplate` object that specifies the underlay headers and the header values. See also NvHeaderDataTemplate annotation.
- `values` [in]: A list expression whose length matches the number of header fields marked "variable" in the `NvTunnelTemplate` object's annotation. The order of the header fields determines which value a field corresponds to (e.g., 3rd header field marked "variable" will be set to the 3rd value in the list). Each value is required to be runtime constant, meaning it may either be an integer value or an action parameter value. Named parameters are not supported in the list expression.

8.10.7.1.7.25 nv_set_l3tunnel_underlay

Description:
Extern function that configures custom underlay followed by an L3 encapsulation of the original packet. The L3 layer must be IP. It is optional, but recommended, that the new tunnel encapsulation be parsable by the DPL parser. For more details see the section on NvHeaderDataTemplate.

Signature:

```
void nv_set_l3tunnel_underlay<HEADERS, NV_HEADER_DATA_TEMPLATE, VALUES>(
    inout HEADERS headers,
    NV_HEADER_DATA_TEMPLATE tunnel,
    in VALUES values)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated
- `tunnel` [in]: The `NvHeaderDataTemplate` object that specifies the underlay headers and the header values. See also NvHeaderDataTemplate annotation.
- `values` [in]: A list expression whose length matches the number of header fields marked "variable" in the `NvTunnelTemplate` object's annotation. The order of the header fields determines which value a field corresponds to (e.g., 3rd header field marked "variable" will be set to the 3rd value in the list). Each value is required to be runtime constant, meaning it may either be an integer value or an action parameter value. Named parameters are not supported in the list expression.

8.10.7.1.7.26 nv_encap_psp_transport

Description:
Extern function that encapsulates a clear text packet with PSP transport mode headers, with an optional virtualization cookie. The resulting packet is ready for PSP encryption.

Signature:

```
void nv_encap_psp_transport<HEADERS>(
    inout HEADERS headers,
    // PSP modify header pattern
    in bit<16> udp_src_port,
    in bit<6> crypt_offset,
    in bit<1> needs_sampling,
    in bit<1> drop,
    in NvPSPVersion version,
    in bit<32> spi,
    in bit<64> init_vector,
    @optional in bit<64> virt_cookie   // optional
)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a PSP headers.
- `udp_src_port` [in]: UDP source port of the PSP transport. Set to zero for hardware to assign.

- `crypt_offset` [in]: The offset from the end of the Initialization Vector to the start of the encrypted portion of the payload, measured in 4-octet units
- `needs_sampling` [in]: Sample at Receiver
- `drop` [in]: Drop after Sampling
- `version` [in]: PSP header version. NvPSPVersion.V0_AES_GCM_128 = 4w0 or NvPSPVersion.V1_AES_GCM_256 = 4w1
- `spi` [in]: A 32-bit value that is used by a receiver to identify the Security Association (SA) to which an incoming packet is bound
- `init_vector` [in]: A unique value for each packet sent over a Security Association
- `virt_cookie` [in]: An optional field, it may contain a Virtual Network Identifier (VNI) or other data.

The UDP destination port is set to 1000 for PSP.

8.10.7.1.7.27 nv_decap_psp_transport

Description:
Extern function that decapsulates a clear text packet with PSP transport mode headers. This function can only be called on a decrypted PSP packet.

Signature:

```
void nv_decap_psp_transport<HEADERS>(inout HEADERS headers)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be decapsulated and the PSP headers removed.

8.10.7.1.7.28 nv_encap_psp_v4_tunnel

Description:
Extern function that encapsulates a clear text packet with PSP L3 tunnel mode headers. A new underlay is provided, with an optional underlay VLAN and PSP virtualization cookie. The resulting packet is ready for PSP encryption.

Signature:

```
void nv_encap_psp_v4_tunnel<HEADERS>(
    inout HEADERS headers,
    // encap
    in nv_mac_addr_t dst_mac,
    in nv_mac_addr_t src_mac,
    in nv_ipv4_addr_t sip,
    in nv_ipv4_addr_t dip,
    in bit<16> udp_src_port,
    // PSP
    in NvIPEncapProtocol next_header,
    in bit<6> crypt_offset,
    in bit<1> needs_sampling,
    in bit<1> drop,
    in NvPSPVersion version,
    in bit<32> spi,
    in bit<64> init_vector,
    @optional in nv_vlan_id_t vid,
    @optional in bit<64> virt_cookie   // optional
```

```
)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a PSP headers.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `src_ip` [in]: Source IPv4 address.
- `dst_ip` [in]: Destination IPv4 address.
- `udp_src_port` [in]: UDP source port of the PSP transport. Set to zero for hardware to assign.
- `next_header` [in]: IP protocol number, identifying the type of the next header. NvIPEncapProtocol.IPV4 or NvIPEncapProtocol.IPv6
- `crypt_offset` [in]: The offset from the end of the Initialization Vector to the start of the encrypted portion of the payload, measured in 4-octet units
- `needs_sampling` [in]: Sample at Receiver
- `drop` [in]: Drop after Sampling
- `version` [in]: PSP header version. NvPSPVersion.V0_AES_GCM_128 = 4w0 or NvPSPVersion.V1_AES_GCM_256 = 4w1
- `spi` [in]: A 32-bit value that is used by a receiver to identify the Security Association (SA) to which an incoming packet is bound
- `init_vector` [in]: A unique value for each packet sent over a Security Association
- vid [in]: An optional VLAN ID to be included in the underlay headers.
- `virt_cookie` [in]: An optional field, it may contain a Virtual Network Identifier (VNI) or other data.

The UDP destination port is set to 1000 for PSP.

8.10.7.1.7.29 nv_encap_psp_v6_tunnel

Description:
Extern function that encapsulates a clear text packet with PSP L3 tunnel mode headers. A new underlay is provided, with an optional underlay VLAN and PSP virtualization cookie. The resulting packet is ready for PSP encryption.

Signature:

```
void nv_encap_psp_v6_tunnel<HEADERS>(
    inout HEADERS headers,
    // encap
    in nv_mac_addr_t dst_mac,
    in nv_mac_addr_t src_mac,
    in nv_ipv6_addr_t sip,
    in nv_ipv6_addr_t dip,
    in bit<16> udp_src_port,
    // PSP
    in NvIPEncapProtocol next_header,
    in bit<6> crypt_offset,
    in bit<1> needs_sampling,
    in bit<1> drop,
    in NvPSPVersion version,
    in bit<32> spi,
```

```
    in bit<64> init_vector,
    @optional in nv_vlan_id_t vid,
    @optional in bit<64> virt_cookie   // optional
)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be encapsulated with a PSP headers.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `src_ip` [in]: Source IPv6 address.
- `dst_ip` [in]: Destination IPv6 address.
- `udp_src_port` [in]: UDP source port of the PSP transport. Set to zero for hardware to assign.
- `next_header` [in]: IP protocol number, identifying the type of the next header. NvIPEncapProtocol.IPV4 or NvIPEncapProtocol.IPv6
- `crypt_offset` [in]: The offset from the end of the Initialization Vector to the start of the encrypted portion of the payload, measured in 4-octet units
- `needs_sampling` [in]: Sample at Receiver
- `drop` [in]: Drop after Sampling
- `version` [in]: PSP header version. NvPSPVersion.V0_AES_GCM_128 = 4w0 or NvPSPVersion.V1_AES_GCM_256 = 4w1
- `spi` [in]: A 32-bit value that is used by a receiver to identify the Security Association (SA) to which an incoming packet is bound
- `init_vector` [in]: A unique value for each packet sent over a Security Association
- `vid` [in]: An optional VLAN ID to be included in the underlay headers.
- `virt_cookie` [in]: An optional field, it may contain a Virtual Network Identifier (VNI) or other data.

The UDP destination port is set to 1000 for PSP.

8.10.7.1.7.30 nv_decap_psp_tunnel

Description:
Extern function that decapsulates a clear text packet with PSP tunnel mode headers. This function can only be called on a decrypted PSP packet.

Signature:

```
void nv_decap_psp_tunnel<HEADERS>(
    inout HEADERS headers,
    // decap headers
    in nv_mac_addr_t dst_mac,
    in nv_mac_addr_t src_mac,
    in NvPspInnerProtocolType l3_ether_type,
    @optional in nv_vlan_id_t vid
)
```

Parameters:

- `headers` [in/out]: The packet headers that are to be decapsulated and the PSP headers removed.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `l3_ether_type` [in]: The ethertype of the inner PSP header/payload. NvPspInnerProtocolType.IPV4 or NvPspInnerProtocolType.IPV6
- `vid` [in]: An optional VLAN ID to be included in the overlay header.

8.10.7.1.7.31 nv_mirror

Description:
Extern function that duplicates the packet, sending each to a different port. Hence this extern is a terminal action.

Signature:

```
void nv_mirror(in nv_logical_port_t vport, in nv_logical_port_t mirror_port)
```

Parameters:

- `vport` [in]: Destination for the first copy of the packet
- `mirror_port` [in]: Destination for the second copy of the packet

8.10.7.1.7.32 nv_mirror_vxlan_v4_to_remote

Description:
Extern function that duplicates the packet, sending each to a different port, with the copy being sent to the mirror port encapsulated with a VXLAN IPV4 underlay

Signature:

```
void nv_mirror_vxlan_v4_to_remote(in nv_logical_port_t vport, in nv_logical_port_t mirror_port, in nv_mac_addr_t dst_mac, in nv_mac_addr_t src_mac, in nv_ipv4_addr_t sip, in nv_ipv4_addr_t dip, in nv_vxlan_id_t vni, @optional in nv_vlan_id_t vid)
```

Parameters:

- `vport` [in]: Destination for the unmodified copy of the packet
- `mirror_port` [in]: The destination for the encapsulated copy of the packet.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `sip` [in]: Source IPv4 address.
- `dip` [in]: Destination IPv4 address.
- `vni` [in]: VXLAN Network Identifier.
- `vid` [in]: Optional VLAN ID.

8.10.7.1.7.33 nv_mirror_vxlan_v6_to_remote

Description:
Extern function that duplicates the packet, sending each to a different port, with the copy being sent to the mirror port encapsulated with a VXLAN IPv6 underlay.

Signature:

```
void nv_mirror_vxlan_v6_to_remote(in nv_logical_port_t vport, in nv_logical_port_t mirror_port, in nv_mac_addr_t
dst_mac, in nv_mac_addr_t src_mac, in nv_ipv6_addr_t sip, in nv_ipv6_addr_t dip, in nv_vxlan_id_t vni, @optional in
nv_vlan_id_t vid)
```

Parameters:

- `vport` [in]: Destination for the unmodified copy of the packet.
- `mirror_port` [in]: Destination for the encapsulated copy of the packet.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `sip` [in]: Source IPv6 address.
- `dip` [in]: Destination IPv6 address.
- `vni` [in]: VXLAN Network Identifier.

8.10.7.1.7.34 nv_mirror_gre_v4_to_remote

Description:
Extern function that duplicates the packet, sending each to a different port, with the copy being sent to the mirror port encapsulated with a GRE IPv4 underlay, including optional VLAN tagging and GRE key.

Signature:

```
void nv_mirror_gre_v4_to_remote(in nv_logical_port_t vport, in nv_logical_port_t mirror_port, in nv_mac_addr_t
src_mac, in nv_mac_addr_t dst_mac, in nv_ipv4_addr_t src_ip, in nv_ipv4_addr_t dst_ip, in NvInnerProtocolType
proto_type, @optional in nv_vlan_id_t vid, @optional in bit<32> key)
```

Parameters:

- `vport` [in]: Destination for the unmodified copy of the packet.
- `mirror_port` [in]: Destination for the encapsulated copy of the packet.
- `src_mac` [in]: Source MAC address.
- `dst_mac` [in]: Destination MAC address.
- `src_ip` [in]: Source IPv4 address.
- `dst_ip` [in]: Destination IPv4 address.
- `proto_type` [in]: Protocol type for the inner payload.
- `vid` [in]: Optional VLAN ID.
- `key` [in]: Optional GRE key.

8.10.7.1.7.35 nv_mirror_gre_v6_to_remote

Description:
Extern function that duplicates the packet, sending each to a different port, with the copy being sent to the mirror port encapsulated with a GRE IPv6 underlay, including optional VLAN tagging and GRE key.

Signature:

```
void nv_mirror_gre_v6_to_remote(in nv_logical_port_t vport, in nv_logical_port_t mirror_port, in nv_mac_addr_t
src_mac, in nv_mac_addr_t dst_mac,, in nv_ipv6_addr_t sip, in nv_ipv6_addr_t dip, in NvInnerProtocolType
proto_type, @optional in nv_vlan_id_t vid, @optional in bit<32> key)
```

Parameters:

- `vport` [in]: Destination for the unmodified copy of the packet.
- `mirror_port` [in]: Destination for the encapsulated copy of the packet.
- `src_mac` [in]: Source MAC address.
- `dst_mac` [in]: Destination MAC address.
- `sip` [in]: Source IPv6 address.
- `dip` [in]: Destination IPv6 address.
- `proto_type` [in]: Protocol type for the inner payload.
- `vid` [in]: Optional VLAN ID.
- `key` [in]: Optional GRE key.

8.10.7.1.7.36 nv_mirror_geneve_v4_to_remote

Description:
Extern function that duplicates the packet, sending each to a different port, with the copy being sent to the mirror port encapsulated with a Geneve IPv4 underlay, including optional VLAN tagging and Geneve options.

Signature:

```
void nv_mirror_geneve_v4_to_remote(in nv_logical_port_t vport, in nv_logical_port_t mirror_port, in nv_mac_addr_t
dst_mac, in nv_mac_addr_t src_mac, in nv_ipv4_addr_t src_ip, in nv_ipv4_addr_t dst_ip, in bit<6> opt_fields_len, in
bit<1> oam, in bit<1> critical, in NvInnerProtocolType proto_type, in bit<24> vni, @optional in nv_vlan_id_t vid,
@optional in bit<16> opt_class, @optional in bit<8> opt_type, @optional in bit<5> opt_len, @optional in bit<32>
opt_data)
```

Parameters:

- `vport` [in]: Destination for the unmodified copy of the packet.
- `mirror_port` [in]: Destination for the encapsulated copy of the packet.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `src_ip` [in]: Source IPv4 address.
- `dst_ip` [in]: Destination IPv4 address.

- `opt_fields_len` [in]: Length of the options field in 4-byte units (must be set to 0 if no options are set, otherwise must be set to 2)
- `oam` [in]: OAM flag.
- `critical` [in]: Critical options flag.
- `proto_type` [in]: Protocol type for the inner payload.
- `vni` [in]: Virtual Network Identifier.
- `vid` [in]: Optional VLAN ID.
- `opt_class` [in]: Optional GENEVE option class.
- `opt_type` [in]: Optional GENEVE option type.
- `opt_len` [in]: Optional GENEVE option length in 4-byte units (must be 1 if set).
- `opt_data` [in]: Optional GENEVE option data.

8.10.7.1.7.37 nv_mirror_geneve_v6_to_remote

Description:
Extern function that duplicates the packet, sending each to a different port, with the copy being sent to the mirror port encapsulated with a Geneve IPv6 underlay, including optional VLAN tagging and Geneve options.

Signature:

```
void nv_mirror_geneve_v6_to_remote(in nv_logical_port_t vport, in nv_logical_port_t mirror_port, in nv_mac_addr_t dst_mac, in nv_mac_addr_t src_mac, in nv_ipv6_addr_t src_ip, in nv_ipv6_addr_t dst_ip, in bit<6> opt_fields_len, in bit<1> oam, in bit<1> critical, in NvInnerProtocolType proto_type, in bit<24> vni, @optional in nv_vlan_id_t vid, @optional in bit<16> opt_class, @optional in bit<8> opt_type, @optional in bit<5> opt_len, @optional in bit<32> opt_data)
```

Parameters:

- `vport` [in]: Destination for the unmodified copy of the packet.
- `mirror_port` [in]: Destination for the encapsulated copy of the packet.
- `dst_mac` [in]: Destination MAC address.
- `src_mac` [in]: Source MAC address.
- `src_ip` [in]: Source IPv6 address.
- `dst_ip` [in]: Destination IPv6 address.
- `opt_fields_len` [in]: Length of the options field in 4-byte units (must be set to 0 if has_option is false, otherwise must be set to 2)
- `oam` [in]: OAM flag.
- `critical` [in]: Critical options flag.
- `proto_type` [in]: Protocol type for the inner payload.
- `vni` [in]: Virtual Network Identifier.
- `vid` [in]: Optional VLAN ID.
- `opt_class` [in]: Optional GENEVE option class.
- `opt_type` [in]: Optional GENEVE option type.

- `opt_len` [in]: Optional GENEVE option length in 4-byte units (must be 1 if set).
- `opt_data` [in]: Optional GENEVE option data.

8.10.7.1.7.38 nv_send_debug_pkt

Description:
Extern function that adds pipeline metadata and packet state to the packet, then sends it to the DPL Debugger. The packet is forwarded to the DPL debugger and will be reinjected back to the pipeline, at a point immediately following the invocation of `nv_send_debug_pkt`. This action may be invoked within a P4 action block or a control's apply block.

Signature:

```
void nv_send_debug_pkt(in nv_debug_cookie_t cookie = 8w0x0)
```

Parameters:

- `cookie` [in]: An optional cookie value can be provided by the user, that will show up in the DPL Debugger with the debug packet

Automatic Debug Points (`--debug-mode auto`)

When the compiler is invoked with `--debug-mode auto`, the DPL compiler now inserts automatic debug points at the end of each P4 action, in addition to the existing debug points before each statement in control `apply` blocks.

This behavior is implemented by inserting an internal `DebugInstruction` (equivalent to `nv_send_debug_pkt(cookie = 0)`) immediately before the terminal instruction of each action.

Placement Rules

For control body, a debug point is inserted prior to each statement. For each action body:

- If the **last instruction** in the action is effectively a **RETURN** or **EXIT** (for example, `nv_send_to_port`, `nv_drop`):
  - A debug point is inserted **immediately before** that terminal instruction.
  - For actions that ultimately call a terminal extern (e.g., `nv_send_to_port`), the debug point observes packet state **after all field updates in the action**, but **before** the packet leaves the pipeline.
- If the action is empty or its last instruction is not terminal, no automatic debug point is added.

Interaction with Manual `nv_send_debug_pkt`

If you explicitly call `nv_send_debug_pkt()` in an action:

- When a manual debug call is placed **immediately before** the terminal instruction, the compiler **does not** insert another automatic debug point at that same location, avoiding duplicate debug packets. A warning may be issued to indicate that the automatic point was suppressed.
- Manual debug calls elsewhere in the action are left **unchanged**. The automatic debug point is still inserted at the end unless it would be adjacent to an existing manual call, as described above.

Debugger Behavior

From the debugger's perspective:

- Each action execution yields a debug point at a **consistent location**:
  - After the action has finished updating headers and metadata.
  - Before any terminating extern that drops or sends the packet.
- This makes it easier to correlate:
  - Table hits → selected actions → final per-action state, and
  - Multiple debug points along the packet path, including across repeated invocations of the same action.

> **Limitations**
>
> You must enable debug mode by compiling your DPL program with the `-g/--debug-mode` flag in addition to calling `nv_send_debug_pkt`. Debugging is not supported for P4 tables larger than 8M in size. To debug packets from both the primary wire port P0 and the second wire port P1 requires configuring the DPU in multi-port eswitch mode. When using the automatic debug point feature, a `nv_send_debug_pkt` will override the automatic debug point, with the specified cookie value.
>
> See DOCA Pipeline Language Developer Tool for more details.

8.10.7.1.7.39 nv_add_entry

Description:
Extern function that inserts a table entry via a data plane insertion mechanism. After invoking `nv_add_entry`, a status code is returned and the packet continues on the pipeline.

Signature:

```
NvAddEntryErrorStatus_t nv_add_entry(<K, A>(
    string table_name,
    in K keys,
    string action_name,
    in A action_params,
    in bit<32> default_timeout_ms = 0
);
```

Parameters:

- `table_name` [in]: The name of the table to which the entry will be added. The table and the invocation of the extern must be in the scope of the same control.
- `keys` [in]: A list of keys, consisting of the supported packet header fields. Only the following list of packet fields are permitted to be used as values for either the key list or the action parameter value list. Runtime variables are also allowed:

Header	Field
ethernet	dst_addr
ethernet	src_addr
std_meta	last_l2_ether_type
mpls	label
mpls	tc
mpls	bos
mpls	ttl
ipv4	src_addr
ipv4	dst_addr
ipv4	ttl
ipv4	diffserv
ipv6	hop_limit
ipv6	diffserv
ipv6	src_addr
ipv6	dst_addr
tcp	ecn
tcp	flags
tcp	src_port
tcp	dst_port
udp	src_port
udp	dst_port

- `action_name` [in]: The name of the action that should be applied if the entry matches. The action must be in the action list declared for the table.
- `action_params` [in]: A list of action parameter values. The number and order of values must match the parameters defined for the action. Values may be compile time constants, a runtime variable or a supported packet header field. The total width of all action parameters is limited to 11 bytes. Parameters that are not byte aligned are padded up to the next byte boundary.
- `default_timeout_ms` [in]: The default timeout for the entry, in milliseconds. Default value is zero, meaning no timeout will be applied.

Returns:

- A bit<1> `NvAddEntryErrorStatus_t` value is returned to the application:
  - ADD_ENTRY_SUCCESS = 0
  - ADD_ENTRY_FAILURE = 1

The table attribute `nv_support_add_entry` must be set to `true` for each table to which this extern applies.

If a non zero timeout is specified, then the table attribute `nv_support_timeout` must be set to true.

Supported usage:

`nv_add_entry` can only be called from the control's apply block. In particular, it cannot be called from within a P4 action body. For example:

```
apply {
    if (dst_table.apply().miss) {
        user_meta.ret = nv_add_entry("dst_table",
            { hdr.ethernet.dst_addr, hdr.ipv6.dst_addr },
            "forward",
            { 4 },
            5000 // 5 seconds
          );
          if (user_meta.ret == 0) {
              nv_send_to_port(4);
          }
    }
    // continue with rest of pipeline processing...
}
```

Limitations:

`nv_add_entry` feature is a beta level feature in the current release. As such, there are number of restrictions on its usage and runtime behavior. The listed limitations reflect this and it is expected that this feature will be expanded in future releases. Not all combinations of the packet fields listed above are supported due to resource limitations. Since this feature is dependent on runtime resources, the compiler may not always issue an error. Instead, the application blob may fail to load with a DPL RT daemon error log message.

8.10.7.1.7.40 nv_get_random_value

Extern function that returns a 16 bit random value from the hardware.

Signature:

```
extern bit<16> nv_get_random_value();
```

Parameters:

- `bit<16>`: a random value between 0 and 65535

8.10.7.1.7.41 nv_get_ut_clock

Extern function that returns a UTC timestamp from the device's Real-Time clock. The MSB of the 64-bit timestamp the time in seconds. The LSB of the 64-bit timestamp holds the time in nanoseconds.

Signature:

```
extern bit<64> nv_get_ut_clock();
```

Parameters:

- `bit<64>` : The UTC time stamp.
  - Seconds in the upper 32 bits
  - Nano-seconds in the lower 32 bits

8.10.7.1.7.42 nv_get_fr_clock

Extern function that returns the free running clock from the device's internal timer.

Signature:

```
extern bit<64> nv_get_fr_clock();
```

Returns:

- `bit<64>` : The free running clock, in units of 1/device frequency.

> ⚠ The following MFT tool can report the device's clock frequency:
> `sudo mlxuptime -d /dev/mst/<device_name>_pciconf`

8.10.7.1.8 DOCA Extern Objects

8.10.7.1.8.1 Counters

BlueField supports per entry counters, shared and direct. A (shared) counter is an extern object that allows the user to access N independent counters via an index. Whereas a direct counter is an extern object that is directly associated with a P4 table where the index is implied by the entry slot. For both types, the counter value is updated when an action calls the count() method.

NvCounter

Instantiates an indirect counter of the specified width and type.

Constructor:

```
extern NvCounter(bit<32> size, NvCounterType type)
```

Parameters*:*

- `size[in]` : Number of counter indices. The size must be a power of 2, and no greater than 16M.
- `type[in]` : Enum indicating counter type. Currently only `NvCounterType.PACKETS_AND_BYTES` is supported.

Methods:

count

Increments the counter at the specified index

```
void count(in bit<32> index)
```

Parameters:

- `index[in]` : Index of the counter to increment

NvDirectCounter

Instantiates a direct counter that can be assigned to a table. Direct counters do not have a separate size, they are as wide as the table. Each action invoked by an entry hit should call the count() method to increment the entry count.

Constructor:

```
extern NvDirectCounter(bit<32> size, NvCounterType type)
```

Parameters*:*

- `type[in]` : Enum indicating counter type. Currently only `NvCounterType.PACKETS_AND_BYTES` is supported.

Methods:

count

Increments the counter associated the the entry that triggered the action execution

`void count()`

⚠ Methods of a NvDirectCounter object may only be called by the P4 Table that owns it via the "direct_counter" property bound to the P4 Table. It is an error to attempt to call the count() method from a P4 Table that does not own the direct counter. While the system supports up to 16M total counters, a small number of counters may be reserved by the kernel.

⚠ If there are no side effects, it is most efficient to call the count method as the first primitive action in a P4 action.

8.10.7.1.8.2 Meters

BlueField supports per-flow metering, following RFC2697, RFC2698, and RFC4115. Similar to counters, both direct meters and shared meters are supported in the DPL target architecture. The packets for a given flow can be colored by the meter into three "colors": red, yellow and green. The meter burst parameters can be specified with units of bytes or packets.

```
typedef bit<8> nv_meter_color_t;

enum nv_meter_color_t NvMeterColor {
    RED = 8w0,
    YELLOW = 8w1,
    GREEN = 8w2,
}

enum NvMeterUnits {
  BYTES,
  PACKETS
}
```

The meter color indicators are:

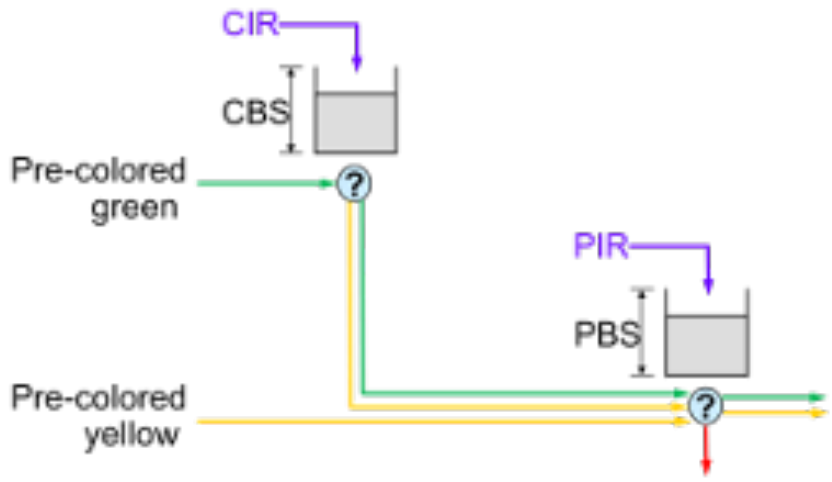
- `GREEN` : The packet conforms to the Committed Information Rate (CIR) and fits within the Committed Burst Size (CBS). It is fully within the agreed traffic profile.
- `YELLOW` : The packet exceeds the CIR but is within the Excess/Peak Information Rate and fits within the Excess Burst Size.
- `RED` : The packet exceeds the information rate or burst sizes and is considered out-of-profile, typically indication the packet should be dropping or set to a lower priority.

The meter units are defined as:

- `BYTES` : packet bytes as indicated by IP.length
- `PACKETS` : number of packets (128 bytes per packet)

NvMeterPeakTrTCM

The `NvMeterPeakTrTCM` extern object Implements RFC 2698.



Constructor:

Instantiates a Two Rate Three Color Marker shared meter object of the specified size, units and burst parameters.

```
extern NvMeterPeakTrTCM(bit<32> size, NvMeterUnits units, bit<64> cir, bit<64> cbs, bit<64> pir, bit<64> pbs)
```

Parameters:

- `size[in]`: Number of meter indices. The size must be a power of 2, and no greater than 16M.
- `units[in]`: Enum indicating the units used by the meter. Metering by `NvMeterUnits.BYTES` or by `NvMeterUnits.PACKETS` is supported.
- `cir[in]`: Committed Information Rate
- `cbs[in]`: Committed Burst Size
- `pir[in]`: Peak Information Rate
- `pbs[in]`: Peak Burst Size

Constructor:

Instantiates a Two Rate Three Color Marker shared meter object of the specified size with a default initial state of GREEN. The bucket parameters can be updated per entry at runtime.

```
extern NvMeterPeakTrTCM(bit<32> size, NvMeterUnits units)
```

Parameters:

- `size[in]`: Number of meter indices. The size must be a power of 2, and no greater than 16M.
- `units[in]`: Enum indicating the units used by the meter. Metering by `NvMeterUnits.BYTES` or by `NvMeterUnits.PACKETS` is supported.

Methods:

meter

Executes the metering of the flow entry at the specified index.

```
nv_meter_color_t meter(in bit<32> index, nv_meter_color_t initial_color = NvMeterColor.GREEN)
```

Parameters:

- `index[in]` : Index of the meter to execute
- `initial_color[in]` : The initial color to assign to the flow. Coloring of `NvMeterColor.RED` , `NvMeterColor.YELLOW` , or `NvMeterColor.GREEN` . The default is `NvMeterColor.GREEN` .

Returns:

- The `nv_meter_color_t` of the flow entry at the specified index.

NvDirectMeterPeakTrTCM

The `NvDirectMeterPeakTrTCM` extern object implements RFC 2698. A direct meter must be assigned to a table and be the same size as the table. Each action invoked by an entry hit should call the `meter()` method to perform the policing.

Constructor:

Instantiates a Two Rate Three Color Marker direct meter object of the specified size, units and burst parameters.

```
extern NvDirectMeterPeakTrTCM(NvMeterUnits units, bit<64> cir, bit<64> cbs,  bit<64> pir, bit<64> pbs)
```

Parameters*:*

- `units[in]` : Enum indicating the units used by the meter. Metering by `NvMeterUnits.BYTES` or by `NvMeterUnits.PACKETS` is supported.
- `cir[in]` : Committed Information Rate
- `cbs[in]` : Committed Burst Size
- `pir[in]` : Peak Information Rate
- `pbs[in]` : Peak Burst Size

Constructor:

Instantiates a Two Rate Three Color Marker direct meter object of the specified size with a default initial state of GREEN. The bucket parameters can be updated per entry at runtime.

```
extern NvDirectMeterPeakTrTCM(NvMeterUnits units)
```

Parameters:

- `units[in]` : Enum indicating the units used by the meter. Metering by `NvMeterUnits.BYTES` or by `NvMeterUnits.PACKETS` is supported.

Methods:

meter

Executes the metering of the flow entry at the specified index.

```
nv_meter_color_t meter(nv_meter_color_t initial_color = NvMeterColor.GREEN)
```

Parameters:

- `initial_color[in]` : The initial color to assign to the flow. Coloring of `NvMeterColor.RED` , `NvMeterColor.YELLOW` , or `NvMeterColor.GREEN` . The default is `NvMeterColor.GREEN` .

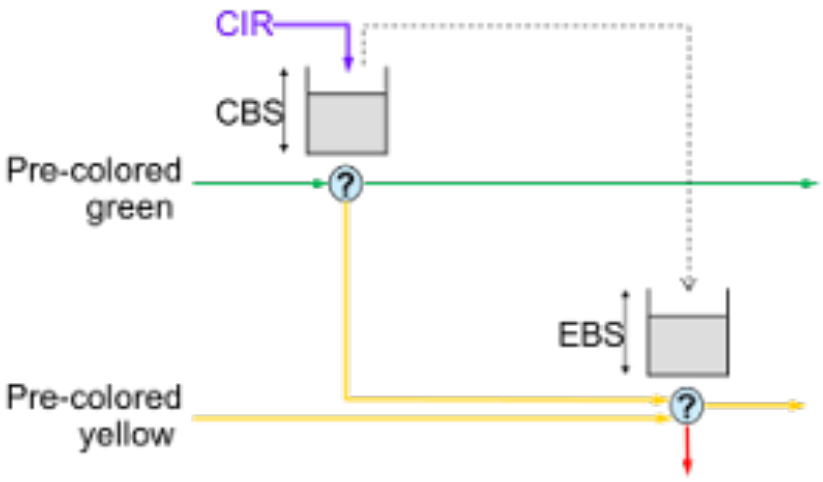
Returns:

- The `nv_meter_color_t` of the flow entry at the specified index.

> ⚠ **Rate and Size Max Values**
>
> Each configuration parameter of `NvMeterPeakTrTCM` and `NvDirectMeterPeakTrTCM` is restricted to certain max values.
>
> When metering by BYTES, max values are the following:
> - cir: 255000000000
> - cbs: 2147483648
> - pir: 510000000000
> - pbs: 4294967296
>
> When metering by PACKETS, max values are the following:
> - cir: 1992187500
> - cbs: 16777216
> - pir: 3984375000
> - pbs: 33554432

NvMeterSrTCM

The `NvMeterSrTCM` extern object implements RFC 2697.



Constructor:

Instantiates a Single Rate Three Color Marker shared meter object of the specified size, units and burst parameters.

```
extern NvMeterSrTCM(bit<32> size, NvMeterUnits units, bit<64> cir, bit<64> cbs, bit<64> ebs)
```

Parameters:

- `size[in]` : Number of meter indices. The size must be a power of 2, and no greater than 16M.
- `units[in]` : Enum indicating the units used by the meter. Metering by `NvMeterUnits.BYTES` or by `NvMeterUnits.PACKETS` is supported.
- `cir[in]` : Committed Information Rate
- `cbs[in]` : Committed Burst Size
- `ebs[in]` : Excess Burst Size

Constructor:

Instantiates a Single Rate Three Color Marker shared meter object of the specified size with a default initial state of GREEN. The bucket parameters can be updated per entry at runtime.

```
extern NvMeterSrTCM(bit<32> size, NvMeterUnits units)
```

Parameters:

- `size[in]` : Number of meter indices. The size must be a power of 2, and no greater than 16M.
- `units[in]` : Enum indicating the units used by the meter. Metering by `NvMeterUnits.BYTES` or by `NvMeterUnits.PACKETS` is supported.

Methods:

meter

Executes the metering of the flow entry at the specified index

```
nv_meter_color_t meter(in bit<32> index, nv_meter_color_t initial_color = NvMeterColor.GREEN)
```

Parameters:

- `index[in]` : Index of the meter to execute
- `initial_color[in]` : The initial color to assign to the flow. Coloring of `NvMeterColor.RED` , `NvMeterColor.YELLLOW` , or `NvMeterColor.GREEN` . The default is `NvMeterColor.GREEN` .

Returns:

- The `nv_meter_color_t` of the flow entry at the specified index.

NvDirectMeterSrTCM

The `NvDirectMeterSrTCM` extern object implements RFC 2697. A direct meter must be assigned to a table and be the same size as the table. Each action invoked by an entry hit should call the `meter()` method to perform the policing.

Constructor:

Instantiates a Single Rate Three Color Marker direct meter object of the specified size, units and burst parameters.

```
extern NvDirectMeterSrTCM(NvMeterUnits units, bit<64> cir, bit<64> cbs, bit<64> ebs)
```

Parameters*:*

- `units` : Enum indicating the units used by the meter. Metering by `NvMeterUnits.BYTES` or by `NvMeterUnits.PACKETS` is supported.
- `cir` : Committed Information Rate
- `cbs` : Committed Burst Size
- `ebs` : Excess Burst Size

Constructor:

Instantiates a Single Rate Three Color Marker direct meter object of the specified size with a default initial state of GREEN. The bucket parameters can be updated per entry at runtime.

```
extern NvDirectMeterSrTCM(NvMeterUnits units)
```

Parameters*:*

- `units` : Enum indicating the units used by the meter. Metering by `NvMeterUnits.BYTES` or by `NvMeterUnits.PACKETS` is supported.

Methods:

meter

Executes the metering of the flow entry at the specified index.

```
nv_meter_color_t meter(in bit<32> index, in nv_meter_color_t initial_color = NvMeterColor.GREEN)
```

Parameters:

- `index[in]` : Index of the meter to execute
- `initial_color[in]` : The initial color to assign to the flow. Coloring of `NvMeterColor.RED` , `NvMeterColor.YELLLOW` , or `NvMeterColor.GREEN` . The default is `NvMeterColor.GREEN` .

Returns:

- The `nv_meter_color_t` of the flow entry at the specified index.

> ⚠ **Rate and Size Max Values**
>
> Each configuration parameter of NvMeterSrTCM and NvDirectMeterSrTCM is restricted to certain max values.
>
> When metering by BYTES, max values are the following:
> - cir: 255000000000
> - cbs, ebs: 2147483648
>
> When metering by PACKETS, max values are the following:
> - cir: 1992187500
> - cbs, ebs: 16777216

> ⚠ Methods of a `NvDirectMeterPeakTrTCM` and a `NvDirectMeterSrTCM` object may only be called by the P4 Table that owns it via the `direct_meter` property bound to the P4 Table. It is an error to attempt to call the `meter()` method from a P4 Table that does not own the direct meter. A meter may not be owned by multiple P4 Tables. The system supports up to 16M total meters.

8.10.7.1.8.3 Options Parser

DPL supports TLV style parsing for protocols with options.

NvOptionsParser

The NvOptionsParser is an extern object used to define the behavior of the TLV (Type-Length-Value) options parser.

```
extern NvOptionParser<VALUE, OPTION> {
    NvOptionParser(
        string options_length_field = "",
        bit<32> options_length_shift = 32w0,
        bit<32> options_length_add = 32w0,
        string option_layout_header_type = "",
        string option_length_field = "",
        bit<32> option_length_shift = 32w0,
        bit<32> option_length_add = 32w0,
        string option_type_field = "",
        list<tuple<VALUE, OPTION>> options
    );

    void parseOptions<H>(packet_in p, inout H headers);
}
```

Parameters:

- `options_length_field` [in]: Optional; omit if ***total*** options length is fixed, otherwise provide the field name that contains the header length value
- `options_length_shift` : Optional; omit if the field can be used without shifting
- `options_length_add` : Optional; omit if the field can be used without adding
- `option_layout_header_type` : Mandatory `header_type_name`
- `option_length_field` : Optional; omit if each option is a constant size, otherwise provide the field name that contains the header length value
- `option_length_shift` : Optional; omit if the field can be used without shifting
- `option_length_add` : Optional; omit if the field can be used without adding
- `option_type_field` : Mandatory `field_name`
- `options` : Mandatory; variable-length (expression-)list of (type, header field)

Methods:

parseOptions

Parses the TLV

Signature: `void parseOptions<H>(packet_in packet, inout H headers);`

Parameters:

- packet[in]: input packet
- headers[in/out]: packet headers struct

Examples:

See Geneve TLV Parsing Example.

8.10.7.1.8.4 Custom Tunnel Encapsulation and Header Insertion

DPL supports the creation of L2 and L3 tunnels using custom tunnel headers, as well as inserting custom headers at specific anchor points in the header stack.

NvHeaderDataTemplate

Instantiates a template object used to inserting custom data to the header stack (e.g., tunnel encapsulations or pushing new headers). This object is used for controlling the behavior of the actions that insert data into the header at predefined locations.

```
extern NvHeaderDataTemplate<HEADERS_DATA_TYPE> {
    NvHeaderDataTemplate();
}
```

Type Variables:

- `HEADERS_DATA_TYPE[in]` : Must be the typename of a user-declared `struct` whose only fields must be of `header` type. The entire set of underlay headers should be defined as a struct. For example:

```
header my_tunnel_h {
    bit<32> field_1;
    bit<32> field_2;
    bit<32> field_3;
}

struct tunnel_headers_t {
    nv_ethernet_h ethernet;
    my_tunnel_h   custom_tunnel;
}
```

Annotation:

`NvHeaderDataTemplate` works slightly differently than other extern objects in that the object has no methods; instead, the object can be passed into the extern functions:

- `nv_set_l2tunnel_underlay`
- `nv_set_l3tunnel_underlay`
- `nv_push_headers`

Declaring a `NvHeaderDataTemplate` object does not use any resources in hardware, as the template construct is provided for simplifying the process of specifying header field values for custom tunnels. When declaring a `NvHeaderDataTemplate` object, the annotation `@nv_header_data_fields` must be present. This annotation contains a key-value entry for each header in the specified struct type. For each header, the header fields must be specified in the order that they appear in the header definition. The value assigned to a field must be one of the following:

- a non-negative integer
- the string "variable"
- the string "ignore" (only for the tunnel externs)

```
@nv_header_data_fields(
    ethernet = {
        dst_addr = "variable",
        src_addr = "variable",
        ether_type = 0xABCD
    },
    custom_tunnel = {
        field_1 = 1,
        field_2 = "ignore",
        field_3 = "variable"
    }
)
NvHeaderDataTemplate<tunnel_headers_t>() my_tunnel;
```

When using a list expression in an action that uses a `NvHeaderDataTemplate` the following restrictions apply:

- The length of the list must match the number of header fields marked "variable" in the `NvTunnelTemplate` object's annotation
- The order of the header fields determines the order of the values in the list expression (e.g., 3rd header field marked "variable" will be set to the 3rd value in the list)
- Each value is required to be runtime constant, meaning it may either be an integer value or an action parameter value
- Unlike the list expressions used in the @nv_header_data_fields annotation, named parameters (e.g. *field_3 = "variable"*) are not supported in the list expression used as an action parameters.

For a complete example, see GTP Tunnel Encapsulation Example.

Header fields overwritten by Encapsulation

Certain header fields will automatically be recalculated by the hardware after encapsulation. These fields cannot be assigned by the user. It is good practice to mark them as "ignore".

Header Field	Value
`ipv4.ecn`	0
`ipv4.identification`	0
`ipv4.hdr_checksum`	Hardware calculated
`ipv4.total_len`	Hardware calculated
`ipv6.traffic_class` (ECN bits only)	0
`ipv6.payload_length`	Hardware calculated
`udp.src_port`	Entropy hash
`udp.length`	Hardware calculated
`udp.checksum`	0
`tcp.checksum`	Hardware calculated
`gre.key` (8 LSB only)	Entropy hash

This extern object is deprecated and may be removed in a future release. Please use NvHeaderDataTemplate instead.

8.10.7.1.8.5 Custom Hash

The DOCA Target Architecture allows the user to define a set of key fields to calculate a hash function on and use the resulting hash value in subsequent match/action tables.

NvHashAlgorithm

The supported native hash functions are listed in the following enumeration:

```
enum NvHashAlgorithm {
    CRC32
}
```

NvHash

The NvHash object is initialized by selecting the hash type. The method can invoked by supplying the fields to calculate the hash value, with the result stored in a variable.

Constructor:

```
NvHash(NvHashAlgorithm algo)
```

Parameters:

- `algo` : The hash algorithm to use.

Methods:

get_hash

Computes the hash value from the specified key fields

```
bit<32> get_hash<DATA>(in bit<32> size, in DATA data)
```

Parameters:

- `size[in]` : Number of hash buckets. The hash value is divided by size to get modulo. The size must be a power of 2, and no greater than 16M.
- `data[in]` : The data over which to calculate the hash. Provided as a list of key fields.

Returns:

- `bit<32>` of the hash value modulo size.

Limitations:

The use of NvHash is limited to the apply block of a P4 control. This extern cannot be invoked from a P4 action body.

8.10.7.1.8.6 TCP State

The DOCA Target Architecture provides a stateful object used to track TCP sequence, acknowledgement, and direction data for a given TCP flow. A flow is defined by a standard 5-tuple consisting of:

- IP source address
- IP destination address
- IP Protocol (IPv4) or Next Header (IPv6)
- TCP source port
- TCP destination port

TCP flows are connection-oriented and bi-directional (established between two applications with distinct IP addresses and ports). To manage this, two hash tuples (lookup keys) are maintained for every connection:

1. Original direction: Packets originating from the endpoint that initiated the connection.
2. Reply direction: Reply packets sent toward the endpoint that initiated the connection.

The TCP connection tracking state is fully maintained in hardware. The packet processing workflow is as follows:

1. Search: Upon receiving a packet with a TCP 5-tuple, the dataplane searches for a matching connection entry.
2. Retrieve: If a connection entry is found, the TCP State object is retrieved.
3. Update: The relevant contexts (sequence numbers, window size, etc.) are updated.
4. Pipeline: The packet returns to the steering pipeline for final processing.

> ⚠ The resulting TCP connection states may be queried by the control plane at any time.

The hardware determines which header to use for stateful tracking based on the flow type:

- Non-tunneled flows: The outer TCP header is used.
- UDP tunneled flows: The inner TCP header is used (the hardware parses past the tunnel encapsulation).

NvTcpFlowDirection

TCP flows are by nature bi-directional. `ORIGINAL` denotes the side that initiates the connection via a TCP SYN packet. Reply denotes the responding side (i.e., the side that sends the SYN-ACK):

```
typedef bit<1> nv_tcp_flow_direction_t;

enum nv_tcp_flow_direction_t NvTcpFlowDirection {
    ORIGINAL = 1w0,
    REPLY = 1w1,
}
```

NvTcpState

The `NvTcpState` object is initialized by selecting a size. The method can then be called in either apply block scope or P4 action scope.

Constructor:

```
NvTcpState(bit<32> size)
```

Parameters:

- `size` : The number of indices to allocate for TCP state tracking. The same index should be used to track both directions of the given flow. The size must be a power of 2, and no greater than 16M.

Methods:

store

Store the TCP state of the packet for the given direction.

```
nv_tcp_state_error_t store(in bit<32> index, in NvTcpFlowDirection direction)
```

Parameters:

- `index[in]` : The identifier for a specific TCP state store in the object.
- `direction[in]` : The sender side versus the receiver side of the bi-directional TCP flow.

Returns:

- The `nv_tcp_state_error_t` of the flow entry at the specified index. The error code is a `bit<8>` with the following definition:

Bits	Description
0	Bad Packet
1	State Changed
2..5	reserved
6..7	0 = valid 1 = invalid 2 = trap

Typically the NvTcpState object would be used as follows:

1. Upon receiving a SYN packet in the pipeline, send the packet to the controller application.
2. Controller adds the TCP 5 tuple entry, with an action that calls the store method with an index and direction of ORIGINAL.
3. Upon receiving the SYN-ACK packet in the pipeline for the same flow, send the packet to the controller application.
4. Controller adds the reverse TCP 5 tuple entry, with an action that calls the store method with the same index as the ORIGINAL and direction of REPLY.
5. Upon receiving the FIN or RST packet in the pipeline for the same flow, send the packet to the controller application.
6. Remove both entries, and the index will be reset and can be reused.

While the TCP ACK/SEQ/direction values are being tracked, the controller can call the query API asynchronously to retrieve the last processed values.

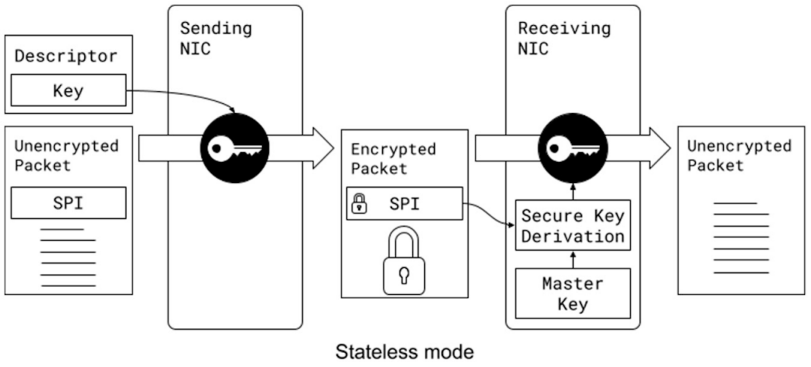
⚠ The BlueField hardware expects to see one TCP header in a packet, therefore HW Connection Tracking (CT) can work on the TCP header whether it is present in the outer or inner header. State tracking is based on the first the first TCP header that is parsed.

8.10.7.1.8.7 PSP

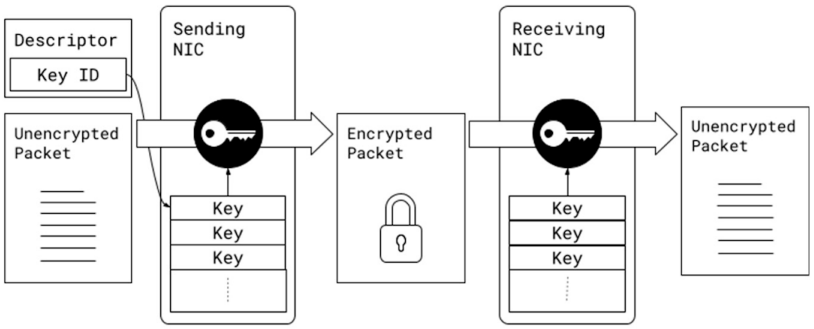
PSP is a transport-independent encryption protocol designed for efficient, large-scale data center and inter-data center network traffic security.

On the Bluefield target, PSP is fully offloaded, meaning cryptographic operations are performed entirely in hardware. This allows for a massive scale of parallel encrypted connections without requiring software state tracking. PSP uses UDP encapsulation with custom headers and standard cryptographic algorithms (AES-GCM) for confidentiality and integrity.

Unlike traditional security protocols (e.g., IPsec or TLS), PSP enables per-connection encryption, supports stateless operation for hardware scalability, and does not mandate a specific key exchange mechanism.



Stateless mode



Stateful mode

⚠ PSP Key Exchange is out of scope for DPL (Data Plane Logic) and must occur prior to pipeline processing. The host application is responsible for:

1. Performing the asynchronous key exchange (e.g., using `doca_flow_crypto_psp_spi_key_bulk_generate`).
2. Supplying the DPL runtime tables with the appropriate keys via P4Runtime.
3. Ensuring encapsulation entries use the SPI values supplied by the key generation step.

NvPSP

The `NvPSP` object is initialized by selecting a size, representing the number of unique SA indices. The method can then be called in either apply block scope or P4 action scope.

Constructor:

```
NvPSP(bit<32> size)
```

Parameters:

- `size`: The number of indices to allocate for PSP crypto object. A different index should be used for each direction of a given flow. The size must be a power of 2, and no greater than 16M.

Methods:

encrypt

Encrypts a clear text PSP packet. See the extern functions `nv_encap_psp_transport`, `nv_encap_psp_v4_tunnel`, and `nv_encap_psp_v6_tunnel`.

```
void encrypt<HEADERS>(inout HEADERS headers, bit<32> sa_index)
```

Parameters:

- `headers[in/out]`: packet headers struct
- `sa_index`: The index to a specific PSP security association data. The index points to a PSP encryption key obtained during key exchange, and is stored at a given slot in the bucket of keys in NIC memory. These slots can be overwritten as needed by the controller.

decrypt

Decrypts an encrypted PSP packet. After decryption, the PSP headers can be removed using the extern functions `nv_decap_psp_tunnel` or `nv_decap_psp_transport`.

```
void decrypt<HEADERS>(inout HEADERS headers)
```

The decrypt function operates in a stateless mode, where the SPI from the packet is used in conjunction with a master key store on the receiving NIC in order to generate the decryption key.

Syndrome

The PSP syndrome is set after a decrypt operation is completed. The possible values are in the following enum:

```
enum nv_psp_status_t NvPSPStatus {
    PSP_OK = 8w0,
    ICV_FAIL = 8w1,
    BAD_TRAILER = 8w2,
    BAD_CONTEXT = 8w3,
    GENERAL_ERROR = 8w4,
}
```

It is recommended that the DPL user checks the `NvPSPStatus` after decrypt by matching on the metadata field `nv_standard_metadata_t.psp_syndrome`. If the status is not `PSP_OK`, then the application can drop the packet or send it to the controller for further error handling.

Limitations on PSP Functionality

The following restrictions apply to PSP capabilities on the BlueField-3 architecture:

Version & Encapsulation

- Only PSP Version 0 and Version 1 are supported.
- UDP and UDP over Tunnel are the only supported transport encapsulations.

- The packet must contain a valid L4 header; otherwise, the encapsulation behavior is undefined.

Hardware Parsing Requirements

The packet must be properly parsed by the native hardware parser (`hdrs.psp.isValid() == true`) to ensure operation success:

- For Encryption: The header must be valid before the encryption action is attempted.
- For Decryption: The header must be valid after decryption (and free of error syndromes) before decapsulation can occur.

State Modes

- PSP Sender: Supports stateful mode.
- PSP Receiver: Supports stateless mode.

Pipeline Configuration Workflow

To successfully implement PSP, the user application must follow this specific configuration order:

1. Load Program: The DPL program is loaded using the P4Runtime API. This step allocates the necessary PSP hardware resources.
2. Key Exchange: The application performs key exchange (see DOCA API References for `doca_flow_crypto_psp_spi_*`).
3. Update Receiver: The receiver application updates the PSP resource with the PSP keys using the P4Runtime API.
4. Update Sender: The sender application updates the hardware with the generated SPIs using the P4Runtime API.

Execution Domains and Directional Constraints

The DPL pipeline executes within the administrative eSwitch, also known as the Forwarding Database (FDB) domain. Within this domain, the hardware strictly distinguishes between two directional sub-domains:

- FDB-Rx (Receive): Traffic moving from the network to the host.
- FDB-Tx (Transmit): Traffic moving from the host to the network.

These sub-domains reflect hardware-specific differences in processing capabilities. Consequently, specific cryptographic functions are direction-dependent:

Function	Supported Path	Direction
Encryption	FDB-Tx Only	Host --> Network
Decryption	FDB-Rx Only	Network --> Host

8.10.7.1.8.8 Memory Context

The **Memory Context** feature provides a stateful, per-index memory resource that can be accessed atomically from the DPL data plane. It is available on ConnectX-9 (and future targets) and is intended for use cases such as:

- Per-flow or per-session state that does not fit in regular metadata
- Stateful counters or bitmaps that must survive across packets
- Saving and restoring header fields across encapsulation/decapsulation

The ConnectX-9 hardware implements the Memory Context as URISC memory objects with **64-byte cache lines**, addressable in **8-byte (64-bit) lines** per index. Each DPL access is translated into a URISC instruction and executed atomically with respect to packet processing.

Two extern types are exposed:

- `NvMemory` – indirect, indexed by an explicit `index` parameter
- `NvDirectMemory` – direct, bound 1:1 to a P4 table entry

> ⚠ These externs are only available on `CX9` and newer targets; they are gated in the target architecture headers and will fail compilation on BlueField-3.

NvMemory Extern

The `NvMemory` extern models a bank of indexed memory contexts. Each index corresponds to one 64-byte cache line, accessed as 64-bit values. The `NvMemory` object is initialized by selecting a size, representing the number of 64-bit values. The methods can then be called in either apply block scope or P4 action scope.

Constructor:

```
NvMemory(bit<32> size)
```

Parameters*:*

- `size`: The number of indices to allocate for Memory Context object. The size must be a power of 2, and no greater than 16M.

Methods:

read

Returns the 64 bit value stored at the given index.

```
bit<64> read(bit<32> index)
```

Parameters:

- `index` : The index to a specific Memory Context entry.

Returns:

- The 64 bit value stored for the specified index.

write

Stores a 64 bit value at the given index.

```
bit<64> read(bit<32> index, bit<64> value)
```

Parameters:

- `index` : The index to a specific Memory Context entry.
- `value` : The value to be stored

Returns:

- The previous value stored at the specified index.

increment

Increments the value stored at the given index by a specified value with wraparound.

```
bit<64> increment(bit<32> index, bit<64> value)
```

Parameters:

- `index` : The index to a specific Memory Context entry.
- `value` : The value to be added to the stored value

Returns:

- The original value stored at the specified index.

xor

Bitwise XOR with the value stored at the given index.

```
bit<64> xor(bit<32> index, bit<64> value)
```

Parameters:

- `index` : The index to a specific Memory Context entry.
- `value` : The value to XOR with the stored value

Returns:

- The original value stored at the specified index.

or

Bitwise OR with the value at the given index.

```
bit<64> or(bit<32> index, bit<64> value)
```

Parameters:

- `index` : The index to a specific Memory Context entry.
- `value` : The value to OR with the stored value

Returns:

- The original value stored at the specified index.

and

Bitwise AND with the value at the given index.

```
bit<64> and(bit<32> index, bit<64> value)
```

Parameters:

- `index` : The index to a specific Memory Context entry.
- `value` : The value to AND with the stored value.

Returns:

- The original value stored at the specified index.

reset

Clears the value at the given index to zero.

```
bit<64> reset(bit<32> index)
```

Parameters:

- `index` : The index to a specific Memory Context entry.

Returns:

- Zero.

find_first_set_offset_msb, find_first_set_offset_lsb

Finds the bit offset of the most/least significant set bit of the 64 bit value at the given index.

```
bit<64> find_first_set_offset_msb(bit<32> index, bool clear = false);
bit<64> find_first_set_offset_lsb(bit<32> index, bool clear = false);
```

Parameters:

- `index` : The index to a specific Memory Context entry.
- `clear` : Default, clears the most/least significant set bit in the stored value.

Returns:

Two values are stored in the 64 bit return variable:

- The bit offset/index of the most/least significant set bit. For a return variable named `result`, then the index is a 6 bit value that can be accessed as `result[63:58]`
- A flag to indicate if the memory value was zero (and hence no bit offset was found). The flag can be accessed as a 1 bit value `result[0:0]`

> ⚠ It is up to the user to check the flag if necessary before accessing the index. If the flag is set, then the offset value is undefined.

find_first_set_bit_msb, find_first_set_bit_lsb

Finds the most/least significant set bit of the 64 bit value at the given index.

```
    bit<64> find_first_set_bit_msb(bit<32> index, bool clear = false);
    bit<64> find_first_set_bit_lsb(bit<32> index, bool clear = false);
```

Parameters:

- `index`: The index to a specific Memory Context entry.
- `clear`: Default, clears the most/least significant set bit in the stored value.

Returns:

- The value with only the most/least set bit retained.

NvDirectMemory Extern

The `NvDirectMemory` extern models a bank of memory contexts that is associated with each entry of a P4 table. Each entry contains a 64-bit memory context that persists across table lookups. The `NvDirectMemory` object is initialized by the associated P4 table so the methods can only be called in the P4 action scope.

Constructor:

```
NvDirectMemory()
```

Restrictions: The size is set according to the size of the table, and must be a power of 2, and no greater than 16M.

Usage:

The`NvDirectMemory` object should be declared in the control. Then it is attached to a table using a new table attribute `nv_direct_memory`. For example:

```
NvDirectMemory() my_memory;

table session_table {
    key = {
        user_meta.session_id : exact;
```

```
    }
    actions = {
        session_hit;
        session_miss;
    }
    default_action = session_miss();
    direct_counter   = direct_session_counter;
    nv_direct_memory = my_memory;
    size             = P4_SESSION_TABLE_SIZE;
}
```

For each entry in `session_table`, the bound `NvDirectMemory` object references a **per-entry memory slot** (index == entry index). Actions may call `read()` / `write()` / `increment()` etc. to manipulate that per-entry state atomically.

Methods:

read

Returns the 64 bit value stored for a given entry.

```
bit<64> read()
```

Returns:

- The 64 bit value stored for the specified entry

write

Stores a 64 bit value for a given entry.

```
bit<64> read(bit<64> value)
```

Parameters:

- `value` : The value to be stored

Returns:

- The previous value stored at the specified entry

increment

Increments the value stored for a given entry by the specified value, with wraparound.

```
bit<64> increment(bit<64> value)
```

Parameters:

- `value` : The value to be added to the stored value

Returns:

- The original value stored for a given entry

xor

Bitwise XOR with the value stored for a given entry.

```
bit<64> xor(bit<64> value)
```

Parameters:

- `value` : The value to XOR with the stored value

Returns:

- The original value stored at the specified entry

or

Bitwise OR with the value for a given entry.

```
bit<64> or(bit<64> value)
```

Parameters:

- `value` : The value to OR with the stored value

Returns:

- The original value stored at the specified entry

and

Bitwise AND with the value for a given entry.

```
bit<64> and(bit<64> value)
```

Parameters:

- `value` : The value to AND with the stored value.

Returns:

- The original value stored at the specified entry

reset

Clears the value for a given entry to zero.

```
bit<64> reset()
```

Returns:

- Zero.

find_first_set_offset_msb, find_first_set_offset_lsb

Finds the bit offset of the most/least significant set bit of the 64 bit value for a given entry.

```
bit<64> find_first_set_offset_msb(bool clear = false);
```

```
bit<64> find_first_set_offset_lsb(bool clear = false);
```

Parameters:

- `clear` : Default, clears the most/least significant set bit in the stored value.

Returns:

Two values are stored in the 64 bit return variable:

- The bit offset/index of the most/least significant set bit. For a return variable named `result` , then the index is a 6 bit value that can be accessed as `result[63:58]`
- A flag to indicate if the memory value was zero (and hence no bit offset was found). The flag can be accessed as a 1 bit value `result[0:0]`

> ⚠ It is up to the user to check the flag if necessary before accessing the index. If the flag is set, then the offset value is undefined.

find_first_set_bit_msb, find_first_set_bit_lsb

Finds the most/least significant set bit of the 64 bit value for a given entry.

```
bit<64> find_first_set_bit_msb(bool clear = false);
bit<64> find_first_set_bit_lsb(bool clear = false);
```

Parameters:

- `clear` : Default, clears the most/least significant set bit in the stored value.

Returns:

- The value with only the most/least set bit retained.

8.10.7.1.9 DPL Expressions

Both the DPL Parser and the DPL standard metadata are part of the DOCA Target Architecture. The hardware has built in header protocols and key field extraction, along with capabilities to set, copy and perform add/subtract on certain fields. The following tables describe the compiler support for expressions using the built in header fields and standard metadata as L-values and R-values. Note: this is separate of header fields that can be used as match keys.

> ⚠ **Alias of header fields**
>
> In the default hardware parser, some fields that are mutually exclusive are extracted to the same buffer location (referred to in the table as an alias). Assignments to and copy from these fields can use either of the aliased field names.

8.10.7.1.9.1 Header Field Support

Fixed Header Fields	Assign	Copy	Add/Sub	Notes
`headers.ethernet.dst_addr`	✔	✔	✘

`source_qp`	✘	
~~`random_value`~~	✔	*Deprecated*. Use the extern method `nv_get_random_value()`.
~~`ut_clock`~~	✔	*Deprecated*. Use the extern method `nv_get_ut_clock()`.
~~`fr_clock`~~	✔	*Deprecated*. Use the extern method `nv_get_fr_clock()`.

8.10.7.1.10 Tables

8.10.7.1.10.1 Match Kinds

The DPL compiler supports following match types with the restrictions below:

- Exact match
  - Support for at least 9 keys of DWORD width and 8 keys of byte width. Note that the actual limit is dependent on HW resources and may fail only at load time.
  - See Exact tables in the PSA spec for general guidance and usage from a programmer perspective.
- LPM match
  - Not supported for bool-type keys.
  - Not supported for standard metadata fields.
  - See LPM tables in the PSA spec for general guidance and usage from a controller perspective.
- Ternary match
  - Not supported for bool-type keys.
  - Not supported for standard metadata fields.
  - See Ternary tables in the PSA spec for general guidance and usage from a programmer perspective.

- Range match
  - Support up to a maximum of 4 range match keys per P4 table .
  - Support for slices of header fields and std_meta fields as keys.
  - Not supported for slices of user-declared variables and user metadata fields as keys.
  - Not supported for keys larger than 32 bits (unless sliced down to 32 bits or less, with some key-specific slice alignment restrictions).
  - Range match keys in the same P4 Table with Ternary match keys or LPM keys are currently not supported.
  - When using multiple range keys in a single P4 table, some combinations of keys may not be supported. Note that this may fail only at load time.
  - See Range tables in the PSA spec for general guidance and usage from a programmer perspective.

8.10.7.1.10.2 DPL Key Support

IsValid method call, local variables excluding packet-in struct instance, fixed or flex header fields, and standard metadata can be used as a table key.

However, there are following restrictions:

- A key cannot be used multiple times within one P4 table; this will actively fail during compilation. When IsValid method call is used as a table key, the compiler allocates a register for the key. Thus, using multiple isValid method calls as keys within a table causes undefined behavior.
- Complex expressions must use `@name` annotation.

The following table lists the match key support for fixed header fields.

Fixed Header Fields	Bit Width	Exact	LPM	Ternary	Range	Notes
`headers.ethernet.dst_addr`	48	✔	✔	✔	✔[1]	
`headers.ethernet.src_addr`	48	✔	✔	✔	✔[1]	
`headers.ethernet.ether_type`	16	✘	✘	✘	✘	Last extracted l2 etherType can be matched through `std_meta.last_l2_ether_type`
`headers.vlan.vlan_pcp`	3	✔	✔	✔	✔	
`headers.vlan.vlan_dei`	1	✔	✔	✔	✔	
`headers.vlan.vlan_id`	12	✔	✔	✔	✔	

Fixed Header Fields	Bit Width	Exact	LPM	Ternary	Range	Notes
`headers.vlan.vlan_ether_type`	16	✘	✘	✘	✘	Last extracted l2 etherType can be matched through `std_meta.last_l2_ether_type`
`headers.inner_ethernet.dst_addr`	48	✔	✔	✔	✔ [1]	
`headers.inner_ethernet.src_addr`	48	✔	✔	✔	✔ [1]	
`headers.inner_ethernet.ether_type`	16	✘	✘	✘	✘	Last extracted inner l2 etherType can be matched through `std_meta.inner_last_l2_ether_type`
`headers.inner_vlan.vlan_pcp`	3	✔	✔	✔	✔	
`headers.inner_vlan.vlan_dei`	1	✔	✔	✔	✔	
`headers.inner_vlan.vlan_id`	12	✔	✔	✔	✔	
`headers.inner_vlan.vlan_ether_type`	16	✘	✘	✘	✘	Last extracted inner l2 etherType can be matched through `std_meta.inner_last_l2_ether_type`
`headers.ipv4.version` Alias with `headers.ipv6.version`	4	✔	✔	✔	✔

1. Must be a slice of upper 16 bits or lower 32 bits
2. Must be a slice of one of 4 dwords

The following table lists the support for `isValid()` for fixed headers:

Header IsValid	Notes
`ethernet`	
`inner_ethernet`	

Header IsValid	Notes
`vlan`	VLAN tag is CVLAN
`inner_vlan`	Inner VLAN tag is CVLAN
`svlan`	VLAN tag is SVLAN
`inner_svlan`	Inner VLAN tag is SVLAN
`ipv4`	L3 header protocol is IPv4
`inner_ipv4`	Inner l3 header protocol is IPv4
`ipv6`	L3 header protocol is IPv6
`inner_ipv6`	Inner l3 header protocol is IPv6
`mpls`	MPLS layer 0 is valid after passing all HW checks
`inner_mpls`	Inner MPLS layer 0 is valid after passing all HW checks
`mpls1`	MPLS layer 1 is valid after passing all HW checks
`inner_mpls1`	Inner MPLS layer 1 is valid after passing all HW checks
`mpls2`	MPLS layer 2 is valid after passing all HW checks
`inner_mpls2`	Inner MPLS layer 2 is valid after passing all HW checks
`mpl3`	MPLS layer 3 is valid after passing all HW checks
`inner_mpls3`	Inner MPLS layer 3 is valid after passing all HW checks
`mpls_4`	MPLS layer 4 is valid after passing all HW checks
`inner_mpls4`	Inner MPLS layer 4 is valid after passing all HW checks
`tcp`	L4 type is TCP
`inner_tcp`	Inner l4 type is TCP
`udp`	L4 type is UDP
`inner_udp`	Inner l4 type is UDP
`gre`	• L3 layer is valid after passing all HW checks • IPv4 protocol field value is 47
`nvgre`	• L3 is OK • IPv4 protocol is 47 • GRE key is present • GRE protocol type is 25944
`esp`	L4 type is IPSEC
`icmp`	L4 type is ICMP
`inner_icmp`	Inner l4 type is ICMP
`icmpv6`	L4 type is ICMP
`inner_icmpv6`	Inner l4 type is ICMP

Header IsValid	Notes
`vxlan`	• L4 type is UDP • headers.udp.dst_port is 4789
`vxlan_gpe`	• L4 type is UDP • headers.udp.dst_port is 4790
`geneve`	• L4 type is UDP • headers.udp.dst_port is 6081
`psp`	• L4 type is UDP • headers.udp.dst_port is 1000

The following table lists the match key support for standard metadata fields:

Standard Metadata Fields	Bit Width	Exact	LPM	Ternary	Range	Notes
`ingress_port`	32	✔	✘	✘	✘	The P4 port ID that the packet ingressed the pipeline
`eth_to_fcs_packet_len`	16	✔	✘	✘	✔	Length of the packet from L2 start to FCS, in bytes
`is_l2_ok`	1	✔	✘	✘	✔	L2 layer is valid after passing all HW checks

~~`random_value`~~	16	✔	✔	✔	✔	*Deprecated*. Match on the return value from calling the extern method `nv_get_random_value()`.
~~`ut_clock`~~	64	✔	✔	✔	✔	*Deprecated*. Match on the return value from calling the extern method `nv_get_ut_clock()`.
~~`fr_clock`~~	64	✔	✔	✔	✔	*Deprecated*. Match on the return value from calling the extern method `nv_get_fr_clock()`.

The maximum number of keys in any P4 table is known only at load time, due to the dynamic nature of the key packing algorithm. The key width limit in BlueField-3 is approximately 40 bytes. If more keys are required, the user should split the keys into two or more tables.

8.10.7.1.10.3 Match Key Annotations

The following annotations for individual P4 table match keys is supported:

- **@name**
  - The @name annotation lets a P4 programmer override the compiler-chosen string name for a P4 object as it is emitted into P4Info (and therefore what is visible to P4Runtime clients), instead of using the default generated name.
  - Because it can change the emitted names, @name can introduce conflicting (duplicate) names for distinct objects if not used with caution.
- **@nv_high_entropy_bits**

- The @nv_high_entropy_bits annotation is used to indicate which bits of the key to prioritize when configuring the table's hash function implementation. This information is used to influence the hash computed to try to reduce the number of hash collisions, which on average increases performance.
- See DPL Performance section for usage, details and restrictions

8.10.7.1.10.4 Size

Each P4 table in the DOCA Target Architecture allows a `size` attribute. This represents the maximum number of entries, excluding the default miss entry. If the `size` attribute is omitted, a default value of 128 is assigned.

Sizing Constraints

A single P4 table supports a maximum size of **20M entries** (20,971,520) on **BlueField3**. The specific requirements for the `size` parameter depend on the scale of the table:

Table Scale	Size Range	Constraint
Standard	1 to 8,388,608 (8M)	Must be a power of two.
Large	8,388,609 to 20,971,520 (20M)	Must be specified in 1M (1,048,576) increments.

Large Table Support (>8M Entries)

When a table is configured with a size greater than 8M, the DPL compiler automatically generates a set of sharded tables. This process is transparent to the user but introduces specific limitations compared to standard tables.

Architecture & Memory Limits

- Total System Limit: The total memory the DPL runtime can allocate for *all* tables combined is 20M entries.
- Hardware Dependency: This limit is constrained by the 32GB DRAM on the BlueField-3 Arm subsystem. The actual limit may be lower if other resource-intensive processes are running on the Arm cores.

Functional Limitations

The following features are not supported for Large Tables:

- Match Type: Only Exact Match keys are supported.
- Direct Objects: Direct resources (e.g., `direct_counter`, `direct_meter`) cannot be attached due to resource constraints. Solution: Use the indexed (indirect) versions of these objects instead.
- Idle Timeout: Entry aging/timeout is not supported.
- Debug Actions: The `nv_send_debug_pkt` action cannot be used within these tables.

The actual number of supported entries in Large Tables is best-effort and subject to hash collisions. For optimal performance and deterministic behavior, it is recommended to keep table sizes to 8M or less whenever possible.

8.10.7.1.10.5 Default Action

The table can contain default action. When there are no matching entries within this table, it will execute the default action. When the default action is not provided, the missing entry will execute NoAction action (continue to the next logical step in the pipeline).

```
table ipv4_fowarding_table {
    key = {
        headers.ipv4.src_addr : exact;
    }
    actions = {
        forward;
        NoAction;
    }
    default_action = forward(1);
}
```

8.10.7.1.10.6 Keyless Tables

A table with no keys is supported, by either omitting the `key` property or specifying an empty key set. Such tables are deemed "always miss", and all packets processed by the table will go to the default action. It is not permitted to insert or remove entries on a keyless table. However, if the default action is not marked `const`, then it is permitted to modify the default action at runtime. While it is a matter of coding style, an alternative is to invoke such P4 actions directly in the apply block logic of the appropriate control.

Instead of using keyless tables, using the apply block for generic logic that applies to all packets (i.e. no key lookup) allows the compiler more opportunities to optimize the DPL program.

8.10.7.1.10.7 Const Entries

Const entries are an optional property of a P4 table, which can be used to insert entries when loading the blob to BlueField. For LPM or ternary matching, the unmasked bits must be zero. As defined in the P4 Language specification, the presence of const entries means the P4 table is not modifiable, and entries cannot be inserted or removed at runtime.

```
table ipv4_fowarding_table {
    key = {
        headers.ipv4.src_addr : lpm;
    }
    actions = {
        forward;
        NoAction;
    }
    default_action = forward(1);
    const entries = {
        (32w0x11111100 &&& 32w0xFFFFFF00) : forward(2);
        (32w0x22220000 &&& 36w0xFFFF0000) : forward(3);
    }
```

```
}
```

8.10.7.1.10.8 Entry Timeout

The DOCA Target Architecture supports the idle timeout and notification mechanisms specified in the P4Runtime specification. This feature is disabled by default and must be explicitly enabled on a per-table basis.

To enable this feature, add the attribute `nv_support_timeout = true` to the table definition.

```
table ipv4_forwarding_table {
    key = {
        headers.ipv4.src_addr : lpm;
    }
    actions = {
        forward;
        NoAction;
    }
    default_action = forward(1);

    /* Required for Timeout Support */
    direct_counter = fwd_counter;
    nv_support_timeout = true;
}
```

Restrictions and Prerequisites

Enabling entry timeout imposes the following constraints on the table:

- Counters Required: The table *must* have the `direct_counter` property set.
- Action Logic: Every action in the table's action list must explicitly call the `count()` method on the associated direct counter.
- Mutability: The table cannot contain `const` entries.
- Size Limit: The table size must be 8M entries or less. (Large Tables >8M do not support timeout).

Timing Precision and Latency

The timeout notification mechanism is subject to the polling frequency of the hardware.

Notification Delay

Notifications may be delivered slightly later than the exact timeout expiration. This delay is governed by the `idle_timeout_polling_interval` parameter in the DPL Runtime Service configuration.

The maximum potential delay is calculated as:

(?) $$Delay_{max} = T_{timeout} + T_{polling_interval}$$

Timestamp Accuracy

The P4Runtime field `time_since_last_hit.elapsed_ns` reflects the polling cycle in which the hit was detected, rather than the exact nanosecond timestamp of the packet hit itself.

⚠ For very large tables with high churn (frequent additions/deletions), the time required to read all counters becomes a factor. Under heavy load, the system guarantees that the notification will eventually be delivered, but strictly never earlier than the defined timeout duration.

8.10.7.1.10.9 Delayed Counter Statistics

The DOCA Target Architecture supports delayed counter statistics, which allows reducing the performance impacts of frequent queries by collecting statistics periodically or on demand. This feature is by default off and must be enabled on a per-table basis.

Under the table definition, add the attribute `nv_delayed_counter_stats = true`. For example:

```
table ipv4_fowarding_table {
    key = {
        headers.ipv4.src_addr : lpm;
    }
    actions = {
        forward;
        NoAction;
    }
    default_action = forward(1);
    direct_counter = fwd_counter;
    nv_delayed_counter_stats = true;
 }
```

Restriction when delayed counter statistics is enabled:

- The table must have the `direct_counter` property set

⚠ The counter values are updated at time intervals that are controlled by the `idle_timeout_polling_interval` setting in the configuration of the DPL Runtime Service.

8.10.7.1.10.10 High Update Rate Tables

P4Runtime provides a gRPC-based API to insert and remove entries from P4 tables. While flexible, platform-independent, and capable of operating remotely within the network, such controllers are inherently limited in terms of performance and scalability. To address this limitation, DPL introduces support for High Update Rate (HUR) tables.

Under the table definition, add the attribute `nv_high_update_rate = true`. For example:

```
    table acl_table {
        key = {
            headers.inner_ipv6.src_addr : exact;
            headers.inner_ipv6.dst_addr : exact;
            headers.inner_ipv6.next_header : exact;
            std_meta.inner_l4_src_port : exact;
            std_meta.inner_l4_dst_port : exact;
        }
        actions = {
            deny;
            allow;
```

```
            NoAction;
        }
        default_action = NoAction;
        nv_high_update_rate = true;
        size = 4194304;
    }
```

The following restrictions apply when high update rate (HUR) table is enabled:

- All keys must be of match kind exact
- HUR tables are not compatible with `nv_add_entry` tables
- HUR tables cannot have const entries
- To use the HUR counter API in conjunction with the HUR insertion API, `nv_support_timeout` must be enabled
- Table size must not be greater than 8M

The HUR table is designed to support table entry insertion and deletion at rates significantly higher than a P4Runtime controller / server model can support. Instead, the HUR model replaces gRPC/protobuf messaging with a compiler generated packed C structure, a DPL Runtime library SDK and a shared memory buffer/pool that a client application can enqueues the table entry for insertion/deletion. See DPL Runtime Controller SDK for details on the programming model.

C API Generation

When a table is marked with `nv_high_update_rate`, the compiler will generate a set of accompanying C header and implementation files in the output directory.
For `program.p4`, the following files are generated:

program_dpl_p4rt.h

- A C header file with the P4Runtime IDs for the tables and actions used in the program.
- C structs for each table keyset and action parameters.
- P4Runtime APIs for inserting, removing and retrieving counters

program_dpl_p4rt.cpp

- An implementation of the P4Runtime APIs in **program_dpl_p4rt.h.**

program_dpl_shm_id.h

- A hash value for `program.p4`, which much match the hash for the program that is loaded into the device.

program_dpl_shm.h

- A C header file with the shared memory linear IDs for the tables and actions used in the program.
- Packed and aligned C structs for each table keyset and action parameters.
- Shared Memory APIs for inserting, removing and retrieving counters

program_dpl_shm.cpp

- an implementation of the Shared Memory APIs in **program_dpl_p4rt.h.**

Example and Usage

Consider the below example `hello_world.p4`

hello_world.p4

```
control main_flow(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    NvDirectCounter(NvCounterType.PACKETS_AND_BYTES) my_shm_table_counter;

    action shm_forward(nv_logical_port_t port) {
        my_shm_table_counter.count();
        nv_send_to_port(port);
    }

    action shm_drop() {
        my_shm_table_counter.count();
        nv_drop();
    }

    action grpc_forward(nv_logical_port_t port) {
        nv_send_to_port(port);
    }

    action grpc_drop() {
        nv_drop();
    }

    table my_grpc_table {
        key = {
            headers.ipv4.protocol : exact;
            headers.tcp.src_port : exact;
            headers.tcp.dst_port : exact;
        }
        actions = {
            grpc_forward;
            grpc_drop;
        }
        default_action = grpc_drop;
        size = 128;
    }

    table my_shm_table {
        key = {
            headers.ipv4.src_addr : exact;
            headers.ipv4.dst_addr : exact;
        }
        actions = {
            shm_forward;
            shm_drop;
            NoAction;
        }
        default_action = NoAction;
        direct_counter = my_shm_table_counter;
        nv_high_update_rate = true;
        size = 128;
    }

    apply {
        if (!my_shm_table.apply().hit)
            my_grpc_table.apply();
    }
}
```

This example has P4 tables where one has the `nv_high_update_rate` set to `true` and the other does not use the high update rate feature.

P4Runtime APIs for Non-high Update Rate Tables

- P4Runtime IDs for the tables and actions used in `hello_world` program for the `my_grpc_table`.

P4Runtime IDs

```
/**
 * Table definitions for main_flow_my_grpc_table
 */
#define DPL_P4RT_HELLO_WORLD_MAIN_FLOW_MY_GRPC_TABLE_TABLE_ID 36982097
/**
 * P4RT IDs for main_flow_my_grpc_table's keys
 */
#define DPL_P4RT_HELLO_WORLD_MAIN_FLOW_MY_GRPC_TABLE_HEADERS_IPV4_PROTOCOL_KEY_ID 1
#define DPL_P4RT_HELLO_WORLD_MAIN_FLOW_MY_GRPC_TABLE_HEADERS_TCP_SRC_PORT_KEY_ID 2
#define DPL_P4RT_HELLO_WORLD_MAIN_FLOW_MY_GRPC_TABLE_HEADERS_TCP_DST_PORT_KEY_ID 3

#define DPL_P4RT_HELLO_WORLD_MAIN_FLOW_MY_GRPC_TABLE_GRPC_DROP_ACTION_ID 23410936

#define DPL_P4RT_HELLO_WORLD_MAIN_FLOW_MY_GRPC_TABLE_GRPC_FORWARD_ACTION_ID 25120277

#define DPL_P4RT_HELLO_WORLD_MAIN_FLOW_MY_GRPC_TABLE_GRPC_FORWARD_PORT_PARAM_ID 1
```

All the auto-generated values follow the naming convention of `DPL_P4RT_{application_name}_{control_name}_{table_name}_{attribute_name}`

- C structs for each table keyset and action parameters.

C structs for table keys and actions

```
/* Keys Structure */
struct dpl_p4rt_hello_world_main_flow_my_grpc_table_keys {
    uint8_t headers_ipv4_protocol;
    uint16_t headers_tcp_src_port;
    uint16_t headers_tcp_dst_port;
};
/* Parameters Structure */
struct dpl_p4rt_hello_world_main_flow_my_grpc_table_grpc_drop_params {
};
struct dpl_p4rt_hello_world_main_flow_my_grpc_table_grpc_forward_params {
    uint32_t port;
};
/**
 * @brief
 * Table main_flow_my_grpc_table's action parameter's union
 */
union dpl_p4rt_hello_world_main_flow_my_grpc_table_action_params
{
    dpl_p4rt_hello_world_main_flow_my_grpc_table_grpc_drop_params_t grpc_drop;
    dpl_p4rt_hello_world_main_flow_my_grpc_table_grpc_forward_params_t grpc_forward;
};

/**
 * @brief
 * Table main_flow_my_grpc_table's table entry structure
 */
struct dpl_p4rt_hello_world_main_flow_my_grpc_table_entry {
    dpl_p4rt_hello_world_main_flow_my_grpc_table_keys_t keys;
    uint32_t action_id;
    union dpl_p4rt_hello_world_main_flow_my_grpc_table_action_params action_params;
};
```

- P4Runtime APIs for inserting entries, deleting entries and retrieving counters information
    - Inserting entries into the table

Insert entries

```
// Create and populate the table entry
dpl_p4rt_hello_world_my_grpc_table_entry_t entry;

// Set the key fields - match TCP traffic from port 8080 to port 443
entry.key.headers_ipv4_protocol = 6;           // TCP protocol
entry.key.headers_tcp_src_port = htons(8080);  // Source port 8080
entry.key.headers_tcp_dst_port = htons(443);   // Destination port 443

// Set the action - forward to port 1
entry.action_id = DPL_P4RT_HELLO_WORLD_MY_GRPC_TABLE_GRPC_FORWARD_ACTION_ID;
entry.action_params.grpc_forward.port = 1;

// Set up attributes if required
struct dpl_rt_controller_add_entry_attr attr;
```

```
    // Insert the entry
    result = dpl_p4rt_hello_world_my_grpc_table_insert_entry(
        device, &entry, &attr, &dpl_entry);

    if (result != DOCA_SUCCESS) {
        DOCA_LOG_ERR("Failed to insert P4RT entry: %s", doca_error_get_descr(result));
        return -1;
    }
```

- Deleting entries from the table

```
Delete entries
```

```
/* Deletes an entry by calling the function whose argument is the handle to entry returned by the
insert entry function*/
doca_error_t result = dpl_p4rt_hello_world_delete_entry(*dpl_entry);
```

- Retrieving counter information

```
Retreive counters
```

```
dpl_rt_controller_counter_data counter_data;
/* The counter_data structure will have the data after the API is called */
doca_error_t result = dpl_p4rt_hello_world_default_entry_counter(device,
    DPL_P4RT_HELLO_WORLD_MAIN_FLOW_MY_GRPC_TABLE_TABLE_ID
    &counter_data);
```

SHM APIs for High Update Rate Tables

- SHM linear IDs for the tables and actions used in `hello_world` program for the `my_shm_table`.

```
Linear IDs
```

```
/**
 * P4Table definitions for main_flow_my_shm_table
 */
#define DPL_SHM_HELLO_WORLD_MAIN_FLOW_MY_SHM_TABLE_TABLE_ID 0

#define DPL_SHM_HELLO_WORLD_MAIN_FLOW_MY_SHM_TABLE_NOACTION_ACTION_ID  0
#define DPL_SHM_HELLO_WORLD_MAIN_FLOW_MY_SHM_TABLE_SHM_FORWARD_ACTION_ID  1
#define DPL_SHM_HELLO_WORLD_MAIN_FLOW_MY_SHM_TABLE_SHM_DROP_ACTION_ID  2
```

- C structs for each table keyset and action parameters.

```
C structs for table keys and action
```

```
/**
 * @brief
 * P4Table main_flow_my_shm_table's keys structure
 */
struct dpl_shm_hello_world_main_flow_my_shm_table_keys {
    uint32_t headers_ipv4_src_addr;
    uint32_t headers_ipv4_dst_addr;
} __attribute__((__packed__));

/**
 * @brief
 * Action NoAction's parameter structure
 */
struct dpl_shm_hello_world_main_flow_my_shm_table_noaction_params {
} __attribute__((__packed__));

/**
 * @brief
 * Action main_flow.shm_forward's parameter structure
 */
struct dpl_shm_hello_world_main_flow_my_shm_table_shm_forward_params {
    uint32_t port;
} __attribute__((__packed__));
```

```
/**
 * @brief
 * Action main_flow.shm_drop's parameter structure
 */
struct dpl_shm_hello_world_main_flow_my_shm_table_shm_drop_params {
} __attribute__((__packed__));

/**
 * @brief
 * P4Table main_flow_my_shm_table's action parameter's union
 */
union dpl_shm_hello_world_main_flow_my_shm_table_action_params
{
    dpl_shm_hello_world_main_flow_my_shm_table_noaction_params_t noaction;
    dpl_shm_hello_world_main_flow_my_shm_table_shm_forward_params_t shm_forward;
    dpl_shm_hello_world_main_flow_my_shm_table_shm_drop_params_t shm_drop;
    uint8_t padding_1[8];
};

/**
 * @brief
 * P4Table main_flow_my_shm_table's table entry structure
 */
struct dpl_shm_hello_world_main_flow_my_shm_table_entry {
    dpl_shm_hello_world_main_flow_my_shm_table_keys_t keys;
    uint32_t action_id;
    uint8_t padding_1[4];
    union dpl_shm_hello_world_main_flow_my_shm_table_action_params action_params;
} __attribute__((__packed__));
```

- SHM APIs for inserting entries, deleting entries and retrieving counters information
    - Inserting entries into the High Update Rate Table

Insert entries

```
    // Allocate shared memory for the entry
    result = dpl_shm_hello_world_my_shm_table_alloc_entry_mem(
        device, dpl_entry, &shm_entry);

    if (result != DOCA_SUCCESS) {
        DOCA_LOG_ERR("Failed to allocate SHM entry: %s", doca_error_get_descr(result));
        return -1;
    }

    // Fill in the entry
    shm_entry->key.headers_ipv4_src_addr = htonl(src_ip);
    shm_entry->key.headers_ipv4_dst_addr = htonl(dst_ip);
    shm_entry->action_id = DPL_SHM_HELLO_WORLD_MY_SHM_TABLE_SHM_FORWARD_ACTION_ID;
    shm_entry->action_params.shm_forward.port = output_port;
    shm_entry->valid = 1;

    // Insert the entry
    result = dpl_shm_hello_world_my_shm_table_insert_entry(device, *dpl_entry, shm_entry);

    if (result != DOCA_SUCCESS) {
        DOCA_LOG_ERR("Failed to insert SHM entry: %s", doca_error_get_descr(result));
        return -1;
    }
```

    - Deleting entries from the High Update Rate Table

Delete entries

```
/* Delete an entry */
doca_error_t result = dpl_shm_hello_world_delete_entry(*dpl_entry);
```

    - Retrieving Counters information of High Update Rate Table

Retreive counters

```
dpl_rt_controller_counter_data counter_data;
/* The counter_data structure will have the data after the API is called */
doca_error_t result = dpl_shm_hello_world_default_entry_counter(device,
    DPL_SHM_HELLO_WORLD_MAIN_FLOW_MY_SHM_TABLE_TABLE_ID,
    &counter_data);
```

8.10.7.1.10.11 Action Parameters

P4 action parameters provide an interface to the control plane for specifying per entry values to user defined actions. These values are sometimes referred to as control-plane constants (versus compile-time constants), where the following restrictions apply:

- Usage is limited in scope to the enclosed P4 action body
- They cannot be assigned to (LHS of an assignment).
- They can be the RHS of an assignment. See P4 Language Support in DPL heading "Operators" for a list of supported operators.

Modifiable Action Parameters

The `@nv_modifiable` annotation allows certain P4 action parameters to be updated atomically in place at runtime, without deleting and reinserting the table entry. This enables high-rate, low-disruption updates of selected header-rewrite fields (for example, NAT addresses and ports) for both gRPC/P4Runtime and SHM insertion modes. For example:

```
action change_tuple(
    @nv_modifiable nv_ipv4_addr_t new_sip,
                   nv_ipv4_addr_t new_dip,
    @nv_modifiable bit<16>       new_sport,
                   bit<16>       new_dport)
{
    headers.ipv4.src_addr = new_sip;
    headers.ipv4.dst_addr = new_dip;
    nv_set_l4_src_port(headers, new_sport);
    nv_set_l4_dst_port(headers, new_dport);
}
```

In this example, `new_sip` and `new_sport` are atomically modifiable; `new_dip` and `new_dport` are not, using either the gRPC/P4Runtime `MODIFY` message or SHM modify APIs.

The following sematics apply for a table entry whose selected action has one or more `@nv_modifiable` parameters:

- The DPL runtime can perform an **atomic in-place update** of those parameters' values.
- The underlying hardware guarantees that no packet will see a partially updated set of values; the change is all-or-nothing at the level of the compiled modify-header resource.
- Match keys, action IDs, and non-annotated parameters remain **immutable** for the purpose of atomic modification. Changing them still requires delete + insert.

Compiler Validation and Restrictions

To ensure that a parameter can be updated atomically on the target hardware, the compiler enforces:

- All `@nv_modifiable` parameters of an action must map into a **single modify-header pattern/cache line** (64 bytes).

- If a candidate parameter set would require touching multiple cache lines, compilation fails with an error.
- Currently, this support is limited to
  - **Modify-header** style assignment expressions (SET/ADD); header reformat (encapsulations), header insertion (`nv_push_headers`)
  - Other modifications such as header removal, packet mirroring and all other actions do not currently support atomic action parameter modifications.
- The annotation guarantees atomicity only if compilation succeeds; the compiler does not attempt to re-order modify-header instructions to make an unsupported pattern modifiable.

The error: "Action has multiple @nv_modifiable parameters that have too many intervening statements between them" indicates that the specified list of actions could not fit into an atomic update. Try reorganizing action statements if possible to place the modifiable parameters separate of other statements.

Modify Runtime APIs

The compiler generates helper APIs on top of the DPL runtime to simplify safe modification:

- For **P4Runtime** tables, a wrapper `*_modify_entry` helper is generated for the specific table and action. The controller API:
  - Supplies the full key and **only** the modifiable parameters.
  - The helper validates that all changes are limited to `@nv_modifiable` fields and uses a low-level “argument write” operation to atomically update the underlying modify-header resource.
- For **SHM insertion mode** tables, the compiler generates per-action helpers such as:

```
doca_error_t dpl_shm_main_ctrl_my_table_change_tuple_action_modify(
    struct dpl_rt_controller_entry *dpl_entry,
    uint32_t *new_sip,   // @nv_modifiable, optional
    uint16_t *new_sport  // @nv_modifiable, optional
);
```

  These helpers:
  - Validate that the entry belongs to the expected table/action.
  - Read and back up the current parameter values from the opaque SHM entry.
  - Patch only the modifiable fields.
  - Issue a `dpl_rt_controller_table_entry_modify()` request.
  - Roll back to the original values on failure.

  Direct use of low-level SHM or P4Runtime APIs remains possible but may bypass these safety checks; atomicity is only guaranteed when the `@nv_modifiable` constraints are respected.

8.10.7.1.11 Packet IO

Controller Packet in (pipeline to controller) and Packet out (controller to pipeline) are supported in the DOCA Target Architecture. To send a packet to the controller with metadata:

- Create a struct with the annotation `@nv_controller_metadata("packet_in")`
- The struct must be exactly 32 bits in width (user must insert padding as needed)
- Use the extern action `extern void nv_send_to_controller<PACKET_META>(in PACKET_META pkt_in_meta);`

To check if a packet that has ingressed the pipeline from the controller:

- Add as a match key "`std_meta.ingress_port`" to a P4 table key set
- Add an entry that specifies the key value to be the `p4_controller_port_id` defined in the DPL Port ID Mapping step.

8.10.7.1.12 P4Runtime Extern Entities

DPL-specific extern entities are extended per the P4Runtime Specification (v1.4.1). These extensions encode vendor specific messages using the `google.protobuf.Any` type to facilitate custom resource configuration.

8.10.7.1.12.1 NvPSP

The following `p4info` Protobuf extension allows a controller to initialize the NvPSP resource and specify its size:

```
// SPDX-FileCopyrightText: Copyright (c) 2025 NVIDIA CORPORATION & AFFILIATES. All rights reserved.

8.10.7.2 P4 Language Support in DPL

This section outlines the P4-16 language features supported by the DOCA Pipeline Language (DPL) and notes any known deviations or limitations. All references are based on the P4 Language Specification version v1.2.5.

8.10.7.2.1 Introduction

NVIDIA® BlueField® networking platforms (DPU or SuperNIC) are designed to accelerate data center workloads by offloading and isolating key infrastructure tasks, including networking, storage, and security. BlueField-3 combines ASIC performance with programmable flexibility, supporting up to 400G connectivity—ideal for AI and HPC environments.

To optimize for high-performance hardware, the P4 implementation on BlueField differs from generic software targets. As a result, DOCA Pipeline Language (DPL) selectively supports P4 features that align with its target architecture. This section details which P4 features are currently supported, restricted, or unsupported.

> A feature labeled as “unsupported” is either not implemented or has not been validated. The compiler may explicitly reject such usage or accept it only if resolved at compile time (e.g., via constant folding). However, acceptance does not mean the feature is supported; do not rely on accepted, unsupported features.

8.10.7.2.2 P4 Language Features

The DPL compiler implements a performance-oriented subset of P4-16, aligned with the capabilities of the BlueField hardware. Unsupported features are typically those that require runtime flexibility (e.g., dynamic parsing or general-purpose control logic) which are not efficient in ASIC-based systems. Developers should reference this section during development to ensure compatibility and portability of P4 programs targeting DPL.

8.10.7.2.2.1 Identifiers

- Identifiers starting with `__` are reserved for internal compiler use
- All other identifiers conform to P4 spec §6.4.1

8.10.7.2.2.2 Data Types

Type	Support Level	Notes
`bool`	Supported	Fully supported

Type	Support Level	Notes
Arbitrary-precision int	Limited	Only for literals (see spec §7.1.6.5)
`int` (signed integers)	Unsupported	
String literals	Unsupported	Accepted, but no operations or validity checks (see spec §6.4.3.3). Only supported in annotations.
Bit strings	Supported	Subject to hardware resource limits

Refer to section "Operators" for support of operations on values with these types.

8.10.7.2.2.3 Derived Types

Type	Support Level	Notes
`enum`	Supported	As per spec §7.2.1, with restrictions based on target-supported types
`header`	Supported	All field types except `varbit<>` (only supported via `NvOptionParser`). See spec §7.2.2.
`header_stack`	Unsupported	
`struct`	Supported	Must use only supported field types. See spec §7.2.5.
`union`	Unsupported	
`tuple` / `list`	Supported	As per spec §7.2.6
`extern` types	Limited	Only the externs provided with the DPL compiler are allowed; no custom externs. See spec §7.2.9.
Type specialization	Supported	As per spec §7.2.10

8.10.7.2.2.4 Statements and Expressions

Feature	Support Level	Notes
`assignment`	Limited	L-values are restricted. Cannot assign to method calls, `packet_out` metadata, flex-header fields, action parameters, or unsupported metadata fields. Only some fixed headers are valid L-values.
`op-assignment (+=, -=)`	Supported	See DLP Expressions, Header Field Support for details.
`if` / conditionals	Limited	Only within control `apply` blocks; must evaluate to a `bool`. Disallowed in `action` blocks.

Feature	Support Level	Notes
`switch`	Limited	Only within control `apply` blocks; switch expression must be `bool`. Disallowed in `action` blocks. Fall-through, default, and empty `switch` cases are supported per spec §11.7.

8.10.7.2.2.5 Operators

The P4-16 language specification lists a wide variety of operations that the language accepts for the supported data types (see Section 8). The table below lists the operators that are officially supported by the NVIDIA P4 compiler:

Operator	Compile-time value	P4 action parameter value	Runtime value	Spec section
bool && bool	✔	✔	✔	8.5
bool || bool	✔	✔	✔	8.5
! bool	✔	✔	✔	8.5
bool == bool	✔	✘ [1]	✘ [1]	8.5
bool != bool	✔	✘ [1]	✘ [1]	8.5
bit<W> == bit<W>	✔	✔ [2]	✔ [2]	8.6
bit<W> != bit<W>	✔	✔ [2]	✔ [2]	8.6
bit<W> << integer	✔ [3]	✔ [3]	✔ [3]	8.6
bit<W> >> integer	✔ [3]	✔ [3]	✔ [3]	8.6
bit<W>[H:L]	✔ [4]	✔ [4]	✔ [4]	8.6
bit<W> > bit<W>	✔	✔ [5]	✔ [5]	8.6
bit<W> >= bit<W>	✔	✔ [5]	✔ [5]	8.6
bit<W> < bit<W>	✔	✔ [5]	✔ [5]	8.6
bit<W> <= bit<W>	✔	✔ [5]	✔ [5]	8.6
All explicit casts between supported types	✔	✔	✔	8.11.1
All implicit casts between supported types	✔	✔	✔	8.11.2
bit<W>..bit<W>	✔ [6]	✔ [6]	✘	8.15.4

Operator	Compile-time value	P4 action parameter value	Runtime value	Spec section
Assignment to user struct fields	✔	✔	✔	8.16
Assignment to packet-in struct fields	✔	✔	✔	8.16
All operations on header fields	✔	✔	✔ [7]	8.17
Method calls	✔	✔	✘	8.20
Function calls with positional args	✔	✔ [8]	✔ [8]	8.20
Extern constructor invocations	✔	✘	✘	8.21
Parser constructor invocations	✔	✘	✘	8.21
Control constructor invocations	✔	✘	✘	8.21
Package constructor invocations	✔	✘	✘	8.21
Decrement (-=)	✔ [9]	✔ [9]	✔ [9]	-
Increment (+=)	✔	✔	✔ [10]	-

1. Cast to bit<32> for runtime comparison
2. If neither LHS nor RHS are constants, then both must be exactly 32 bits wide
3. RHS must be compile-time constant. See *spec 8.9.2*
4. H and L are subject to the restrictions described in the *spec 8.6.*
5. Width must be exactly 32 bits
6. Only valid in P4 Table entries
7. Limited to those fields that can be a copy source
8. Limited on a per extern function basis
9. RHS must be compile-time constant.
10. Width must be no more than 32 bits

8.10.7.2.2.6 Variables

Variables are supported in accordance with the following spec items:

- Constants (*spec 11.1*)

    - "Compile-time known values" are evaluated on a best-effort basis. It is possible that a compile-time known value may not be recognized by the compiler as such.
- Variables (*spec 11.2*)
- Instantiations (*spec 11.3*)
    - Instantiations with abstract methods (*spec 11.3.1*) are allowed in BlueField Target Architecture
    - Named arguments are not supported

Variables may be declared in any of the locations described in (*spec 11.2*) and follow the scope rules described there.

The compiler will emit errors for uninitialized values. In some cases where a struct is partially initialized, only a warning may be produced. In some cases there may be no error emitted when an uninitialized struct field is accessed. The accessed field will then contain an undefined value.

On BlueField-3 the maximum amount of user metadata is 256 bits at any single point in the program. The remaining register space is utilized internally by the firmware.

8.10.7.2.2.7 Control Apply Block

The `apply` block within a control logic supports a specific subset of P4 statements to ensure deterministic execution and hardware compatibility.

Supported Statements

The following statements are supported within the control flow:

- `table.apply()` calls
- `if` / `else` statements
- `switch` statements
- Extern function and method calls
- Assignment statements (using supported operators)
- The empty statement (`;`)
- `return` statements

The `exit` statement is not supported in this target architecture.

Loop Constructs

The `for` loop is supported, provided it adheres to strict structural restrictions. These constraints are necessary to ensure the compiler can statically verify loop termination (preventing infinite loops in the hardware pipeline).

Both `break` and `continue` statements are supported within the loop body.

Loop Constraints

To ensure validity, the loop must follow this specific decrementing pattern:

1. Init Clause: Must be a single assignment defining the loop variable.
2. Condition Clause: Must test that the loop variable is not equal to zero (`!= 0`).
3. Update Clause: Must be a single operation-assignment that decrements the variable by 1 (`-= 1`).
4. Body Constraint: The loop body must not modify the loop control variable.

Example Implementation

for loop

```
bit<32> sum = 1;

/* Valid Decrementing Loop */
for (
    bit<8> i = headers.ipv4.ttl;  // Init statement
    i != 0;                       // Condition
    i -= 1                        // Update statement
) {
    if (i == 64) {
        continue;
    } else if (i == 1) {
        break;
    } else {
        sum += 1;
    }
}
```

Hardware Constraints: Steering Hop Limits

The BlueField hardware enforces a global limit on the absolute number of steering hops in the pipeline. This acts as a safety mechanism to prevent infinite loops in the data path.

- Scope: This "TTL" (Time To Live) or hop limit is managed by the firmware. It is an accumulation over all steering domains (not just the DPL program).
- Validation: Because this is a runtime hardware state dependent on the total system configuration, it is out of the scope of DPL to validate at compile time.
- Behavior: Once the limit is exceeded, the packet is immediately dropped.

Troubleshooting Steering Violations

Violations of this limit can be detected by monitoring specific steering failure counters exposed to the kernel.

Relevant counters:

- `generated_pkt_steering_fail`
- `handled_pkt_steering_fail`

These can be inspected using the `devlink` health reporter. See the command `devlink health diagnose` in the Linux Kernel Documentation.

8.10.7.2.2.8 Table Apply

Calling the apply method on a table produces a result object that can return specific attributes about the table lookup outcome:

- bool hit
- bool miss
- enum action_run

8.10.7.2.2.9 Actions

Actions support the same statements as controls except for the following:

- `table.apply()` calls are not supported
- Conditional statements - `if` and `switch` - are not allowed

Actions support the same expressions as controls except for the following:

- Boolean logical operators - `&&`, `||`, ternary operator are not supported
- Comparisons (`==`, `!=`, etc.) are not supported

8.10.7.2.3 P4Runtime Features

The DPL compiler generates a `p4info` file compliant with the P4Runtime Specification (v1.4.1) for all supported DPL features.

8.10.7.2.3.1 Supported Annotations

The compiler supports the following package annotations as outlined in the P4Runtime PkgInfo Message. These allow for better documentation and versioning of the P4 program.

- `@pkginfo` with the following fields:
  - `name`
  - `version`
  - `doc`
  - `arch`
- `@brief`
- `@description`

8.10.7.2.3.2 Limitations and Unsupported Features

The following P4Runtime features are not supported in this target architecture:

Unsupported P4Info Objects

- ValueSet
- Register
- Digest

Unsupported P4 Entity Messages

The following runtime entities cannot be manipulated via P4Runtime on this target:

- Packet Replication:
  - `PacketReplicationEngineEntry`
  - `MulticastGroupEntry`
  - `CloneSessionEntry`
- State and Metadata:
  - `ValueSetEntry`
  - `RegisterEntry`
  - `DigestEntry`

8.10.7.3 DPL Installation Guide

8.10.7.3.1 Introduction

The DPL Development Container (`dpl_dev`) bundles several tools for compiling, controlling, and debugging DPL programs.

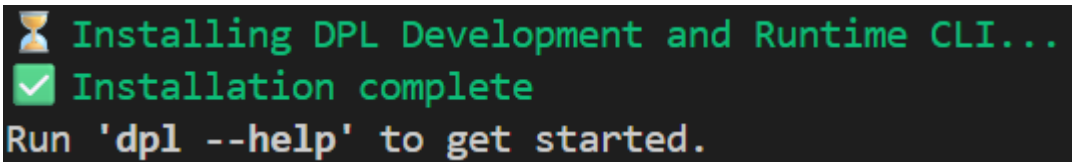
> First, select and pull the appropriate container tag that matches the DOCA version you intend to use. You can find available releases at NVIDIA DOCA DPL Container Tags.
>
> ```
> docker pull nvcr.io/nvidia/doca/dpl_dev:X.X.X-docaX.X.X-host
> ```

We'll use `nvcr.io/nvidia/doca/dpl_dev:1.4.0-doca3.3.0-host` for all examples in this page.

Running the container requires a set of base `docker run` **options** to work as intended. Most use cases involve in extending the base options, for example adding mounts to files the tools interact with. We recommend to first understand the base options before you extend them with your own.

8.10.7.3.2 Installation

```
docker run -it -e HOME=${HOME} -v ${HOME}:${HOME} -u $(id -u):$(id -g) nvcr.io/nvidia/doca/dpl_dev:1.4.0-doca3.3.0-
host install
```



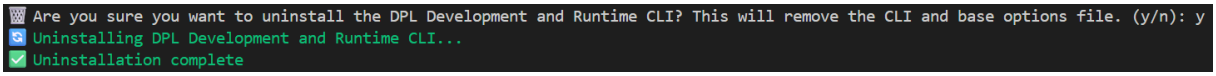
8.10.7.3.2.1 The options file

The installation creates an options file at `~/dpl.opts` which contains options to be passed to the `docker run` command running the container.

Removing any of the default options is not recommended.
However adding more options may be needed per your use case, the options file contain commented out examples of such use cases.

8.10.7.3.3 Uninstallation

```
docker run -it -e HOME=${HOME} -v ${HOME}:${HOME} -u $(id -u):$(id -g) nvcr.io/nvidia/doca/dpl_dev:1.4.0-doca3.3.0-
host uninstall
```



8.10.7.3.4 Working with `dpl`

> ⚠ Running `dpl` requires access to `docker` so either run it with user `root` or with non-root user that is part of the docker group.

Running the installed `dpl` executes a CLI with commands of the bundled developer tools.

```
dpl --help
```

```
dpl - DPL Development and Runtime CLI

Usage:
  dpl COMMAND
  dpl [COMMAND] --help | -h
  dpl --version | -v

Commands:
  compile        Runs the DPL NVP4 Compiler (alias command: nvp4c)
  admin          Runs the DPL Admin
  nspect         Runs the DPL Nspect
```

```
  debugger       Runs the DPL Debugger
  p4runtime_sh   Runs the P4Runtime Shell

Options:
  --help, -h
    Show this help

  --version, -v
    Show version number

Environment Variables:
  DPL_COMPILE_DEFAULT_ARGS
    Default arguments for the DPL Compile command

  DPL_ADMIN_DEFAULT_ARGS
    Default arguments for the DPL Admin command

  DPL_NSPECT_DEFAULT_ARGS
    Default arguments for the DPL Nspect command

  DPL_DEBUGGER_DEFAULT_ARGS
    Default arguments for the DPL Debugger command

  DPL_P4RUNTIME_SHELL_DEFAULT_ARGS
    Default arguments for the P4Runtime Shell command
```

Using the CLI is self explanatory, use the `--help` flag for further help on each command. For example, `dpl compile --help` will show the compiler tool's usage and full help message.

The environment variables `DPL_..._DEFAULT_ARGS` should be defined in the options file, a commented out template already exists.

8.10.7.3.5 Next Steps

1. Compiling DPL Applications that you wish to examine using the developer tools.
2. Loading DPL Applications can now be done with the compilation outputs.
3. Use the DOCA Pipeline Language Developer Tools to further examine the DPL programs correct operation.

8.10.7.4 Compiling DPL Applications

This page describes how to use the NVIDIA DPL compiler to build DPL applications.

8.10.7.4.1 Introduction

DOCA Programming Language (DPL) sample applications serve as educational resources that demonstrate how to program on the NVIDIA BlueField networking platform (DPU or SuperNIC) using DPL.

The NVIDIA DPL compiler (`nvp4c`) is provided as an executable within a self-contained Docker image. This image is available to partners via the NVIDIA NGC platform. To access it, log in to NVIDIA NGC and download the latest DPL Docker containers.

8.10.7.4.2 Installation

- For system requirements, refer to DPL Runtime Service.
- For compiler installation instructions refer to the DPL Installation Guide.
- For information about the development environment, refer to the DOCA Pipeline Programming Model and the DPL System Overview.

8.10.7.4.3 Dependencies

- BlueField-3 DPU or CX-9 SuperNIC
- Ubuntu 22.04 hosts (x86) or greater
- A P4Runtime controller based on API version 1.4.0 or greater

8.10.7.4.4 Compiling Applications

The DPL compiler is provided with all its dependencies in the `dpl-dev` container. For details on how to obtain and install the Docker images refer to the DPL Installation Guide.

A script command, `dpl nvp4c`, is provided to execute the DPL compiler from the `dpl-dev` container:

```
dpl nvp4c --target [doca|doca-bf3|doca-cx9] nvp4c_args* program.p4
```

- `--target` – the DPL target architecture
- `dplp4c_args` – arguments to be passed to the compiler (e.g., `program.p4`)

The following example compiles `hello_packet` using DPL:

```
user@host:~/p4-samples/doca/hello_packet$ dpl nvp4c --target doca hello_packet.p4
Generating compiler output in "_out"
```

The following files in this example are produced in the `_out` directory:

File name	Description
`compiler.log`	Log of any compiler warnings or errors to the specified program
`hello_packet.dplconfig`	Binary blob, containing all the data needed for the DPL Runtime daemon to load the program
`hello_packet.p4info.txt`	P4Runtime protobuf file, in text format

Additional `nvp4c` specific arguments include:

```
--help                                  Print this help message
--version                               Print compiler version
-I path                                 Specify include path (passed to preprocessor)
-D arg=value                            Define macro (passed to preprocessor)
-U arg                                  Undefine macro (passed to preprocessor)
-E                                      Preprocess only, do not compile (prints program on stdout)
-M                                      Output `make` dependency rule only (passed to preprocessor)
-MD                                     Output `make` dependency rule to file as side effect (passed to
preprocessor)
-MF file                                With -M, specify output file for dependencies (passed to preprocessor)
-MG                                     with -M, suppress errors for missing headers (passed to preprocessor)
-MP                                     with -M, add phony target for each dependency (passed to preprocessor)
-MT target                              With -M, override target of the output rule (passed to preprocessor)
-MQ target                              Like -Mt, override target but quote special characters (passed to
preprocessor)
--nocpp                                 Skip preprocess, assume input file is already preprocessed.
--Wdisable[=diagnostic]                 Disable a compiler diagnostic, or disable all warnings if no diagnostic is
specified.
--Winfo[=diagnostic]                    Report an info message for a compiler diagnostic.
--Wwarn[=diagnostic]                    Report a warning for a compiler diagnostic, or treat all info messages as
warnings if no diagnostic is specified.
--Werror[=diagnostic]                   Report an error for a compiler diagnostic, or treat all warnings as errors
if no diagnostic is specified.
--maxErrorCount errorCount              Set the maximum number of errors to display before failing.
--target target                         Compile for the specified target device.
--metrics metric1[,metric2]             Select which code metrics will be collected.
                                        Valid options: all, loc, cyclomatic, halstead, unused-code, duplicit-code,
                                        nesting-depth, header-general, header-manipulation, header-modification,
                                        match-action, parser, inlined, extern.
--odir out_directory                    Write output to out directory
--enable feature[,feature]*|--help      Enable a feature, or comma-separated list of features
--disable feature[,feature]*|--help     Disable a feature, or comma-separated list of features
-g                                      Enable debugging via DPLnspect. Equivalent to --debug-mode=extern
--debug-mode debug_mode                 Enable debugging via DPLnspect. Options: extern, auto
--log filename                          [Compiler debugging] Compiler log file name
--list-pass-params                      List known pass parameters and exit
--pass-param pass.key=value             Pass parameter (repeatable). Example: --pass-param
merge_adjacent_hwtables.max_merges=256
-v logLevel                             [Compiler debugging] Backend log level
-T fileLogSpec                          [Compiler debugging] Backend logging level per file
```

The binary `<sample_name>.` is created under `_out/<sample_name>.dplconfig`.

The P4Runtime file is created under `_out/<sample_name>.p4info.txt`.

8.10.7.4.5 Compiling Applications in Debug Mode

To enable packet debugging, you must ensure the following:

- Compile your DPL program with the `-g` flag. This enables parsing for a debug flow.
- Ensure you have at least one `nv_send_debug_pkt()` call in your DPL program. A debug packet will be emitted where `nv_send_debug_pkt()` is placed, and represents the program state at that point.
- If using `debug-mode=auto`, debug points will be placed before each statement in each control's apply block, and at the end of each P4 action block. The user can still manually place calls to `nv_send_debug_pkt()` in a P4 action.

Packet debugging is supported for packets received from a wire port (RX direction) and for packets sent by the CPU (TX direction).

You may optionally include a cookie in your `nv_send_debug_pkt()` call (e.g., `nv_send_debug_pkt(8w0x42)`). This cookie can help distinguish between different debug extern calls and will appear in the debugging output.

If `nv_send_debug_pkt()` is placed in an apply block and `debug-mode=auto`, the user's specified debug point will override the automatic debug point.

8.10.7.5 Loading DPL Applications

NVIDIA DPL programs are deployed to the NVIDIA® BlueField® networking platform (DPU or SuperNIC) using the P4Runtime API. This allows platform-independent, standards-based integration with SDN controllers.

8.10.7.5.1 Introduction

The DPL compiler generates a pipeline binary optimized for execution on BlueField. Pipeline loading and control—such as installing the program and populating P4 tables—are handled via the P4Runtime API, an open and well-defined interface.

The P4Runtime server, running on the BlueField device, enables a P4 Controller to:

- Connect over gRPC
- Set the `ForwardingPipelineConfig` (i.e., install the compiled DPL binary and `p4info`)
- Query the device for its current pipeline config and table state
- Maintain runtime P4 tables as defined in the DPL source

This model enables integration with open-source, proprietary, or custom-built controllers in a standardized way.

8.10.7.5.2 Prerequisites

Before loading a DPL application, ensure the following services and components are properly set up:

- DPL Runtime Service is running and configured on the BlueField (Arm side). See the DPL Container Deployment page for setup instructions.
- DPL Development Container and the `p4runtime_sh.sh` launch script are installed on the host. See the DPL Installation Guide for more details.

8.10.7.5.3 Loading the Application

A DPL application can be loaded using:

- A custom P4Runtime controller
- The NVIDIA-supplied Python controller
- An open source controller

In the following example, we'll be using the P4Runtime controller bundled within the DPL Development Container.

8.10.7.5.3.1 Using p4runtime_sh Script

```
./p4runtime_sh.sh help
```

```
usage: dpl p4runtime_sh [--help] [--grpc-addr <dpl_rtd_ip:port>] [--device-id <device ID>] [--config
program.p4info.txt,program.dplconfig]
```

Arguments:

- `--help` - Show all the command line arguments.
- `--config` - A list of the DPL program compilation output for P4info and dplconfig (Compiling DPL Applications).
- `--grpc-addr` - Address of the DPL Runtime daemon and the P4Runtime port as specified in the DPL Runtime DPL Service Configuration.
- `--device-id` – ID of the target device

> To configure the `dpl` command see DPL Installation Guide (Configuring Launch Scripts). The docker image used can be changed by setting the environment variable $DPL_DEV_IMAGE.
>
> The examples below assumes that everything was pre-configured using the `dpl-dev` install procedure.

Example Command

```
dpl p4runtime_sh --grpc-addr 192.168.100.2:9559 --device-id 1000 --config
hello_packet.p4info.txt,hello_packet.dplconfig
```

8.10.7.5.3.2 p4runtime_sh python application

After successfully loading a program, the script launches an interactive Python shell (`p4runtime_sh` python application) connected to the P4Runtime server on the dpl-rt-service running on the DPU.
From here, you can inspect and manage tables entries using this tool. For more details about using the `p4runtime_sh` application see:

- Our P4 Runtime Controller documentation.
- Official p4runtime-shell project documentation.

8.10.7.5.4 P4Runtime Optimizations

DPL table entries are added via a P4Runtime controller, which may run remotely or locally on the device.

- The standard gRPC-based controller model supports ~50K rule insertions per second

8.10.7.5.5 Troubleshooting

Loading a program might fail when the dpl-rt-service processes the compiled program due to various reasons (mostly configuration issues), in such cases, you might see error message like:

Program load failure example

```
# dpl p4runtime_sh --device-id 1000 --config p.p4info.txt,p.dplconfig
CRITICAL:root:Error when setting config
CRITICAL:root:P4Runtime RPC error (INVALID_ARGUMENT): Error setting program: Failed creating P4 tables
```

Refer to the following for common troubleshooting issues:

Checkpoint	Guidance/Command
Inspect the `dpl-rt-service` log for more error details	There are two methods to get the `dpl-rt-service` log: 1. Using the dpl admin utility: `# dpl admin -a 192.168.100.2:9600 get-log-recent --number_of_lines 50` 2. Manually logging into the DPU and finding the log file at: `/var/log/doca/dpl_rt_service/dpl_rtd.log`. Look for the last info and error messages at the end of the log file.
Inspect the current `dpl-rt-service` configurations	Use the dpl admin utility: `# dpl admin -a 192.168.100.2:9600 config` Verify that all required ports are present with the expected IDs. The devices and ports correspond to the `/etc/dpl_rt_service/devices.d/*.conf` configuration file(s) on the DPU.
Inspect the DPU non-volatile configurations (nvconfig)	Use the dpl admin utility: `# dpl admin -a 192.168.100.2:9600 nv-config --device_id 1000` Check if there are missing required firmware settings per DPL Runtime Service (Firmware Settings).

Checkpoint	Guidance/Command
Inspect the hardware/ firmware capabilities configurations	Use the dpl admin utility: `# dpl admin -a 192.168.100.2:9600 hca-capabilities --device_id 1000` Check if your hardware/firmware combination supports the required features.
The `dpl-rt-service` log contains error message like: `[dpl_port_id_to_ib_port_num] Cannot find port ID (16)`	This indicates that the DPL program refers to a port ID that does not exist in the device configuration files. Fix the program to use the correct port ID(s), and/or update the `/etc/dpl_rt_service/devices.d/*.conf` configuration file(s) on the DPU.
The `dpl-rt-service` log contains error message like: `NV_HWS[table_process_attr:434]: Unified FDB not supported by current FW`	This indicates that the DPU does not have a Firmware version that meets the minimum required version. Upgrade the DOCA and/or the Firmware version on the DPU to the minimum required version as documented at DPL Runtime Service (Software Prerequisites).

8.10.7.6 Sample DPL Applications

This section provides NVIDIA DOCA Pipeline Language sample applications that demonstrate how to develop, compile, and deploy programs using the NVIDIA DOCA Pipeline Language (DPL). These examples are intended to help developers become familiar with DPL concepts and runtime behavior on both host and BlueField®-3 platforms.

8.10.7.6.1 Sample Prerequisites

DPL programs can be compiled on any host machine with the DPL compiler installed. Once compiled, the output binary can be loaded onto:

- The same host machine (for development/debugging purposes), or
- A BlueField-3 DPU where the DPL Runtime daemon is running

Refer to the following documents for setup and troubleshooting:

- DPL Runtime Service – For instructions on installing and configuring DPL on BlueField
- DPL Release Notes – For known issues and guidance on installation, compilation, and execution of DPL sample applications

8.10.7.6.2 Running the Sample

1. Compile the DPL program using the DPL compiler.

2. Locate the generated output files in the compiler output directory:
    - `.p4info` – Describes the program's tables and actions
    - `.dplconfig` – Contains the binary pipeline configuration
3. Load the program onto the BlueField target using a P4Runtime controller (e.g., `p4runtime_sh.sh`, NVIDIA's controller, or a custom solution)

Once loaded, you can use the controller to populate flow tables, query runtime state, and validate pipeline behavior.

8.10.7.6.3 Sample Applications

- Hello Packet Example
- GTP Parsing Example
- GTP Tunnel Encapsulation Example
- GTP Full Application
- Geneve TLV Parsing Example
- VXLAN Tunnel Gateway Example
- Connection Tracking Example
- TCP State tracking
- Host-based Networking Example
- Equal-Cost Multi-Path Routing
- Entropy in Hash-Based Load Balancing
- NAT64 Example
- Add on Miss
- PSP encryption

8.10.7.6.4 Hello Packet Example

This example demonstrates the most basic pipeline in the DOCA target architecture. It consists of:

- Match on L2 source MAC address
- Action to either forward to a P4 port ID, drop, or no action

8.10.7.6.4.1 Sample Code

The following #includes are required for every DPL program. They define the DOCA target architecture. In particular, they contain things like the default DOCA parser, default headers struct, etc. Note that the symbol names are prefixed with "nv_" and are reserved for NVIDIA DOCA TA usage.

```
#include <doca_model.p4>
#include <doca_headers.p4>
#include <doca_externs.p4>
```

```
#include <doca_parser.p4>
```

The DOCA TA features a single control, which requires a headers struct and standard metadata. User metadata and packet out metadata, defined by the user, are optional.

```
control hello_packet(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    action drop() {
        nv_drop();
    }

    action forward(bit<32> port) {
        nv_send_to_port(port);
    }

    table forward_table {
        key = {
            headers.ethernet.dst_addr : exact;
        }
        actions = {
            drop;
            forward;
            NoAction;
        }
        default_action = forward(3);
        const entries = {
            (48w0x001111111111) : forward(1);
            (48w0x002222222222) : forward(2);
            (48w0x00dddddddddd) : drop();
            (48w0x00aaaaaaaaaa) : NoAction();
            (48w0x00bbbbbbbbbb) : NoAction();
        }
    }
    apply {
        forward_table.apply();
    }
}
```

Finally, the main package must be instantiated:

```
NvDocaPipeline(
    nv_fixed_parser(),
    hello_packet()
) main;
```

See below for the complete DPL example.

```

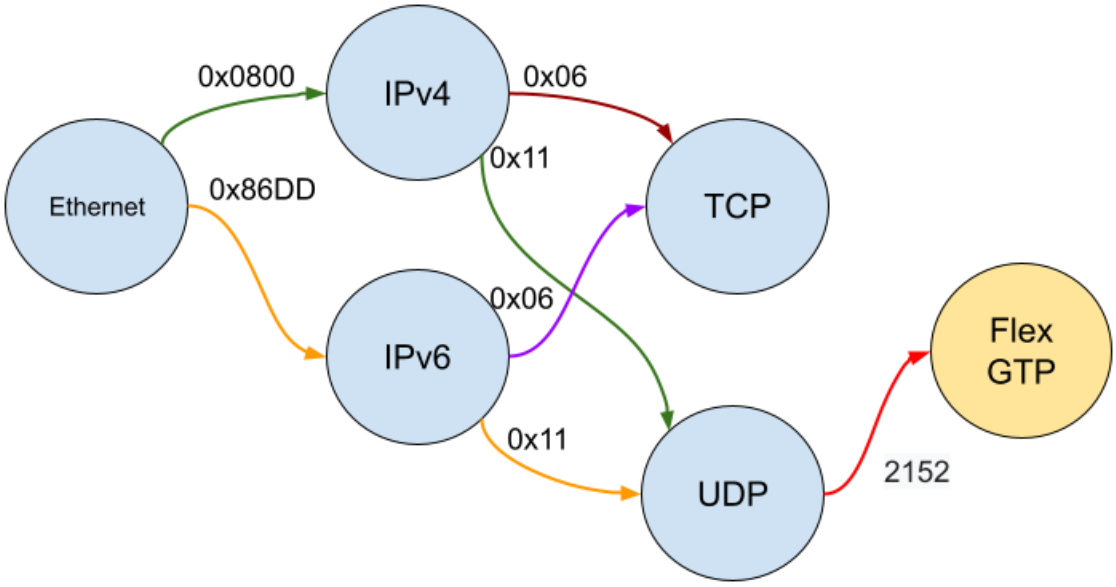
23   */
24
25  control hello_packet(
26      inout nv_headers_t headers,
27      in nv_standard_metadata_t std_meta,
28      inout nv_empty_metadata_t user_meta,
29      inout nv_empty_metadata_t pkt_out_meta
30  ) {
31      action drop() {
32          nv_drop();
33      }
34
35      action forward(bit<32> port) {
36          nv_send_to_port(port);
37      }
38
```

```
39      table forward_table {
40          key = {
41              headers.ethernet.dst_addr : exact;
42          }
43          actions = {
44              drop;
45              forward;
46              NoAction;
47          }
48          default_action = forward(3);
49          const entries = {
50              (48w0x001111111111) : forward(1);
51              (48w0x002222222222) : forward(2);
52              (48w0x00dddddddddd) : drop();
53              (48w0x00aaaaaaaaaa) : NoAction();
54              (48w0x00bbbbbbbbbb) : NoAction();
55          }
56      }
57      apply {
58          forward_table.apply();
59      }
60  }
61
62  NvDocaPipeline(
63      nv_fixed_parser(),
64      hello_packet()
65  ) main;
```

8.10.7.6.5 GTP Parsing Example

This example demonstrates how to add a simple flex parser node to the existing hardware defined parse graph.



8.10.7.6.5.1 Sample Code

This example starts with some basic definitions.

```
#include <doca_model.p4>
#include <doca_headers.p4>
#include <doca_externs.p4>
#include <doca_parser.p4>

const bit<32> WIRE_PORT = 32w00;
const bit<32> GTP_VPORT = 32w01;
const bit<32> DEFAULT_VPORT = 32w04;

struct metadata_t {
}
#define GTP_U_PORT 2152
```

Then we define the GTP-U version 1 header.

```
header Gtp_v1_h {
    bit<3>        version;               /** For GTPv1, this has a value of 1. */
    bit           protocol_type;         /** GTP (value 1) from GTP' (value 0) */
    bit           reserved;
    bit           extension_header_flag; /** extension header optional field. */
    bit           seq_number_flag;       /** Sequence Number optional field */
    bit           n_pdu_number_flag;     /** N-PDU number optional field */
    bit<8>        message_type;          /** types of messages are defined in 3GPP TS 29.060 section 7.1 */
    bit<16>       message_length;        /** length of the payload in bytes */
    bit<32>       teid;                  /** Tunnel endpoint identifier */
    bit<16>       sequence_number;       /** optional */
    bit<8>        n_pdu_number;          /** optional */
    bit<8>        next_extension_hdr_type; /** optional if any of the E, S, or PN bits are on. The field must be
interpreted only if the E bit is on */
}
```

Then we add `NV_FIXED_HEADERS` to the headers struct, along with the new GTP header.

```
struct headers_t {
    NV_FIXED_HEADERS
    Gtp_v1_h   gtpv1;
}
```

Using the `nv_transition_from` annotation, the GTP parser state is connected as a select transition from the UDP state.

```
parser packet_parser(packet_in packet, out headers_t headers) {
    NV_FIXED_PARSER(packet, headers)

    @nv_transition_from("nv_parse_udp", GTP_U_PORT)
    state parse_gtp
    {
        packet.extract(headers.gtpv1);
        transition accept;
    }
}
```

The control example uses a single flow table that matches on input port and GTP tunnel endpoint ID. The policy is then to forward the GTP packet to a port or drop the packet.

```
/**
 * This control admits GTP packets only if the tunnel ID matches
 *
 */
 control gtp_tunnel(
    inout headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    NvDirectCounter(NvCounterType.PACKETS_AND_BYTES) gtp_counter;

    action send_to_port_gtp_table(nv_logical_port_t port) {
        gtp_counter.count();
        nv_set_l4_src_port(headers, 1234);
        nv_send_to_port(port);
    }

    action drop_gtp_table() {
        gtp_counter.count();
        nv_drop();
    }

    table gtp_table {
        key = {
            std_meta.ingress_port: exact;
            headers.gtpv1.teid: exact;
        }
        actions = {
            send_to_port_gtp_table;
            drop_gtp_table;
            NoAction;
        }
        default_action = NoAction;
        direct_counter = gtp_counter;
    }

    apply {
        if (headers.gtpv1.isValid()) {
            if (gtp_table.apply().miss) {
                nv_send_to_port(DEFAULT_VPORT);
            }
```

```
        }
        drop();
    }
}

NvDocaPipeline(
    packet_parser(),
    gtp_tunnel()
) main;
```

Example P4Runtime shell entries:

```
te_tunnel_1 = table_entry["gtp_tunnel.gtp_table"](action="gtp_tunnel.send_to_port_gtp_table")
te_tunnel_1.match["std_meta.ingress_port"] = "0"
te_tunnel_1.match["headers.gtpv1.teid"] = "0x000000001"
te_tunnel_1.action["port"] = "1"
te_tunnel_1.insert()
te_tunnel_2 = table_entry["gtp_tunnel.gtp_table"](action="gtp_tunnel.send_to_port_gtp_table")
te_tunnel_2.match["std_meta.ingress_port"] = "1"
te_tunnel_2.match["headers.gtpv1.teid"] = "0x000000001"
te_tunnel_2.action["port"] = "0"
te_tunnel_2.insert()
te_tunnel_3 = table_entry["gtp_tunnel.gtp_table"](action="gtp_tunnel.drop_gtp_table")
te_tunnel_3.match["std_meta.ingress_port"] = "4"
te_tunnel_3.match["headers.gtpv1.teid"] = "0x000000001"
te_tunnel_3.insert()

te_tunnel_1.read(lambda te_tunnel_1: print(te_tunnel_1))
te_tunnel_2.read(lambda te_tunnel_2: print(te_tunnel_2))
te_tunnel_3.read(lambda te_tunnel_3: print(te_tunnel_3))
```

Example Scapy packets:

```
from scapy.contrib.gtp import GTP_U_Header

tunnel = Ether(src=""3C:6D:66:11:11:11",dst="ff:ff:ff:ff:ff:ff")/IP(src="100.100.100.1", dst="100.100.100.81")/
UDP(sport=2152, dport=2152)
p_l3 = IP(dst='1.2.3.4', src='4.4.4.4') / TCP(sport=100,dport=100,seq=1001,flags='S')

gtp = tunnel / GTP_U_Header(teid=1)/ p_l3
gtp2 = tunnel / GTP_U_Header(teid=2)/ p_l3

sendp(gtp, iface="p1")
sendp(gtp, iface="enp3s0f0s0")
sendp(gtp, iface="enp3s0f0s3")
sendp(gtp2, iface="p1")
```

Expected results:

- Packet gtp is sent on port 0 and is received on port 1 with UDP src port of 1234
- Packet gtp is sent on port 1 and is received on port 0 with UDP src port of 1234
- Packet gtp is sent on port 4 and is dropped
- Packet gtp2 is sent on port 0 and is received on port 4 unmodified

See below for the complete DPL example.

        nv_drop();
    }

    table gtp_table {
        key = {
            std_meta.ingress_port: exact;
            headers.gtpv1.teid: exact;
        }
        actions = {
            send_to_port_gtp_table;
            drop_gtp_table;
            NoAction;
        }
        default_action = NoAction;
        direct_counter = gtp_counter;
    }

    apply {
        if (headers.gtpv1.isValid()) {
            if (gtp_table.apply().miss) {
                nv_send_to_port(DEFAULT_VPORT);
            }
        }
        drop();
    }
}

NvDocaPipeline(
    packet_parser(),
    gtp_tunnel()
) main;
```

8.10.7.6.6 GTP Tunnel Encapsulation Example

The following example demonstrates GTPv1 encapsulation which must be declared as a custom header:

GTPv1 definition

```
header gtp_v1_h {
    bit<3>        version;               /** For GTPv1, this has a value of 1. */
    bit           protocol_type;         /** GTP (value 1) from GTP' (value 0) */
    bit           reserved;
    bit           extension_header_flag; /** extension header optional field. */
    bit           seq_number_flag;       /** Sequence Number optional field */
    bit           n_pdu_number_flag;     /** N-PDU number optional field */
    bit<8>        message_type;          /** types of messages are defined in 3GPP TS 29.060 section 7.1 */
    bit<16>       message_length;        /** length of the payload in bytes */
    bit<32>       teid;                  /** Tunnel endpoint identifier */
    bit<16>       sequence_number;       /** optional */
    bit<8>        n_pdu_number;          /** optional */
    bit<8>        next_extension_hdr_type; /** optional if any of the E, S, or PN bits are on. The field must be
interpreted only if the E bit is on */
}
```

The custom GTPv1 header can optionally be added to the parse graph (see Custom Parser States) is optional, and is only required if any of the custom header fields need to be read from or modified after encapsulation.

GTPv1 Parsing

```
struct headers_t {
    NV_FIXED_HEADERS
    gtp_v1_h   gtpv1;
}

parser packet_parser(packet_in packet, out headers_t headers) {
    NV_FIXED_PARSER(packet, headers)

    @nv_transition_from("nv_parse_udp", GTP_U_PORT)
    state parse_gtp
    {
        packet.extract(headers.gtpv1);
        transition nv_parse_inner_ipv4;
    }
}
```

The extern object NvTunnelTemplate<HEADER_TYPE> requires a struct type, for which the entire underlay header is defined as a struct:

Underlay headers

```
struct tunnel_headers_t {
    nv_ethernet_h ethernet;
    nv_ipv4_h     ipv4;
    nv_udp_h      udp;
    gtp_v1_h      gtpv1;
}
```

Finally, when declaring a NvTunnelTemplate object, the annotation `@nv_tunnel_fields` must be present. This annotation contains a key-value entry for each header in the specified struct type. Under each header, each header field must be specified in the order that the field appears in the header. For the GTPv1 example, a NvTunnelTemplate would be declared in the main control:

NvTunnelTemplate declaration

```
@nv_tunnel_fields(
    ethernet = {
        dst_addr = "variable",
        src_addr = "variable",
        ether_type = 0x0800
    },
    ipv4 = {
        version = 0x4,
        ihl = 0x5,
        diffserv = 0,
        ecn = "ignore",            // Cannot set
        total_len = "ignore",      // reparse will calculate, cannot set
        identification = "ignore", // Cannot set
        flags = 0,
        frag_offset = 0,
        ttl = 64,
        protocol = 17,
        hdr_checksum = "ignore",   // reparse will calculate, cannot set
        src_addr = "variable",
        dst_addr = "variable"
    },
    udp = {
        src_port = "ignore",       // reparse will set, cannot be set manually
        dst_port = "variable",
        length   = "ignore",       // reparse will calculate, cannot set
        checksum = "ignore"        // Cannot set
    },
    gtpv1 = {
        version = 1,
        protocol_type = 1,
        reserved = 0,
        extension_header_flag = 1,
        seq_number_flag = 1,
        n_pdu_number_flag = 1,
        message_type = 0xFF,    // T-PDU
        message_length = "variable",
        teid = "variable",
        sequence_number = 0,
        n_pdu_number = 0,
        next_extension_hdr_type = 0
    }
)
NvTunnelTemplate<tunnel_headers_t>() gtpv1Tunnel;
```

The type `tunnel_headers_t` determines the required structure of the annotation. Fields marked "variable" will be determined according to the arguments passed to `nv_set_l2tunnel_underlay` or `nv_set_l3tunnel_underlay`. Some fields will always be overwritten by reparse, such as IPv4 length, IPv4 checksum, UDP length, etc which must be calculated and cannot be set by the user. Such fields can be marked "ignore". Marking other fields "ignore", would set them to zero.

Finally, the instantiated NvTunnelTemplate object can be used in one of the custom tunnel externs. For example:

NvTunnelTemplate usage

```
action tunnel(nv_ipv4_addr_t src_addr) {
    nv_set_l3tunnel_underlay(headers, gtpv1Tunnel, {
        48w0x001A2B3C4D5E, // ethernet.dst_addr
        48w0x00F1E2D3C4B5, // ethernet.src_addr
        src_addr,          // ipv4.src_addr
        32w0xC07B7B01,     // ipv4.dst_addr
        16w0x868,          // udp.dst_port for GTP-U
        16w0x4,            // gtpv1.message_length
        32w0x1234567       // gtpv1.teid
    });
    nv_send_to_port(1);
}
```

The third argument to `nv_set_l3tunnel_underlay` is required to be a list expression where each element corresponds to a header field marked "variable" in the NvTunnelTemplate annotation. The order of the values in the list is the order in which the header fields appear in the packet.

The main table logic first checks the IP source, and then creates the GTP tunnel. Since header modifications are performed immediately, the reparsed packet can now be matched for TEID in the next table apply.

```
table ip_as_key {
    key = {
        headers.ipv4.src_addr : exact;
    }
    actions = {
        NoAction;
        drop;
        forward;
        tunnel;
    }
    size = 128;
    default_action = NoAction;
}

table teid_as_key {
    key = {
        headers.gtpv1.teid : exact;
    }
    actions = {
        NoAction;
        drop;
        forward;
    }
    size = 128;
    default_action = forward(3);
}

apply {
    ip_as_key.apply();
    if (headers.gtpv1.isValid()) {
        teid_as_key.apply();
    }
    forward(3);
}
```

See below for the complete DPL example.

8.10.7.6.7 GTP Full Tunnel Application

This DPL program implements a complete GTP tunnel handler on Bluefield, providing parsing, encapsulation, decapsulation, and flexible forwarding for mobile network traffic. Incoming packets are processed to:

- extract GTP tunnel information
- encapsulate plain IP packets into GTP tunnels
- decapsulate GTP-tunneled packets to deliver the inner payload

The program supports both user equipment (UE)-to-core uplink and core-to-UE downlink paths, as well as plain IP and GTP transit forwarding. Each operation is hardware-accelerated and leverages programmable match-action tables and tunnel header templates for optimal performance.

8.10.7.6.7.1 Sample Code

Custom Header and Metadata Structures

- **GTP Header (`gtp_v1_h`)**: Defines GTPv1 protocol fields, enabling extraction and manipulation of GTP tunnel information.
- **Custom Metadata (`metadata_t`)**: Stores flags and tunnel parameters to guide encapsulation or decapsulation during pipeline execution.

Parser

- **Flexible Parsing**: Leverages the fixed parser for standard headers, and adds a GTP-specific parsing state that triggers when the UDP destination port is GTP-U (2152). When detected, it extracts the GTP header and transitions to parsing the inner IP payload.

Tunnel Header Template

- **Header Composition (`tunnel_headers_t`)**: Specifies the exact order and content of Ethernet, IPv4, UDP, and GTP headers for encapsulation, using variables for fields filled at runtime (e.g., TEID, address fields).

Main Control Block – Actions

- **Drop Action**: Immediately drops non-conforming or unwanted packets.
- **Encapsulation (`encapsulate_gtp`)**: Encapsulates an IP packet within GTP, UDP, IPv4, and Ethernet outer headers, using the DPL extern for L3 tunnel offload.

- **Decapsulation (`decapsulate_gtp`)**: Removes the GTP tunnel header and the outer headers, then rewrites the Ethernet header for the inner packet.
- **Forwarding**: Directs packets to their designated output port.

Main Control Block – Tables

- **Uplink Encapsulation Table**: Matches on input port and source IP to select the correct GTP tunnel for encapsulation (UE to core network).
- **Downlink Decapsulation Table**: Matches on input port and TEID, applying decapsulation to GTP packets for delivery to the user side (core network to UE).
- **GTP Forwarding Table**: Forwards GTP packets by TEID for nodes that act as GTP relays without terminating or modifying the tunnel.
- **Plain IP Forwarding Table**: Routes non-GTP IP traffic using destination address longest prefix match.

Packet Processing Logic (`apply` block)

- **Non-IPv4 Packets**: Dropped immediately, ensuring pipeline only processes valid IPv4.
- **GTP Packets**: Processed through downlink decapsulation and, if appropriate, GTP forwarding tables.
- **Non-GTP Packets**: Subject to uplink encapsulation (for new tunnel flows) or regular IP forwarding.

See below for the complete DPL example.

    gtp_processor()
) main;
```

8.10.7.6.8 Geneve TLV Parsing Example

This example demonstrates how to add a custom protocol header that supports optional Type-Length-Value (TLV) fields. In the P4-16 specification, there is no first class support in the parser primitives, and the user needs to manually.

Geneve is short for Generic Network Virtualization Encapsulation, a common L2 tunnel header. The Geneve header format is:

```
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|Ver|  Opt Len  |O|C|    Rsvd.  |          Protocol Type        |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|        Virtual Network Identifier (VNI)       |    Reserved   |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|                                                               |
~                    Variable-Length Options                    ~
|                                                               |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+

The Geneve option header is:

 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|          Option Class         |       Type    |R|R|R|  Length |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|               ~ Variable-Length Option Data ~                 |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

8.10.7.6.8.1 Sample Code

First we define the Geneve header, per RFC 8926.

```
header geneve_t {
    bit<2> ver;
    bit<6> opt_len;
    bit<1> o;
    bit<1> c;
```

```
    bit<6> reserved1;
    bit<16> protocol_type;
    bit<24> vni;
    bit<8> reserved2;
};
```

Next we define a struct that contains the base Geneve Option header, shared by all option types.

```
// Struct so it can be a field within other headers
struct geneve_option_t {
    bit<24> option_class_type;
    bit<3> reserved;
    bit<5> length;
};
```

Lastly, depending on the option class and type, the variable length option data can be defined. In this example, we model the Geneve options used by the P4 Inband Telemetry (INT) specification.

```
// Intermediate nodes (INT Transit Hops) must process this type of INT Header.
header geneve_option_int_md_t {
    geneve_option_t base;
    bit<4> version;
    bit<1> discard;
    bit<1> exceeded_max_hops;
    bit<1> mtu_exceeded;
    bit<12> reserved;
    bit<5> hop_ml;
    bit<8> remaining_hop_count;
    bit<16> instruction_bitmap;
    bit<16> ds_id;
    bit<16> ds_instruction;
    bit<16> ds_flags;
};
// Destination headers can be used to enable Edge-to-Edge communication between
// the INT Source and INT Sink.
header geneve_option_int_destination_t {
    geneve_option_t base;
    // Destination headers must only be consumed by the INT Sink
};

// Intermediate nodes (INT Transit Hops) must process this type of INT Header
// and generate reports to the monitoring system as instructed.
header geneve_option_int_mx_t {
    geneve_option_t base;
    bit<4> version;
    bit<1> discard;
    bit<27> reserved1;
    bit<16> instruction_bitmap;
    bit<16> ds_id;
    bit<16> ds_instruction;
    bit<16> ds_flags;
};
```

All the above headers and structs must be added to the application's headers struct, along with the NV_FIXED_HEADERS.

```
struct app_headers {
    NV_FIXED_HEADERS

    geneve_t custom_geneve;
    // geneve_option_t is not explicitly used by the P4 program, so a reference
    // placed in the headers the type is not optimized out. The NvOptionParser
    // instantiation references this type it by string name.
    geneve_option_t geneve_opt;
    geneve_option_int_md_t geneve_opt_int_md;
    geneve_option_int_destination_t geneve_opt_int_destination;
    geneve_option_int_mx_t geneve_opt_int_mx;
};
```

The last step for the parser is to define the parser state that will perform Geneve parsing. An extern object, NvOptionsParser, is used to further parse into the Geneve options. In this example, the TLV "type" is a combination of Option class and type:

- Class 0x103, type 1 (INT-MD)
- Class 0x103, type 2 (Destination-type)

- Class 0x103, type 3 (INT-MX)

```
parser geneve_parser(
    packet_in packet,
    out app_headers headers
) {
    NvOptionParser<bit<24>, _>(
        "opt_len",                  // options_length_field
        2,                          // options_length_shift
        0,                          // options_length_add
        "geneve_option_t",          // option_layout_header_type
        "length",                   // option_length_field
        0,                          // option_length_shift
        4,                          // option_length_add
        "option_class_type",        // option_type_field
        (list<tuple<bit<24>, _>>){  // options
            {24w0x010301, "headers.geneve_opt_int_md"},
            {24w0x010302, "headers.geneve_opt_int_destination"},
            {24w0x010303, "headers.geneve_opt_int_mx"}
        }
    ) geneveOptions;

    NV_FIXED_PARSER(packet, headers)

    @nv_transition_from("nv_parse_udp", GENEVE_PORT)
    state parse_geneve {
        // Fixed geneve is only an example; "base" header must be flex.
        packet.extract(headers.custom_geneve);
        geneveOptions.parseOptions(packet, headers);
        transition select(headers.custom_geneve.protocol_type) {
            NV_TYPE_IPV4 : nv_parse_inner_ipv4;
            NV_TYPE_IPV6 : nv_parse_inner_ipv6;
            NV_TYPE_MAC : nv_parse_inner_ethernet;
            default : accept;
        }
    }
}
```

The control below shows how a match action table can be configured to now match on a specific INT domain, and perform per ID forwarding.

```
control int_over_geneve(
    inout app_headers headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    action forward(bit<32> port) {
        nv_send_to_port(port);
    }

    action drop() {
        nv_drop();
    }

    table geneve_option_int_md_table {
        key = {
            headers.geneve_opt_int_md.ds_id : exact;
        }
        actions = {
            forward;
            NoAction;
        }
        default_action = NoAction();
        const entries = {
            (16w0x100) : forward(1);
        }
    }

    table geneve_option_int_destination_table {
        key = {
            headers.custom_geneve.vni : exact;
        }
        actions = {
            forward;
            NoAction;
        }
        default_action = NoAction();
        const entries = {
            (24w0x200) : forward(2);
        }
    }

    table geneve_option_int_mx_table {
        key = {
            headers.geneve_opt_int_mx.ds_id : exact;
        }
        actions = {
            forward;
            NoAction;
        }
        default_action = NoAction();
        const entries = {
            (16w0x300) : forward(3);
        }
```

```
    }

    apply {
        if (headers.custom_geneve.isValid()) {
            geneve_option_int_md_table.apply();
            geneve_option_int_destination_table.apply();
            geneve_option_int_mx_table.apply();
        }
        drop();
    }
}
```

See below for the complete DPL example.

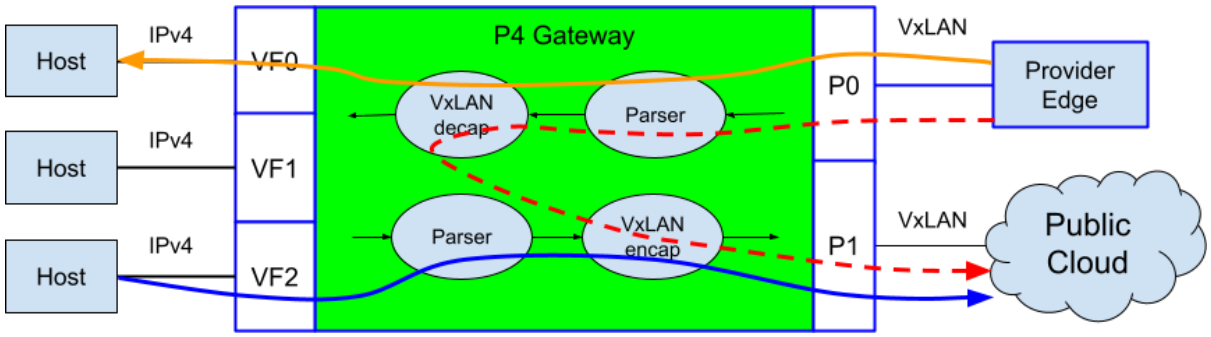
8.10.7.6.9 VXLAN Tunnel Gateway Example

This example illustrates how to write a basic VXLAN tunnel gateway using the DOCA target architecture. A tunnel gateway allows programmatic control over how VXLAN traffic can be "stitched" packets across tenant domains. In this example, end point traffic destined to local bare metal hosts can be decapsulated and forwarded to a VF, while gateway traffic can be decapsulated, re-encapsulated and sent back to the wire. For example, this program can be easily extended to be a gateway connecting legacy NVGRE networks to a VXLAN-GPE network.



8.10.7.6.9.1 Sample Code

This example users the native parser and 2 tables, of size 32K each. The wire port is configured with P4 port ID 0. A single bit in the user metadata structure is used to keep the decapsulation state.

```
/*
* Table sizes.
*/
const bit<32> DECAP_TABLE_SIZE = 32768;
const bit<32> ENCAP_TABLE_SIZE = 32768;

/* The directionality is based on network to host
 * The user will configure the DPL port IDs in the DPL RT configuration
 */
const bit<32> WIRE_PORT = 32w0;

struct headers_t {
    NV_FIXED_HEADERS
}

parser packet_parser(packet_in packet, out headers_t headers) {
    NV_FIXED_PARSER(packet, headers)
 }
```

The encapsulation control has a single table, matching on IPv4 destination address. If an entry matches, the packet is VXLAN encapsulated and forwarded to the specified port. If the packet does not hit any entry, then the packet is dropped. It is simple to add more complex policy rules such as a 5 tuple ACL.

```
/*
* This control performs the overlay policy including L2 encap with VXLAN
*/
control overlay_encap(
    inout headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
```

```
) {
    NvDirectCounter(NvCounterType.PACKETS_AND_BYTES) encap_counter;

    action deny() {
        nv_drop();
    }

    action to_port(nv_logical_port_t port) {
        nv_send_to_port(port);
    }

    action vxlan_v4_encap(nv_mac_addr_t underlay_src_mac, nv_mac_addr_t underlay_dst_mac,
                nv_ipv4_addr_t underlay_sip, nv_ipv4_addr_t underlay_dip, bit<24> vni, nv_logical_port_t port) {
        nv_set_vxlan_v4_underlay(headers, underlay_dst_mac, underlay_src_mac, underlay_sip, underlay_dip, vni);
        encap_counter.count();
        nv_send_to_port(port);
    }

    table encap_v4_table {
        key = {
            headers.ipv4.dst_addr : exact;
        }
        actions = {
            vxlan_v4_encap;
            to_port;
            deny;
        }
        size = ENCAP_TABLE_SIZE;
        default_action = deny;
        direct_counter = encap_counter;
    }

       if (headers.ipv4.isValid()) {
           encap_v4_table.apply();
       }
    }
}
```

The decapsulation control simply checks if the packet is VXLAN, and decapsulates it. From there the packet can be sent directly to a port, or hair-pinned back to the wire.

```
/*
* This control is for packets from wire to host (RX)
* and includes policy for L2 decap
*/
control underlay_decap(
    inout headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    NvDirectCounter(NvCounterType.PACKETS_AND_BYTES) decap_counter;

    action deny() {
        nv_drop();
    }

    action decap() {
        decap_counter.count();
        nv_l2_decap(headers);
    }

    action to_port(nv_logical_port_t port) {
        nv_send_to_port(port);
    }

    action decap_to_port(nv_logical_port_t port) {
        decap_counter.count();
        nv_l2_decap(headers);
        nv_send_to_port(port);
    }

    table decap_v4_table {
        key = {
            headers.vxlan.vni : exact;
        }
        actions = {
            decap;
            to_port;
            decap_to_port;
            deny;
            NoAction;
        }
        size = DECAP_TABLE_SIZE;
        direct_counter = decap_counter;
        default_action = NoAction;
    }

    apply {
        if (headers.vxlan.isValid()) {
            decap_v4_table.apply();
        }
    }
}
```

The main control checks the ingress port to determine if the packet is Network to Host, or Host to Network. Depending on the direction, it applies the decap_flow control, or performs an overlay encapsulation.

```
control gateway(
    inout headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    overlay_encap() over;
    underlay_decap() under;

    /* user should add entries that correspond to the wire ports
     * A hit means this is an RX packet, miss means a TX packet
    */
    table direction_table {
        key = {
            std_meta.ingress_port : exact;
        }
        actions = {
            NoAction;
        }
        default_action = NoAction;
        const entries = {
            (WIRE_PORT) : NoAction();
        }
    }

    apply {
        if (direction_table.apply().hit) {
            under.apply(headers, std_meta, user_meta, pkt_out_meta);
        }
        else {
            over.apply(headers, std_meta, user_meta, pkt_out_meta);
        }
    }
}
```

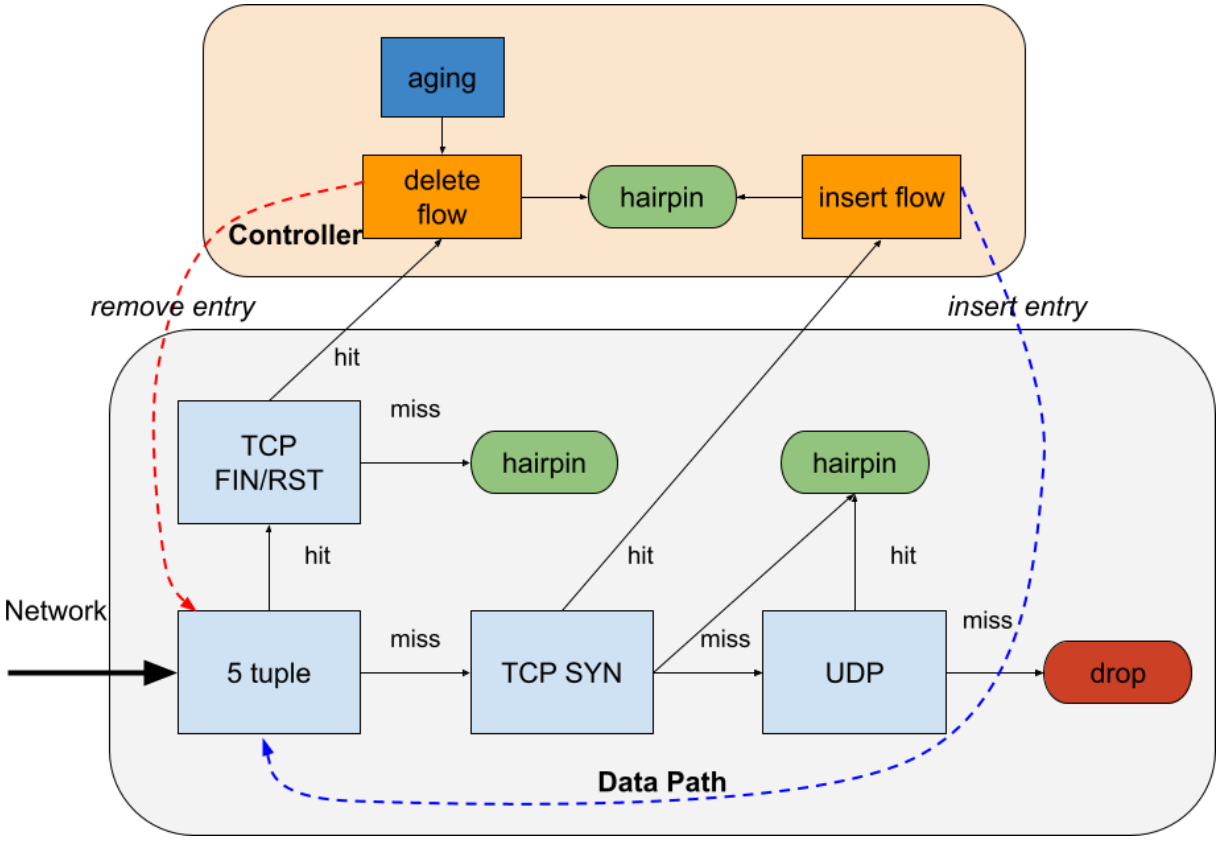
8.10.7.6.10 Connection Tracking Example

Connection tracking is a stateful process that follows the a TCP/UDP session from establishment to termination. It consists of a 5 tuple match on <Source IP address, Destination IP address, IP protocol, L4 Source port, L4 Destination port>. The DPL datapath relies on a controller to insert entries for new 5 tuple flows that have not been seen yet.



8.10.7.6.10.1 Sample Code

Connection metadata is a struct that sent with a packet that is sent to the P4Runtime controller. It requires a special annotation with the label "packet_in". The user can define up to 32 bits of data in this data structure.

```
#include <doca_model.p4>
#include <doca_headers.p4>
#include <doca_externs.p4>
#include <doca_parser.p4>

@nv_controller_metadata("packet_in")
struct connection_meta_t {
    bit<2> type;
    bit<2> _reserved;
    bit<28> zone;
}
```

In this sample, the packet processing pipeline examines the state of the connection based on the TCP flags and set in the connection metadata an enum type describing the state of the flow.

```
/* Meta connection type */
enum bit<2> ct_type {
    PASS = 0,
    NEW = 1,
    RST = 2,
    FIN = 3
}
```

For readability, constants are used to assign P4 port IDs to more a more meaningful symbol name. The mapping of PFs and VFs to P4 port IDs is done separately in the Service Configuration.

```
/*
   VF port to SW entity that manages the flow insertion,
   deletion and expiry times
*/
const bit<32> WIRE_PORT = 32w0;
const bit<32> HAIRPIN_PORT = 32w1;
```

```
control conn_track(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    connection_meta_t ctrl_meta;

8.10.7.6.11 TCP State Tracking

The TCP State feature in the DOCA Target Architecture provides a robust mechanism for tracking TCP flow parameters, specifically sequence and acknowledgment numbers, directly within the data plane of the BlueField device. The ability to monitor and maintain stateful information about TCP flows offloads this task that traditionally required host CPU processing. With the DPL NvTcpState extern object, developers can programmatically store and query TCP state for each flow at high speeds, enabling fine-grained management of network connections on the DPU.

Tracking TCP sequence and acknowledgment numbers in networking devices, especially within network interface controllers (NICs), empowers a wide range of advanced use cases:

- Enables in-line enforcement of connection security and integrity by validating packet order, detecting replayed or duplicated segments, and preventing sequence-based attacks.
- Provides the basis for in-hardware filtering or offloading of application protocols, as flows can be programmatically distinguished by their connection phases (SYN, SYN-ACK, FIN, RST), supporting real-time acceleration, monitoring, and troubleshooting.
- Facilitates granular stateful firewalling, DDoS mitigation, and anomaly detection by mapping the bi-directional progress of TCP sessions and quickly identifying abnormal or terminated connections at line-rate without host intervention.

By integrating TCP state tracking at the NIC level, operators gain a powerful tool for building scalable, high-performance network functions—from load balancers and firewalls to traffic steering and protocol offloading—while conserving host resources and reducing application latency.

8.10.7.6.11.1 Sample Code

This pipeline consists of a single control, with the following control level objects:

- Three direct counters: for connection tracking, RX/TX forwarding, and ARP table accesses.
- A hardware-accelerated TCP state tracker (`NvTcpState`) for storing and updating TCP connection state information.

```
control c(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout usermeta_conntrack_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    NvDirectCounter(NvCounterType.PACKETS_AND_BYTES) conntrack_counter;
    NvDirectCounter(NvCounterType.PACKETS_AND_BYTES) rx_tx_table_counter;
    NvDirectCounter(NvCounterType.PACKETS_AND_BYTES) arp_table_counter;
    NvTcpState(TABLE_SIZE) ct_tcp_state;
```

An ARP table is used to:

- tracks ARP requests and responses, matching packets based on EtherType and ingress port, and forwarding them to the opposite side (uplink or VF) as appropriate.
- Includes per-entry counters and default no-op handling for unmatched ARP messages.

```
    action arp_forward(nv_logical_port_t port) {
        arp_table_counter.count();
        nv_send_to_port(port);
    }

    table arp_table {
        key = {
            std_meta.last_l2_ether_type : exact;
            std_meta.ingress_port : exact;
```

```
        }
        actions = {
            arp_forward;
            NoAction;
        }
        size = TABLE_SIZE;
        direct_counter = arp_table_counter;
        default_action = NoAction();
        const entries = {
            (NV_TYPE_ARP, UPLINK_DPL_LOGICAL_PORT_ID): arp_forward(VF_DPL_LOGICAL_PORT_ID);
            (NV_TYPE_ARP, VF_DPL_LOGICAL_PORT_ID): arp_forward(UPLINK_DPL_LOGICAL_PORT_ID);
        }
    }
```

If the packet has TCP flags of FIN, RST or SYN-ACK, the packet is sent to a controller to insert or remove flow entries. The handshake packets are then reinjected to the pipeline by the controller, and are forwarded using a RX/TX table. This table

- Defines actions to forward (`rx_tx_forward`) packets to a given port with accounting, or to drop (`rx_tx_drop`) a packet, both incrementing their respective counters.
- Uses the packet's IPv4 source address to determine its forwarding. Its entries map well-known local/remote IPs to hardware port IDs, forwarding accordingly or dropping unmatched packets.
- By default drops unrecognized traffic

```
    action rx_tx_forward(nv_logical_port_t port) {
        rx_tx_table_counter.count();
        nv_send_to_port(port);
    }

    action rx_tx_drop() {
        rx_tx_table_counter.count();
        nv_drop();
    }

    table rx_tx_table {
        key = {
            headers.ipv4.src_addr : exact;
        }
        actions = {
            rx_tx_forward;
            rx_tx_drop;
            NoAction;
        }
        size = TABLE_SIZE;
        direct_counter = rx_tx_table_counter;
        default_action = rx_tx_drop();
        const entries = {
            (LOCAL_IP_ADDRESS): rx_tx_forward(UPLINK_DPL_LOGICAL_PORT_ID);
            (REMOTE_IP_ADDRESS): rx_tx_forward(VF_DPL_LOGICAL_PORT_ID);
        }
    }
```

The remaining TCP session packets are processed by the main Match/Action block consisting of a Conntrack Table, with:

- An action (`track_tcp_conn`) that increments a connection tracking counter and updates the TCP state tracker with flow index and direction.
- A stateful table (`conntrack_table`) that matches on the IPv4 5-tuple and protocol for each TCP flow and applies either `track_tcp_conn` or no action.
- A per-entry direct counter for packet and byte statistics on each tracked connection.

The `NvTcpState` method `store` is called for all ongoing packets of the TCP session, which records the current SEQ/ACK numbers in stateful memory. The TCP state can be

retrieved by the controller application via APIs, and are not available to be read by the data plane.

```
action track_tcp_conn(bit<32> index, NvTcpFlowDirection direction) {
    conntrack_counter.count();
    user_meta.conntrackOut = ct_tcp_state.store(index, direction);
}

table conntrack_table {
    key = {
        headers.ipv4.src_addr : exact;
        headers.ipv4.dst_addr : exact;
        headers.ipv4.protocol : exact;
        headers.tcp.src_port : exact;
        headers.tcp.dst_port : exact;
    }
    actions = {
        track_tcp_conn;
        NoAction;
    }
    size = TABLE_SIZE;
    direct_counter = conntrack_counter;
    default_action = NoAction();
}
```

Finally, the TCP session data packets are sent to the `rx_tx_table` to reached the desired destination.

See below for the complete DPL example.

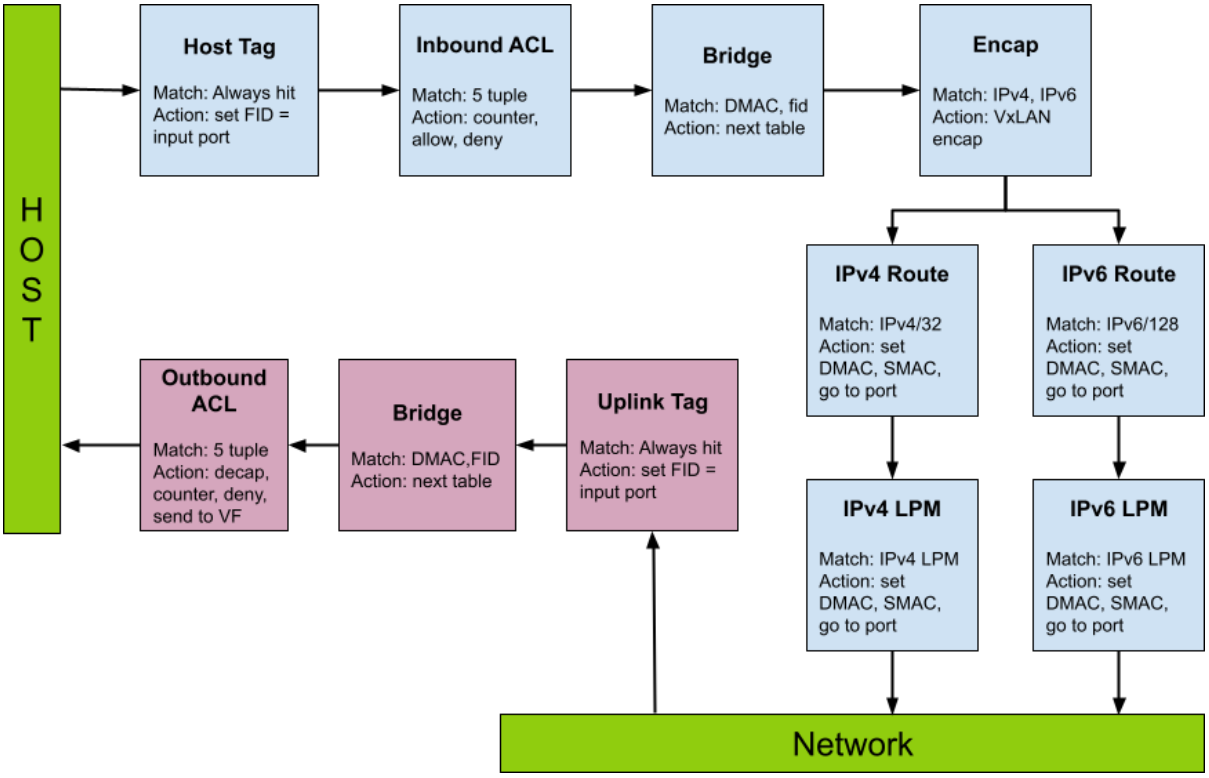
8.10.7.6.12 Host-based Networking Example

HBN is service that provides controller-less VPC networking solution for bare metal as a service (BMaaS), featuring tenant isolation with EVPN VXLAN and accelerated routing on the host. This example demonstrates how to build a DPL datapath that supports host-based networking (HBN).



8.10.7.6.12.1 Sample Code

This example uses indirect counters to monitor the number of packets that are allowed, denied and encapsulated/decapsulated. A user defined forwarding ID is used for determining how the bridge behaves.

```
enum bit<32> AdmissionCounter_t {
    DENY = 0,
    ALLOW = 1,
    VXLAN_V4_ENCAP = 2,
    VXLAN_V6_ENCAP = 3
}

enum bit<32> DecapFlowCounter_t {
    DENY = 0,
    ALLOW = 1,
}
```

```
/* The directionality is based on network to host
 * The user will configure the P4 port IDs in OVS
 */
const bit<32> WIRE_PORT = 32w0;

/* fid is 32 bits
*/
typedef bit<32> fid_t;

struct metadata_t {
    fid_t fid;
}
```

The default parser is used for this example:

```
struct headers_t {
    NV_FIXED_HEADERS
}

parser packet_parser(packet_in packet, out headers_t headers) {
    NV_FIXED_PARSER(packet, headers)
 }
```

Finally, the main control body invokes three separate sub-controls:

- `overlay_encap` – defines the logic and policies for applying VXLAN encapsulations along with ACLs
- `underlay_route` – applies a custom IPv4/IPv6 routing tables with exact and LPM matching. The next hop is set, TTL decremented, and the packet is routed.

```
/**
* This control performs the overlay policy including L2 encap with VxLAN
*/
control overlay_encap(
    inout headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    NvDirectCounter(NvCounterType.PACKETS_AND_BYTES) fid_counter;
    NvCounter(4, NvCounterType.PACKETS_AND_BYTES) admission_counter;

    action set_fid(fid_t fid) {
        user_meta.fid = fid;
    }
    action deny() {
        admission_counter.count(AdmissionCounter_t.DENY);
        nv_drop();
    }
    action allow() {
        admission_counter.count(AdmissionCounter_t.ALLOW);
    }

            }
        }
    }
}
```

The main control checks which direction the packet came from.

- if the packet is from network to host, it invokes the decap_flow control
- if the packet is from host to network, it invokes the overlay_encap and routing controls

```
control host_based_networking(
    inout headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    overlay_encap() overlay;
    underlay_route() route;
    decap_flow() decap;

    /* user should add entries that correspond to the wire ports
     * A hit means this is an RX packet, miss means a TX packet
    */
    table direction_table {
        key = {
            std_meta.ingress_port : exact;
        }
        actions = {
            NoAction;
        }
        default_action = NoAction;
        const entries = {
            (WIRE_PORT) : NoAction();
        }
    }

    apply {
        if (direction_table.apply().miss) {
```

```
            overlay.apply(headers, std_meta, user_meta, pkt_out_meta);
            route.apply(headers, std_meta, user_meta, pkt_out_meta);
        }
        else {
            decap.apply(headers, std_meta, user_meta, pkt_out_meta);
        }
    }
}
```

See below for the complete DPL example.

8.10.7.6.13 Equal-Cost Multi-Path Routing Example

Equal-Cost Multi-Path Routing (ECMP) is a network routing strategy that enables packet forwarding to a single destination over multiple paths that have the same routing cost or metric. This approach is widely used in modern data center and enterprise networks to improve bandwidth utilization, redundancy, and network resilience. ECMP allows the eSwitch on the DPU install multiple next-hop entries for a destination prefix if those paths have equal cost according a hash function based on selected packet header fields. When forwarding packets, the DPL program can select among these equal-cost paths, ensuring that all packets belonging to the same flow follow the same path, while different flows may be distributed across different paths.

8.10.7.6.13.1 Sample Code

The ECMP metadata is a struct that will be used to store the result of a hash calculation over the desired fields.

```
struct usermeta_t {
    bit<4> ecmp_select;
};
```

In he main control of the ECMP example, the logic is as follows:

- create a NvHash object
- define an ECMP group table that filters out the destination IP addresses that will be routed
- calculate the hash over the desired packet fields
- apply a second table that matches on the hash result, and performs the next hop according to the table entries.

```
#define ECMP_BUCKETS 16

control c(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout usermeta_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    // Create a hash object with the selected algorithm
    NvHash(NvHashAlgorithm.CRC32) hash;

    action drop() {
        nv_drop();
    }

    action next_hop(
        nv_mac_addr_t dmac,
        nv_ipv4_addr_t ipv4,
        nv_logical_port_t port
    ) {
        headers.ethernet.dst_addr = dmac;
        headers.ipv4.dst_addr = ipv4;
        headers.ipv4.ttl -= 1;
        nv_send_to_port(port);
    }

    table ecmp_group {
        key = {
            headers.ipv4.dst_addr: lpm;
        }
        actions = {
            drop;
            NoAction;
        }
        default_action = drop;
        size = 1024;
    }

    table ecmp_nhop {
        key = {
            user_meta.ecmp_select: exact;
        }
        actions = {
            drop;
            next_hop;
        }
        default_action = drop;
        size = ECMP_BUCKETS;
    }
```

In this apply block example, once the packet is validated and part of an ECMP group policy, the hash is calculated over the 5-tuple. Then the next hop is applied with a final destination.

The user has control of how many ECMP buckets are needed. By varying the entries added to the ecmp_nhop table, equal cost can be assigned to each final port destination. Fine grain weighted ECMP can be achieved by increasing the number of buckets and by weighting the entries in an unequal distribution (e.g. to favor one path more than the others). The DPL programmer can also create additional custom logic to affect the distribution.

```
apply {
```

```
    if (headers.ipv4.isValid() && std_meta.is_l4_ok && headers.ipv4.ttl != 0) {
        ecmp_group.apply();
        user_meta.ecmp_select =
            (bit<4>)hash.get_hash(
                ECMP_BUCKETS, // size
                {
                    headers.ipv4.src_addr,
                    headers.ipv4.dst_addr,
                    headers.ipv4.protocol,
                    std_meta.l4_src_port,
                    std_meta.l4_dst_port
                }
        );
        ecmp_nhop.apply();
    }
}
```

See below for the complete DPL example.

8.10.7.6.14 Entropy in Hash-Based Load Balancing Example

Most load-balancing systems use hash functions to map traffic flows to specific paths. A typical example of a hash input includes packet header fields of IP source/destination addresses, L4 source/destination port, and IP protocol. The effectiveness of load balancing depends on the entropy (randomness) of these fields. A high entropy is obtained when the input values are varied (e.g. diverse source ports) lead to even traffic distribution.

This example demonstrates how DPL can be used to set the entropy for the UDP source port, based on a hash of the 5-tuple. Then for load balancing devices further downstream of the DPU, the UDP source port is consumed as a part of the load balancer's algorithm.

8.10.7.6.14.1 Sample Code

A user metadata struct is defined to hold the temporary result of the entropy calculation:

```
struct usermeta_t {
    bit<32> entropy;
};
```

In this sample, the control needs to

- define the hash object
- match and select the VxLAN packets which to apply the entropy calculation
- calculate the hash over the inner 5-tuple
- set the outer UDP destination port with the hash value

Since the underlay header 5-tuple is often the same for different inner 5 tuple flows, setting the outer UDP destination port in this manner allows external network devices to load balance based solely on the underlay packet fields.

```
control c(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout usermeta_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    // Create a hash object with the selected algorithm
    NvHash(NvHashAlgorithm.CRC32) hash;

    action drop() {
        nv_drop();
    }

    action transmit(nv_logical_port_t port) {
        nv_send_to_port(port);
    }
```

```
    table balancer {
        key = {
            headers.ipv4.dst_addr: lpm;
        }
        actions = {
            drop;
            set_entropy;
        }
        default_action = drop;
        size = 1024;
    }
```

The apply logic glues the tables details above by filtering out VxLAN packets with a valid inner TCP/UDP.

```
apply {
    if (headers.vxlan.isValid() && std_meta.is_inner_l4_ok != 0) {
        user_meta.entropy =
            hash.get_hash(
                65536,
                {
                    headers.inner_ipv4.src_addr,
                    headers.inner_ipv4.dst_addr,
                    headers.inner_ipv4.protocol,
                    std_meta.inner_l4_src_port,
                    std_meta.inner_l4_dst_port
                }
        );
        nv_set_l4_src_port(headers, (bit<16>)user_meta.entropy);
        balancer.apply();
    }
}
```

See below for the complete DPL example.

8.10.7.6.15 NAT64 Example

Network Address Translation (NAT64) is a mechanism enabling connections between IPv6 clients and IPv4 servers. It serves as a gateway, allowing devices on IPv6-only networks to access resources available over IPv4.

Unlike RFC 6052, which uses an algorithmic mapping of IPv6 prefixes to embed IPv4 addresses, this example demonstrates Stateful NAT64. In this model, the gateway maintains a mapping table for active flows, allowing for per-entry user policies.

8.10.7.6.15.1 Sample Code

When translating an IP packet, various packet fields can be saved between IPv6 and IPv4. To accommodate this, create a metadata structure to hold these temporary values:

```
struct ip_data_t {
    bit<16> packet_len_field;
    bit<8> ttl;
    bit<6> tos_field;
    bit<2> ecn_field;
    bit<8> ip_protocol;
}
```

Next, instantiate a `NvHeaderDataTemplate` object. This object is used to define the header and field values that will be pushed into the packet. The template requires two items:

- A `struct` containing the set of headers that will be pushed. The headers are pushed in the order in which they appear in the `struct`, and can be natively supported headers for custom headers.
- An annotation `@nv_header_data_fields` on the `NvHeaderDataTemplate` object that serves as an initializer to the `struct` of headers. Each header must be initialized in the order in which they appear in the structure, and each header field must be initialized in the order in which they appear in the header.

```
struct v4_headers_t {
    nv_ipv4_h      nat_v4;
}

control nat64(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout ip_data_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
      @nv_header_data_fields(
        nat_v4 = {
            version = 4,
```

```
            ihl = 5,
            diffserv = 0,
            ecn = 0,
            total_len = 0,
            identification = 0,
            flags = 2,       // Do not fragment
            frag_offset = 0,
            ttl = 64,
            protocol = 6,
            hdr_checksum = 0xf93a, //  Prealculated CRC based on this pattern data
            src_addr = 0,          // must be zero for TCP pseudo-header CRC
            dst_addr = 0,
        }
    )
    NvHeaderDataTemplate<v4_headers_t>() v4DataTemplate;
```

The P4 action contains the logical steps to translate the incoming IPv6 packet to an IPv4 packet. The steps are:

1. Save the necessary IPv6 fields in the `user_metadata` `struct`, such as the TTL and DSCP fields. These will be restored later.
2. Calculate the new packet length field.
3. Push the new IPv4 header, with mostly empty fields. The IPv4 addresses are set to zero for the pseudo-header CRC calculation. Since the push operation leaves the packet in an intermediate state, set the `do_reparse` = false so that the offsets for `IP_START_OF_HEADER` are not updated yet.
4. Pop the IPv6 header with packet updates and reparse disabled.
5. Change the L2 ethertype to IPv4 and trigger a reparse now the packet header rearrangement is complete.
6. Copy the `user_metadata` to the new IPv4 header, and set the source and destination IP addresses.

```
action translate64(nv_ipv4_addr_t src_ip, nv_ipv4_addr_t dst_ip) {
    ip64_counter.count();
    user_meta.packet_len_field = headers.ipv6.payload_length;
    user_meta.packet_len_field += 20;
    user_meta.ip_protocol = headers.ipv6.next_header;
    user_meta.ttl = headers.ipv6.hop_limit;
    user_meta.tos_field = headers.ipv6.diffserv;
    user_meta.ecn_field = headers.ipv6.ecn;
    // partial TCP pseudo-header CRC calculation
    headers.ipv6.src_addr = 0;
    headers.ipv6.dst_addr = 0;
    // push a mostly empty IPv4 header with the partial checksum
    nv_push_headers(headers, v4DataTemplate,
        { },
        NvAnchor.IP_START_OF_HEADER,
        0, false, false);
    // remove IPv6 header without updates or reparse as packet is in mid-modification
    nv_pop_headers(headers, NvAnchor.IP_START_OF_HEADER, NvAnchor.L4_START_OF_HEADER,
        false, false);
    // change the ethertype to IPv4
    nv_set_l2_ethertype(headers, 16w0x0800);
    // Trigger reparse
    nv_force_reparse(headers);
    // restore the remaining IP fields
    headers.ipv4.src_addr = src_ip;
    headers.ipv4.dst_addr = dst_ip;
    headers.ipv4.ttl = user_meta.ttl;
    headers.ipv4.total_len = user_meta.packet_len_field;
    nv_set_ip_protocol(headers, user_meta.ip_protocol);
    nv_set_ip_ecn(headers, user_meta.ecn_field);
    nv_set_ip_dscp(headers, user_meta.tos_field);
}
```

Based on the desired policy, a P4 table with the desired keyset is defined. In the `apply` block, the packet is determined to be a valid IPv6 packet. The table is applied during the final step; when a match is found, NAT64 is performed, and the packet is sent to a specific port.

```
    table ipv6_to_ipv4 {
```

```
        key = {
            headers.ethernet.src_addr : exact;
        }
        actions = {
            translate64;
            NoAction;
        }
        default_action = NoAction;
        direct_counter = ip64_counter;
    }

    apply {
        if (std_meta.is_l4_ok == 1) {
            if (ipv6_to_ipv4.apply().hit) {
                nv_send_to_port(3);
            }
        }
    }
```

See below for the complete DPL example.

8.10.7.6.16 Add on Miss

This DPL program implements an efficient model for dynamic IPv6 flow tracking and statistics collection within the DPU's programmable data plane. By leveraging the `nv_add_entry` extern, the program autonomously inserts new entries into a match-action table based on observed traffic patterns, effectively offloading connection learning and state management from the control plane. Each invocation dynamically creates an entry keyed by programmable fields (e.g., the IPv6/TCP 5-tuple) assigns an action with parameters, and configures an optional timeout for expiration. This approach enables on-the-fly flow learning directly in hardware, optimizing real-time performance. The program adheres to the run-to-completion DPL architecture, ensuring that packets are parsed, matched, processed, and forwarded in a single logical pass through the pipeline.

8.10.7.6.16.1 Sample Code

IPv6 Flow Match Table Definition (`fiveTupleTable_v6`)

- Defines a match-action table keyed on a five-tuple corresponding to IPv6 TCP flows: source address, destination address, protocol (next header), source port, and destination port.
- Uses a direct counter (`NvDirectCounter`) to measure per-entry packet and byte statistics.
- Enables dynamic data-plane learning through `nv_support_add_entry` and time-based expiration with `nv_support_timeout` .
- The `nv_delayed_counter_stats` attribute ensures efficient updates to counters.

Table Actions (`count_v6_hit`)

- Implements an action that increments the per-entry counter and forwards the packet to a specified destination port.

Dynamic Entry Insertion (`nv_add_entry`)

- On table miss, the data plane uses `nv_add_entry` to dynamically install a new table entry into `fiveTupleTable_v6` .
- This entry is created using runtime key values extracted directly from the incoming packet headers (IPv6 and TCP fields).
- The entry associates the `count_v6_hit` action with parameters such as the forwarding port and sets a timeout of 1000 ms before aging out.
- This approach significantly reduces round-trips to the P4Runtime controller for flow installation, achieving fast insertion of new flows.

Apply Logic (Control Flow)

- The `apply` block orchestrates the overall packet-processing sequence:
    a. Verifies that the packet includes valid IPv6 headers.
    b. Applies the match table to attempt flow lookup.
    c. On a miss, invokes `nv_add_entry` to install the flow rule dynamically.
    d. Forwards all packets to a predefined logical port (`nv_send_to_port(1)`), representing a final egress or next processing stage.

See below for the complete DPL example.

8.10.7.6.17 PSP Encryption

This DPL program implements the PSP security protocol to provide line-rate cryptographic protection and encapsulation for IPv4 packets. By leveraging BlueField's PSP hardware primitives, the program offloads encryption and decryption tasks, establishing secure, transparent tunnels between endpoints. The pipeline dynamically distinguishes between outbound (TX) encryption and inbound (RX) decryption paths based on the ingress port, incorporating integrated error handling for cryptographic failures. Flow identifiers are used within match-action tables to select the appropriate keys, tunnel parameters, or remediation actions. Notably, PSP key exchange is out of scope for this DPL program and is assumed to have been completed prior to pipeline execution.

8.10.7.6.17.1 Sample Code

Direction Selection Stage

- Purpose: Directs each packet through either encryption or decryption logic.

- Table `direction_table`: Matches ingress port against configured “wire port” numbers, distinguishing between RX (decap) and TX (encap) path.
- Logic:
  - Miss: Packet is from the host/network stack, send it through encapsulation/encryption logic.
  - Hit: Packet is from the wire, run through decapsulation/decryption logic.

PSP Encapsulation/Encrypt Stage

- Purpose: Used for TX/network-bound packets, encapsulates and encrypts matching flows.
- Table `encap_table`: Matches outgoing IPv4 flows using source and destination address. For matched flows, triggers encapsulation with given MACs, tunnel IPs, and Security Association—applies DOCA PSP tunnel header and performs hardware encryption.
- Actions: The `encap` action builds the outer encapsulation (Ethernet, IPv4, UDP, PSP), sets keys/crypt parameters, and calls the hardware to encrypt payload.
- Packet Output: After encapsulation, packets are sent to the wire (external port) if matched, or to a default “other” port if not.

PSP Decrypt/Decapsulation Stage

- Purpose: Used for RX/wire-to-host direction, decompresses, decrypts, and validates PSP-encrypted packets.
- Decryption: If PSP header is present, calls hardware decryption with flow state defined in the hardware.
- Table `decap_table`: Matches on PSP SPI field. For matched packets, runs the `decap` action which strips outer tunnel and restores the original packet.
- Syndrome/Error Handling: Table `syndrome` matches on decryption error syndromes (ICV, bad trailer/context, general error). For recognized errors, counts and drops the packet; otherwise, processing continues.
- Packet Output: Successfully decrypted/decapsulated packets go to a designated internal port; others are sent to a fallback port.

8.10.7.7 Inspecting DPL Programs

This page describes the DPL Nspect tool, which is used to inspect DPL programs loaded onto the NVIDIA® BlueField® DPU.

8.10.7.7.1 Introduction

The DOCA Dependency Compatibility Policy is designed to provide customers with high velocity and flexibility during updates, enabling them to update specific layers of their system without requiring a full stack overhaul.

The primary objectives of this policy are to support decoupled updates for teams managing separate firmware and software stacks, allow for targeted upgrades on specific devices, minimize maintenance downtime by updating only necessary components, and guarantee investment protection by ensuring application continuity across platform releases.

This policy applies to all NVIDIA network device products and their associated software and firmware stacks.

8.10.7.7.2 DPL Nspect Execution

To view basic usage information, run the `dpl nspect` without arguments. For a detailed usage guide, use the `-h` or `--help` flags. You can also view command-specific help by running `dpl nspect [command] -h`.

8.10.7.7.2.1 Prerequisites and Configuration

- Server Connection: DPL Nspect requires a connection to a host (local or remote) where the DPL Nspect Server is running as part of the DPL Runtime Service.
- Address Configuration: The host address and port can be configured in two ways:
  a. Directly using the `-a` / `--address` argument.
  b. By setting the `DPL_NSPECT_SERVER_ADDRESS` environment variable (e.g., `DPL_NSPECT_SERVER_ADDRESS=127.0.0.1:9560`).

  > ⚠ Hostnames are resolved at runtime (e.g., `localhost` resolves to `127.0.0.1`).

- Data Directory: Configuration and logs are stored in the Data directory.

8.10.7.7.2.2 Command Usage

```
usage: dpl_nspect [-h] [-v] [-ll] [-nh] -a ADDRESS [-t TIMEOUT] [--cacert PATH_TO_CA_CERT] [--cert PATH_TO_CERT]
[--private-key PATH_TO_KEY]
                  {system-info,devices,tables,query,graph,config,counters,meters,hw-steering,debug,perf} ...

options:
  -h, --help            show this help message and exit
  -v, --version         show program's version number and exit
  -ll, --low-level      Display low level internal information. (default: False)
  -nh, --no-hints       Disable hints for further information.
                        You may set the DPL_NSPECT_DISABLE_HINTS environment variable instead of using this flag:
                        "export DPL_NSPECT_DISABLE_HINTS=1" (default: False)
  -a ADDRESS, --address ADDRESS
                        The dpl_nspect server socket address of the form IPv4/IPv6* [address][:port]
                        IPv6*: To use with a port the address must be enclosed in literal square brackets.
                        Example: ipv6:[2607:f8b0:400e:c00::ef]:443 or ipv6:[::]:1234
```

```
                        The address/port can be assigned to and read from the environment variable:
DPL_NSPECT_SERVER_ADDRESS. (default: None)
  -t TIMEOUT, --timeout TIMEOUT
                        [Optional] gRPC channel connectivity timeout. (default: 0)

commands:
  For further info run dpl_nspect <command> -h

  {system-info,devices,tables,query,graph,config,counters,meters,hw-steering,debug,perf}
    system-info         Display system information, e.g. HW Model, OS, OFED.
    devices             List the configured virtual devices.
    tables              List tables of programs loaded on the DPU.
    query               List table entries, keys and actions.
    externs             List externs details and values.
    graph               Display a graph of the Pipeline, using DOT language.
                        This graph can be graphically rendered using DOT renderers, such as online DOT graphics
visualizer websites
    config              Get/Set the device configuration.
    hw-steering         Display HW Steering rules dump.
    debug               Start a debug recording session.
    perf                Display live performance monitor statistics.

Authentication:
  Mutually inclusive arguments for secure connection using SSL authentication

  --cacert PATH_TO_CA_CERT
                        CA certificate path for secure connections (default: None)
  --cert PATH_TO_CERT   Client certificate path for mutual authentication (default: None)
  --private-key PATH_TO_KEY
                        Client private key path for mutual authentication (default: None)

Data directory: /root/.local/share/dpl_devtools
```

8.10.7.7.3 DPL Nspect Commands and Flags

The following sections describe specific commands and their outputs.

> ⚠ The DPL program `hello_packet.p4` (referenced at the end of this section) was used to generate the examples below.

> ✔ Most commands support the `--json` argument to output data in JSON format, facilitating integration with automated scripts.

8.10.7.7.3.1 system-info

```
dpl nspect system-info
```

Displays system information.

Example output:

System Information

Key	Value
DOCA version	3.1.0105-1
DPL Runtime daemon version	1.2.0-1.rel-1.2.0
Debug Schema Version	Device ID: 1000, doctype: /nvp4c/devtools/base/v9, target_doctype: /nvp4c/devtools/doca/v3
Linux OS version	"Ubuntu 22.04.5 LTS"
OFED Version	OFED-internal-25.07-0.9.7:
RDMA Core Version	2507mlnx58-1.2507097

8.10.7.7.3.2 devices

```
dpl nspect devices
```

Lists all configured DPL devices, displaying a table for each device.

- Title: Contains program details only if a program is loaded.
- Interface: The interface name as defined in the DP device configuration file.
- ID: The port ID as defined in the DPL device configuration file.
- IB: The physical InfiniBand port ID used for the DPL port ID.

Example output:

Device 1000

Program: hello_packet, Loaded At: 2025-10-22 12:29:36, Load Duration: 0.174s

Ports					Configuration	
Interface	ID	IB	REG_C0	MAC	Key	Value
ens6f0np0	0	50	0x10000/0xffff0000	00:00:00:00:00:00	P4 Controller Port ID	9876
ens6f0r0	1	2	0x30000/0xffff0000	00:00:00:00:00:00		
ens6f0r1	2	3	0x40000/0xffff0000	00:00:00:00:00:00		
ens6f0r2	3	4	0x50000/0xffff0000	00:00:00:00:00:00	FW Version	32.47.0218
ens6f0r3	4	5	0x60000/0xffff0000	00:00:00:00:00:00		
ens6f0r4	5	6	0x70000/0xffff0000	00:00:00:00:00:00	HW Model	BlueField-3
ens6f0r5	6	7	0x80000/0xffff0000	00:00:00:00:00:00		
ens6f0r6	7	8	0x90000/0xffff0000	00:00:00:00:00:00	Multiport eSwitch	Disabled
ens6f0r7	8	9	0xa0000/0xffff0000	00:00:00:00:00:00		

8.10.7.7.3.3 tables

```
dpl nspect tables [--json]
```

Lists all tables defined in the DPL program.

- ID: The P4 runtime ID of the object as defined in the `p4info.txt` file.
- Direct Externs: Lists the names of all direct extern instances defined for the table (e.g., direct counter, direct meter).

Output example:

hello_packet.forward_table - 50144908

Keys			Actions			Direct Externs	Entries Count	Source Location	Supports Timeout
ID	Name	Type	ID	Name	Params				
1	headers.ethernet.src_addr	exact	19510525	hello_packet.drop		hello_packet.hello_direct_counter hello_packet.hello_direct_meter	6	hello_packet.p4:46	False
			19237259	hello_packet.forward	ID: 1, Name: port, Size: 32				
			21257015	NoAction					

The `--json` flag provides the output in JSON format. For example:

```
[
  {
    "title": {
      "Table ID": 40048916,
      "Table Name": "tbl_drop"
    },
    "rows": [
      {
        "Keys": {
          "title": {},
          "rows": []
        },
        "Actions": {
          "title": {},
          "rows": [
            {
              "ID": "19510525",
              "Name": "hello_packet.drop",
              "Params": ""
            }
          ]
        },
        "Direct Externs": [],
        "Entries Count": "1",
        "Source Location": "None",
        "Supports Timeout": "False"
      }
    ]
  },
  {
    "title": {
      "Table ID": 50144908,
      "Table Name": "hello_packet.forward_table"
    },
    "rows": [
      {
        "Keys": {
          "title": {},
          "rows": [
            {
              "ID": "1",
              "Name": "headers.ethernet.src_addr",
              "Type": "exact"
            }
          ]
        },
        "Actions": {
          "title": {},
          "rows": [
            {
              "ID": "19510525",
              "Name": "hello_packet.drop",
              "Params": ""
            },
            {
              "ID": "19237259",
              "Name": "hello_packet.forward",
              "Params": {
                "title": {},
                "rows": [
                  {
                    "ID": "1",
                    "Name": "port",
                    "Size": "32"
                  }
                ]
              }
            },
            {
              "ID": "21257015",
              "Name": "NoAction",
              "Params": ""
            }
          ]
        },
        "Direct Externs": [
          "hello_packet.hello_direct_counter",
          "hello_packet.hello_direct_meter"
        ],
        "Entries Count": "6",
        "Source Location": "hello_packet.p4:46",
        "Supports Timeout": "False"
      }
    ]
  }
]
```

8.10.7.7.3.4 query

```
dpl nspect query
```

Lists all entries currently contained in each table.

- Entry ID: The runtime ID assigned to the entry at creation time (not a P4 context ID).
- Keys: If no key is displayed, it indicates a default entry.
- Extern entries: Displays data for extern entries associated with the table entry (result of an explicit extern call within the Action).

Example output:

hello_packet.forward_table - 50144908

Entry ID [Priority]	Keys	Action	Extern Entries
5[0]	headers.ethernet.src_addr == 0xbbbbbbbbbb (exact)	NoAction()	
4[0]	headers.ethernet.src_addr == 0xaaaaaaaaaa (exact)	NoAction()	
3[0]	headers.ethernet.src_addr == 0xddddddddd (exact)	hello_packet.drop()	hello_packet.hello_counter[1] = (packets=0, bytes=0)
2[0]	headers.ethernet.src_addr == 0x2222222222 (exact)	hello_packet.forward(port=0x2)	hello_packet.hello_direct_counter[2] = (packets=0, bytes=0)
1[0]	headers.ethernet.src_addr == 0x1111111111 (exact)	hello_packet.forward(port=0x1)	hello_packet.hello_direct_counter[1] = (packets=0, bytes=0)
0[0]		hello_packet.forward(port=0x3)	hello_packet.hello_direct_counter[0] = (packets=0, bytes=0)

8.10.7.7.3.5 externs

```
dpl nspect externs
```

Lists all externs in the DPL program (one table per extern instance???).

- Indirect Externs: First column shows Index.
- Direct Externs: First column shows Table Entry ID (corresponds to the ID seen in the `query` command).

NvDirectCounter(Pkts/Bts) hello_packet.hello_direct_counter - 320479669

Table Entry ID	Packets	Bytes
5	0	0
4	0	0
3	0	0
2	0	0
1	0	0
0	0	0

NvCounter(4, Pkts/Bts) hello_packet.hello_counter - 307179965

Index	Packets	Bytes
0	0	0
1	0	0
2	0	0
3	0	0

NvDirectMeterPeakTrTCM(Pkts) hello_packet.hello_direct_meter - 359616562

Table Entry ID	CIR	CBS	PIR	PBS
5	1	2	3	4
4	1	2	3	4
3	1	2	3	4
2	1	2	3	4
1	1	2	3	4
0	1	2	3	4

NvTcpState(4) hello_packet.hello_tcp - 2319426381

Index	Last Direction	Last ACK Number	Last SEQ Number
0	ORIGINAL	0	0
1	ORIGINAL	0	0
2	ORIGINAL	0	0
3	ORIGINAL	0	0

NvMemory(4) hello_packet.hello_memory - 2360326091

Index	Bytes

The `--types` argument allows querying specific extern categories (counter, meter, tcp_state, memory) and/or scope (direct for table-bound, indirect for standalone).

```
dpl nspect externs --types counter,meter,direct
```

NvDirectCounter(Pkts/Bts) hello_packet.hello_direct_counter - 320479669

Table Entry ID	Packets	Bytes
5	0	0
4	0	0
3	0	0
2	0	0
1	0	0
0	0	0

NvDirectMeterPeakTrTCM(Pkts) hello_packet.hello_direct_meter - 359616562

Table Entry ID	CIR	CBS	PIR	PBS
5	1	2	3	4
4	1	2	3	4
3	1	2	3	4
2	1	2	3	4
1	1	2	3	4
0	1	2	3	4

8.10.7.7.3.6 graph

```
dpl nspect --low-level graph
```

Generates a DOT graph representing all potential packet paths within the pipeline.

Example output:

```
digraph hello_packet_pipeline {
    graph [compound=true nodesep=0.1]
    node [height=0 width=0]
    // Legend
    subgraph cluster_legend {
        graph [fontsize="6pt" label=Legend]
        control [label=Control color=blue fontsize="6pt" id=control shape=rectangle]
        table [label=Table color=orange fontsize="6pt" id=table shape=rectangle]
        ll_table [label=<<B>Low Level Table ID</B><BR/>[Origin(s)]> fontsize="6pt" id=ll_table shape=diamond]
```

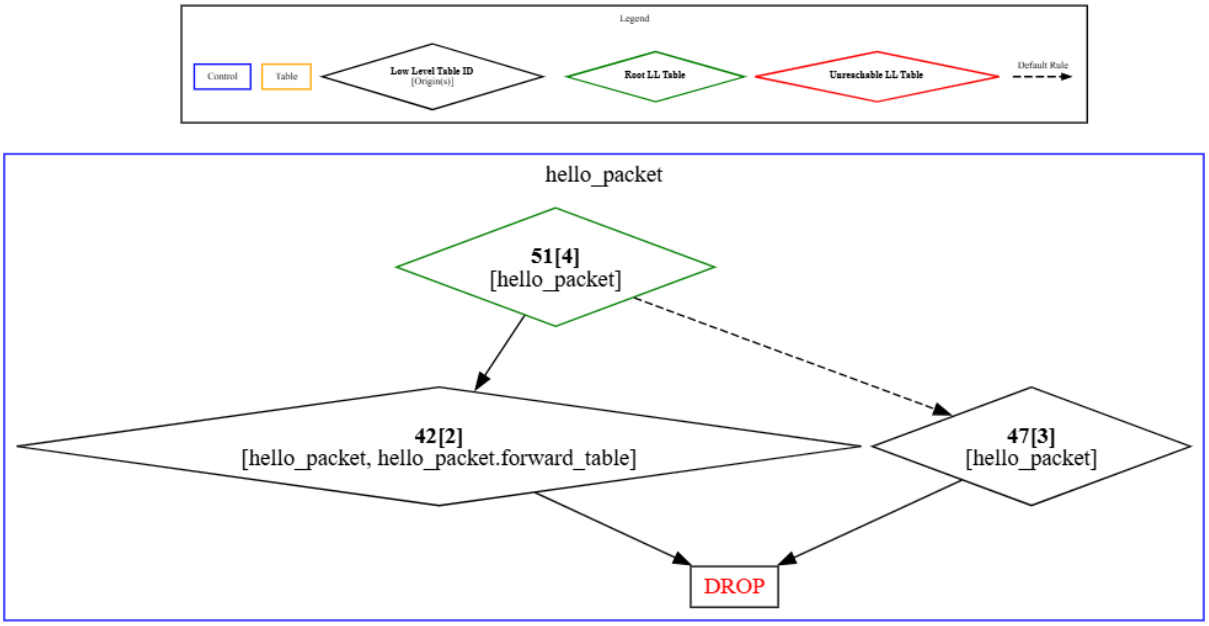
```
        legend_invis [height=0 id=legend_invis shape=point style=invis width=0]
        ll_root_table [label=<<B>Root LL Table</B>> color=green fontsize="6pt" id=ll_root_table shape=diamond]
        ll_unreachable_table [label=<<B>Unreachable LL Table</B>> color=red fontsize="6pt" id=ll_unreachable_table
shape=diamond]
        default_rule_invis_tail [fontsize="6pt" height=0 id=default_rule_invis_tail shape=point style=invis
width=0]
        default_rule_invis_head [fontsize="6pt" height=0 id=default_rule_invis_head shape=point style=invis
width=0]
        default_rule_invis_tail -> default_rule_invis_head [label="Default Rule" arrowsize="0.5px" fontsize="6pt"
id="default_rule_invis_tail-default_rule_invis_head" style=dashed]
        subgraph rank_0 {
            rank=same
            control [id=control]
            default_rule_invis_head [id=default_rule_invis_head]
            default_rule_invis_tail [id=default_rule_invis_tail]
            ll_root_table [id=ll_root_table]
            ll_table [id=ll_table]
            ll_unreachable_table [id=ll_unreachable_table]
            table [id=table]
        }
    }
    // Pipeline Stage: main
    subgraph cluster_hello_packet {
        graph [color=blue label=hello_packet shape=rectangle]
        legend_invis [height=0 id=legend_invis shape=point style=invis width=0]
        "51[4]" [label=<<B>51[4]</B><BR/>[hello_packet]> color=green id="51[4]" shape=diamond]
        "42[2]" [label=<<B>42[2]</B><BR/>[hello_packet, hello_packet.forward_table]> id="42[2]" shape=diamond]
        DROP [fontcolor=red id=DROP shape=box]
        "47[3]" [label=<<B>47[3]</B><BR/>[hello_packet]> id="47[3]" shape=diamond]
        legend_invis -> "51[4]" [id="legend_invis-51[4]" style=invis]
        "51[4]" -> "42[2]" [id="51[4]-42[2]"]
        "42[2]" -> DROP [id="42[2]-DROP"]
        "51[4]" -> "47[3]" [id="51[4]-47[3]" style=dashed]
        "47[3]" -> DROP [id="47[3]-DROP"]
        subgraph rank_0 {
            rank=same
            "51[4]" [id="51[4]"]
        }
        subgraph rank_1 {
            rank=same
            "42[2]" [id="42[2]"]
            "47[3]" [id="47[3]"]
        }
        subgraph rank_2 {
            rank=same
            DROP [id=DROP]
        }
    }
}
```

```
dpl nspect --low-level graph --url
```

The `--url` flag generates an HTTP URL link to render the graph using GraphvizOnline.

Legend:

- Low Level Table (LL Table): Refers to the internal HWS Table object created from loading the DPL program.
- Root LL Table: The starting point of the generated pipeline.



8.10.7.7.3.7 debug

Starts a debug session. Packets sent during this session are traced and recorded to an output archive, which can be inspected using the DPL Debugger.

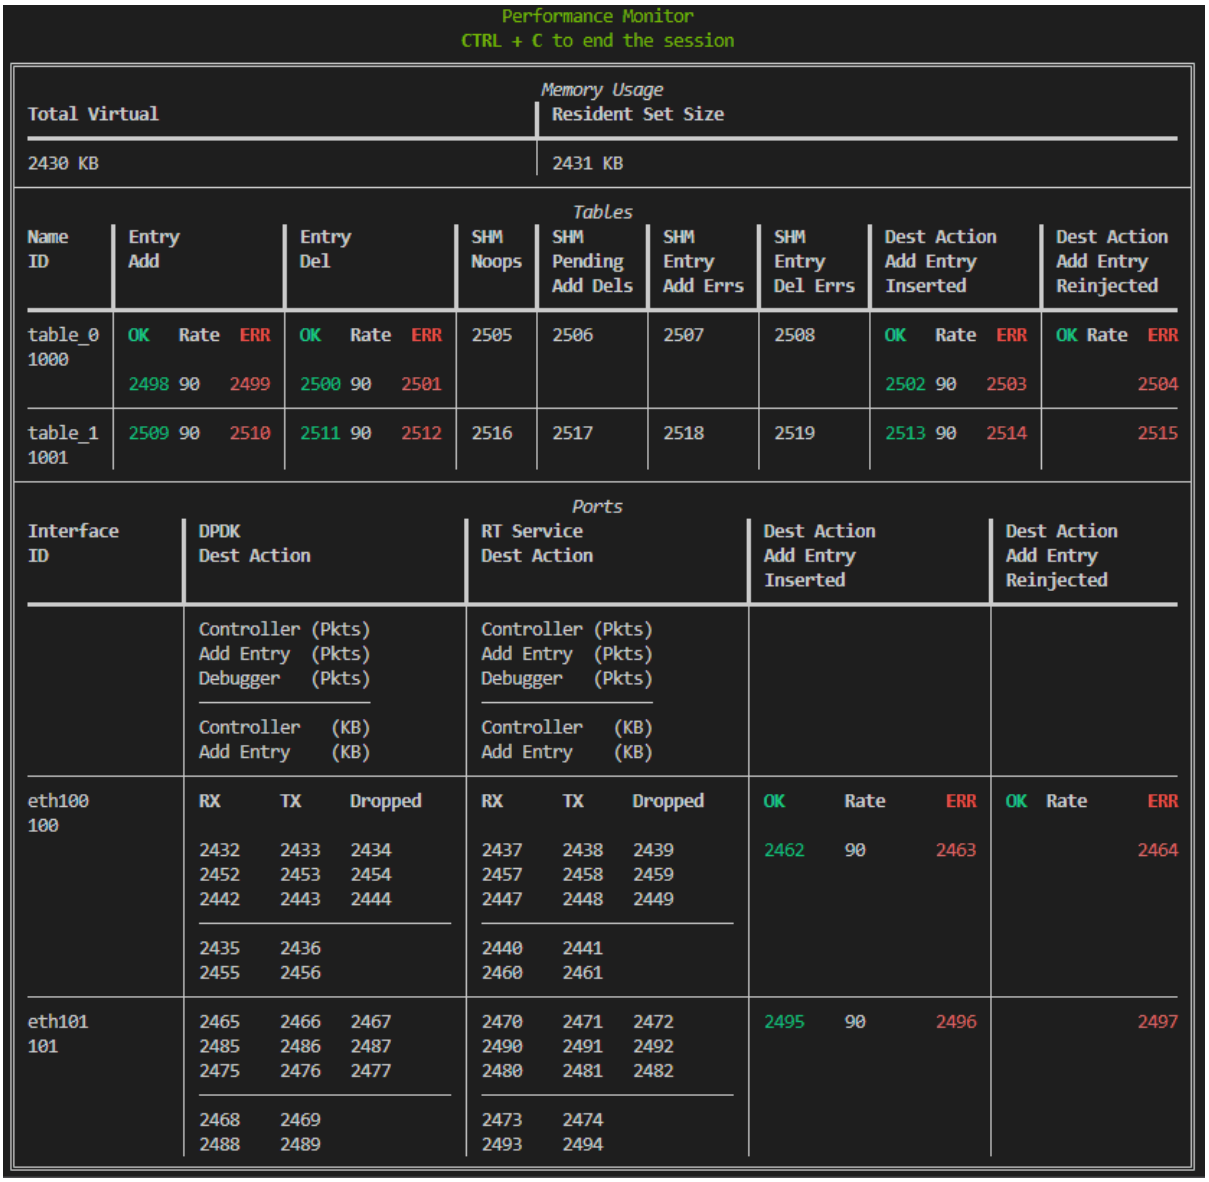
```
dpl nspect debug -o hello_packet.tar.gz
```

8.10.7.7.3.8 perf

```
dpl nspect perf
```

Displays real-time performance statistics.

Example output:



The following sections breakdown the statistics provided in the example output.

Memory Usage Statistics

Displays the real-time memory consumption of the DPL Runtime Service.

Metric	Description
Total Virtual Memory	The total amount of virtual memory used by the service.
Resident Set Size	The amount of physical memory (RAM) currently being used (in KB).

Table Entry Operations Statistics

Tracks operations for each DPL table (one row per table).

Category	Column	Description	Notes
Entry Add/ Del	OK	Total number of successful additions or deletions	Tracks *all* table entry operations.
	ERR	Total number of failed additions or deletions	
	Rate	The difference in successful operations between the current and previous sample	
SHM	Noops	Count of entries where a delete was requested before the addition was fully processed	**Verbose mode only.** Tracks *entries*. Only for SHM-enabled tables
	Pending Add Dels	Count of delete operations received for entries that are still pending hardware confirmation	**Verbose mode only.** Tracks *operations*
	Entry Add/Del Errs	Total number of failed SHM entry additions or deletions	**Verbose mode only.** Tracks *operations*
Dest Action Add Entry	Inserted	Successful table entry additions triggered specifically by the *Add Entry* action	**Verbose mode only.** Tracks *table entries*
	Reinjected	Total number of *failed* reinjection attempts (ERR column).	**Verbose mode only.** Tracks *packets*. The OK/Rate columns are always empty

Port Statistics Statistics

Tracks packet flow through destination actions (one row per Port Interface ID).

Layer	Row/ Action	Description	Notes
DPDK Dest Action	N/A	Packet flow statistics at the hardware (DPDK) layer	
RT Service Dest Action	N/A	Packet flow statistics at the application (RT Service) layer	
Action Types	Controller	Flow statistics for packets destined for the Controller	
	Add Entry	Flow statistics for packets destined for the Add Entry action	Same metrics as the *Tables* section, but tracked per port
	Debugger	Flow statistics for packets destined for the Debugger	Only displays Packet Counts (no KB)
Flow Direction	RX / TX	Packets received or transmitted in this layer/ action	Displays both Packet Counts and KB
	Dropped	Packets dropped in this layer/action	Only displays Packet Counts (no KB)

8.10.7.8 Debugging DPL Programs

This section describes the DPL Debugger Tools, used to debug pipeline packets that DPL programs are processing in NVIDIA® BlueField®.

> ⚠ The debugger works only with DPL programs that compiled in one of the available debug modes.

8.10.7.8.1 Introduction

The DPL Debugger is a GUI application that can run a debug session or open a pre-recorded (through `nspect debug`) debug session file.
Debug session shows the flow of network packets throughout a DPL program's pipeline and lets the developer trace the details of each packet's course. See the documentation on the extern function nv_send_debug_pkt.

Running `dpl debugger` with no additional arguments will open the GUI application.

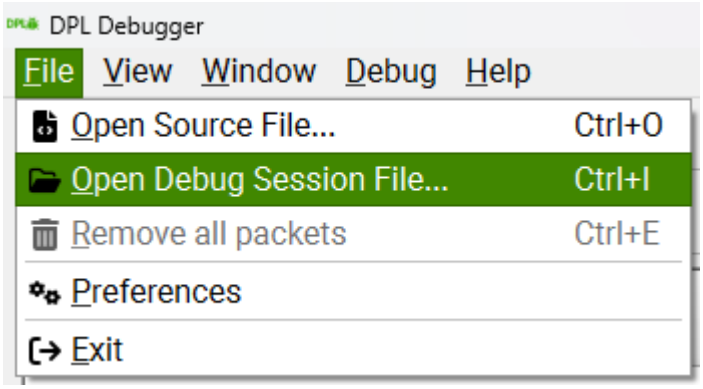
8.10.7.8.2 Opening Pre-recorded Debug Session File

The pre-recorded debug session file is a `tar.gz` archive and is the output of a recorded debug session created with the `nspect debug` command.

Option 1: Specify the file to open when running the debugger from the command line.

```
dpl debugger hello_packet.tar.gz
```

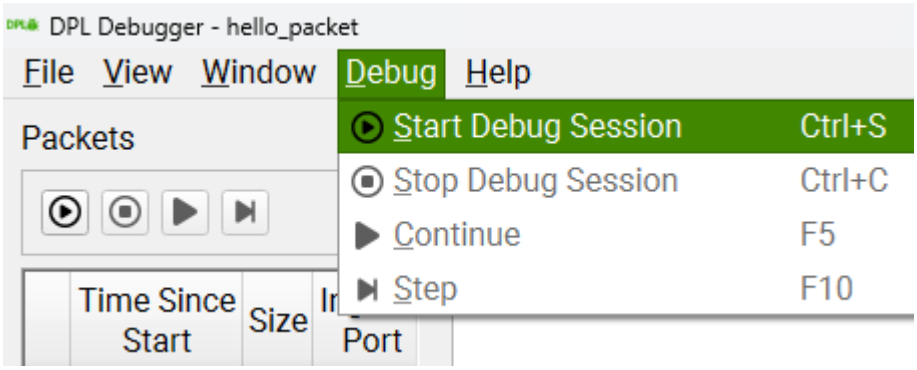
Option 2: Click **File** → **Open Debug Session File** and select your file.



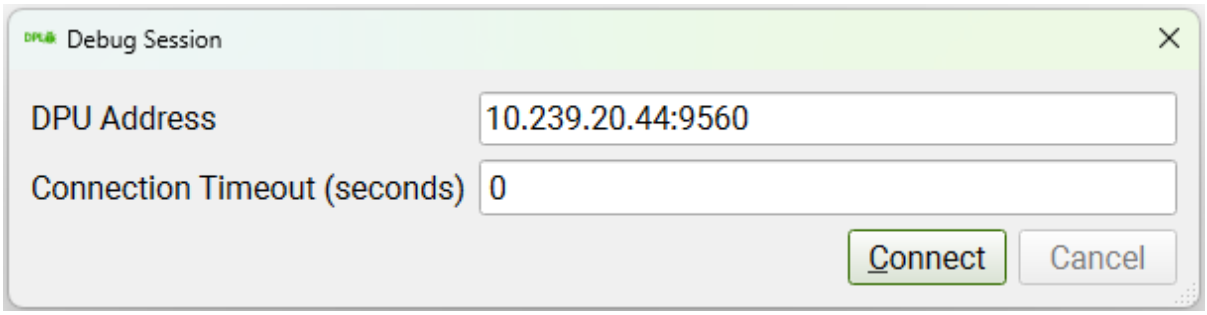
8.10.7.8.3 Starting Debug Session

Running a debug session from the debugger is possible and has the advantage of processing and inspecting the packets at runtime.

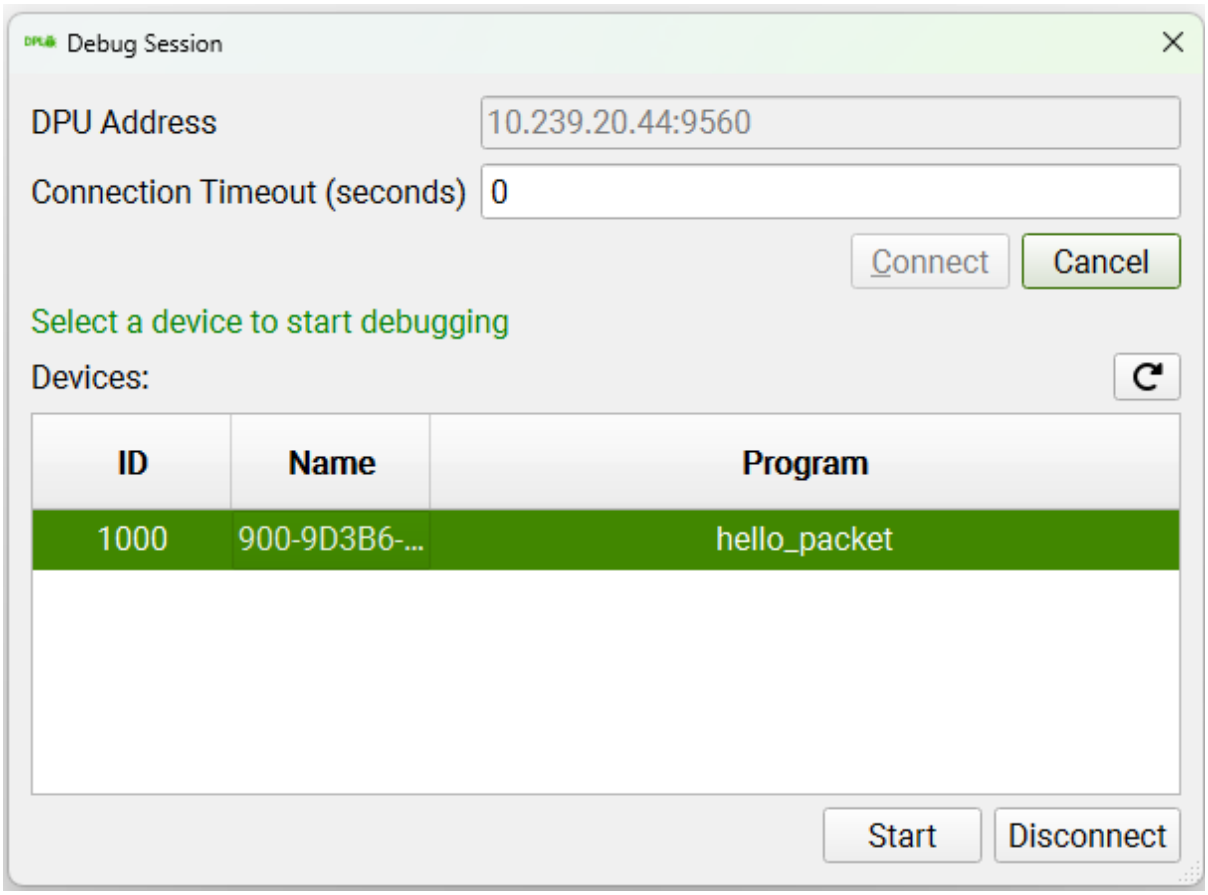
You can click on the Start Debug Session button, click Ctrl+S, or click **Debug** → **Start Debug Session**



Set the DPU address and port (the default port is 9560), and the connection timeout if required (0 = no timeout), and click **Connect**.



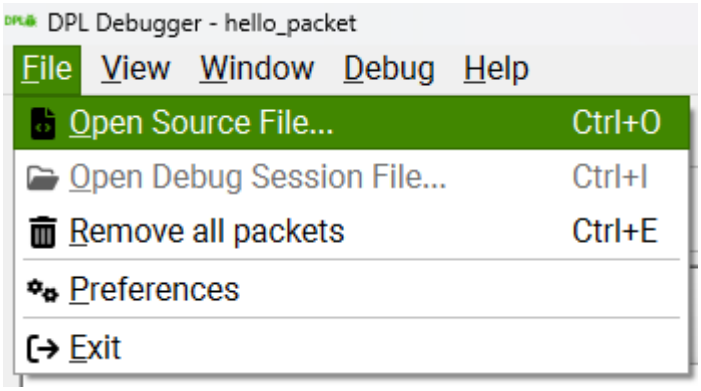
Select the desired device to debug and click Start



8.10.7.8.4 Enabling Debug Points

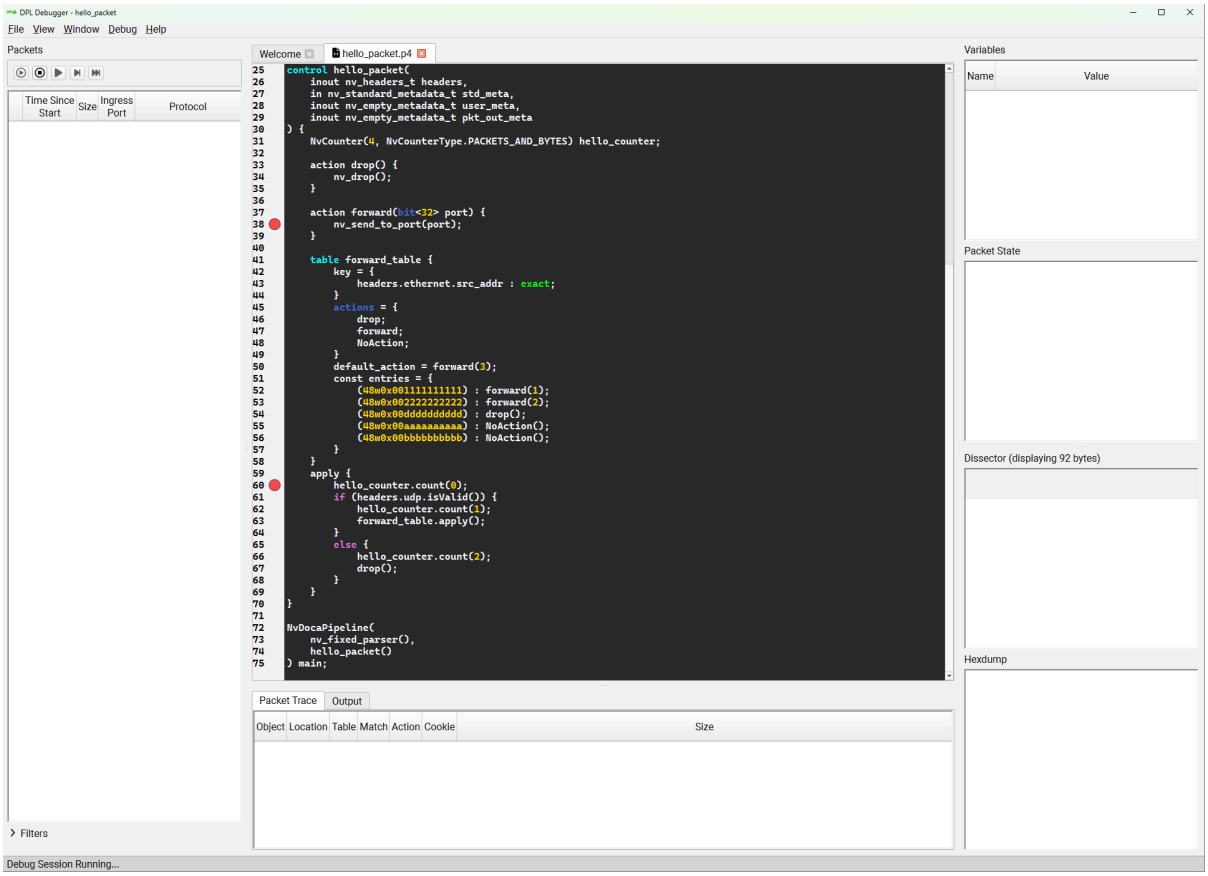
First, remember that to enable debug points, you must compile your program in one of the available debug modes (see more details here). After a debug session is started from the debugger GUI application, all the debug points in the program are DISABLED by default and don't affect the pipeline of the packet. When a packet hits an enabled debug point, it is sent to the debugger, displayed, and can be injected back to the same point in the pipeline on user demand.

Enabling and disabling debug points is done the same as in traditional debugger GUI applications - open the source file of the program and click on the left margin next to the requested line. Additionally, pressing F9 will toggle a breakpoint on the line where the caret currently stands, similar to how a mouse press on the margin would.



The available debug points to enable depend on which debug mode you compiled the program with.

Similar to traditional debugger GUI applications, if the line doesn't have a debug point associated with it, the next available debug point will be enabled instead.



8.10.7.8.5 Debugging the Program Pipeline

hello_packet.p4

The following program was used for the screen captures in this section. The program was compiled with the debug-mode=auto flag.

```

 */

control hello_packet(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    NvCounter(4, NvCounterType.PACKETS_AND_BYTES) hello_counter;

    action drop() {
```

```
        nv_drop();
    }

    action forward(bit<32> port) {
        nv_send_to_port(port);
    }

    table forward_table {
        key = {
            headers.ethernet.src_addr : exact;
        }
        actions = {
            drop;
            forward;
            NoAction;
        }
        default_action = forward(3);
        const entries = {
            (48w0x001111111111) : forward(1);
            (48w0x002222222222) : forward(2);
            (48w0x00dddddddddd) : drop();
            (48w0x00aaaaaaaaaa) : NoAction();
            (48w0x00bbbbbbbbbb) : NoAction();
        }
    }
    apply {
        hello_counter.count(0);
        if (headers.udp.isValid()) {
            hello_counter.count(1);
            forward_table.apply();
        }
        else {
            hello_counter.count(2);
            drop();
        }
    }
}

NvDocaPipeline(
    nv_fixed_parser(),
    hello_packet()
) main;
```

send_hello_packet

The following script was used for sending traffic
Assume port "p1" is connected via loopback to port "p0".

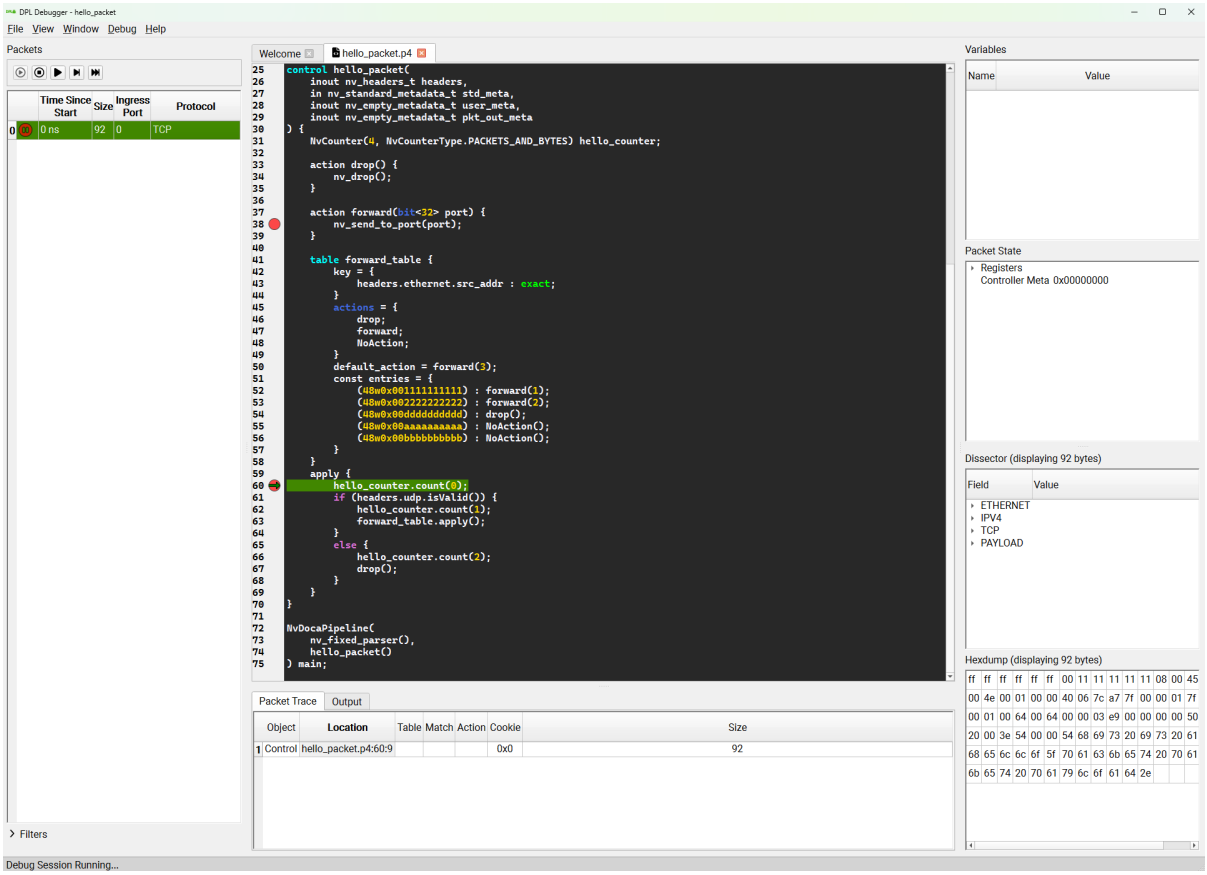
```
from scapy.all import IP, TCP, Ether, Packet, Raw, sendp

packet = (Ether(src='00:11:11:11:11:11', dst='ff:ff:ff:ff:ff:ff') /
          IP() /
          TCP(sport=100, dport=100, seq=1001, flags='P') /
          Raw(load=b'This is a hello_packet packet payload.'))

sendp(packet, "p1", count=1)
```

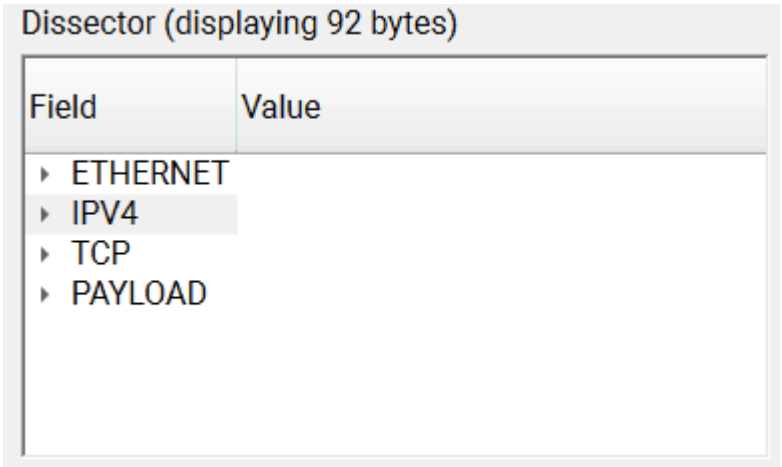
When a packet hits an enabled debug point, it is sent to the debugger and displayed. A red icon is shown to indicate that the packet is paused by the debugger. Clicking the packet reveals the packet data and state. A green arrow is shown to indicate the current debug-point the packet is paused on.

Note: The packet in the **Packets** list correlates directly to the **first row** in the **Packet Trace** list, any change that the packet will undergo (for example its size or protocol) after reinjection will only be reflected in the **next row** of the **Packet Trace** list.



Once the packet is paused, it is possible to edit its content through either the Dissector or the Hexdump.

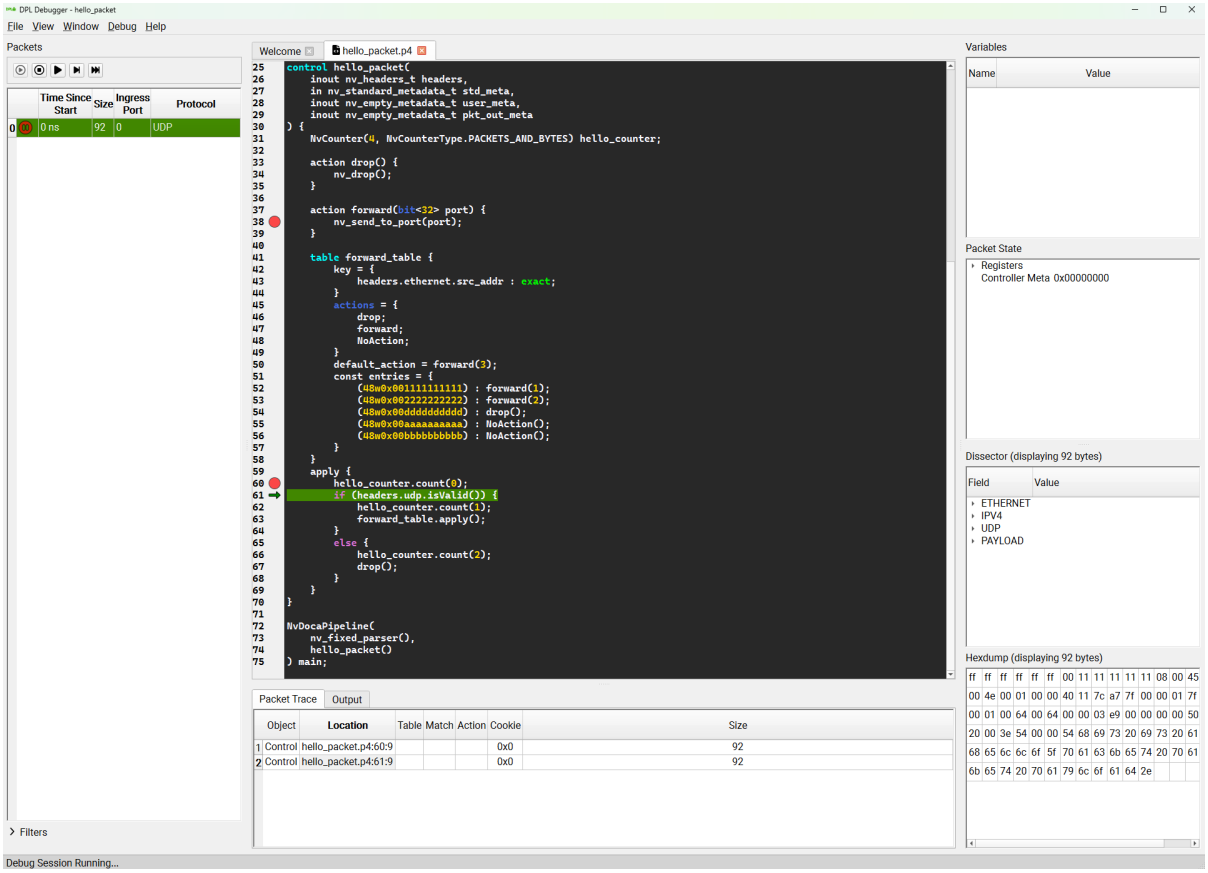
For example, we can edit the packet's protocol from TCP to UDP using the dissector.



We now inject the packet back to the same point at the pipeline, by clicking either **Debug** → **Continue**, **Debug** → **Step** or **Debug** → **Continue with Trace**.

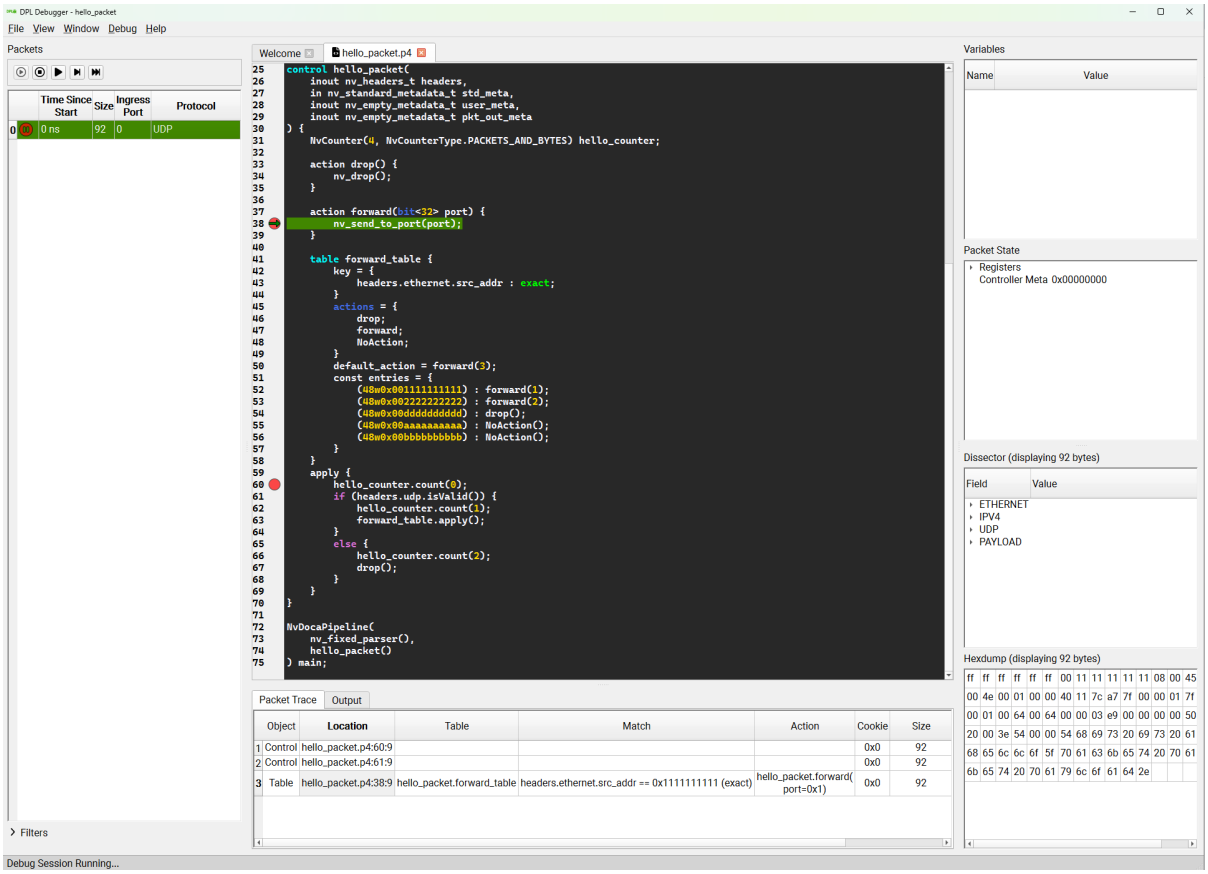
> ⚠ All three debug operations apply for all currently paused packets.

By clicking **Step**, the packet pauses in the next line, even though there is no breakpoint enabled. In addition, a new row in the "Packet Trace" widget is displayed, which represents a single debug point hit.



We click **Continue**, and the packet pauses only at the next enabled breakpoint. Moreover, we observe that the packet's path diverged as a result of our edit - we changed its protocol from TCP to UDP, and therefore the condition of the if statement was satisfied.

> ⚠ Clicking **Continue with Trace** advances the packet the same as clicking continue, but it additionally shows the trace of the packet in all debug points it passes along the way.



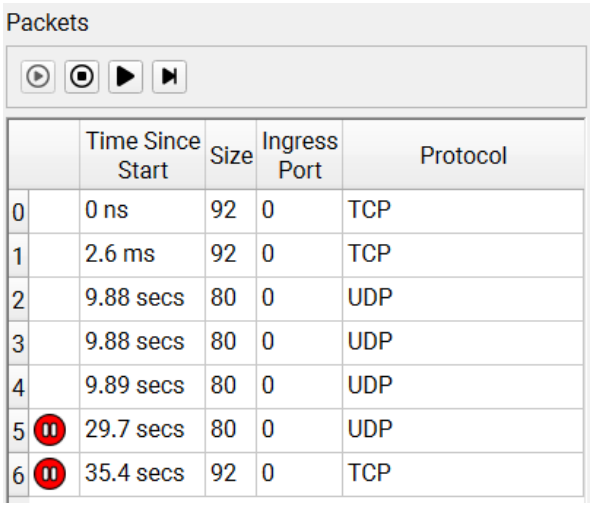
Continuing the packet once again causes the "Pause" icon to disappear, as there are no more breakpoints in the rest of the packet's pipeline.

8.10.7.8.6 Widgets

8.10.7.8.6.1 Packet List

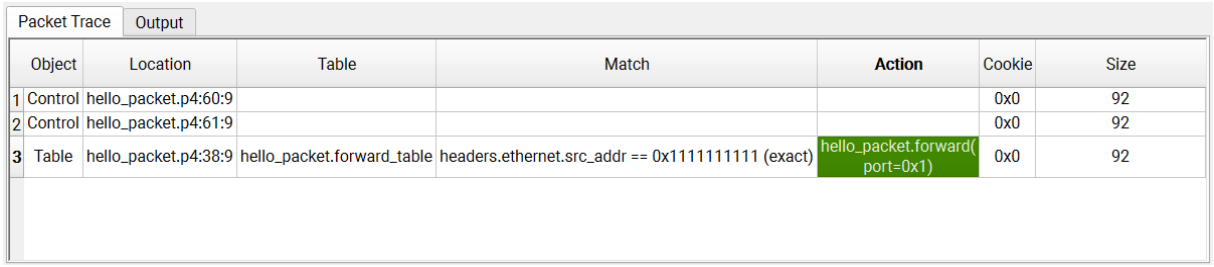
Displays the packets that were sent to the debugger. Selecting a packet in the list reveals the packet trace of the packet.

The list can be cleared by clicking **File** → **Remove all packets**.



8.10.7.8.6.2 Packet Trace

Each row represents a single debug point hit. Selecting a debug point reveals the packet data, state, and pipeline at the time the packet hit the debug point.



8.10.7.8.6.3 Filter

Packets can be filtered by:

- Table name
- Action
- Match Field
- Match Type
- Match Value
- Ingress port
- Packet Size
- Protocol

Toggle the Filters view, click the '**+**' button to add a filter, and the **Apply** button to apply the filters.

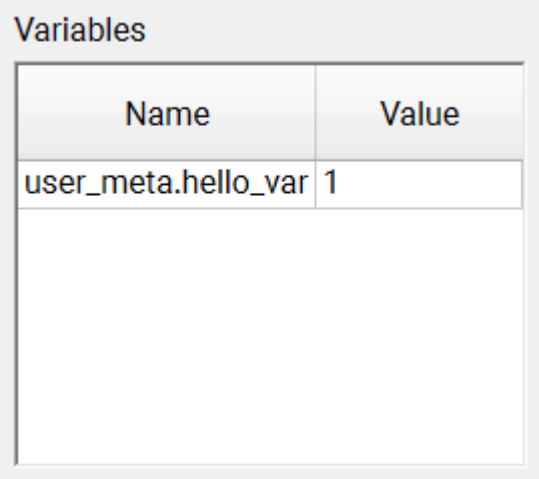
Apply
Clear All
Showing 3 out of 7 packets

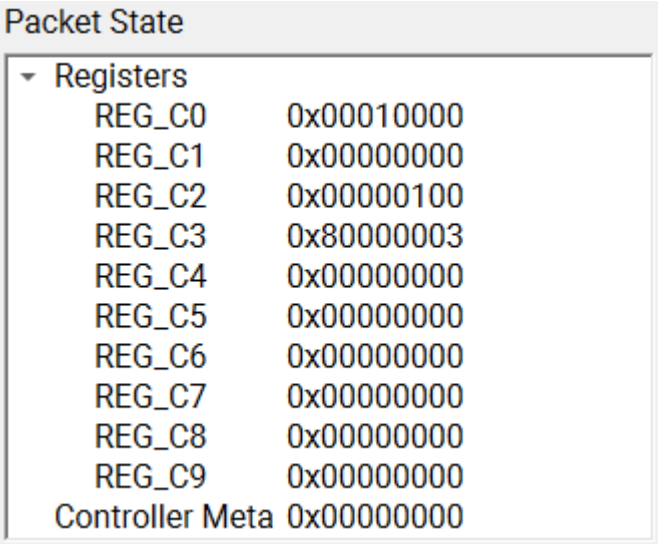
8.10.7.8.6.4 Variables

Shows the variables defined in the program, and their respective values at the time the selected debug-point was hit.



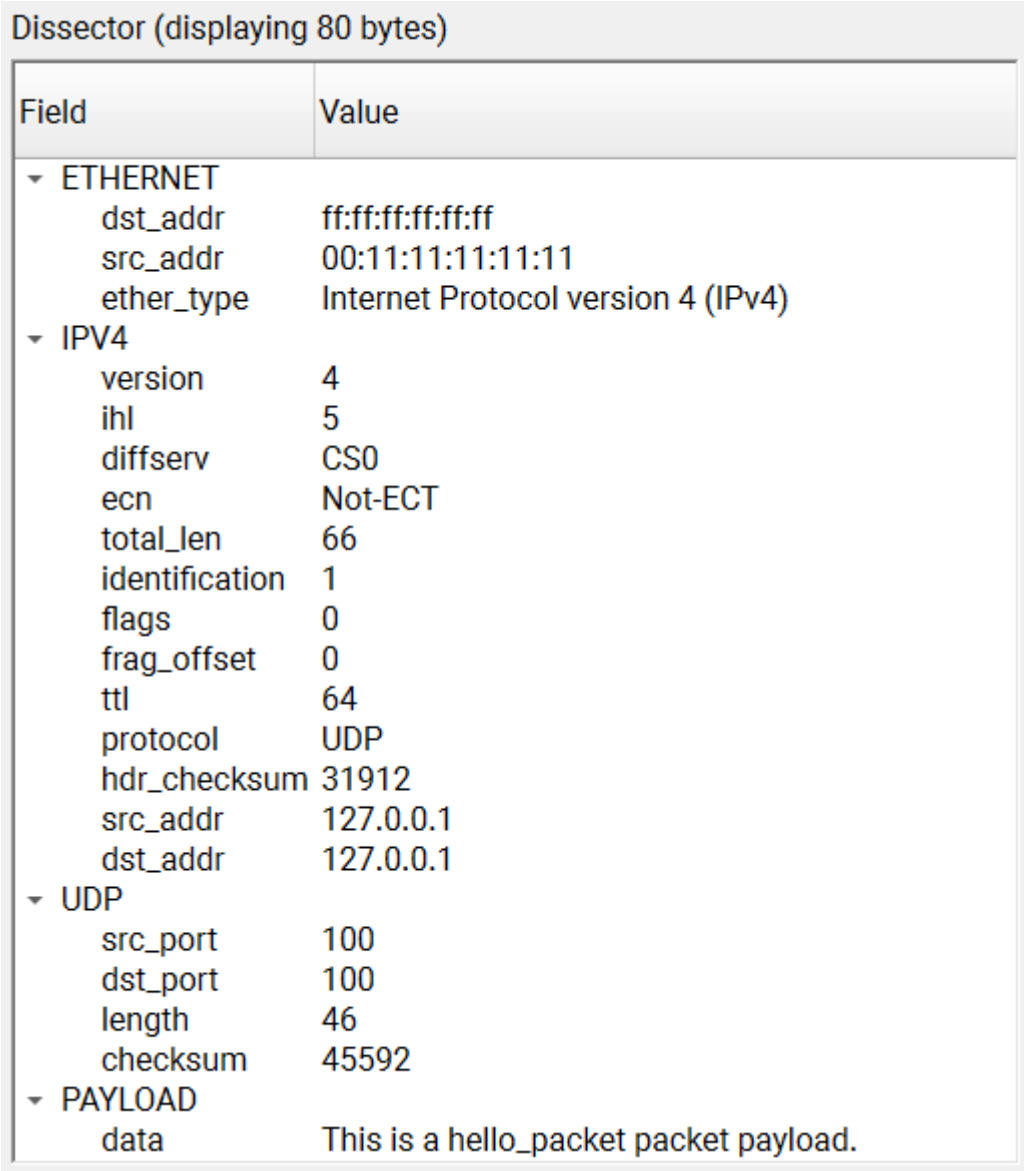
8.10.7.8.6.5 Packet State

Shows low level variables such as registers and controller meta.



8.10.7.8.6.6 Packet Dissector

Shows the parsed packet. Any paused packet can be edited by double-clicking any of the view's values (or using F2). Note that the editable values are always shown in decimal format, and are translated to the expected format upon saving.



8.10.7.8.6.7 Hex Dump

Shows a raw hex dump of the packet. Any paused packet can be edited by double-clicking the hexdump values (or using F2).

Hexdump (displaying 80 bytes)

ff	ff	ff	ff	ff	ff	00	11	11	11	11	11	08	00	45	00
00	42	00	01	00	00	40	11	7c	a8	7f	00	00	01	7f	00

73	20	61	20	68	65	6c	6c	6f	5f	70	61	63	6b	65	74
20	70	61	63	6b	65	74	20	70	61	79	6c	6f	61	64	2e

8.10.7.8.6.8 Source Code

Source files can be opened by clicking **File** → **Open Source File**. Additionally, sources are displayed when clicking objects that have a correlation to a source location (e.g., debug points, tables, actions, etc...).

The debugger seeks the DPL source file using the search paths defined in the Settings, or by browsing manually for the file.

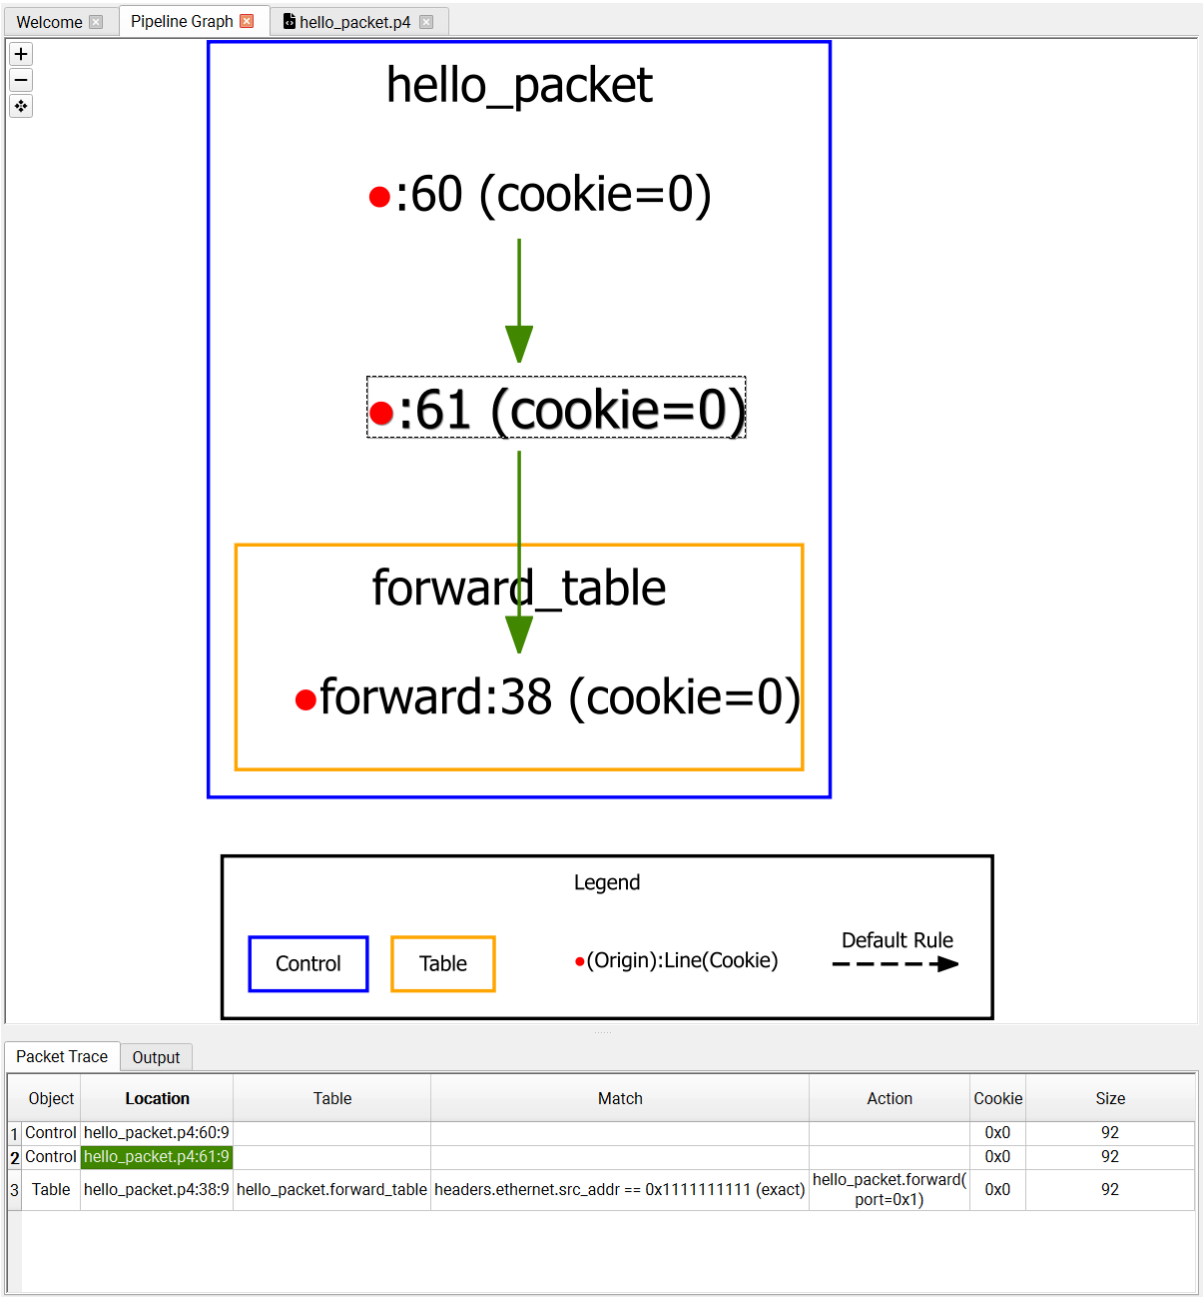
54              (48w0x00dddddddddd) : drop();
55              (48w0x00aaaaaaaaaa) : NoAction();
56              (48w0x00bbbbbbbbbb) : NoAction();
57          }
58      }
59      apply {
60          hello_counter.count(0);
61          if (headers.udp.isValid()) {
62              hello_counter.count(1);
63              forward_table.apply();
```

Packet Trace | Output

	Object	Location	Table	Match	Action	Cookie	Size
1	Control	hello_packet.p4:60:9				0x0	92
2	Control	hello_packet.p4:61:9				0x0	92
3	Table	hello_packet.p4:38:9	hello_packet.forward_table	headers.ethernet.src_addr == 0x1111111111 (exact)	hello_packet.forward(port=0x1)	0x0	92

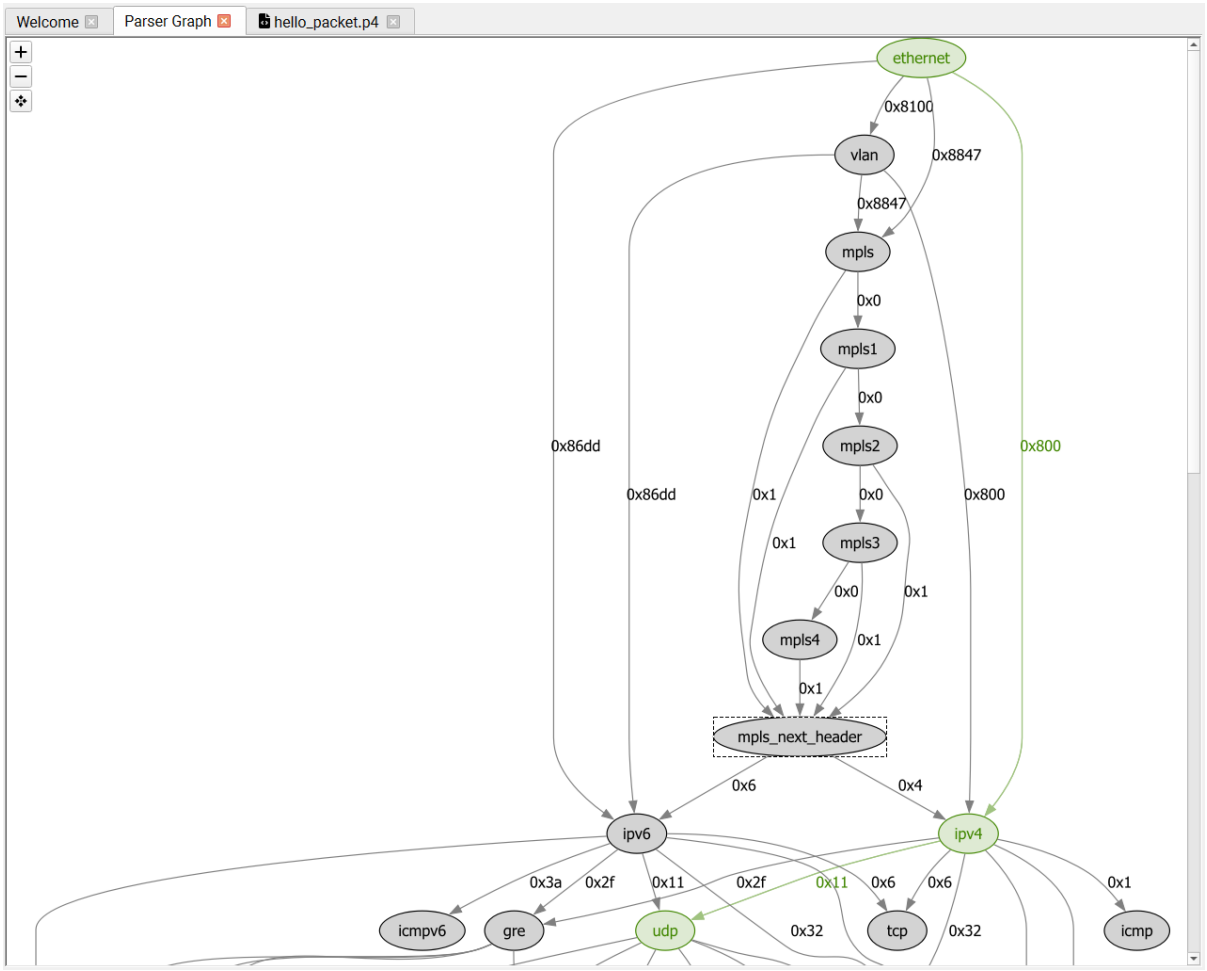
8.10.7.8.6.9 Pipeline

The pipeline graph can be opened by clicking **View** → **Pipeline Graph**. It shows the pipeline of the currently selected packet. Clicking on a row in the packet trace highlights (with a dashed outline) the respective debug point in the pipeline.



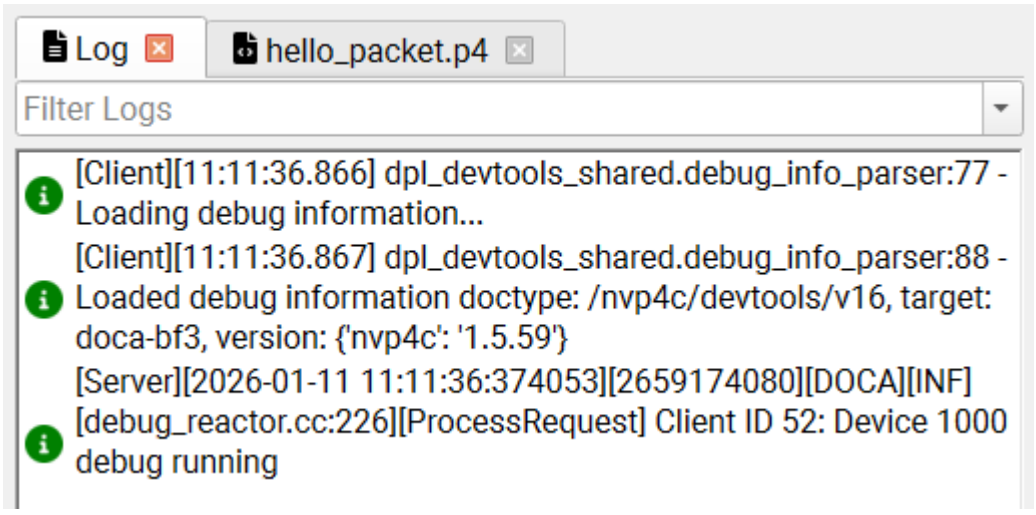
8.10.7.8.6.10 Parser

The parser graph can be opened by clicking **View** → **Parser Graph**. It shows the complete parser graph of the program, and outlines how the currently selected packet is parsed. The graph consists of both flex nodes which the DPL programmer instigated and static (fixed) nodes which are inherent part of the hardware.



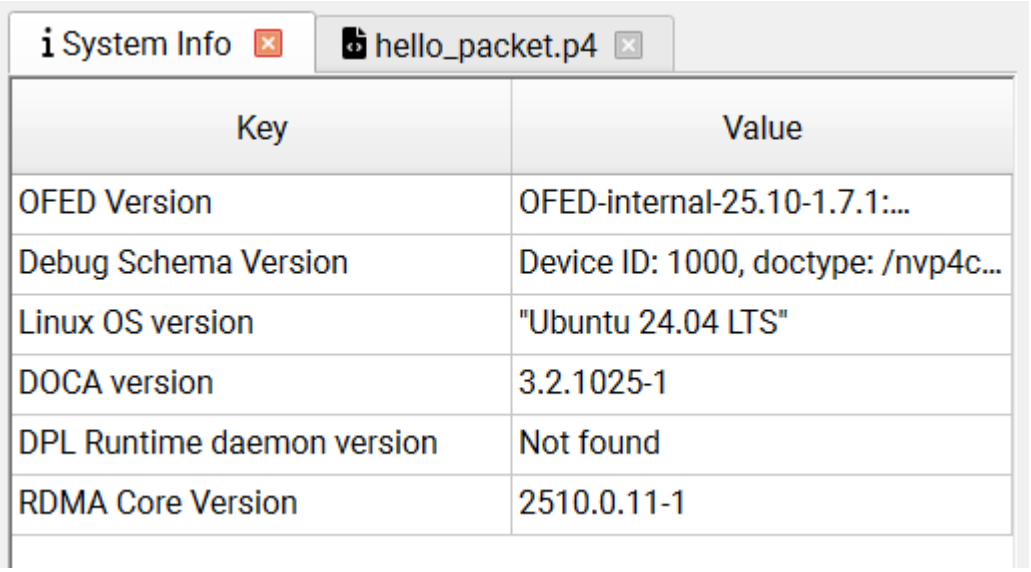
8.10.7.8.6.11 Log

The Log view can be opened by clicking **View** → **Log**. It shows the internal logs of the DPL Runtime daemon. The logs can be filtered by severity levels.



8.10.7.8.6.12 System Info

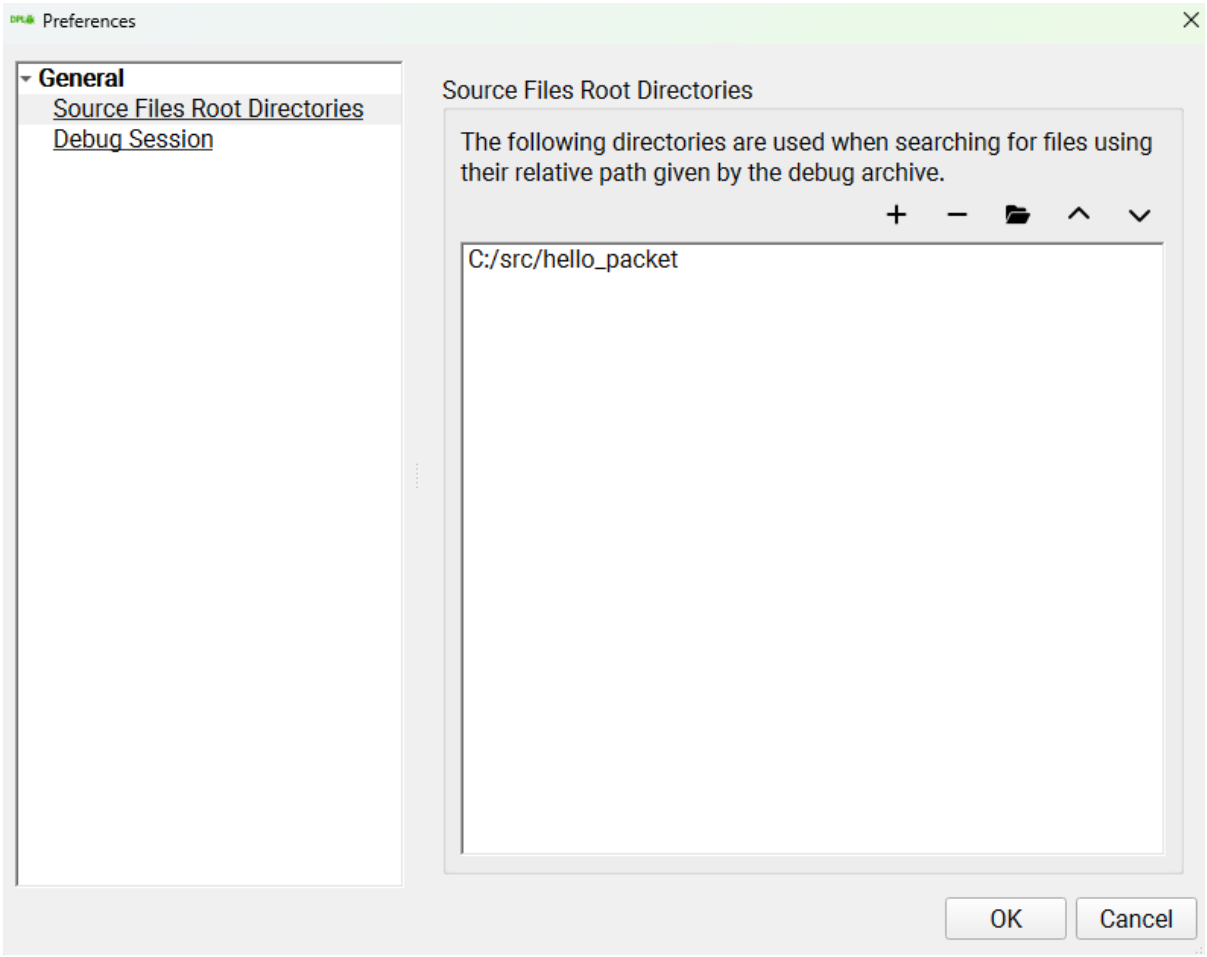
The System Info view can be opened by clicking **View**→ **System Info.**



8.10.7.8.7 Setting Source Directories

When an object with a correlation to a source location is clicked, the debugger searches in the source directories for the source file and display it.

Click **File** → **Preferences** menu and set the location of the DPL program sources.



8.10.7.9 DPL Program Metrics

8.10.7.9.1 Introduction

The DPL compiler produces metrics information for compiled DPL programs to provide developers with insight into how their programs are implemented in the target hardware architecture. This information is critical for identifying potential performance bottlenecks, such as expensive P4 tables, complex P4 actions, or critical processing paths through a complete program.

The information in this section describes what visibility the DPL compiler currently provides and how it can be used to guide DPL program development to achieve required performance.

8.10.7.9.2 Configuration and Output

By default, the DPL compiler outputs metrics information in the `p4-build` directory alongside other standard compiler outputs

8.10.7.9.2.1 Enable/Disable Metrics

- Default Behavior: Equivalent to including the compilation flag `--enable metrics`.
- Disable Metrics: Generation can be turned off using the flag `--disable metrics`.

8.10.7.9.2.2 Generated Files

- `program_name.metrics.log`: A text-based log summary of the compiled program's metrics.
- `program_name.metrics.json`: A JSON-structured representation, useful for tracking metrics programmatically over time.

8.10.7.9.3 Report Details (`program_name.metrics.log`)

The metrics log is based on a "lowered" representation of the DPL program, mapping high-level P4 constructs to hardware-aligned blocks called matchers and rules.

- Matcher: Generally correlates to a P4 Table.
- Rule: Generally correlates to a P4 Action.
- STE (Steering Table Entry): The fundamental hardware unit of work, consisting of a match phase and an action phase.

The log file contains three main sections:

8.10.7.9.3.1 DOCA HWS Metrics Report

This section summarizes resource usage and associated costs for matchers and rules. It begins with a summary of the total estimated memory usage and total unique STEs.

Column definitions:

Column	Description
ID	A unique identifier generated by the compiler, corresponding to ID values found in the `program_name.program.json` file
Table Name	The P4 table from which the matcher was derived (blank for synthesized matchers)
Domain	The hardware domain the matcher resides in. Currently allowed domains: FDB, FDB_RX, and FDB_TX.
Table Size	The capacity of rules (entries) the table can hold. This is expected to be a power of two due to memory allocation constraints.

Column	Description
Action Name	The P4 action from which the rule was derived.
Memory	Matcher: Bytes allocated to implement the matcher (enough for worst-case rules). Rule: Bytes required for a single rule of that type.
Packet Processing	A unitless estimate of execution cost. Higher numbers indicate more processing time. Matcher: Cost of processing a table miss (search + branching). Rule: Cost to execute the rule.
Insertion	A unitless estimate of the cost to insert a rule into a given matcher. Complex rules with many STEs take longer to insert.
Match STEs	The number of STEs required to perform the match operation (typically 1 or 2 for BlueField targets).
Action STEs	The number of STEs required to perform all of a rule's actions. A value of 0 indicates actions are performed in the same STE as the match.

8.10.7.9.3.2 DOCA HWS Metrics Report

This section summarizes the worst-case execution paths through the DPL program based on two different criteria:

1. Steps: The path requiring the highest number of STE steps.
2. Cost: The path with the highest cumulative packet processing cost.

Column definitions:

Column	Description
Step	The step order of the execution path, at the granularity of a hardware rule.
Table	The matcher ID visited at this step (includes P4 table name when possible).
Entry	The rule ID visited at this step (includes P4 action name when possible.
STEs	The number of STEs executed to perform the rule.
Pkt Processing	A unitless estimate of the cost of exercising the rule at this specific step.
Total	The sum of STE count and Packet Processing cost for the entire execution path.

8.10.7.9.3.3 Static entry hash distribution

When a program uses static entry tables (tables that have constant entries known at compile-time), the `metrics.log` will output a section that shows the hashing properties of each table. This section shows how the static entries are distributed across the allocated hash table. An example is shown below.

```
Static entry hash distribution:
Table 101 :
  0x00000000: x
  0x00000004: x
Table 102 :
  0x00000001: x
```

```
0x00000003: x
0x00000178: xxx
0x00000563: x
```

In this example, two tables are implemented that have static entries, table 101 and table 102. For each table, a histogram of entries per (occupied) hash bucket is shown. For example, Table 102 has six entries (denoted by x's in the histogram). One entry is at bucket 0x1, one entry is at bucket 0x3, three entries are at bucket 0x178, and one entry is at bucket 0x563. We say that bucket 0x178 has hash collisions, because more than one entry is found within the hash bucket.

Hash collisions incur a cost in terms of performance, because more memory locations have to be examined to resolve the collision. The best performant table would have no hash collisions. While the compiler attempts to implement static entry tables to avoid hash collisions, it is not always possible. Refer to the Performance User Guide for tips on improving hashing performance.

8.10.7.9.4 Optimization Guidelines

The metrics output serves as a guide for optimizing DPL programs. Consider the following principles:

1. Minimize STE Execution: The total number of STEs executed has a direct adverse effect on packets per second (PPS). Fewer STEs result in faster processing times per packet.
2. Simplify Rules: Rule complexity impacts both memory footprint and insertion cost. Smaller, simpler rules execute faster and are faster to insert from the control plane.
3. Focus on Critical Paths: Complex tables or actions usually only impact performance when located on a critical program execution path. Optimizing rarely used paths (e.g., error handling) may not yield observable performance improvements.

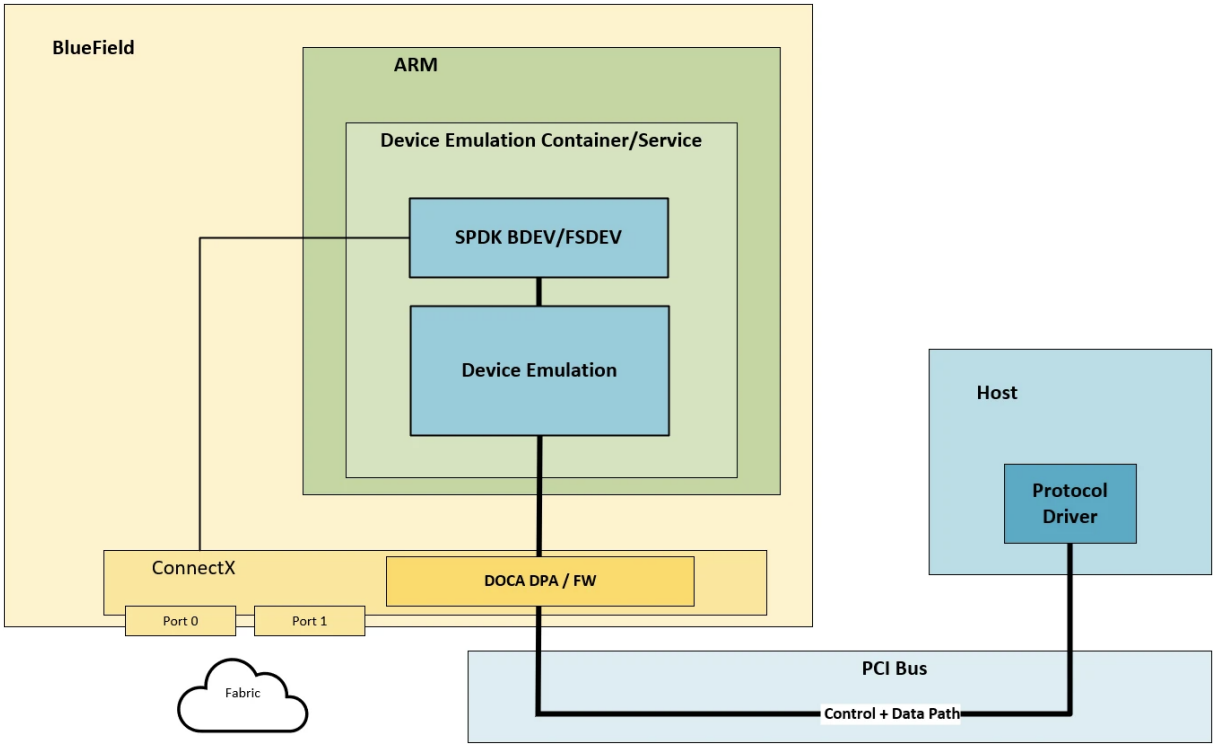
8.10.7.9.5 Disclaimers

- Estimates Only: The output provided in these metrics are estimates.
- Runtime Variables: The compiler cannot predict system caching performance or the specific characteristics of rules inserted at runtime.
- Memory Impact: Because fetch/retrieval times from system memory contain unknowns, actual packet processing costs may vary from these static estimates

8.11 DOCA SNAP Services

NVIDIA® DOCA™ Storage-Defined Network Accelerated Processing (SNAP) technology encompasses a family of services that enable hardware-accelerated virtualization of local storage running on NVIDIA® BlueField® products. The SNAP services present networked storage as local block or file system devices to the host, emulating local drives on the PCIe bus. The host OS or hypervisor utilizes its standard storage or file system driver, remaining unaware that communication is occurring not with a physical drive, but with a protocol-specific SNAP framework. This framework allows for any logic to be applied to the I/O requests or data before redirecting the requests and/or data over a fabric-based network to remote or local storage targets.

The DOCA SNAP services are built on BlueField technology, offering unique hardware-accelerated storage virtualization and isolation, combined with advanced networking and programmability. Together, SNAP and BlueField support a wide range of applications aimed at enhancing storage and networking efficiency, security, and performance.



NVIDIA offers the following DOCA SNAP services:

- NVIDIA DOCA SNAP Virtio-fs service – Virtio-fs for file system emulation on BlueField-3
- NVIDIA DOCA SNAP-4 service – NVMe and virtio-block for block device emulation on BlueField-3
- NVIDIA DOCA SNAP-3 – NVMe and virtio-block for block device emulation on BlueField-2

8.11.1 DOCA SNAP Virtio-fs Service Guide

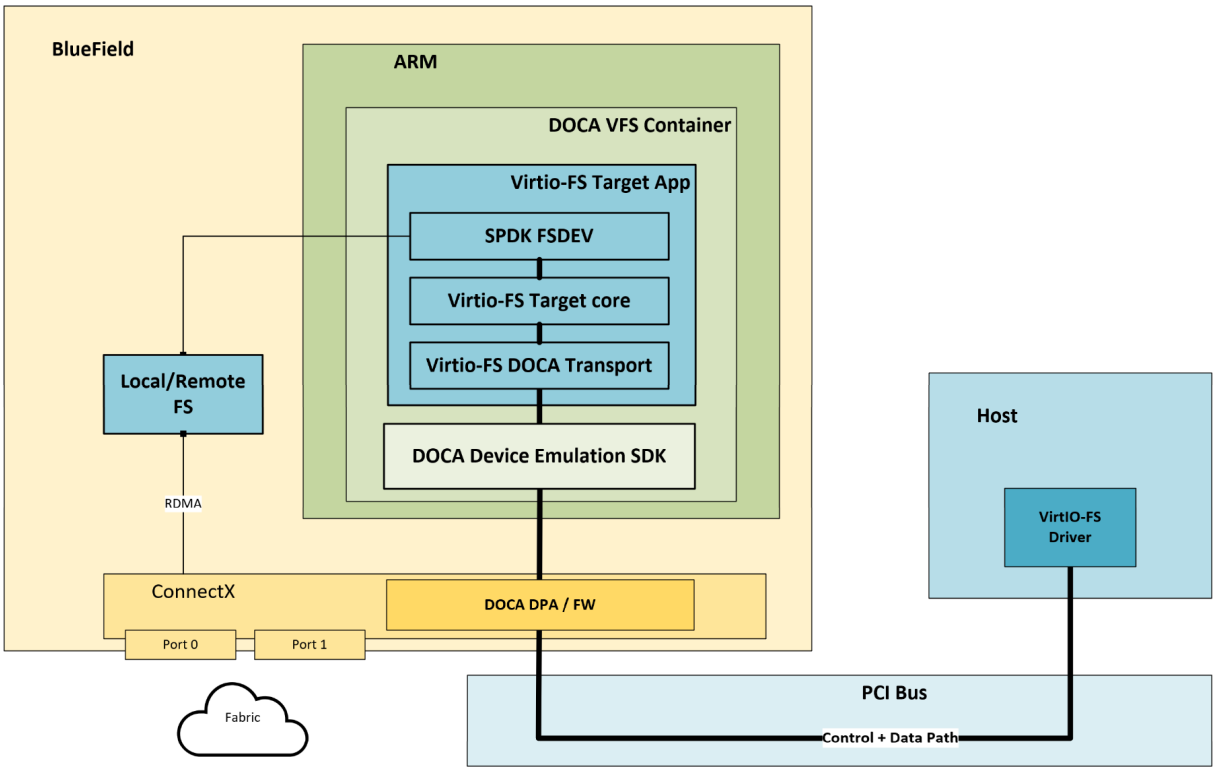
8.11.1.1 Introduction

> ⚠ The DOCA SNAP Virtio-fs Service is supported at beta level.

NVIDIA BlueField enables hardware-accelerated, software-defined virtio-fs PCIe device emulation. This leverages the power of BlueField networking platforms (DPUs or SuperNICs) to provide high-performance file system access in bare-metal and virtualized environments. Using BlueField, users can offload and accelerate networked file system operations from the host/guest, freeing up resources for other tasks and improving overall system efficiency. In this solution, the host/guest uses its own standard virtio-fs driver which is fully isolated from the networked filesystem mounted within the BlueField.

Built upon the DOCA and SPDK frameworks, virtio-fs device emulation on BlueField devices offers a comprehensive set of libraries for BlueField-based solutions and for storage solutions. This architecture consists of several key components:

- DOCA DevEmu subsystem and DOCA Virtio-fs library – These core libraries are responsible for the low-level hardware management and the translation of virtio descriptors carrying FUSE (filesystem in userspace) requests into abstract virtio-fs requests, which are then processed by the SPDK virtio-fs DOCA transport component.
- SPDK virtio-fs transport – This component is responsible for the interaction with the low-level DOCA components and translating the incoming abstract DOCA SNAP Virtio-fs requests into generic virtio-fs request which are then processed by the virtio-fs target core.
- SPDK virtio-fs target – This component implements and manages the virtio-fs device, transports, and the interface with a backend file system. Upon arrival on a new generic virtio-fs request from the transport, it processes and translates the requests according to virtio-fs and FUSE specifications, translating FUSE-based commands into the generic filesystem protocol.
- SPDK fsdev – This component provides generic filesystem abstraction and interfaces with the low-level filesystem modules implementing a specific backend filesystem protocol.



8.11.1.1.1 DOCA SNAP Virtio-fs as Container

The DOCA SNAP Virtio-fs container image may be downloaded from NVIDIA NGC and easily deployed on the BlueField using a YAML file. The YAML file points to the docker image that includes DOCA SNAP Virtio-fs binaries aligned with the latest `spdk.nvda` version.

DOCA SNAP Virtio-fs is not pre-installed on the BFB but can be downloaded manually on demand. For instructions on how to install the DOCA SNAP Virtio-fs container, refer to DOCA SNAP Virtio-fs Container Deployment.

8.11.1.2 DOCA SNAP Virtio-fs Deployment

This section describes how to deploy DOCA SNAP Virtio-fs as a container.

> ⚠ DOCA SNAP Virtio-fs does not come pre-installed with the BFB bundle.

> ⚠ The default virtio-blk emulation provider is set to `DPU`. In this mode, SNAP Virtio-fs and SNAP Virtio-blk can operate simultaneously only if they are assigned to different DPA execution units (EUs).

This separation is achieved by setting the environment variable `dpu_helper_core_mask=0x1fffe`, which is configured in the `set_environment_variables.sh` script included in the SNAP Virtio-fs package.

8.11.1.2.1 Installing Full DOCA Image on BlueField

To install the BFB on BlueField:

```
[host] sudo bfb-install --rshim <rshimN> --bfb <image_path.bfb>
```

For more information, refer to "Installing Full DOCA Image on DPU" in the NVIDIA DOCA Installation Guide for Linux.

8.11.1.2.2 Firmware Installation

```
[dpu] sudo /opt/mellanox/mlnx-fw-updater/mlnx_fw_updater.pl --force-fw-update
```

For more information, refer to "Upgrading Firmware" in the NVIDIA DOCA Installation Guide for Linux.

8.11.1.2.3 Firmware Configuration

Firmware configuration may expose new emulated PCIe functions, which can be later used by the host's OS. As such, the user must make sure all exposed PCIe functions (static/hotplug) are backed by a supporting virtio-fs software configuration. Otherwise, these functions would malfunction and host behavior would be anomalous.

1. Clear the firmware configuration before implementing the required configuration:

   ```
   [dpu] mst start
   [dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 reset
   ```

2. Verify the firmware configuration:

   ```
   [dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 query
   ```

   Output example:

   ```
   mlxconfig -d /dev/mst/mt41692_pciconf0 -e query | grep VIRTIO_FS
   Configurations:                                 Default             Current             Next Boot
   *        VIRTIO_FS_EMULATION_ENABLE             False(0)            True(1)             True(1)
            VIRTIO_FS_EMULATION_NUM_VF             0                   0                   0
   *        VIRTIO_FS_EMULATION_NUM_PF             0                   2                   2
            VIRTIO_FS_EMU_SUBSYSTEM_VENDOR_ID      6900                6900                6900
            VIRTIO_FS_EMULATION_SUBSYSTEM_ID       4186                4186                4186
   ```

```
*        VIRTIO_FS_EMULATION_NUM_MSIX                2                3                3
```

The output provides 5 columns (listed from left to right):

- Non-default configuration marker (`*`)
- Firmware configuration name
- Default firmware value
- Current firmware value
- Firmware value after reboot – shows configuration update pending system reboot

3. To enable storage emulation options, BlueField must be set to work in internal CPU model:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s INTERNAL_CPU_MODEL=1 PF_BAR2_ENABLE=0
```

`PF_BAR2_ENABLE` is a deprecated option and must be explicitly disabled.

4. To enable the firmware config with virtio-fs emulation PF:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s VIRTIO_FS_EMULATION_ENABLE=1 VIRTIO_FS_EMULATION_NUM_PF=1
VIRTIO_FS_EMULATION_NUM_MSIX=3
```

For a complete list of the DOCA SNAP Virtio-fs firmware configuration options, refer to "Appendix – BlueField Firmware Configuration".

Power cycle is required to apply firmware configuration changes.

8.11.1.2.3.1 RDMA/RoCE Firmware Configuration

RoCE communication is blocked for the default interfaces of BlueField OS's (named ECPFs), `mlx5_0` and `mlx5_1` typically. If RoCE traffic is required, scalable functions (or SFs) must be added which are network functions which support RoCE transport.

To enable RDMA/RoCE:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PER_PF_NUM_SF=1
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0.1 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
```

This is not required when working over TCP or RDMA over InfiniBand.

⚠ When using 64KB page size OS on BlueField, replace `PF_SF_BAR_SIZE=8` with `PF_SF_BAR_SIZE=10 BAR_PAGE_ALIGNMENT=2`.

8.11.1.2.3.2 SR-IOV Firmware Configuration

DOCA SNAP Virtio-fs supports up to 2000 total VFs on virtio-fs. The VFs may be spread between up to 4 virtio-fs PFs.

- Common example:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s SRIOV_EN=1 PER_PF_NUM_SF=1 LINK_TYPE_P1=2 LINK_TYPE_P2=2
PF_TOTAL_SF=1 PF_SF_BAR_SIZE=8
```

- Virtio-fs 250 VFs example (2 queue per VF):

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s VIRTIO_FS_EMULATION_ENABLE=1 VIRTIO_FS_EMULATION_NUM_VF=125
VIRTIO_FS_EMULATION_NUM_PF=2 VIRTIO_FS_EMULATION_NUM_MSIX=5 VIRTIO_FS_EMULATION_NUM_VF_MSIX=6
```

8.11.1.2.3.3 Hot-plug Firmware Configuration

When PCIe switch emulation is enabled, BlueField can support `PCI_SWITCH_EMULATION_NUM_PORT`-1 hotplug virtio-fs function. These PCIe functions are shared among all BlueField users and applications and may hold hot-plugged devices of type NVMe, virtio-blk, virtio-fs, and more (e.g., virtio-net).

To enable PCIe switch emulation and configure 31 hot-plugged ports to be used, run:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PCI_SWITCH_EMULATION_ENABLE=1 PCI_SWITCH_EMULATION_NUM_PORT=32
```

`PCI_SWITCH_EMULATION_NUM_PORT` equals 1 plus the number of hot-plugged PCIe functions.

⚠ On AMD machines, hotplug is not guaranteed to work and enabling `PCI_SWITCH_EMULATION_ENABLE` may impact SR-IOV capabilities.

8.11.1.2.4 DPA Core Mask

The Data Path Accelerator (DPA) is an auxiliary processor designed to offload and accelerate data-path operations. It consists of a cluster of 16 cores, each containing 16 Execution Units (EUs).

- Total Capacity: 256 EUs (16 cores × 16 EUs)
- SNAP Allocation: 170 EUs are specifically available to SNAP (which runs a DPA application to accelerate the `virtio-fs` protocol).

The YAML-Based DPA Execution Unit Management Tool is the default mechanism for controlling DPA EUs. For the standard setup, refer to the DPA Resource Management Default Configuration.

If other DPA applications (e.g., `virtio-net`) are running concurrently with SNAP, you must explicitly configure the DPA resource YAML file to allocate specific EUs to each application.

> ⚠ For more details, see Single Point of Resource Distribution.

8.11.1.2.4.1 DPA EU Reservation

SNAP supports reserving DPA EUs for virtio-fs controllers. By default, all available EUs (0–170) are shared among all DPA applications on the system, including `virtio-fs` and `virtio-blk`.

8.11.1.2.4.2 YAML-based DPA Resource Management

DPA EU allocation is managed via a YAML-based resource file. For more details, see the documentation on Single Point of Resource Distribution.

This method centralizes and enforces consistent EU allocation across applications.

Requirements:

- Application name in the YAML file must match SNAP's DPA app:
  - `doca_devemu_virtio_dpa_app` → for `virtio-fs`
- At least one EU must be allocated for the `virtio-fs` DPA application.
- EU IDs must be in the range 1–170 (EU 0 is reserved).
- EU allocations must not overlap between applications.
- EU groups are not supported.
- SNAP's DPA application must run on the ROOT partition. EUs allocated to other partitions are not available.

8.11.1.2.4.3 DPA Resource Management Default Configuration

Default YAML input format for SNAP

```
---
version: 25.04
---
DPA_APPS:
  doca_devemu_virtio_dpa_app:
    - partition: ROOT
      affinity_EUs: [17-169]
  dpa_helper:
    - partition: ROOT
      affinity_EUs: [1-16]
  dpa_virtq_split:
    - partition: ROOT
      affinity_EUs: [1-169]
  dpa_nvme:
    - partition: ROOT
      affinity_EUs: [1-169]
```

8.11.1.2.4.4 Usage Instructions

1. Generate the output YAML file using the `dpa-resource-mgmt` tool:

```
dpa-resource-mgmt
```

```
dpa-resource-mgmt config -d mlx5_0 -f ~/DPA_RESOURCE_INPUT.yaml
```

2. Set the `DEVEMU_DPA_RESOURCES_FILE_PATH` environment variable to point to the generated YAML file

```
dpa-resource-mgmt
```

```
export DEVEMU_DPA_RESOURCES_FILE_PATH=~/ROOT.yaml
```

> ⚠ If running in a container, ensure the YAML file is exposed to the container (e.g., using a shared folder like `/etc/nvda_snap`).

Notes:

- Do not manually edit the YAML file generated by `dpa-resource-mgmt`.
- Each DPA EU supports up to 128 queues (threads).
- SNAP DPA applications only operate on the ROOT partition.

8.11.1.2.5 Virtio-fs DOCA Host Drive Installation (Optional)

The NVIDIA DOCA host package includes an optimized and extended version of the Virtio-fs driver; it provides better performance and additional features when compared to the upstream package.

- Optimized performance using Virtio-fs multi-queue with a better locking design.
- Support for a notification queue, allowing for a more accurate cached view of the filesystem by the host when remote changes happen.
- Support for GPU Direct Storage, allowing for zero-copy transfers between storage devices and GPUs.

> ⚠ Virtio-fs DOCA host package supports FLR only with Ubuntu 25.04
>
> DOCA Host optimized virtiofs module support starts at kernel version 6.6

8.11.1.2.5.1 Supported OS

Optimized virtio-fs driver support is available for:

- Ubuntu 24.04
- Ubuntu 25.04 (with FLR)
- RHEL 10
- CentOS 10 (same package as RHEL10)
- OpenEuler 24.03

> ⚠ Debian does not support the optimized driver. Debian users have to fallback on the inbox drivers (no FLR, no notification queue).

8.11.1.2.5.2 Installation

To install DOCA host, install the following package:

1. Install the doca repo

```
[host] apt install doca-host_<version>-ubuntu2404_amd64.deb
```

2. Update the package cache list:

```
[host] apt update
```

3. Install NVIDIA virtio-fs:

```
[host] apt install virtiofs-dkms
```

> ⚠ Install OFED version 25.04-0.2.3.0 or later.

The virtio-fs DOCA host driver takes over your system version of the virtio-fs driver. It does not affect your system version of FUSE. Existing FUSE-based application should run unaffected.

8.11.1.2.5.3 Configuration

Once installed, configure your DPU to run a SNAP Virtio-fs service and reboot the host. The host system will be stuck during the boot process until the SNAP Virtio-fs service becomes available.

You can confirm you are running Virtio-fs DOCA Host driver by looking in your kernel log for mentions of it:

```
[host] dmesg | grep 'virtio-fs' virtio-fs: Loading NVIDIA-virtiofs +mq +lockless +nvq
```

You can now mount your Virtio-fs drive as usual:

```
[host] mount -t virtiofs <tagname> /mnt/virtiofs/
```

8.11.1.2.5.4 Advanced Configuration to Optimize Virtiofs Performance

Beginning with package `virtiofs-dkms version 25.07-OFED.25.07.0.2.3.1`, the sysfs file used to display CPU mappings has become writable. This means user can now manually assign CPUs to queues to adjust the default mapping.

Additionally, a new file called irq_affinity is now available under procfs for each queue. This file allows the user to specify one or more CPUs to direct that queue's interrupts accordingly. Note that user can only write to this file; to verify its impact, the user will need to manually check the system's interrupts.

These features allow users to experiment with and optimize CPU-to-queue mappings.

Example usage:

Assign CPUs 4, 5, and 6 to queue 4 (removing them from any previous assignment)

```
[host] echo 4,5,6 > /sys/fs/virtiofs/5/mqs/4/cpu_list
```

Direct queue 4's interrupts to CPUs 4, 5, and 6

```
[host] echo 4,5,6 > /sys/fs/virtiofs/5/mqs/4/irq_affinity
```

8.11.1.2.5.5 Uninstallation

If you wish to remove the Virtio-fs DOCA Host driver, you can do so with the following command. It will also remove packages automatically installed as dependencies:

```
[host] apt purge --autoremove virtiofs-dkms
```

8.11.1.2.6 DOCA SNAP Virtio-fs Container Deployment

DOCA SNAP Virtio-fs container is available on the DOCA SNAP Virtio-fs NVIDIA NGC page.

To deploy DOCA SNAP Virtio-fs container on top of BlueField, the following procedure is required:

1. Setup preparation and DOCA SNAP Virtio-fs resource download for container deployment. See section "Preparation Steps" for details.
2. Adjust the `doca_vfs.yaml` for advanced configuration if needed according to section "Adjusting YAML Configuration".

3. Deploy the container. The image is automatically pulled from NGC. See section "Spawning DOCA SNAP Virtio-fs Container" for details.

8.11.1.2.6.1 Preparation Steps

Step 1: Allocate Hugepages

Allocate `8GiB` hugepages for the DOCA SNAP Virtio-fs container according to the DPU OS's `Hugepagesize` value:

1. Query the `Hugepagesize` value:

   ```
   [dpu] grep Hugepagesize /proc/meminfo
   ```

   In Ubuntu22 and Ubuntu24, the value should be 2048KB. In Ubuntu24 with 64k page size, the value should be 524288KB.
2. For OS with 2048KB hugepage, use the `doca-hugepages` tool to configure the requested hugepages:

   ```
   [dpu] doca-hugepages config --app snap --size 2048 --num 4096
   ```
3. For OS with 524288KB hugepage, use the `doca-hugepages` tool to configure the requested hugepages:

   ```
   [dpu] doca-hugepages config --app snap --size 524288 --num 16
   ```
4. Reload the hugepages configuration for all applications based on the current database settings:

   ```
   [dpu] doca-hugepages reload
   ```

If live upgrade is utilized in this deployment, it is necessary to allocate twice the number of resources listed above for the upgraded container.

If other applications are running concurrently within the setup and are consuming hugepages, make sure to allocate a quantity of hugepages appropriate to accommodate all applications.

Step 2: Create /etc/virtiofs Folder

The folder `/etc/virtiofs` is used by the container for automatic configuration after deployment.

The default YAML configuration only mounts the `/etc/virtiofs` folder for exposure and sharing between the container and the BlueField. This folder is used to expose configuration files or local file backends (e.g., AIO fsdev) from the DPU to the container.

8.11.1.2.6.2 Downloading YAML from NGC

The `.yaml` configuration file for the DOCA SNAP Virtio-fs container, `doca_vfs.yaml`, is uploaded to DOCA NGC.

Internet connectivity is necessary to download DOCA SNAP Virtio-fs resources.

8.11.1.2.6.3 Adjusting YAML Configuration

The `.yaml` file can easily be edited for advanced configuration.

- The DOCA SNAP Virtio-fs `.yaml` file is configured by default to support Ubuntu setups (i.e., `Hugepagesize` = 2048 kB) by using hugepages-2Mi.
  To support other setups, edit the hugepages section according to the relevant `Hugepagesize` value for the BlueField OS. For example, to support CentOS 8.x or configure `Hugepagesize` to 512MB:

  ```
  limits:
     hugepages-512Mi: "<number-of-hugepages>Gi"
  ```

- The following example edits the `.yaml` file to request 6G memory for the DOCA SNAP Virtio-fs container:

  ```
      resources:
        requests:
          memory: "6Gi"
        limits:
          memory: "6Gi"
  ```

  On Ubuntu 24.04, DOCA SNAP Virtio-fs with a high number of queues requires more memory than the default configuration provides.

- The following example edits the `.yaml` file to request 8 CPU cores for the DOCA SNAP Virtio-fs container:

  ```
  resources:
      cpu: "8"
    limits:
      cpu: "8"
  env:
    - name: APP_ARGS
      value: "-m 0xff"
  ```

> If all BlueField-3 cores are requested, the user must verify no other containers are in conflict over CPU resources.

- To automatically configure the DOCA SNAP Virtio-fs container upon deployment:
  a. Add the `spdk_rpc_init.conf` file under `/etc/virtiofs/`. File example:

```
fsdev_ aio0 /etc/virtiofs/test
virtio_fs_transport_create -t DOCA
virtio_fs_transport_start -t DOCA
virtio_fs_device_create --transport-name DOCA --dev-name vfsdev0 --tag docatag --fsdev aio0 --num-request-queues 1 --queue-size 32 --driver-platform x86_64
virtio_fs_doca_device_modify --dev-name vfsdev0 --manager mlx5_0 --vuid "MT2251XZ02WZVFSS0D0F3"
virtio_fs_device_start --dev-name vfsdev0
```

  b. Edit the `.yaml` file accordingly (uncomment):

```
env:
  - name: SPDK_RPC_INIT_CONF
    value: "/etc/virtiofs/spdk_rpc_init.conf"
```

> It is user responsibility to make sure DOCA SNAP Virtio-fs configuration matches firmware configuration. That is, an emulated controller must be opened on all existing (static/hotplug) emulated PCIe functions (either through automatic or manual configuration). A PCIe function without a supporting controller is considered malfunctioned, and host behavior with it is anomalous.

8.11.1.2.6.4 Spawning DOCA SNAP Virtio-fs Container

Run the Kubernetes tool:

```
[dpu] systemctl restart containerd
[dpu] systemctl restart kubelet
[dpu] systemctl enable kubelet
[dpu] systemctl enable containerd
```

Copy the updated `doca_vfs.yaml` file to the `/etc/kubelet.d` directory.

Kubelet automatically pulls the container image from NGC described in the YAML file and spawns a pod executing the container.

```
cp doca_vfs.yaml /etc/kubelet.d/
```

The DOCA SNAP Virtio-fs Service starts initialization immediately, which may take a few seconds.

To verify whether DOCA SNAP Virtio-fs is running, send `spdk_rpc.py spdk_get_version` to confirm whether DOCA SNAP Virtio-fs is operational or still initializing.

8.11.1.2.6.5 Debug and Log

View currently active pods, and their IDs (it might take up to 20 seconds for the pod to start):

```
crictl pods
```

Example output:

```
POD ID              CREATED              STATE         NAME
0379ac2c4f34c       About a minute ago   Ready         virtiofs
```

View currently active containers, and their IDs:

```
crictl ps
```

View existing containers and their ID:

```
crictl ps -a
```

Examine the logs of a given container (virtio-fs logs):

```
crictl logs <container_id>
```

Examine the kubelet logs if something does not work as expected:

```
journalctl -u kubelet
```

The container log file is saved automatically by Kubelet under `/var/log/containers`.

8.11.1.2.6.6 Stop, Start, Restart DOCA SNAP Virtio-fs Container

- To stop the container, remove the `.yaml` file form `/etc/kubelet.d/`.
- To start the container, copy the `.yaml` file to the same path:

  ```
  cp doca_vfs.yaml /etc/kubelet.d
  ```

- To restart the container (with sig-term), use the `-t` (timeout) option:

  ```
  crictl stop -t 10 <container-id>
  ```

- To restart the SNAP service without restarting the entire container, the user can either use the `supervictl` tool or manually terminate the SNAP service process on the DPU. Different termination signals trigger different behaviors. For example, using `pkill` with the `-9` option sends a `SIGKILL`, which forcefully stops the process:

```
pkill -9 -f virtiofs
```

After containers in a pod exit, the Kubelet restarts them using an exponential back-off strategy (e.g., 10s, 20s, 40s), with the delay capped at five minutes. If a container runs successfully for 10 minutes, the Kubelet resets the restart back-off timer for that container.

The termination of the `virtiofs` service may take time, as it must release all allocated resources. The duration depends on the scale of the use case and whether other applications are sharing resources with SNAP. Kubelt may display errors if the container termination timeout is shorter than the actual time required for cleanup.

8.11.1.2.7 DOCA SNAP Virtio-fs with SNAP Support

The DOCA SNAP virtio-fs container, along with its associated packages, natively supports DOCA SNAP-4, which is implemented as an SPDK subsystem module. This design enables the concurrent operation of both virtio-fs, virtio-blk and NVMe as a unified service. Additionally, DOCA SNAP is integrated as part of the DOCA SNAP virtio-fs deployment.

DOCA SNAP deployment sets `snap`, `snap_nvme`, and `snap_vblk` as SPDK subsystems which can be disabled as needed.

Refer to DOCA SNAP-4 Service Guide documentation for more information.

DOCA SNAP RPCs can be used as an SPDK plugin, the recommended method for running RPCs with the SPDK RPC script. Users may need to set the `PYTHONPATH` environment variable to include the path to `snap_rpc.py`.

This command creates a Virtio block controller using the DOCA SNAP RPC plugin, specifying `--pf_id 0` and using `Null0` as the block device:

```
spdk_rpc.py  --plugin snap_rpc virtio_blk_controller_create --pf_id 0 --bdev Null0
```

For further details on using RPC plugins, refer to the SPDK official documentation.

8.11.1.3 RPC Commands

Like other standard SPDK applications, the remote procedure call (RPC) protocol is used to control the DOCA SNAP Virtio-fs Service and supports JSON-based RPC protocol commands to control any resources and create, delete, query, or modify commands easily from the CLI.

DOCA SNAP Virtio-fs supports all standard SPDK RPC commands in addition to an extended DOCA SNAP Virtio-fs command set. Standard SPDK commands are executed by the `spdk_rpc.py` tool.

Virtio-fs-specific command set is implemented as a separate RPC plugin. When working with container, this RPC plugin is loaded automatically on `spdk_rpc.py` execution. When working with sources, users must explicitly load the plugin by adding the `--plugin rpc_virtio_fs_tgt` flag to the SPDK's `spdk_rpc.py` command.

The following is an example of an RPC when using DOCA SNAP Virtio-fs from the source:

```
/opt/nvidia/spdk-subsystem/src/spdk/install-$(hostname)/bin/spdk_rpc.py --plugin rpc_virtio_fs_tgt --help
```

You may need to define the path to the folder with `rpc_virtio_fs_tgt.py` using the `PYTHONPATH` environment variable. It is normally located in the root of virtio-fs sources folder. More details on the RPC plugins can be found in SPDK's official documentation.

Full `spdk_rpc.py` command set documentation can be found in the SPDK official documentation site.

DOCA SNAP Virtio-fs extended commands are detailed in the following subsections.

8.11.1.3.1 Using JSON-based RPC Protocol

The JSON-based RPC protocol can be used with the `spdk_rpc.py` script inside the DOCA SNAP Virtio-fs container and `crictl` tool.

The DOCA SNAP Virtio-fs container is CRI-compatible.

- To query the active container ID:

  ```
  crictl ps -s running -q --name virtiofs
  ```

- To post RPCs to the container using `crictl`:

```
crictl exec <container-id> spdk_rpc.py -v <RPC-method>
```

The flag `-v` controls verbosity. For example:

```
crictl exec 0379ac2c4f34c spdk_rpc.py -v virtio_fs_doca_get_functions
```

Alternatively, an alias can be used:

```
crictl exec -it $(crictl ps -s running -q --name virtiofs) spdk_rpc.py -v virtio_fs_doca_get_functions
```

- To open a bash shell to the container that can be used to post RPCs:

```
crictl exec -it <container-id> bash
```

8.11.1.3.2 PCIe Function Management

Emulated PCIe functions are managed through DOCA devices called emulation managers. Emulation managers have special privileges to control, manipulate, and expose the emulated PCIe devices towards the host PCIe subsystem.

To operate a virtio-fs device/function by the DOCA transport, it is necessary to locate the appropriate emulation manager for it. The emulation manager maintains a list of the emulated PCIe functions it controls. Each of those functions is assigned a globally unique serial called a vendor unique identifier or VUID (e.g., MT2251XZ02WZVFSS0D0F2), which serves as unambiguous reference for identification and tracking purposes.

8.11.1.3.2.1 virtio_fs_doca_get_managers

List existing emulation managers for virtio-fs. This method has no input parameters.

Example response:

```
{
  "jsonrpc": "2.0",
  "id": 1,
  "result": [
    {
      "name": "mlx5_0"
    }
  ]
}
```

8.11.1.3.2.2 virtio_fs_doca_get_functions

List functions for virtio-fs with their characteristics. The user may specify no parameters to list all emulated virtio-fs functions managed by any emulation manager device, or specify an emulation manager device name to list virtio-fs functions managed by that emulation manager device.

Example response:

```
{
  "jsonrpc": "2.0",
  "id": 1,
  "result": [
    {
      "manager": "mlx5_0",
      "Function List": [
      {
        "hot pluggable": "false",
        "pci_address": "0000:86:00.2",
        "vuid": "MT2306XZ00A7VFSS0D0F2",
        "function_type": "PF",
        "total_vfs": 2
      },
      {
        "hot pluggable": "false",
        "pci_address": "0000:86:04.5",
        "vuid": "MT2306XZ00A7VFSS0D0F2VF1",
        "function_type": "VF",
        "pf_vuid": "MT2306XZ00A7VFSS0D0F2"
      },
      {
        "hot pluggable": "false",
        "pci_address": "0000:86:04.6",
        "vuid": "MT2306XZ00A7VFSS0D0F2VF2",
        "function_type": "VF",
        "pf_vuid": "MT2306XZ00A7VFSS0D0F2"
      }
      ]
    }
  ]
}
```

Parameter Name	Optional/Mandatory	Type	Description
`manager`	Optional	String	Emulation manager device name to list emulated virtio-fs functions specific to it

8.11.1.3.2.3 virtio_fs_doca_get_possible_managers

List possible emulation managers for virtio-fs. This method has no input parameters.

Example response:

```
{
  "jsonrpc": "2.0",
  "id": 1,
  "result": [
    {
      "name": "mlx5_0",
    }
  ]
}
```

8.11.1.3.2.4 virtio_fs_doca_manager_create

Create a virtio-fs emulation manager.

Parameter Name	Optional/Mandatory	Type	Description
`manager`	Mandatory	String	Emulation manager device name

8.11.1.3.2.5 virtio_fs_doca_manager_destroy

Destroy a virtio-fs emulation manager.

Parameter Name	Optional/Mandatory	Type	Description
`manager`	Mandatory	String	Emulation manager device name

The RPC may take a long time to complete or even timeout when many queues (>1000) are created.

8.11.1.3.3 Hot-pluggable PCIe Functions Management

Hotplug PCIe functions are configured dynamically at runtime using RPCs.

The commands outlined in the following subsections hot plug a new PCIe function to the system.

8.11.1.3.3.1 virtio_fs_doca_get_functions

List DOCA transport functions for virtio-fs with their characteristics.

Users may specify no parameters to list all emulated virtio-fs functions managed by any emulation manager device, or an emulation manager device name to list virtio-fs functions managed by a specific emulation manager device.

Parameter Name	Optional/Mandatory	Type	Description
`manager`	Mandatory	String	Emulation manager device name for creating a new Virtio FS function

8.11.1.3.3.2 virtio_fs_doca_function_create

Create a DOCA virtio FS function. The return value of this method is a VUID. This is not needed for static functions as the VUID can be retrieved from `virtio_fs_doca_get_functions`.

Parameter Name	Optional/Mandatory	Type	Description
`manager`	Mandatory	String	Emulation manager device name for creating a new virtio-fs function

8.11.1.3.3.3 virtio_fs_doca_function_destroy

Destroy a DOCA SNAP Virtio-fs function.

This function should not be associated to any virtio-fs device.

Parameter Name	Optional/Mandatory	Type	Description
`manager`	Mandatory	String	Emulation manager device name for destroying a virtio-fs function
`vuid`	Mandatory	String	VUID of the function to destroy

8.11.1.3.3.4 virtio_fs_doca_device_hotplug

Hot plug a DOCA SNAP Virtio-fs device. The virtio-fs device must be started.

Parameter Name	Optional/ Mandatory	Type	Description
`dev_name`	Mandatory	String	Virtio-fs device name to hot plug
`wait-for-done`	Optional	Flag	If used, the method waits until the device is visible by the host PCIe subsystem. Otherwise, only issue hot-plug operation and exit.

8.11.1.3.3.5 virtio_fs_doca_device_hotunplug

Hot unplug a DOCA virtio FS device. The virtio FS device must be started.

Parameter Name	Optional/ Mandatory	Type	Description
`dev_name`	Mandatory	String	Virtio-fs device name to hot unplug
`wait-for-done`	Optional	Flag	If exists, the method waits until the device is non-visible by the host PCIe subsystem. Otherwise, only issue hot-unplug operation and exit.

8.11.1.3.4 SPDK Fsdev Management

DOCA SNAP Virtio-fs uses the SPDK file system (fsdev) device framework as a backend for its virtio-fs controllers. Therefore, an SPDK fsdev must created and configured in advance.

Although the SPDK fsdev framework is generic and allows different types of the backend file system devices to be implemented. Currently, the only available backend devices are AIO and NFS.

8.11.1.3.4.1 fsdev_get_fsdevs

Get information about the SPDK filesystem devices (fsdevs). The user may specify no parameters to list all filesystem devices, or a filesystem device may be specified by name.

Parameter Name	Optional/Mandatory	Type	Description
`name`	Optional	string	Name of the fsdev of interest

8.11.1.3.4.2 fsdev_get_iostat

Get I/O statistics of filesystem devices (fsdevs).

Parameter Name	Optional/Mandatory	Type	Description
`name`	Optional	string	Fsdev name
`per_channel`	Optional	bool	Display per channel data.

If `name` is not specified, the RPC shows stats for all filesystem devices. If `per_channel` is not specified, the RPC shows the cumulative per-fsdev stat.

8.11.1.3.4.3 fsdev_reset_iostat

Reset I/O statistics of filesystem devices (fsdevs).

Parameter Name	Optional/Mandatory	Type	Description
`name`	Optional	string	Fsdev name

If `name` is not specified, the RPC resets the stats for all filesystem devices.

8.11.1.3.4.4 fsdev_aio_set_options

Set SPDK AIO fsdev module options. This method can be executed only in SPDK STARTUP state, i.e. it requires the service to be started with `--wait-for-rpc` CLI parameter.

Parameter Name	Optional/Mandatory	Type	Description
`max_io_depth`	Optional	int	Maximum I/O depth per channel
`enable_io_uring`	Optional	Flag	`true` to enable IO uring

8.11.1.3.4.5 fsdev_aio_create

Create an SPDK AIO fsdev. This is the file system device that provides passthrough access to a local folder using either the Linux-native async I/O or POSIX async I/O. It can also use Linux io_uring APIs for read and write operations. IO uring is disabled by default and can be enabled with `fsdev_aio_set_options` RPC.

AIO fsdev IO uring implementation requires a compatible kernel version and is only supported with Ubuntu 24.04 and above.

Parameter Name	Optional/ Mandatory	Type	Default	Description
`name`	Mandatory	string		Name of the AIO fsdev to create
`root_path`	Mandatory	string		Path on the system directory to be exposed as an SPDK filesystem
`enable-xattr`	Optional	bool	`false`	Enable extended attributes if set to `true`
`enable-writeback-cache`	Optional	bool	`false`	Enable the writeback cache if set to `true`
`max-xfer-size`	Optional	int	`0x00020000`	Max data transfer size in bytes
`max-readahead`	Optional	int	`0x00020000`	Max readahead size in bytes
`skip-rw`	Optional	bool	`false`	Enable skipping read/write IOs if set to `true` ⚠ For debug purposes only.
`enable-notifications`	Optional	bool	`false`	Enable notifications if set to `true` ⚠ `fsdev_aio` relies on the Linux fanotify API to implement event notifications and therefore inherits all its limitations. For instance, notifications are not supported on filesystems that report a zero FSID, such as FUSE and NFS. For a complete list of limitations and behaviors, refer to the official fanotify documentation.
`attr-valid-ms`	Optional	int	`0`	File attribute validity time in milliseconds. Used for entry cache. A value of `0` disables entry caching entirely.

⚠ When using an `aio` fsdev backed by a Linux kernel NFS mount, certain file operations may result in 'silly-renamed' files (prefixed with `.nfs`) that are not automatically removed. These files can only be cleared by dropping caches on the host: `echo 3 > /proc/sys/vm/drop_caches`.

8.11.1.3.4.6 fsdev_aio_delete

Delete an AIO fsdev.

Parameter Name	Optional/Mandatory	Type	Description
`name`	Mandatory	string	Name of the AIO fsdev to delete

8.11.1.3.4.7 fsdev_nfs_set_options

Set SPDK NFS fsdev module options. This method can be executed only in SPDK STARTUP state (i.e., it requires the service to be started with `--wait-for-rpc` CLI parameter).

Parameter Name	Optional/Mandatory	Type	Description
`min_srcport`	Optional	int	Minimum source TCP port number
`max_srcport`	Optional	int	Maximum source TCP port number
`max_fobjects`	Optional	int	Maximum number of file objects allowed across all NFS fsdevs (default: 13M)

> **TCP Source Port Configuration**
>
> Defining the minimum and maximum source TCP port numbers is important depending on your specific NFS target:
>
> - Required: If the NFS target strictly accepts TCP connections from reserved privileged ports (0-1023). Keep in mind that MOUNT connections always use TCP, even when operating over NFS RDMA.
> - Recommended: For NFS TCP targets that require replayed requests to originate from the exact same TCP source port during recovery scenarios.

8.11.1.3.4.8 fsdev_nfs_create

Create an SPDK NFS fsdev:

Parameter Name	Optional/Mandatory	Type	Description
`name`	Mandatory	string	Name of the NFS fsdev to create
`server`	Mandatory	string	NFS server's IP
`exportname`	Mandatory	string	NFS export's name
`nfsport`	Optional	int	Use this port for NFS instead of using the portmapper
`protocol`	Optional	string	`tcp` (default) or `rdma`
`max_fobjects`	Optional	int	Maximum number of file objects (default: 100K)

> Only NFSv3 is supported.

> **NFS Target Port Configuration**

To establish a successful connection, the NFS `fsdev` requires one of the following two port configurations:

- Allow non-privileged ports (target-side) – The NFS server must be configured to accept connections from non-privileged TCP ports. On Linux kernel NFS targets, you can enable this by adding the `insecure` flag to your export options.
- Enforce privileged ports (client-side) – You can configure the `fsdev` itself to use privileged local ports. To enforce this, specify the exact port range using the `min-srcport` and `max-srcport` parameters within the `fsdev_nfs_set_options` RPC.

FUSE Notifications and File Object Limits

To actively manage capacity, NFS `fsdev` uses FUSE notifications. Whenever the size of the file object map exceeds 80% of the defined `max_fobjects` limit, these notifications automatically trigger the host to "forget" (evict) older file objects.

Maximum NFS fsdev Capacity

The system supports a maximum of 66 NFS `fsdev` instances. Keep in mind that reaching this maximum concurrently depends heavily on your underlying storage performance; you may need to distribute these instances across multiple NFS servers to avoid bottlenecks.

Connection Timeouts with NFS RDMA at Scale

When operating at higher scales (e.g., attaching multiple hotplug PFs or VFs), the Linux Kernel NFS RDMA server may establish incoming connections slowly, which can result in timeouts. To prevent this, add a staggered delay between mounting different hotplug PFs on the host. A 5-second delay is typically sufficient, though you may need to adjust this depending on your specific NFS server's performance and load.

Device Recovery Time

Recovery of 10 virtio-fs/NFS fsdev devices can take up to 20 seconds, with additional devices further increasing recovery time.

8.11.1.3.4.9 fsdev_nfs_delete

Delete an NFS fsdev.

Parameter Name	Optional/Mandatory	Type	Description
`name`	Mandatory	string	Name of the NFS fsdev to delete

8.11.1.3.5 Virtio-fs Emulation Management

Virtio-fs emulation is a protocol belonging to the virtio family of devices. These mount points are found in virtual environments yet by design look like physical mount points to the user within the virtual machine. Each virtio-fs mount point (e.g., virtio-fs PCIe entry) exposed to the host, whether it is PF or VF, must be backed by a virtio-fs controller.

> ⚠ Probing a virtio-fs driver on the host without an already functioning virtio-fs controller may cause the host to hang until such controller is opened successfully (no timeout mechanism exists).

8.11.1.3.5.1 virtio_fs_transport_create

Create a virtio-fs transport. This RPC includes all the common parameters/options for all transports. The transport becomes operational once it is started.

Parameter Name	Optional/Mandatory	Type	Description
`transport_name`	Mandatory	String	Transport type name. For DOCA SNAP Virtio-fs, `transport_name` should be DOCA.

8.11.1.3.5.2 virtio_fs_transport_destroy

Destroy a virtio-fs transport.

> ⚠ The transport must be stopped for destruction.

Parameter Name	Optional/Mandatory	Type	Description
`transport_name`	Mandatory	String	Transport type name. For DOCA SNAP Virtio-fs, `transport_name` should be DOCA.

8.11.1.3.5.3 virtio_fs_transport_start

Start a virtio-fs transport. This RPC finalizes the transport configuration. From this point, the transport is fully operational and can be used to create new devices.

Parameter Name	Optional/Mandatory	Type	Description
`transport_name`	Mandatory	String	Transport type name. For DOCA SNAP Virtio-fs, `transport_name` should be DOCA.

8.11.1.3.5.4 virtio_fs_transport_stop

Stop a virtio-fs transport. This RPC makes the transport configurable again.

> ⚠ A transport cannot be stopped if any devices are associated to it.

Parameter Name	Optional/Mandatory	Type	Description
`transport_name`	Mandatory	String	Transport type name. For DOCA SNAP Virtio-fs, `transport_name` should be DOCA.

8.11.1.3.5.5 virtio_fs_get_transports

Display virtio-fs transports or requested transport.

Parameter Name	Optional/Mandatory	Type	Description
`transport_name`	Optional	String	Transport type name. For DOCA SNAP Virtio-fs, `transport_name` should be DOCA.

8.11.1.3.5.6 virtio_fs_device_create

Create a virtio-fs device. This RPC creates a device with common parameters which are acceptable to all the transport types. To configure transport-specific parameters, users should use the `virtio_fs_doca_device_modify` command. The device becomes operational once it is started.

Parameter Name	Optional/Mandatory	Type	Description
`transport_name`	Mandatory	String	Transport type name. For DOCA SNAP Virtio-fs, `transport_name` should be DOCA.
`dev_name`	Mandatory	String	Virtio-fs device name to use
`tag`	Optional	String	Virtio-fs tag according to the virtio specification. ⚠ Must be provided during the `virtio_fs_device_create` RPC before the `virtio_fs_device_start` RPC.
`num_request_queues`	Optional	Number	Virtio-fs `num_request_queues` according to the virtio specification (default 31, range 1-254)

Parameter Name	Optional / Mandatory	Type	Description
`queue_size`	Optional	Number	The maximal queue size for all virtio queues (default 64; range 8-256) ⚠ The maximum supported I/O size is influenced by the `queue_size` value. Each virtio descriptor maps to a 4KB region of host memory, and each queue entry references one descriptor. For example, a 128KB I/O request requires 32 descriptors (one per 4KB block). If `queue_size` is set to 16, the queue cannot accommodate the full I/O in a single operation. In such cases, the host driver splits the I/O into smaller segments to fit within the available queue entries.
`fsdev`	Optional	String	The name of the SPDK filesystem backend device ⚠ Must be provided during the `virtio_fs_device_create` RPC before the `virtio_fs_device_start` RPC. ⚠ RPC does not verify if fsdev is valid. If a wrong fsdev is attached to the device, the user would experience failure during mount of the FS on the host.
`packed_vq`	Optional	Bool	Expose packed virtqueues feature to the driver for negotiation.
`driver_platform`	Optional	String	Set the driver's platform architecture. Possible values: `native`; `x86`; `x86_64`; `aarch32`; `aarch64`. Using the `native` platform option sets the driver platform to be identical to the device platform.
`notification_vq`	Optional	Bool	Expose notification virtqueue feature to the driver for negotiation

8.11.1.3.5.7 virtio_fs_device_start

Start a virtio-fs device. This RPC finalizes the device configuration. From this point, the transport is fully operational.

Parameter Name	Optional/Mandatory	Type	Description
`dev_name`	Mandatory	String	Virtio-fs device name

8.11.1.3.5.8 virtio_fs_device_stop

Stop a virtio-fs device.

Parameter Name	Optional/Mandatory	Type	Description
`dev_name`	Mandatory	String	Virtio-fs device name

> ⚠ The RPCs `virtio_fs_device_stop` and `virtio_fs_device_start` are supported during traffic. The user can stop the device while traffic is ongoing using `virtio_fs_device_stop`, then restart it using `virtio_fs_device_start`, and the device would continue handling I/O without any errors.

> ⚠ If the RPC returns an ETIMEDOUT (-110) error, the user is expected to retry the RPC.

8.11.1.3.5.9 virtio_fs_device_destroy

Destroy a virtio-fs device.

> ⚠ The device must be stopped before destruction.

Parameter Name	Optional/Mandatory	Type	Description
`dev_name`	Mandatory	String	Virtio-fs device name

8.11.1.3.5.10 virtio_fs_device_modify

Modify a virtio-fs device. This RPC is used to modify/set common properties of the device which are acceptable to all the transports.

Parameter Name	Optional/ Mandatory	Type	Description
`dev_name`	Mandatory	String	Virtio-fs device name to use
`tag`	Optional	String	Virtio-fs tag according to the virtio specification ⚠ Must be provided during `virtio_fs_device_create` or `virtio_fs_device_modify` RPCs, before `virtio_fs_device_start` RPC.
`num_request_queues`	Optional	Number	Virtio-fs `num_request_queues` according to the virtio specification (default 31; range 1-254)
`queue_size`	Optional	Number	The maximal queue size for all virtio queues (default 64; range 8-256)

Parameter Name	Optional/ Mandatory	Type	Description
`fsdev`	Optional	String	The name of the SPDK filesystem backend device ⚠ Must be provided during `virtio_fs_device_create` or `virtio_fs_device_modify` RPCs, before `virtio_fs_device_start` RPC. ⚠ RPC does not verify if fsdev is valid. If a wrong fsdev is attached to the device, the user would experience failure during mount of the FS on the host.
`packed_vq`	Optional	Bool	Expose packed virtqueues feature to the driver for negotiation
`driver_platform`	Optional	String	Set the driver's platform architecture. Possible values: `native`; `x86`; `x86_64`; `aarch32`; `aarch64`. Using the `native` platform option sets the driver platform to be identical to the device platform.

8.11.1.3.5.11 virtio_fs_get_devices

Display virtio-fs devices with their characteristics.

- The user may specify no parameters to list the virtio-fs devices associated with all transports
- The user may specify the name of a transport to list the virtio-fs devices associated with it
- The user may specify the name of a virtio-fs device to display its characteristics

Transport name and device name parameters should be mutually exclusive.

Example response:

```
[
  {
    "name": "vfsdev0",
    "transport_name": "DOCA",
    "state": "running",
    "fsdev": "aio0",
    "tag": "doca_pf0",
    "queue_size": 256,
    "num_request_queues": 8,
    "packed_ring": false,
    "notification_vq": false,
    "manager": "mlx5_0",
    "vuid": "MT2306XZ00A7VFSS0D0F2",
    "num_msix": 0,
    "total_vfs": 128,
    "num_vfs": 2,
    "free_msix": 12,
    "free_queues": 138
  },
  {
    "name": "vfsdev0vf0",
    "transport_name": "DOCA",
    "state": "running",
    "fsdev": "aio1",
    "tag": "doca_pf0_vf0",
    "queue_size": 256,
    "num_request_queues": 1,
    "packed_ring": false,
    "notification_vq": false,
    "manager": "mlx5_0",
    "vuid": "MT2306XZ00A7VFSS0D0F2VF1",
    "num_msix": 2
```

```
  },
  {
    "name": "vfsdev0vf1",
    "transport_name": "DOCA",
    "state": "running",
    "fsdev": "aio2",
    "tag": "doca_pf0_vf1",
    "queue_size": 256,
    "num_request_queues": 1,
    "packed_ring": false,
    "notification_vq": false,
    "manager": "mlx5_0",
    "vuid": "MT2306XZ00A7VFSS0D0F2VF2",
    "num_msix": 2
  }]
```

Parameter Name	Optional/Mandatory	Type	Description
`transport_name`	Optional	String	Name of transport whose associated virtio-fs devices to list
`dev_name`	Optional	String	Virtio-fs device name

8.11.1.3.5.12 virtio_fs_doca_device_modify

Modify a virtio-fs device created from DOCA transport.

> ⚠ Validation of params is not done. If an invalid param is set, `virtio_fs_device_start` RPC fails.

> ℹ This RPC is for configuring DOCA target specific parameters.

Parameter Name	Optional/Mandatory	Type	Description
`dev-name`	Mandatory	String	Virtio-fs device name
`manager`	Optional (must be provided before start)	String	Emulation manager
`vuid`	Optional (must be provided before start)	String	Vendor unique identifier
`num-msix`	Optional	Number	Total number of MSI-X vectors allocated for the device. • For hotplug devices: If unspecified, the system assigns a default value of 2. • For VFs: This parameter can only be modified if the parent PF was explicitly configured with the `reset_dynamic_resources` flag (enabling dynamic resource allocation).
`reset-dynamic-resources`	Optional	Flag	Reset all the dynamic resources (e.g MSIX/DB/VQs) allocated for VFs. Only valid PF device that supports SR-IOV.

8.11.1.3.5.13 virtio_fs_device_get_stat

Displays stats for a specified `virtio-fs` device, or for all devices if none is specified.

Parameter Name	Optional/ Mandatory	Type	Description
`dev_name`	Optional	String	Virtio-fs device name ⚠ The statistics of a virtio-fs device are valid only when the device is in "started" state.

⚠ This RPC command cannot be executed in parallel. Only one instance of the command can run at a time.

Example response:

```
{
jsonrpc": "2.0",
  "id": 1,
  "result": {
      "devices": [
        {
          "name": "vfsdev0",
          "fsdev": "aio0",
          "state": "running",
          "transport_name": "DOCA",
          "transport_specific": {
            "queues": [
              {
                "queue_id": 0,
                "queue_enabled": 1,
                "queue_depth": 256,
                "queue_inflights": 0,
                "hw_available_index": 8,
                "driver_available_index": 8,
                "hw_used_index": 8,
                "driver_used_index": 8
              },
              {
                "queue_id": 1,
                "queue_enabled": 1,
                "queue_depth": 256,
                "queue_inflights": 0,
                "hw_available_index": 104,
                "driver_available_index": 104,
                "hw_used_index": 104,
                "driver_used_index": 104
              }
            ]
          }
        }
      ]
    }
}
```

8.11.1.3.6 Configuration Example

8.11.1.3.6.1 Static Function - Bring up

The following is an example of creating virtio-fs DOCA transport and associating it to a virtio-fs device using a static physical function.

- In BlueField:
    a. Create an AIO fsdev backend:

```
spdk_rpc.py fsdev_aio_create aio0 /etc/virtiofs
```

    b. List possible emulation managers:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_get_possible_managers
```

    c. Create DOCA transport, emulation manager and start transport:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_transport_create -t DOCA
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_manager_create -m mlx5_0
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_transport_start -t DOCA
```

    d. Get transport information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_get_transports
```

    e. Get managers information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_get_managers
```

    f. Get function information, including their VUIDs:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_get_functions
```

    g. Create the virtio-fs device associated with DOCA transport:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_create --transport-name DOCA --dev-name
vfsdev0 --tag docatag --fsdev aio0 --num-request-queues 8 --queue-size 256 --driver-platform x86_64
```

    h. Set and modify virtio-fs parameters (VUID must be provided before calling `virtio_fs_device_start` RPC):

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_device_modify --dev-name vfsdev0 --manager
mlx5_0 --vuid MT2333XZ0VJQVFSS0D0F2
```

    i. Start the virtio-fs device:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_start --dev-name vfsdev0
```

    j. Get device information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_get_devices
```

- In VM/host:
    - To mount a device with the tag `docatag` and load `virtio_pci` driver if not loaded:

```
mkdir "/tmp/test"
modprobe -v virtiofs
mount -t virtiofs docatag /tmp/test
```

8.11.1.3.6.2 Static Function - Teardown

- In BlueField:
  a. Get device information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_get_devices
```

  b. Stop and destroy the virtio-fs device:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_stop --dev-name vfsdev0
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_destroy --dev-name vfsdev0
```

  c. Stop the DOCA transport and destroy emulation manager and transport:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_transport_stop -t DOCA
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_manager_destroy -m mlx5_0
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_transport_destroy -t DOCA
```

- In VM/host:
  - To unmount the device:

```
umount /tmp/test
modprobe -rv virtiofs
```

8.11.1.3.6.3 Hotplug Function

The following is an example of creating virtio-fs DOCA transport, creating a virtio-fs function, associating it to a virtio-fs device, and hot-plugging it:

- In BlueField:
  a. Create AIO fsdev backend:

```
spdk_rpc.py fsdev_aio_create aio0 /etc/virtiofs
```

  b. List possible emulation managers:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_get_possible_managers
```

  c. Create the DOCA transport and emulation manager and start the transport:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_transport_create -t DOCA
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_manager_create -m mlx5_0
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_transport_start -t DOCA
```

  d. Get transport information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_get_transports
```

  e. Get managers information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_get_managers
```

  Some managers would show hotplug capability.
  f. Get functions information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_get_functions
```

g. Create virtio-fs function:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_function_create --manager mlx5_0
```

Returns VUID `MT2333XZ0VJQVFSS0D0F2`.

h. Get functions information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_get_functions
```

Returns the function that has been created with the appropriate VUID.

i. Create the virtio-fs device associated with DOCA transport:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_create --transport-name DOCA --dev-name
vfsdev0 --tag docatag --fsdev aio0 --num-request-queues 8 --queue-size 256 --driver-platform x86_64
```

j. Set and modify virtio-fs parameters:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_device_modify --dev-name vfsdev0 --manager
mlx5_0 --vuid MT2333XZ0VJQVFSS0D0F2
```

The VUID must be provided before calling the `virtio_fs_device_start` RPC.

k. Start the virtio FS device:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_start --dev-name vfsdev0
```

l. Get device information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_get_devices
```

The output for `vfsdev0` would show it is not yet plugged.

m. Hot plug the DOCA device to the host and wait until it becomes visible by the host:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_device_hotplug --dev-name vfsdev0 --
wait-for-done
```

- In VM/host:
  - To mount a device with the tag `docatag` and load `virtio_pci` driver if not loaded:

```
mkdir "/tmp/test"
modprobe -v virtiofs
mount -t virtiofs docatag /tmp/test
```

8.11.1.3.6.4 Hot-unplug Function

The following is an example of cleaning up and destroying the flow described under section "Hotplug Function":

- In VM/host:
  - To unmount the device:

```
umount /tmp/test
modprobe -rv virtiofs
```

- In BlueField:
  a. Get device information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_get_devices
```

  b. Hot unplug the DOCA device from the host and wait until it becomes non-visible by the host:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_device_hotunplug --dev-name vfsdev0 --
wait-for-done
```

  c. Get device information:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_get_devices
```

  d. Stop and destroy the virtio-fs DOCA device:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_stop --dev-name vfsdev0
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_destroy --dev-name vfsdev0
```

  e. Destroy the virtio-fs function:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_function_destroy --manager mlx5_0 --vuid
MT2333XZ0VJQVFSS0D0F2
```

Stop the DOCA transport and destroy the emulation manager and transport:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_transport_stop -t DOCA
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_manager_destroy -m mlx5_0
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_transport_destroy -t DOCA
```

8.11.1.4 RPC Log History

> Supported from SPDK version `spdk23.01.2-12` and above.

RPC log history (enabled by default) records all RPC requests and their responses in `/var/log/virtiofs/rpc-log`. This file is also available outside the container at `/var/log/snap-log/rpc-log` on the DPU.

The file is continuously updated in append mode. Monitor its size, and delete it before launching the SNAP pod if it becomes too large.

8.11.1.5 Saving and Loading Configuration

To recover and reuse configurations for virtio-fs, you can save the desired configuration and load it later using a saved configuration file. This process allows for quick recovery and ensures consistent device/application setup.

To save the configuration of virtio-fs devices:

1. Use RPCs to configure your virtio-fs device/application as needed.
2. Save the configuration after each configuration cycle using the `save_config` RPC. This creates a JSON configuration file for future use:

```
spdk_rpc.py save_config -o <json_config>.json
```

To initiate a configuration cycle, create a new configuration file using the same format as `spdk_rpc_init.conf` files:

```
cat <new_config>.conf | spdk_rpc.py
```

The last line of the `<new_config>.conf` file must include a call to save the RPC configuration. Example:

```
--plugin rpc_virtio_fs_tgt -v fsdev_aio_create aio0 /tmp/fsdev-test
--plugin rpc_virtio_fs_tgt -v virtio_fs_transport_create -t DOCA
--plugin rpc_virtio_fs_tgt -v virtio_fs_transport_start -t DOCA
--plugin rpc_virtio_fs_tgt -v virtio_fs_device_create --transport-name DOCA --dev-name vfsdev0 --tag
docatest --fsdev aio0 --num-request-queues 1 --queue-size 256 --driver-platform x86_64
--plugin rpc_virtio_fs_tgt -v virtio_fs_doca_device_modify --dev-name vfsdev0 --manager mlx5_0 --vuid
MT2306XZ00HKVFSS0D0F4
--plugin rpc_virtio_fs_tgt -v virtio_fs_device_start --dev-name vfsdev0
save_config -o <json_config>.json
```

Saving configuration at the end of the script ensures the configuration is saved only after all the script changes are successfully applied.

To load a saved configuration for virtio-fs, use the following methods based on your environment:

- When using virtio-fs from a container, set the following in the YAML configuration file:

```
SPDK_RPC_INIT_CONF_JSON: <json_config>.json
```

- When using virtio-fs from source, re-run the DOCA SNAP Virtio-fs application, recovering the configuration from the saved file:

```
/opt/nvidia/spdk-subsystem/src/virtio-fs-target/app/virtio_fs_tgt -c <json_config>.json --json-ignore-init-
errors
```

When modifying controller or function configurations, ensure the host driver remains unloaded until the configuration change is fully applied. If the driver loads before completion, the system may fail to recover from a partial or interrupted configuration.

When using `SPDK_RPC_INIT_CONF_JSON`, disable other initialization methods such as `SPDK_RPC_INIT_CONF` to avoid conflicts.

Hotplugged emulation functions persist across process restarts (but not BlueField resets). These functions should be configured once during the process's initial setup. Only controllers created on these functions are saved in the configuration state.

The `--reset_dynamic_resources` parameter is not persisted in the PF device configuration file. Therefore, after a system reboot, you must explicitly re-apply this flag using the `virtio_fs_doca_device_modify` RPC. Failure to do so restricts the VF `num_msix` setting to the maximum value defined by `VIRTIO_FS_EMULATION_NUM_VF_MSIX` in `mlxconfig`.

8.11.1.6 Disabling/enabling SPDK Subsystem

Virtio-fs is defined as an SPDK subsystem and can be disabled or enabled as required.

The Virtio-fs subsystem is enabled by default. To disable it:

1. Start the Virtio-fs application in a waiting state for RPC commands:

```
/opt/nvidia/spdk-subsystem/src/virtio-fs-target/app/virtio_fs_tgt --wait-for-rpc
```

2. Use the following RPC command to disable the `virtio_fs` subsystem:

```
spdk_rpc.py framework_disable_subsystem  virtio_fs
```

3. Restart the SPDK framework initialization:

```
spdk_rpc.py framework_start_init
```

To view the status of all subsystems:

```
spdk_rpc.py framework_get_subsystems
```

This subsystem configuration can be saved in SPDK configuration for future use with the command `spdk_rpc.py save_config`. This ensures the configuration persists across application restarts.

8.11.1.7 SR-IOV

SR-IOV configuration depends on the kernel version and must be handled carefully to ensure device visibility and system stability across both the hypervisor and DPU orchestrators.

8.11.1.7.1 General Setup Procedure

To ensure a safe and stable SR-IOV setup, follow these steps in order:

8.11.1.7.1.1 Step 1: Preconfigure VF Controllers (DPU Side)

Before configuring SR-IOV on the host, ensure that the DPU is properly configured with all required VF devices created and started.

- Verify Visibility: VF functions are always visible and configurable on the DPU side. Verify the current state:

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_get_functions
```

- Lock-in: Once host-side configuration begins, further modifications to these resources may not be possible.

8.11.1.7.1.2 Step 2: Disable Autoprobing

In deployments with many virtual devices (large-scale), autoprobing must be disabled to ensure stable device discovery. Failing to do so may result in incomplete device visibility, system hangs during initialization, or unreliable behavior (specifically with >100 VFs).

Configuration:

```
# Recommended for large-scale deployments
echo 0 > /sys/bus/pci/devices/<BDF>/sriov_drivers_autoprobe
```

8.11.1.7.1.3 Step 3: Configure SR-IOV (Host Side)

Enable the Virtual Functions on the host. Note that hot-plugged PFs do not support SR-IOV.

- Small-scale deployments (<100 VFs):

```
echo <number_of_vfs> > /sys/bus/pci/devices/<BDF>/sriov_totalvfs
```

- Newer drivers:

```
echo <number_of_vfs> > /sys/bus/pci/devices/<BDF>/sriov_numvfs
```

8.11.1.7.2 Dynamic MSI-X and Queue Management

Message Signaled Interrupts eXtended (MSI-X) provides efficient interrupt handling for high-performance devices. By default, BlueField distributes MSI-X vectors evenly between all virtual PCIe functions (VFs). However, this is often suboptimal for heterogeneous environments where different VMs require different resource footprints.

Dynamic MSI-X Management allows users to manually control the number of MSI-X vectors provided per VF independently.

8.11.1.7.2.1 Behavior & Persistence

Once configured, the MSI-X link to the VFs remains persistent. Configuration changes only when:

1. The PF explicitly reclaims all VF MSI-X vectors back to the pool (after VF destruction).
2. An Arm reboot (FE reset/cold boot) occurs.

> ⚠ Application restarts, crashes, or closing/reopening PFs without dynamic MSI-X support will not change the configuration.

8.11.1.7.2.2 Configuration Workflow

1. Reset Resources to Free Pool: After creating a `virtio-fs` PF device, reclaim all MSI-X vectors from the VFs into the PF's free pool.

```
spdk_rpc.py --plugin --plugin rpc_virtio_fs_tgt -v virtio_fs_device_create \
  --transport_name DOCA \
  --dev_name vfsdev0 \
  --tag doca_test \
  --fsdev aio0 \
  --num_request_queues 1 \
  --queue_size 256 \
  --driver_platform x86_64

spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_device_modify \
  --dev_name <PF_DEV_NAME> \
  --manager mlx5_0 \
  --vuid <PF_DEV_VUID> \
  --reset_dynamic_resources

spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_start --dev-name vfsdev0
```

   - *Prerequisite:* No VF devices can be open on the host.
2. Assess Available Resources: Query the controller list to determine the constraints for the PF (`free_msix` and `free_queues`).

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_get_devices
```

3. Create VF with Specific Allocation: Distribute MSI-X and queues to the VF during creation.
    a. Create the device with specific queues.

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_create \
  --transport_name DOCA \
  --dev_name vfsdev0vf1 \
  --tag doca_test_vf \
  --fsdev aio1 \
  --num_request_queues 4 \
  --queue_size 128 \
  --driver_platform x86_64
```

    b. Modify the device to assign MSI-X vectors.

```
Modify the device to assign MSI-X vectors
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_device_modify \
  --dev_name vfsdev0vf1 \
  --manager mlx5_0 \
  --vuid <VF_DEV_VUID> \
  --num_msix 8
```

    c. Start the device.

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_start --dev-name vfsdev0vf1
```

    > ⚠ MSI-X vectors are allocated per virtqueue. A safe calculation for the required MSI-X count is:
    >
    > (?) $$MSIX_{total} = N_{queues} + 3$$
    >
    > 1 for BAR config + 1 for high priority queue + 1 for notification queue.

4. VF Teardown and Reclamation: When destroying a VF, you may choose to release its resources back to the global pool. This can only be done once all VFs are destroyed and the PF device is stopped.
    a. Destroy the VF.

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_destroy --dev_name vfsdev0vf1
```

    At this point all VF devices are destroyed.
    b. Stop PF device.

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_device_stop --dev-name <PF_DEV_NAME>
```

    c. Reclaim resources.

```
spdk_rpc.py --plugin rpc_virtio_fs_tgt -v virtio_fs_doca_device_modify \
  --dev_name <PF_DEV_NAME> \
  --manager mlx5_0 \
  --vuid <PF_DEV_VUID> \
  --reset_dynamic_resources
```

5. Enable on Host: Finally, enable SR-IOV on the host driver.

```
echo <N> > /sys/bus/pci/devices/<BDF>/sriov_numvfs
```

It is strongly recommended to open all VF controllers in SNAP before binding VFs to the host or guest driver.

- If you bind VFs to the driver before configuration is complete, the driver may attempt to use resources that are not yet allocated.
- This can lead to a host deadlock that is only recoverable via a cold boot. Configuring in SNAP first ensures the process remains reversible if you encounter insufficient resource errors.

8.11.1.8 NFS/TCP XLIO

XLIO is a high-performance user-space TCP stack that offloads traffic handling from the kernel to achieve significant throughput improvements. NFS over TCP leverages XLIO to deliver enhanced performance, utilizing an XLIO socket module integrated directly into SPDK.

The minimum supported version of `libxlio` is 3.60.4.

8.11.1.8.1 Configuration and Resource Management

XLIO is enabled by default in the container.

8.11.1.8.1.1 Memory Implications

Because XLIO consumes additional memory, you may wish to disable it in non-TCP configurations to conserve resources.

If XLIO is disabled, the required hugepage allocation for the default configuration can be decreased to 4GiB.

8.11.1.8.1.2 Disabling XLIO

To disable XLIO, set the `XLIO_ENABLED` environment variable to `"0"` within the `doca_vfs.yaml` configuration file:

```
env:
  - name: XLIO_ENABLED
    value: "0"
```

8.11.1.9 Appendix – NVIDIA GPUDirect Storage (GDS) Support in VirtioFS

NVIDIA GPUDirect Storage (GDS) is a technology that enables direct data transfer between storage devices and NVIDIA GPUs. By bypassing the CPU and system memory, GDS significantly reduces data transfer latency and improves bandwidth efficiency for I/O-intensive applications. GDS is particularly beneficial for workloads such as deep learning, high-performance computing (HPC), and large-scale data analytics.

See Getting Started with NVIDIA GPUDirect Storage for more information.

8.11.1.9.1 Prerequisites

Make sure the following are available:

- NVIDIA GPU with GPUDirect storage support (via P2P DMA)
- Linux kernel with `CONFIG_PCI_P2PDMA` enabled.
- NVIDIA-optimized virtio-fs drivers. Refer to Virtio-fs DOCA Host Drive Installation (Optional).
- NVIDIA CUDA repository (**version 13.1 or above**). Refer to the CUDA Installation Guide.
- Installed NVIDIA GPU drivers. Refer to the NVIDIA GPUDirect Storage Troubleshooting Guide for additional details.
- Properly configured virtio-fs target

8.11.1.9.2 Enabling GDS Support in Virtio-fs

1. Configure the system for GDS support:
   a. Enable PCIe peer-to-peer DMA in `libcufile`:

```
// Edit /usr/local/cuda/gds/cufile.json:

// Enable use_pci_p2pdma property
"properties": {
  ...
  "use_pci_p2pdma": true
  ...
}

// Add "virtiofs" and enable use_pci_p2pdma for it under "fs"
"fs": {
   ...
   "virtiofs": { "use_pci_p2pdma": true },
   ...
 }
```

   b. Configure NVIDIA driver parameters – Create a modprobe configuration file to enable the required parameters for the NVIDIA driver:

```
echo 'options nvidia
NVreg_RegistryDwords="RMForceStaticBar1=1;RmForceDisableIomapWC=1;FORCE_P2P=1"' | sudo tee /etc/
modprobe.d/nvidia-gds.conf
```

c. Configure kernel boot parameters – Edit the `GRUB_CMDLINE_LINUX_DEFAULT` variable in `/etc/default/grub` to add:
   - `nokaslr` to disable Kernel Address Space Layout Randomization.
   - Depending on your CPU:
     - For AMD CPUs: `amd_iommu=off`
     - For Intel CPUs: `intel_iommu=off`

```
#For example:
GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 nokaslr intel_iommu=off"
#After saving the file, update GRUB:
sudo update-grub
```

Then, reboot your system for the changes to take effect.

2. Verify system compatibility:
   a. After rebooting, run the following command to check for GDS support:

```
/usr/local/cuda/gds/tools/gdscheck.py -p | grep -e VIRTIOFS -e properties.use_pci  -e virtiofs.use_
```

You should see an output similar to:

```
VIRTIOFS           : p2pdma, compat
 properties.use_pci_p2pdma : true
 fs.virtiofs.use_pci_p2pdma : true
```

3. Mount the virtio-fs drive with GDS:
   a. To enable GDS workloads on your virtio-fs drive, mount it with the `gds` option.

```
sudo mount -t virtiofs -o gds <tagname> /mnt/vfs/
```

   b. Replace `<tagname>` with the appropriate identifier for your setup. Once mounted, test GDS performance using the `gdsio` tool:

```
/usr/local/cuda/gds/tools/gdsio -T 1 -D /mnt/vfs/ -d0 -I1 -s10m -i1m -w1 -x0
```

This command outputs performance metrics and generates a `cufile.log` in the current working directory. Check the log for any errors or issues.

8.11.1.10 Appendix – BlueField Firmware Configuration

Before configuring DOCA SNAP Virtio-fs, the user must ensure that all firmware configuration requirements are met. By default, virtio-fs is disabled and must be enabled by running both common DOCA SNAP Virtio-fs configurations and additional protocol-specific configurations depending on the expected usage of the application (e.g., hot-plug, SR-IOV, UEFI boot, etc).

After configuration is finished, the host must be power cycled for the changes to take effect.

To verify that all configuration requirements are satisfied, users may query the current/next configuration by running the following:

```
mlxconfig -d /dev/mst/mt41692_pciconf0 -e query
```

8.11.1.10.1 System Configuration Parameters

Parameter	Description	Possible Values
`INTERNAL_CPU_MODEL`	Enable BlueField to work in internal CPU model Must be set to `1` for storage emulations.	0/1
`PCI_SWITCH_EMULATION_ENABLE`	Enable PCIe switch for emulated PFs	0/1
`PCI_SWITCH_EMULATION_NUM_PORT`	The maximum number of hotplug emulated PFs which equals `PCI_SWITCH_EMULATION_NUM_PORT` minus 1. For example, if `PCI_SWITCH_EMULATION_NUM_PORT=32`, then the maximum number of hotplug emulated PFs would be 31. One switch port is reserved for all static PFs.	[0-32]

8.11.1.10.2 RDMA/RoCE Configuration

BlueField's RDMA/RoCE communication is blocked for BlueField's default OS interfaces (nameds ECPFs, typically mlx5_0 and mlx5_1). If RoCE traffic is required, additional network functions (scalable functions) must be added which support RDMA/RoCE traffic.

The following is not required when working over TCP or even RDMA/IB.

To enable RoCE interfaces, run the following from within the BlueField device:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PER_PF_NUM_SF=1
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0.1 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
```

8.11.1.10.3 Virtio-fs Configuration

Before configuring Virtio-fs emulation, ensure the following prerequisites are met:

- A reliable communication channel (e.g., RShim, serial) is available for accessing the Arm subsystem even if the host fails to boot.

  > Refer to NVIDIA BlueField DPU BSP documentation for more details.

- The controller must be created on the static virtio-fs PF using the initial configuration file.

  > For more information, please refer to section "Virtio-fs Emulation Management".

Parameter	Description	Possible Values
`VIRTIO_FS_EMULATION_ENABLE`	Enables virtio-fs device emulation	0/1
`VIRTIO_FS_EMULATION_NUM_PF`	Number of static emulated virtio-fs PFs Misconfiguration may cause the host server OS to fail during boot.	[0-2]
`VIRTIO_FS_EMULATION_NUM_MSIX`	Number of MSI-X vectors assigned to the emulated virtio-fs PFs or VFs I/O queue requires one MSI-X vector. Additional vectors are required if the following features are enabled: • Config interrupt: +1 (enabled by default) • High-priority queue: +1 (enabled by default) • Notification queue: +1 (disabled by default) For example, to support 32 I/O queues: • With notification data disabled, set `MSIX` to 34 • With notification data enabled, set `MSIX` to 35	[0-256]

8.11.1.11 Appendix – Host OS Configuration

With Linux environment on host OS, additional kernel boot parameters may be required to support DOCA SNAP Virtio-fs related features:

- To use PCIe hotplug, `pci=realloc` must be added
- `modprobe.blacklist=virtio_pci,virtiofs` for the virtio-fs driver which is not built-in
- `modprobe.blacklist=virtio_pci` for the `virtio_pci` driver which is not built-in

To view boot parameter values, run:

```
cat /proc/cmdline
```

It is recommended to use the following command with virtio-fs:

```
[dpu] cat /proc/cmdline BOOT_IMAGE … pci=realloc modprobe.blacklist=virtio_pci,virtiofs
```

8.11.1.11.1 Intel Server Performance Optimizations

```
cat /proc/cmdline
BOOT_IMAGE=(hd0,msdos1)/vmlinuz-5.15.0_mlnx root=UUID=91528e6a-b7d3-4e78-9d2e-9d5ad60e8273 ro crashkernel=auto
resume=UUID=06ff0f35-0282-4812-894e-111ae8d76768 rhgb quiet pci=realloc modprobe.blacklist=virtio_pci,virtiofs
```

8.11.1.11.2 AMD Server Performance Optimizations

```
cat /proc/cmdline
cat /proc/cmdline BOOT_IMAGE=(hd0,msdos1)/vmlinuz-5.15.0_mlnx root=UUID=91528e6a-b7d3-4e78-9d2e-9d5ad60e8273 ro
crashkernel=auto resume=UUID=06ff0f35-0282-4812-894e-111ae8d76768 rhgb quiet pci=realloc
modprobe.blacklist=virtio_pci,virtiofs
```

8.11.1.12 Appendix – Custom Fsdev Modules

This section explains how to extend the Virtio-fs service with custom fsdev modules. Two methods are provided:

- Building a new production container (recommended for production)
- Manual build and run inside a development container (ideal for development and testing)

The Dockerfiles and commands provided in this chapter are intended as examples and are designed to work with the external fsdev module example included with SPDK, located at `spdk/test/external_code/fsdev_passthru`. These examples demonstrate the integration process and should be adapted to suit real-world use cases, including adjustments for custom fsdev modules, deployment environments, and specific application requirements.

8.11.1.12.1 Building a New Production Container

This option allows to create a new container that includes both the original service and the custom fsdev module. The resulting container will run Virtio-fs service with custom functionality built-in.

8.11.1.12.1.1 Environment Preparation

> This example uses `/opt/build` as working directory but any other directory can be used.

The working directory should contain the `spdk` sources and the `Dockerfile`.

> See an example of the Dockerfile in the next section.

```
root@bf:/# mkdir -p /opt/build
root@bf:/# cd /opt/build
root@bf:/opt/build# git clone https://github.com/Mellanox/spdk --branch v25.01.1.nvda
root@bf:/opt/build# ll
total 16
drwxr-xr-x  3 root root 4096 Dec  2 14:16 ./
drwxr-xr-x  6 root root 4096 Dec  2 13:30 ../
-rw-r--r--  1 root root  723 Dec  2 14:15 Dockerfile
drwxr-xr-x 37 root root 4096 Dec  2 14:01 spdk/
```

8.11.1.12.1.2 Dockerfile Example

```
FROM nvcr.io/nvstaging/doca/doca_vfs:1.2.0-2-doca2.10.0 as builder

RUN apt-get update && apt-get install -y autoconf libtool python3-pyelftools libaio-dev libncurses-dev libfuse3-dev
patchelf libcmocka-dev make

COPY spdk/test/external_code /external_code

WORKDIR /external_code
ENV SPDK_HEADER_DIR=/opt/nvidia/spdk-subsystem/virtiofs/include
ENV SPDK_LIB_DIR=/opt/nvidia/spdk-subsystem/virtiofs/lib
ENV DPDK_LIB_DIR=/opt/nvidia/spdk-subsystem/virtiofs/include
RUN make fsdev_passthru_shared

FROM nvcr.io/nvstaging/doca/doca_vfs:1.2.0-2-doca2.10.0

COPY --from=builder /external_code/fsdev_passthru/libfsdev_passthru_external.so /opt/nvidia/spdk-subsystem/
virtiofs/lib/
ENV VIRTIOFS_LD_PRELOAD=/opt/nvidia/spdk-subsystem/virtiofs/lib/libfsdev_passthru_external.so

COPY --from=builder /external_code/fsdev_passthru/fsdev_passthru.py /usr/lib/python3/dist-packages/spdk/rpc/
ENV SPDK_RPC_PLUGIN="spdk.rpc.rpc_virtio_fs_tgt:spdk.rpc.fsdev_passthru"
```

8.11.1.12.1.3 Building and Running the Container

1. Build the new container:

   ```
   docker build -t doca_vfs_custom_fsdev:latest -f Dockerfile .
   ```

2. Run the new container with Kubelet service:

   ```
   docker save doca_vfs_custom_fsdev:latest > doca_vfs_custom_fsdev.tar
   ctr -n=k8s.io images import doca_vfs_custom_fsdev.tar

   # Copy doca_vfs.yaml into /etc/kubelet.d/
   # Open doca_vfs.yaml and change "image" section:
       image: doca_vfs_custom_fsdev:latest
   ```

3. To configure running container with custom fsdev module:

   ```
   # DPU
   mkdir /etc/virtiofs/AIO0
   crictl exec $(crictl ps -s running -q --name virtiofs) spdk_rpc.py fsdev_aio_create AIO0 /etc/virtiofs/AIO0
   crictl exec $(crictl ps -s running -q --name virtiofs) spdk_rpc.py fsdev_passthru_ext_create --name
   CUSTOM_FSDEV_PT0 --base-fsdev-name AIO0
   crictl exec $(crictl ps -s running -q --name virtiofs) spdk_rpc.py virtio_fs_transport_create -t DOCA
   crictl exec $(crictl ps -s running -q --name virtiofs) spdk_rpc.py virtio_fs_doca_manager_create -m mlx5_0
   ```

```
crictl exec $(crictl ps -s running -q --name virtiofs) spdk_rpc.py virtio_fs_transport_start -t DOCA
crictl exec $(crictl ps -s running -q --name virtiofs) spdk_rpc.py virtio_fs_device_create --transport-name
DOCA --dev-name vfsdev0 --tag CUSTOM_FSDEV_PT0 --fsdev CUSTOM_FSDEV_PT0 --num-request-queues 62 --queue-
size 64 --driver-platform x86_64
crictl exec $(crictl ps -s running -q --name virtiofs) spdk_rpc.py virtio_fs_doca_device_modify --dev-name
vfsdev0 --manager mlx5_0 --vuid MT2334XZ0LEDVFSS0D0F3
crictl exec $(crictl ps -s running -q --name virtiofs) spdk_rpc.py virtio_fs_device_start --dev-name
vfsdev0

# x86
modprobe -v virtio_pci
modprobe -v virtiofs
test -d /tmp/CUSTOM_FSDEV_PT0 || mkdir -p /tmp/CUSTOM_FSDEV_PT0
mount -t virtiofs CUSTOM_FSDEV_PT0 /tmp/CUSTOM_FSDEV_PT0
```

8.11.1.12.2 Manual Build and Run in a Development Container

This approach is suitable for development workflows where frequent updates, builds, and tests are required. It sets up a development container with the necessary environment to manually build and run the Virtio-fs service with a custom fsdev module.

8.11.1.12.2.1 Environment Preparation

> This example uses `/opt/build` as working directory but any other directory can be used.

The working directory should contain the `spdk` sources and the `Dockerfile`.

> See an example of the Dockerfile in the next section.

```
root@bf:/# mkdir -p /opt/build
root@bf:/# cd /opt/build
root@bf:/opt/build# git clone https://github.com/Mellanox/spdk --branch v24.01.4.nvda
root@bf:/opt/build# ll
total 16
drwxr-xr-x  3 root root 4096 Dec  2 14:16 ./
drwxr-xr-x  6 root root 4096 Dec  2 13:30 ../
-rw-r--r--  1 root root  723 Dec  2 14:15 Dockerfile
drwxr-xr-x 37 root root 4096 Dec  2 14:01 spdk/
```

8.11.1.12.2.2 Dockerfile Example

```
FROM nvcr.io/nvstaging/doca/doca_vfs:1.2.0-2-doca2.10.0 as builder

RUN apt-get update && apt-get install -y autoconf libtool python3-pyelftools libaio-dev libncurses-dev libfuse3-dev
patchelf libcmocka-dev make

ENTRYPOINT /bin/bash
```

8.11.1.12.2.3 Building and Running the Development Container

1. Build the container using the provided `Dockerfile`:

```
docker build -t doca_vfs_custom_fsdev_dev:latest -f Dockerfile .
```

2. Start the container and enter the bash shell:

```
docker run -ti --privileged --net=host \
    --volume /dev/hugepages:/dev/hugepages \
```

```
    --volume /dev/shm:/dev/shm \
    --volume /dev/infiniband:/dev/infiniband \
    --volume /etc/virtiofs:/etc/virtiofs \
    --volume ${PWD}/spdk/test/external_code:/external_code \
    doca_vfs_custom_fsdev_dev:latest
```

3. Once inside the container, one can manually build and test custom module:

```
cd /external_code/
export SPDK_HEADER_DIR=/opt/nvidia/spdk-subsystem/virtiofs/include
export SPDK_LIB_DIR=/opt/nvidia/spdk-subsystem/virtiofs/lib
export DPDK_LIB_DIR=/opt/nvidia/spdk-subsystem/virtiofs/include
make fsdev_passthru_shared
```

4. Start the virtio-fs service with the custom module for testing:

```
cp /external_code/fsdev_passthru/fsdev_passthru.py /usr/bin/
/opt/nvidia/spdk-subsystem/doca_snap/bin/set_environment_variables.sh
LD_PRELOAD=/external_code/fsdev_passthru/libfsdev_passthru_external.so \
    /opt/nvidia/spdk-subsystem/virtiofs/bin/virtio_fs_tgt -m 0xff &
```

5. To configure the service with custom fsdev module:

```
# DPU
mkdir /etc/virtiofs/AIO0
spdk_rpc.py fsdev_aio_create AIO0 /etc/virtiofs/AIO0
spdk_rpc.py --plugin fsdev_passthru fsdev_passthru_ext_create --name CUSTOM_FSDEV_PT0 --base-fsdev-name
AIO0
spdk_rpc.py virtio_fs_transport_create -t DOCA
spdk_rpc.py virtio_fs_doca_manager_create -m mlx5_0
spdk_rpc.py virtio_fs_transport_start -t DOCA
spdk_rpc.py virtio_fs_device_create --transport-name DOCA --dev-name vfsdev0 --tag CUSTOM_FSDEV_PT0 --fsdev
CUSTOM_FSDEV_PT0 --num-request-queues 62 --queue-size 64 --driver-platform x86_64
spdk_rpc.py virtio_fs_doca_device_modify --dev-name vfsdev0 --manager mlx5_0 --vuid MT2334XZ0LEDVFSS0D0F2
spdk_rpc.py virtio_fs_device_start --dev-name vfsdev0

# x86
modprobe -v virtio_pci
modprobe -v virtiofs
test -d /tmp/CUSTOM_FSDEV_PT0 || mkdir -p /tmp/CUSTOM_FSDEV_PT0
mount -t virtiofs CUSTOM_FSDEV_PT0 /tmp/CUSTOM_FSDEV_PT0
```

8.11.1.13 Appendix – Custom Bdev Modules

With DOCA SNAP-4 block emulation subsystems enabled (as described in DOCA SNAP Virtio-fs with SNAP Support), DOCA SNAP virtio-fs service allows to load custom bdev modules.

> Refer to DOCA SNAP-4 Service Guide documentation for more information.

8.11.1.15 SNAP Virtio-fs Service Release Notes

The release notes provide information for the DOCA SNAP Virtio-fs Service such as changes and new features, software known issues, and bug fixes.

> ⚠ The DOCA SNAP Virtio-fs Service is supported at beta level.

8.11.1.15.1 Key Features in Version 1.6.0-doca3.3.0

- Various bug fixes to enhance system stability.

8.11.1.15.2 Limitations

The following features are not supported in this version:

- Live update and live migration

8.11.1.15.3 Known Issues

8.11.1.15.3.1 DOCA SNAP Virtio-fs Issues

Ref #	Issue
–	Description: The NFS `fsdev` module does not garbage collect its file objects. Once referenced, internal file objects persist unless the associated file is deleted, leading to stale object accumulation. When the per- `fsdev` limit of 1 million objects is reached, new file creation and directory listing operations fail.
	Workaround: N/A
	Keywords: File deletion/creation
	Discovered in version: 1.4.0-doca3.1.0
–	Description: For hotplugged devices, mounting the device immediately after loading the driver may fail.
	Workaround: Introduce a minimum delay of 3 seconds between driver load and mount operations to ensure proper device readiness.
	Keywords: Wrong fs type; bad option; bad superblock; tag not found
	Discovered in version: 1.4.0-doca3.1.0
–	Description: Repeatedly running `virtio_fs_doca_device_hotplug` and `virtio_fs_doca_device_hotunplug` RPCs in a loop can lead to recovery-related issues.
	Workaround: Insert a minimum delay of 2 seconds between the `hotplug` and `hotunplug` operations to ensure system stability.
	Keywords: Recovery failed, DOCA error
	Discovered in version: 1.4.0-doca3.1.0
–	Description: The maximum supported scale for virtio-blk is 218 controllers.
	Workaround: N/A
	Keywords: Virtio-blk
	Discovered in version: 1.3.0-doca3.0.0
–	Description: Invoking the `virtio_fs_device_hotunplug` RPC while the device is still mounted on the host, followed by a `virtio_fs_device_hotplug` call, may result in I/O errors on the mount point.
	Workaround: Before issuing the `virtio_fs_device_hotunplug` RPC, ensure that the emulated file system is no longer mounted on the host. Use the `umount` command to cleanly unmount the device's mount point.
	Keywords: Hotunplug; mount
	Discovered in version: 1.3.0-doca3.0.0
–	Description: Under high-scale scenarios, the `virtio_fs_doca_manager_destroy` RPC may time out.
	Workaround: Run the RPC with an extended timeout value. For example: `rpc.py -t 120 virtio_fs_doca_manager_destroy -m mlx5_0`.
	Keywords: Timeout

Ref #	Issue
	Discovered in version: 1.3.0-doca3.0.0
–	Description: The Linux Kernel NFS RDMA server is known to handle incoming connections slowly. At high scale (e.g., when using multiple hotplug functions), this can result in connection timeouts.
	Workaround: Introduce a delay between mount operations of different hotplug functions on the host to avoid overwhelming the NFS RDMA server.
	Keywords: Timeout, hotplug, mount
	Discovered in version: 1.3.0-doca3.0.0
–	Description: The combination of virtio-fs, virtio-blk, and InfiniBand in a single use case is not supported.
	Workaround: N/A
	Keywords: IB
	Discovered in version: 1.3.0-doca3.0.0
–	Description: I/O operations larger than 255 KB are not supported due to a data pool size limitation in the VirtioFS process running on the DPU.
	Workaround: Set the `max_xfer_size` parameter in the `fsdev_aio_create` RPC to a value less than 255 KB. This parameter is used as `max_write` in the FUSE layer of the host kernel. If an I/O operation exceeds `max_xfer_size`, the FUSE layer automatically splits the request into smaller chunks. The default `max_xfer_size` value is 128 KB. For example, if an I/O request is 1 MB and `max_xfer_size` is set to 64 KB, the FUSE layer on the host splits the operation into 16 separate 64 KB chunks, which are then individually handled by the virtio-fs process on the DPU.
	Keywords: IO error; host error; io_size
	Discovered in version: 1.2.0-doca2.10.0
–	Description: Due to the lack of recovery support, negative or resilience operations (e.g., destroy and restore) are not supported during active I/O traffic. Restarting the device using `virtio_fs_device_stop` followed by `virtio_fs_device_start` is supported in such cases.
	Workaround: N/A
	Keywords: Recovery; negative/resilience operations
	Discovered in version: 1.0.0-doca2.8.0
4862565	Description: The following FUSE commands are unsupported: `BMAP`, `SETUPMAPPING`, `REMOVEMAPPING, STATX`
	Workaround: N/A
	Keywords: FUSE
	Discovered in version: 1.0.0-doca2.8.0
–	Description: Application restart is not supported if the application controller has already processed FUSE commands.
	Workaround: Unload the virtio-fs driver on the host before restarting the application.

Ref #	Issue
	Keywords: FUSE
	Discovered in version: 1.0.0-doca2.8.0
–	Description: The following operations are not supported when using Linux's virtio-fs inbox/upstream kernel driver: FLR and the virtio-fs notification queue.
	Workaround: N/A
	Keywords: FLR; virtio-fs; inbox/upstream kernel driver
	Discovered in version: 1.0.0-doca2.8.0
4650660	Description: Running virtio_fs_transport_create and virtio_fs_transport_destroy in loop is possible for 16 iterations. After that, virtio_fs_transport_create will fail.
	Workaround: Restart the virtio_fs_tgt application
	Keywords: DOCA Log backend Error
	Discovered in version: 1.5.0-doca3.2.0
4687235	Description: Driver load on host or "echo <count> > /sys/bus/pci/devices/0000\:07\:00.2/sriov_numvfs" can get stuck forever due to resource constraint in DPU
	Workaround: Restart the virtio_fs_tgt application
	Keyworks: flexio, process stuck
	Discovered in version: 1.5.0-doca3.2.0
4692130	Description: Triggering an FLR using `echo 1 > /sys/bus/pci/devices/0000:07:00.2/reset` on a PF with active VFs causes the VFs to become unusable.
	Workaround: n/A
	Keywords: FLR, VF
	Discovered in version: 1.5.0-doca3.2.0
4706291	Description: Passthourgh both PF and its VFs into a VM will fail
	Workaround: Only pass the VFs to the VM
	Keywords: VF, VM
	Discovered in version: 1.5.0-doca3.2.0
4552213	Description: Certain file operation sequences when using an aio fsdev backed by a Linux kernel NFS mount may result in silly-renamed files (with `.nfs` prefix) that are not automaticall removed.
	Workaround: They can be removed by dropping caches (`echo 3 > /proc/sys/vm/drop_caches`) from the host.
	Keywords: AIO
	Discovered in version: 1.5.0-doca3.2.0

8.11.1.15.3.2 OS or Vendor Issues

Ref #	Issue
–	Description: Triggering a Function Level Reset (FLR) from the host by writing `1` to the reset file under `/sys/bus/pci/devices/<bdf>/` (e.g., `echo 1 > /sys/bus/pci/devices/0000:29:00.2/reset`) causes the host driver to skip virtqueue creation. As a result, the mount point becomes unresponsive.
	Workaround: Avoid initiating FLR while a virtio-fs mount is active on the host. To resume I/O after FLR, unload and reload the virtio-fs driver on the host.
	Keywords: Driver; FLR
	Discovered in version: 1.0.0-doca2.8.0
–	Description: On the host, when the virtio-fs mount is idle (i.e., no I/O operations), the `dmesg` log is repeatedly filled with AppArmor DENIED messages. These messages indicate that the `ntpd` service is being denied access to specific files, such as `/snap/bin/` and `/etc/ssl/openssl.cnf`, due to restrictions in its AppArmor profile.

	Workaround: Modify the AppArmor profile for `ntpd` to grant the necessary read permissions.
	1. Locate the AppArmor profile for `ntpd` (typically located at `/etc/apparmor.d/usr.sbin.ntpd`).
	2. Edit the profile and add the permissions using a text editor. For example:
	a. Run:
	`sudo nano /etc/apparmor.d/usr.sbin.ntpd`
	b. Add the following lines to allow ntpd to read the necessary files:
	`/snap/bin/ r,`
	`/etc/ssl/openssl.cnf r,`
	3. Reload the AppArmor profile to apply the changes:
	`sudo apparmor_parser -r /etc/apparmor.d/usr.sbin.ntpd`

	Keywords: AppArmor, ntpd
	Discovered in version: 1.0.0-doca2.8.0
3949202	Description: On kernels older than version 6.10, repeatedly loading and unloading the `virtio_pci` and `virtiofs` drivers (or mounting and unmounting filesystems using these drivers) can cause the drivers to hang or become unresponsive.
	Workaround: Insert a delay of at least 1 second between load and unload operations to reduce the risk of driver instability.
	Keywords: Virtio_pci; virtiofs
	Discovered in version: 1.0.0-doca2.8.0
-	Description: FUSE_STATX was introduced in FUSE version 7.39. If the negotiated version is less than this, kernel can still send FUSE_STATX.
	Workaround: N/A
	Keywords: Unsupported opcode

Ref #	Issue
	Discovered in version: 1.4.0-doca3.1.0
-	Description: On modern Linux distributions, unplugging a PCIe function from the host while there are inflight I/Os can cause the virtiofs driver to hang and virtio_fs_doca_device_hotunplug RPC will timeout
	Workaround: N/A
	Keywords: Hotplug, Linux
	Discovered in version: 1.5.0-doca3.2.0

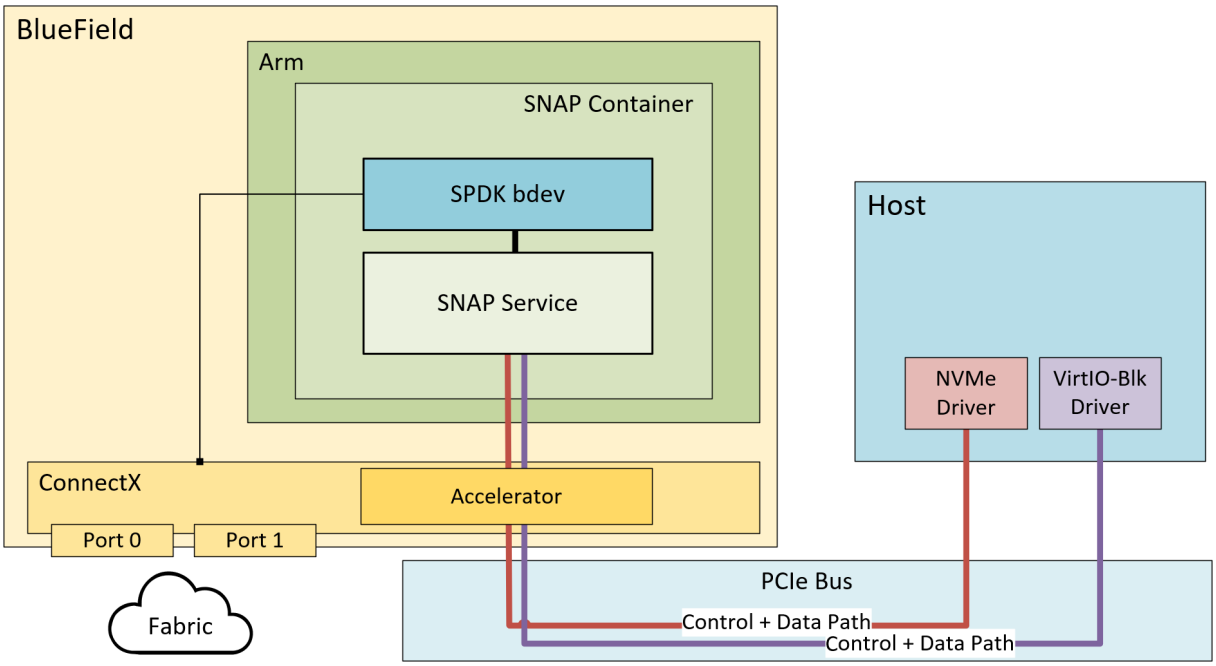
8.11.2 DOCA SNAP-4 Service Guide

This guide provides instructions on using the DOCA SNAP-4 service on top of the NVIDIA® BlueField®-3 DPU.

8.11.2.1 Introduction

NVIDIA® BlueField® SNAP and virtio-blk SNAP (storage-defined network accelerated processing) technology enables hardware-accelerated virtualization of local storage. NVMe/virtio-blk SNAP presents networked storage as a local block-storage device (e.g., SSD) emulating a local drive on the PCIe bus. The host OS or hypervisor uses its standard storage driver, unaware that communication is done, not with a physical drive, but with NVMe/virtio-blk SNAP framework. Any logic may be applied to the I/O requests or to the data via the NVMe/virtio-blk SNAP framework prior to redirecting the request and/or data over a fabric-based network to remote or local storage targets.

NVMe/virtio-blk SNAP is based on the NVIDIA® BlueField® DPU family technology and combines unique software-defined hardware-accelerated storage virtualization with the advanced networking and programmability capabilities of the DPU. NVMe/virtio-blk SNAP together with the BlueField DPU enable a world of applications addressing storage and networking efficiency and performance.



The traffic arriving from the host towards the emulated PCIe device is redirected to its matching storage controller opened on the `mlnx_snap` service.

The controller implements the device specification and may expose backend device accordingly (in this case, SPDK is used as the storage stack that exposes backend devices). When a command is received, the controller executes it.

Admin commands are mostly answered immediately, while I/O commands are redirected to the backend device for processing.

The request-handling pipeline is completely asynchronous, and the workload is distributed across all Arm cores (allocated to SPDK application) to achieve the best performance.

The following are key concepts for SNAP:

- Full flexibility in fabric/transport/protocol (e.g. NVMe-oF/iSCSI/other, RDMA/TCP, ETH/IB)
- NVMe and virtio-blk emulation support
- Programmability
- Easy data manipulation
- Allowing zero-copy DMA from the remote storage to the host
- Using Arm cores for data path

> ⚠ BlueField SNAP for BlueField-2 DPU is licensed software. Users must purchase a license per BlueField-2 DPU to use them. BlueField-3 DPU does not have license requirements to run BlueField SNAP.

8.11.2.1.1 SNAP as Container

In this approach, the container could be downloaded from NVIDIA NGC and could be easily deployed on the DPU.

The yaml file includes SNAP binaries aligned with the latest `spdk.nvda` version. In this case, the SNAP sources are not available, and it is not possible to modify SNAP to support different SPDK versions (SNAP as an SDK package should be used for that).

> ⚠ SNAP 4.x is not pre-installed on the BFB but can be downloaded manually on demand.

For instructions on how to install the SNAP container, please see "SNAP Container Deployment".

8.11.2.1.2 SNAP as a Package

The SNAP development package (custom) is intended for those wishing to customize the SNAP service to their environment, usually to work with a proprietary bdev and not with the `spdk.nvda` version. This allows users to gain full access to the service code and the lib headers which enables them to compile their changes.

8.11.2.1.2.1 SNAP Emulation Lib

This includes the protocols libraries and the interaction with the firmware/hardware as well as:

- Plain shared objects (`*.so`)
- Static archives (`*.a`)
- pkgconfig definitions (`*.pc`)
- Include files (`*.h`)

8.11.2.1.2.2 SNAP Service Sources

This includes the following managers:

- Emulation device managers:
- Emulation manager – manages the device emulations, function discovery, and function events
- Hotplug manager – manages the device emulations hotplug and hot-unplug
- Config manager – handles common configurations and RCPs (which are not protocol-specific)
- Service infrastructure managers:

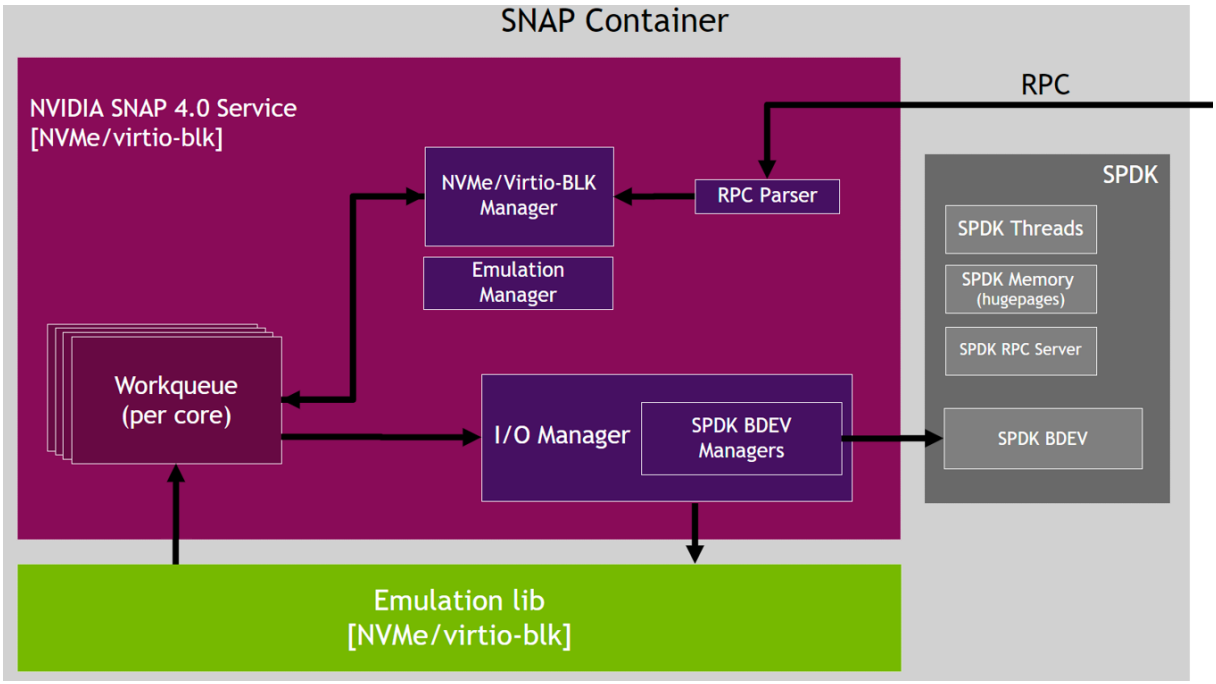
- Memory manager – handles the SNAP mempool which is used to copy into the Arm memory when zero-copy between the host and the remote target is not used
- Thread manager – handles the SPDK threads
- Protocol specific control path managers:
- NVMe manager – handles the NVMe subsystem, NVMe controller and Namespace functionalities
- VBLK manager – handles the virtio-blk controller functionalities
- IO manager:
- Implements the IO path for regular and optimized flows (RDMA ZC and TCP XLIO ZC)
- Handles the bdev creation and functionalities

SNAP Service Dependencies

SNAP service depends on the following libraries:

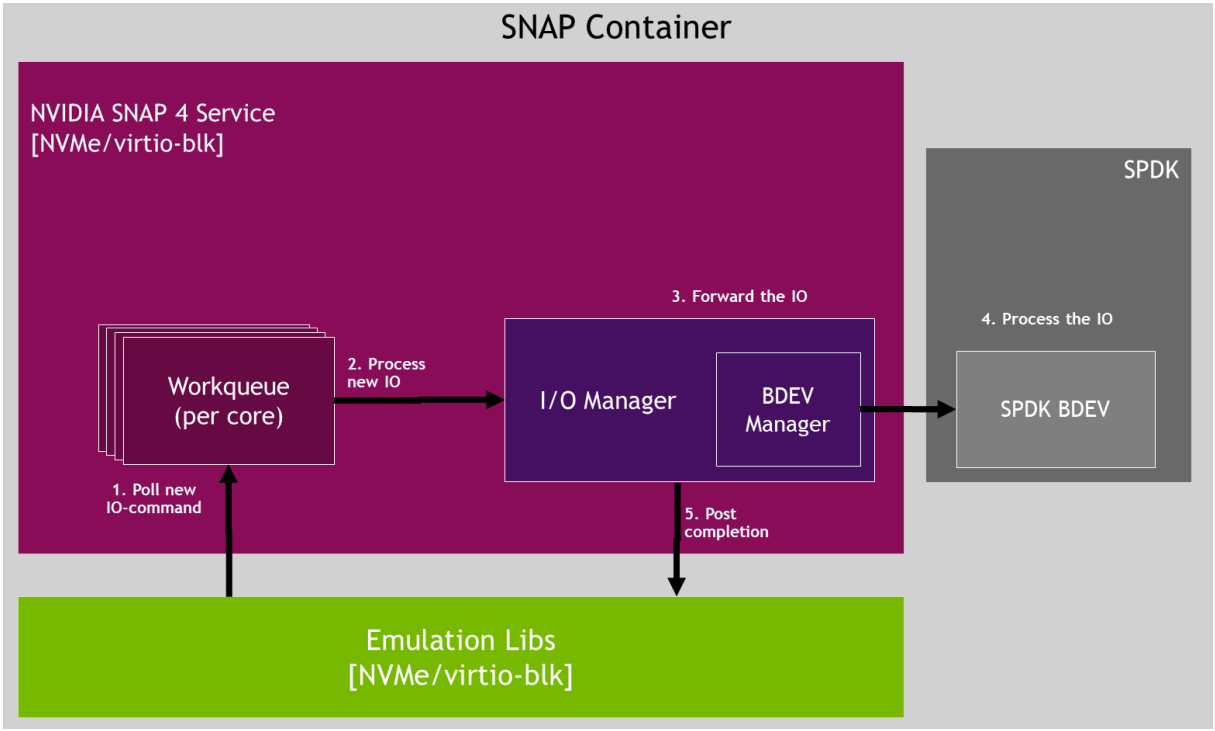
- SPDK – depends on the bdev and the SPDK resources, such as SPDK threads, SPDK memory, and SPDK RPC service
- XLIO (for NVMeTCP acceleration)

SNAP Service Flows

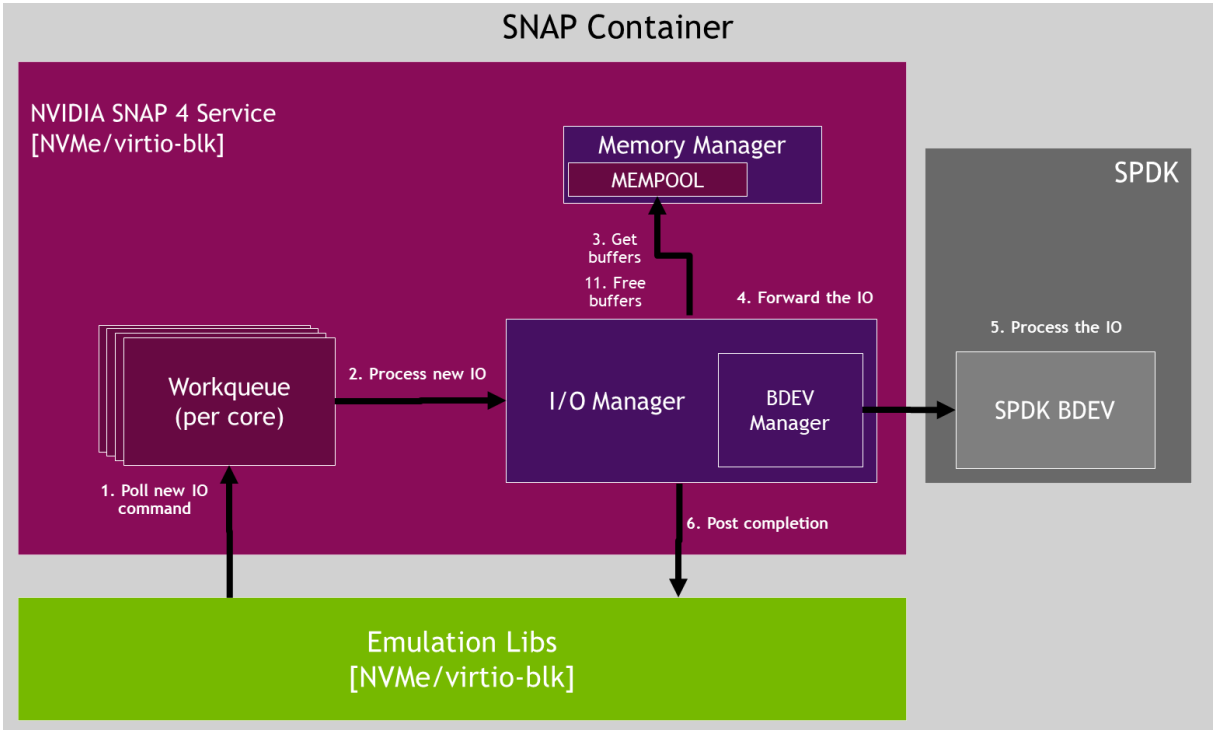


IO Flows

Example of RDMA zero-copy read/write IO flow:



Example of RDMA non-zero-copy read IO flow:



8.11.2.2 SNAP-4 Service Release Notes

This page describes new features, known issues, and bug fixes for NVIDIA® BlueField®-3 SNAP software.

8.11.2.2.1 Changes and New Features in NVIDIA SNAP 4.10.0

New features:

- Introduced an advanced two-step hot-plug flow for the NVMe protocol, including additional host-aware functionality.
- Introduced improvements to the virtio-blk hot-plug flow, including fixes for unplug during traffic and support for Attention Button functionality.

Bug fixes:

- Various bug fixes to enhance system stability.

Compatibility:

- The SNAP 4.10.0 container is compatible with the SNAP 4.9.0 firmware.

8.11.2.2.2 Bug Fixes

Ref #	Issue
-	Description: Fixes for I/O hangs in NVMe and Virtio-blk after repeated live updates and post–live update crash recovery.
	Discovered in version: 4.9.0

8.11.2.2.3 Known Issues

8.11.2.2.3.1 SNAP Issues

Ref #	Issue
4829857	Description: `emulation_resource_list` is not updated following NVMe emulation hotplug/unplug/modify operations.
	Workaround: create all desired hotplug functions (`nvme_function_create` RPC) in advance before exposing it to host, to make sure there are sufficient resources (and gradually decrease if allocation fails)
	Keywords: NVMe, hotplug
	Discovered in version: 4.10.0

Ref #	Issue
4836095	Description: SNAP does not support live downgrade (moving from newer to older SNAP version)
	Workaround: Stop existing (new) SNAP process, then start the desired one (old) instead
	Keywords: live update, nvme, virtio-blk
	Discovered in version: 4.9.0
4796121	Description: SNAP configuration recovery is unsupported in combination with live update. If it crashes config file may contain partial configuration.
	Workaround : Use different `SNAP_RPC_INIT_CONF_JSON` for src and dest. Save a copy of json config file before LU. If snap crashes during LU, kill both src and dest and replace the config file with the saved version. Recover with the saved config file and retry the LU flow.
	Keywords: configuration recovery; live update
	Discovered in version: 4.9.0
4691998	Description: On systems running Linux Kernel 6.14 or higher, triggering an FLR (`echo 1 >sys/bus/pci/devices/0000:07:00.2/reset`) on a PF while VFs are active causes the VFs to become unusable.
	Workaround: Choose one of the following: • Destroy or unbind all active VFs associated with the PF before triggering the reset. • After performing the PF FLR, triggering FLRs on all associated VFs restores VF functionality.
	Keywords: Virtio-blk; FLR; SR-IOV
	Discovered in version: 4.9.0
4561583	Description: NVMe drivers may experience I/O timeouts if `queue_depth` is configured to a value that is not a power of two. This applies to both the driver parameter (`io_queue_depth`) and the queue depth set during controller creation (`nvme_controller_create`).
	Workaround: N/A
	Keywords: NVMe; queue_depth
	Discovered in version: 4.9.0
4636221	Description: If SNAP crashes during live migration (LM), running recovery may cause subsequent LM commands to fail.
	Workaround: N/A
	Keywords: Live migration; recovery
	Discovered in version: 4.9.0
4499506	Description: Live update fails when multiple remote bdevs are configured, due to a QP creation timeout.
	Workaround: N/A
	Keywords: Live update; remote bdev
	Discovered in version: 4.8.0
4561599	Description: NVMe UEFI expansion ROM driver requires at least 2 IO queues to be supported by SNAP controller.
	Workaround: Use `--num_queues=2` (or higher) with `nvme_controller_create` RPC for NVMe boot devices.

Ref #	Issue
	Keywords: NVMe; UEFI boot
	Discovered in version: 4.8.0
4499506 4502937	Description: When working with high scale (>=16) of virtio-blk or NVMe functions, backed by SPDK's NVMe-oF/RDMA bdevs as a backend, live update process may fail.
	Workaround: Use "regular" update process (close + reopen SNAP application).
	Keywords: NVMe; virtio-blk; live update; SPDK; NVMe-oF/RDMA
	Reported in version: 4.8.0
4513104	Description: If the virtio-blk driver in the VM is unprobed or there is an FLR on the VM function during virtio-blk VFIO live migration, the driver may get stuck.
	Workaround: N/A
	Keywords: virtio-blk; live migration; FLR; reset; driver unprobe
	Reported in version: 4.8.0
-	Description: Linux kernel's `virtio-blk` driver expects `--size_max` to be at least the size of the of OS page. If it is not, a driver warning will be prompted on the host side.
	Workaround: Use the `--size_max` option with a value equal to. the OS page size (typically 4096).
	Keywords: virtio_blk; linux; kernel; size_max
	Reported in version: 4.7.0
4396707	Description: SPDK's `virtio-blk` driver uses 4K segment sizes, even though `size_max` technically allows for larger segments. This might cause large logical block size IO handling to fail.
	Workaround: When using the SPDK `virtio-blk` driver, always set the `--size_max` option with a value of 4096.
	Keywords: virtio_blk; size_max; SPDK
	Reported in version: 4.7.0
4409344	Description: When performing live update too fast (using automated script), destination process might not yet create all necessary resources, when prompted to handshake with source process.
	Workaround: Add a `sleep(3)` between creation of controller on destination process (with `--live_update_listener` flag) and the succeeding request to suspend source controller (with `--live_update_notifier` flag). That will increase the overall automated script runtime but should not affect the host driver's downtime.
	Keywords: virtio_blk; nvme; live update
	Reported in version: 4.7.0
4412341	Description: When using high scale (512<=) of virtio-blk VFs on a single PF, sudden hypervisor crash (or brutal warm reboot) may result in hypervisor hang, due to the long FLR processing time.
	Workaround: Split the opened VFs among more PFs; gracefully shutdown VMs before performing hard OS reset
	Keywords: virtio-blk; FLR; SR-IOV
	Reported in version: 4.7.0

Ref #	Issue
4104709	Description: Some legacy operating systems (e.g., RockyLinux with kernel 4.18) issues virtio-blk zero-length I/Os during boot (e.g., during EDD probing).
	Workaround: Set `VIRTIO_BLK_ZERO_LEN_IO_FAIL=1` environment variable to configure SNAP to fail zero-length I/Os in virtio-blk.
	Keywords: virtio-blk; zero-length I/Os
	Reported in version: 4.6.0
-	Description: When using both NVMe and Virtio-blk protocols in SNAP, their data providers may share the same DPA HARTS, potentially causing NVMe configuration or performance issues. This is especially relevant when Virtio-blk is in DPU mode and NVMe is in DPA mode.
	Workaround: Use `dpa_helper_core_mask` and `dpa_nvme_core_mask` environment variable as DPA core masks, for example `dpa_helper_core_mask=0x0000FFFF` and `dpa_nvme_core_mask=0xFFFF0000`
	Keywords: Virtio-blk and NVMe; DPA core mask.
	Reported in version: 4.6.0
4110943	Description: Hot-unplugging a hotplugged Virtio BLK device is not allowed unless a Virtio BLK controller has previously been created for the device.
	Workaround: Create a Virtio BLK controller on the device which need to do hotunplug
	Keywords: hotplug; hotunplug
	Discovered in version: 4.5.0
3631346	Description: When using dynamic MSIX with NVMe protocol, the `free_queues` PF controller property is not valid and always shows `0`.
	Workaround: Ignore the value and assume the `free_queues` pool is large enough.
	Keywords: NVMe; MSIX
	Discovered in version: 4.4.1
-	Description: The SPDK `bdev_uring` is not supported.
	Workaround: N/A
	Keywords: NVMe
	Discovered in version: 4.4.0
3817040	Description: When running `nvme_controller_suspend` RPC with the `--timeout` parameter, the device is no longer operational and cannot be resumed if the timeout expires.
	Workaround: Destroy and re-create the controller.
	Keywords: NVMe
	Discovered in version: 4.4.0
3809646	Description: When working with a new DPA provider, if an interrupt is sent to DPA immediately after a DMA operation, DPA may wake up before the DMA is fully written to the buffer, causing it to miss events.
	Workaround: Add a software-based periodic wake-up mechanism.
	Keywords: NVMe

Ref #	Issue
	Discovered in version: 4.4.0
3773346	Description: When configuring the virtio-blk controller, using an unaligned `size_max` value with the SPDK NVMe-oF initiator as the backend can lead to memory corruption.
	Workaround: `size_max` and `seg_max` values must be a power of 2.
	Keywords: Virtio-blk; NVMe-oF; spdk
	Discovered in version: 4.3.1
3745842	Description: When using the NVMe/TCP SPDK block device as a backend, SNAP is limited to working with no more than 8 cores.
	Workaround: Work with Arm core mask which uses only 8 cores.
	Keywords: NVMe; TCP; SPDK
	Discovered in version: 4.3.1
-	Description: Container images may become corrupted, resulting in a container status of `exited` with the error message `/usr/bin/supervisord: exec format error`.
	Workaround: Remove the YAML from kubelet, use `crictl images` to list the images and `crictl rmi <image-id>` to remove the images. Run `systemctl restart containerd` and `systemctl restart kubelet`, then copy the YAML file again to kubelet.
	Keywords: NGC; container image
	Discovered in version: 4.3.1
3757171	Description: When running virtio-blk emulation with large IOs (>128K) and SPDK's NVMe-oF initiator as a backend, IOs might fail in the SPDK layer due to poor alignment.
	Workaround: `size_max` value of `virtio_blk_controller_create` RPC must be set and be a power of 2.
	Keywords: SPDK; virtio-blk; size_max
	Discovered in version: 4.3.1
3689918 3753637	Description: The SNAP container takes a long time to start up when configured with a large number of emulations, potentially exceeding the default NVMe driver timeout.
	Workaround: Increase the NVMe driver IO timeout from 30 to 300 seconds.
	Keywords: NVMe; recovery; kernel driver
	Discovered in version: 4.3.0
-	Description: NVMeTCP XLIO is not supported when running 64K page size kernels on the DPU Arm cores (as is the case for CentOS 8.x, Rocky 8.x, or openEuler 20.x).
	Workaround: N/A
	Keywords: 64K page size; NVMeTCP XLIO
	Discovered in version: 4.1.0
3264154	Description: NVMeTCP XLIO is not supported when running 64K page size kernels on the DPU Arm cores (such is the case with CentOS 8.x, Rocky 8.x, or openEuler 20.x).
	Workaround: N/A
	Keywords: Page size; NVMeTCP XLIO

Ref #	Issue
	Discovered in version: 4.1.0
-	Description: NVMe over RDMA full offload is not supported.
	Workaround: N/A
	Keywords: NVMe over RDMA; support
	Discovered in version: 4.0.0

8.11.2.2.3.2 OS or Vendor Issues

Ref #	Issue
4583923	Description: Windows OS virtio-blk driver sends corrupted commands incompatible with virtio-blk specification conventions, making it impossible for the device to provide any reply (even with error status).
	Workaround: N/A
	Keywords: Windows, Windows OS, virtio-blk
	Discovered in version: 4.9.0
4408109	Description: When using a Windows OS on the host side, the controller must be created with a `--num_queues` value greater than or equal to the number of CPU cores on the Windows server. Failing to do so may result in undefined behavior, and the disk might fail to initialize properly.
	Workaround: N/A
	Keywords: Windows, Windows OS
	Discovered in version: 4.8.0
4573304	A call trace with the message “Bad FPU state detected” may appear in the host dmesg during consecutive host reboots when using hotplug functions. This is a known Linux kernel issue and has been fixed starting from Linux v6.1 and later.
	Workaround: disable AMX/XSAVE/XRSTOR feature to CPU, Hotplug
	Keywords: Linux Kernal, Call Trace, reboot, FPU
	Discovered in Version: 4.8.0
4540848	Description: Windows NVMe driver ignores MQEs value set on the PCI BAR, and forcefully trying to open queues with the size of 256.
	Workaround: Set `NVME_EMULATION_MAX_QUEUE_DEPTH` in mlxconfig to be >= 8 (default is 12), to support MQES >= 256 queue depth.
	Keywords: NVMe, Windows
	Discovered in version: 4.8.0
-	Description: Windows OS assumes NVMe devices support at least 2 IO CQs (CQ ID 2 exists), even when the controller declares it only supports 1 IO queue.
	Workaround: Open NVMe controller with `-num_queues` value >= 2
	Keywords: Windows, NVMe
	Discovered in version: 4.7.0

Ref #	Issue
4418372	Description: On Windows OS, hot-unplugging a virtio-blk PCIe function can cause unexpected behavior, and a host reboot might be necessary to recover. This is because the Windows OS does not support online PCIe rescan, unlike Linux.
	Workaround: Before unplugging a PCIe function, disable its storage controller in `Device Manager`
	Keywords: Windows, virtio-blk, hotplug
	Discovered in version: 4.7.0
4206444	Description: The Linux kernel driver does not restrict `seg_max` based on the maximum `queue_size` reported by the device. This can lead to a `WARN_ON_ONCE()` trigger in the kernel, resulting in driver misbehavior and potential system hangs.
	Workaround: Ensure that all virtio-blk controllers are configured with a `seg_max` value smaller than `(queue_size-2)`.
	Keywords: Virtio-blk; kernel driver; `seg_max`; `queue_size`
	Reported in version: 4.6.0
-	Description: When using hotplugged PCIe devices, after all devices are plugged, the host must be rebooted for Windows to detect all devices (some Windows versions may perform reboot automatically). This is requires as Windows OS does not support online PCIe rescan (as in Linux).
	Workaround: N/A
	Keywords: Hotplug, Windows
	Reported in version: 4.5.0
3748674	Description: On most modern Linux distributions, unplugging a PCIe function from the host while there are inflight I/Os can cause the virtio-blk driver to hang. To clarify, inflights I/Os might also be implicitly generated by other actions (e.g. driver load/unload).
	Workaround: N/A
	Keywords: Hotplug, Linux
	Reported in version: 4.5.0
-	Description: Some old Windows OS NVMe drivers have buggy usage of SGL support.
	Workaround: Disable SGL support when using Windows OS by setting the `--quirks` bit 4 to 1 in `snap_rpc.py nvme_controller_create` RPC.
	Keywords: Windows; NVMe
	Reported in version: 4.4.0
2879262	Description: When the virtio-blk kernel driver cannot find enough MSI-X vectors to satisfy all its opened virtqueues, it failovers to assign a single MSI-X vector to all virtqueues which negatively impacts performance. In addition, when a large number (e.g., 64) of virtqueues are associated with a single MSI-X, the kernel may enter a soft-lockup (kernel bug) and the IO will hang.
	Workaround: Always keep `num_queues` < `num_msix`.
	Keywords: Virtio-blk; kernel driver; MSI-X; soft-lockup
	Reported in version: 4.3.0

Ref #	Issue
-	Description: If PCIe devices are inserted before the hot-plug driver is loaded on the host, the hot-plug driver in kernel versions less than 4.19 does not enable the slot, even if the slot is occupied (i.e., presence detected in the slot status register). This means that only the presence state of the slot is updated by the firmware, but the PCIe slot is not enabled by the kernel after the host boots up. As a result, the PCIe device will not be visible when using `lspci` on the host side, and the bus, device, and function (BDF) identifier will show as 0 on the controller.
	Workaround: Add `pciehp.pciehp_force=1` to the boot command line on host.
	Keywords: Virtio-blk; kernel driver; hot-plug
	Reported in version: 4.2.1
-	Description: RedHat/Centos 7.x does not handle "online" (post driver probe) namespace additions or removals correctly.
	Workaround: Use `--quirks=0x2` option in `snap_rpc.py nvme_controller_create`.
	Keywords: NVMe; CentOS; RedHat; kernel
	Reported in version: 4.1.0
-	Description: Some Windows drivers have experimental support for "online" (post driver probe) namespace additions/removal, although such support is not communicated with the device.
	Workaround: Use `--quirks=0x1` option in `snap_rpc.py nvme_controller_create`.
	Keywords: NVMe; Windows
	Reported in version: 4.1.0
-	Description: VMWare ESXi supports "online" (post driver probe) namespace additions/removal, only if “Namespace Management” is supported by controller.
	Workaround: Use `--quirks=0x8` option in `snap_rpc.py nvme_controller_create`.
	Keywords: NVMe, ESXi
	Reported in version: 4.1.0
-	Description: Ubuntu 22.04 does not support 500 VFs.
	Workaround: N/A
	Keywords: Virtio-blk; kernel driver; Ubuntu 22.04
	Reported in version: 4.1.0
-	Description: Virtio-blk Linux kernel driver does not handle PCIe FLR events. This issue was fixed in kernel 6.14 and above.
	Workaround: N/A
	Keywords: Virtio-blk; kernel driver
	Reported in version: 4.0.0
	Description: SPDK NVMe-oF/RDMA initiator fails to connect to kernel NVMe-oF/RDMA remote target.
	Workaround: Use setting `spdk_rpc.py bdev_nvme_set_options --io-queue-requests=128` on SPDK configuration
	Keywords: SPDK, NVMe-oF, RDMA, kernel
	Reported in version: 4.3.1

Ref #	Issue
-	Description: Windows OS virtio-blk driver expects at least 64K data to be available for a single IO request
	Workaround: Use `seg_max` and `size_max` parameters configuration to match requirements (`seg_max` * `size_max` > 64K).
	Keywords: Windows, virtio-blk
	Reported in version: 4.3.1
-	Description: Some older Windows OS versions have malfunctioning inbox virtio-blk driver, expects a 3-party virtio-blk driver to be pre-installed to operate properly.
	Workaround: Use a verified 3rd-party driver from Fedora
	Keywords: Windows, virtio-blk
	Reported in version: 4.3.1
3679373	Description: Virtio-blk spdk driver (vfio-pci based) does not handle PCIe FLR events.
	Workaround: N/A
	Keywords: Virtio-blk; SPDK driver
	Reported in version: 4.3.0
-	Description: A new virtio-blk Linux kernel driver (starting kernel 4.18) does not support hot-unplug during traffic. Since the kernel may self-generate spontaneous IOs, on rare occasions, an issue may arise even when there is no traffic.
	Workaround: N/A
	Keywords: Virtio-blk; kernel driver
	Reported in version: 4.0.0
-	Description: When using SRIOV with VFs sharing the same driver as their PF (`sriov_driver_autoprobe=1`), unprobing the driver may take a long time, and some admin commands might timeout
	Workaround: N/A
	Keywords: SRIOV; driver.
	Discovered in version: 3.8.0-8

8.11.2.3 SNAP-4 Service Deployment

This section describes how to deploy SNAP as a container.

> ⚠ SNAP does not come pre-installed with the BFB.

8.11.2.3.1 Installing Full DOCA Image on DPU

To install NVIDIA® BlueField®-3 BFB:

```
[host] sudo bfb-install --rshim <rshimN> --bfb <image_path.bfb>
```

For more information, please refer to section "Installing Full DOCA Image on DPU" in the DOCA Installation Guide for Linux.

8.11.2.3.2 Firmware Installation

```
[dpu] sudo /opt/mellanox/mlnx-fw-updater/mlnx_fw_updater.pl --force-fw-update
```

For more information, please refer to section "Upgrading Firmware" in the DOCA Installation Guide for Linux.

8.11.2.3.3 Firmware Configuration

> ⚠ FW configuration may expose new emulated PCI functions, which can be later used by the host's OS. As such, user must make sure all exposed PCI functions (static/hotplug PFs, VFs) are backed by a supporting SNAP SW configuration, otherwise these functions will continue malfunctioning and host behavior will be undefined.

1. Clear the firmware config before implementing the required configuration:

   ```
   [dpu] mst start
   [dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 reset
   ```

2. Review the firmware configuration:

   ```
   [dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 query
   ```

   Output example:

   ```
   mlxconfig -d /dev/mst/mt41692_pciconf0 -e query | grep NVME
   Configurations:                                 Default         Current         Next Boot
   *        NVME_EMULATION_ENABLE                  False(0)        True(1)         True(1)
   *        NVME_EMULATION_NUM_VF                  0               125             125
   *        NVME_EMULATION_NUM_PF                  1               2               2
            NVME_EMULATION_VENDOR_ID               5555            5555            5555
            NVME_EMULATION_DEVICE_ID               24577           24577           24577
            NVME_EMULATION_CLASS_CODE              67586           67586           67586
            NVME_EMULATION_REVISION_ID             0               0               0
            NVME_EMULATION_SUBSYSTEM_VENDOR_ID     0               0               0
   *       NVME_EMULATION_NUM_MSIX                 0               2               2
   *       NVME_EMULATION_NUM_VF_MSIX              0               2               2
   *       NVME_EMULATION_MAX_QUEUE_DEPTH          0               12              12
   ```

   Where the output provides 5 columns:

   - Non-default configuration marker (*)
   - Firmware configuration name
   - Default firmware value
   - Current firmware value

- Firmware value after reboot – shows a configuration update which is pending system reboot

3. To enable storage emulation options, the first DPU must be configured to operate in internal CPU model:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s INTERNAL_CPU_MODEL=1 PF_BAR2_ENABLE=0
```

⚠ `PF_BAR2_ENABLE` is a deprecated option and must be explicitly disabled.

4. To enable the firmware config with virtio-blk emulation PF:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s VIRTIO_BLK_EMULATION_ENABLE=1 VIRTIO_BLK_EMULATION_NUM_PF=1
```

5. To enable the firmware config with NVMe emulation PF:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s NVME_EMULATION_ENABLE=1 NVME_EMULATION_NUM_PF=1
```

6. To enable the firmware configuration for any system (host or DPU) with a kernel page size of 64k (which can be verified using `getconf PAGESIZE`):

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s BAR_PAGE_ALIGNMENT=2
```

⚠ For a complete list of the SNAP firmware configuration options, refer to appendix "DPU Firmware Configuration".

⚠ Power cycle is required to apply firmware configuration changes.

8.11.2.3.3.1 RDMA/RoCE Firmware Configuration

RoCE communication is blocked for BlueField OS's default interfaces (named ECPFs, typically `mlx5_0` and `mlx5_1`). If RoCE traffic is required, additional network functions must be added, scalable functions (or SFs), which do support RoCE transport.

To enable RDMA/RoCE:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PER_PF_NUM_SF=1
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0.1 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
```

⚠ When using an OS with a 64KB page size, set `PF_SF_BAR_SIZE=10` instead of the default value of `8`.

This is not required when working over TCP or RDMA over InfiniBand.

8.11.2.3.3.2 SR-IOV Firmware Configuration

SNAP supports up to 512 total VFs on NVMe and up to 2000 total VFs on virtio-blk. The VFs may be spread between up to 4 virtio-blk PFs or 2 NVMe PFs.

The following examples are for reference. For complete details on parameter ranges, refer to appendix "DPU Firmware Configuration".

- Common example:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s SRIOV_EN=1 PER_PF_NUM_SF=1 LINK_TYPE_P1=2 LINK_TYPE_P2=2
PF_TOTAL_SF=1 PF_SF_BAR_SIZE=8
```

- Virtio-blk 250 VFs example (2 queue per VF):

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s VIRTIO_BLK_EMULATION_ENABLE=1
VIRTIO_BLK_EMULATION_NUM_VF=125 VIRTIO_BLK_EMULATION_NUM_PF=2 VIRTIO_BLK_EMULATION_NUM_MSIX=2
VIRTIO_BLK_EMULATION_NUM_VF_MSIX=2
```

- Virtio-blk 500 VFs example (2 queue per VF):

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s VIRTIO_BLK_EMULATION_ENABLE=1
VIRTIO_BLK_EMULATION_NUM_VF=250 VIRTIO_BLK_EMULATION_NUM_PF=2 VIRTIO_BLK_EMULATION_NUM_MSIX=2
VIRTIO_NET_EMULATION_ENABLE=0 NUM_OF_VFS=0 PCI_SWITCH_EMULATION_ENABLE=0 VIRTIO_BLK_EMULATION_NUM_VF_MSIX=2
```

- NVMe 250 VFs example (2 IO-queue per VF):

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s NVME_EMULATION_ENABLE=1 NVME_EMULATION_NUM_VF=125
NVME_EMULATION_NUM_PF=2 NVME_EMULATION_NUM_MSIX=2 NVME_EMULATION_NUM_VF_MSIX=2
NVME_EMULATION_MAX_QUEUE_DEPTH=12
```

8.11.2.3.3.3 Hot-plug Firmware Configuration

Once enabling PCIe switch emulation, BlueField can support up to 31 hotplug NVMe/Virtio-blk functions. "`PCI_SWITCH_EMULATION_NUM_PORT`-1" hot-plugged PCIe functions. These slots are shared among all DPU users and applications and may hold hot-plugged devices of type NVMe, virtio-blk, virtio-fs, or others (e.g., virtio-net).

To enable PCIe switch emulation and determine the number of hot-plugged ports to be used:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PCI_SWITCH_EMULATION_ENABLE=1 PCI_SWITCH_EMULATION_NUM_PORT=32
```

`PCI_SWITCH_EMULATION_NUM_PORT` equals 1 + the number of hot-plugged PCIe functions.

For additional information regarding hot plugging a device, refer to section "Hot-pluggable PCIe Functions Management".

⚠ Hotplug is not guaranteed to work on AMD machines.

⚠ Enabling `PCI_SWITCH_EMULATION_ENABLE` could potentially impact SR-IOV capabilities on Intel and AMD machines.

⚠ Currently, hotplug PFs do not support SR-IOV.

8.11.2.3.3.4 UEFI Firmware Configuration

To use the storage emulation as a boot device, it is recommended to use the DPU's embedded UEFI expansion ROM drivers to be used by the UEFI instead of the original vendor's BIOS ones.

To enable UEFI drivers:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s EXP_ROM_VIRTIO_BLK_UEFI_x86_ENABLE=1 EXP_ROM_NVME_UEFI_x86_ENABLE=1
```

8.11.2.3.4 DPU Configurations

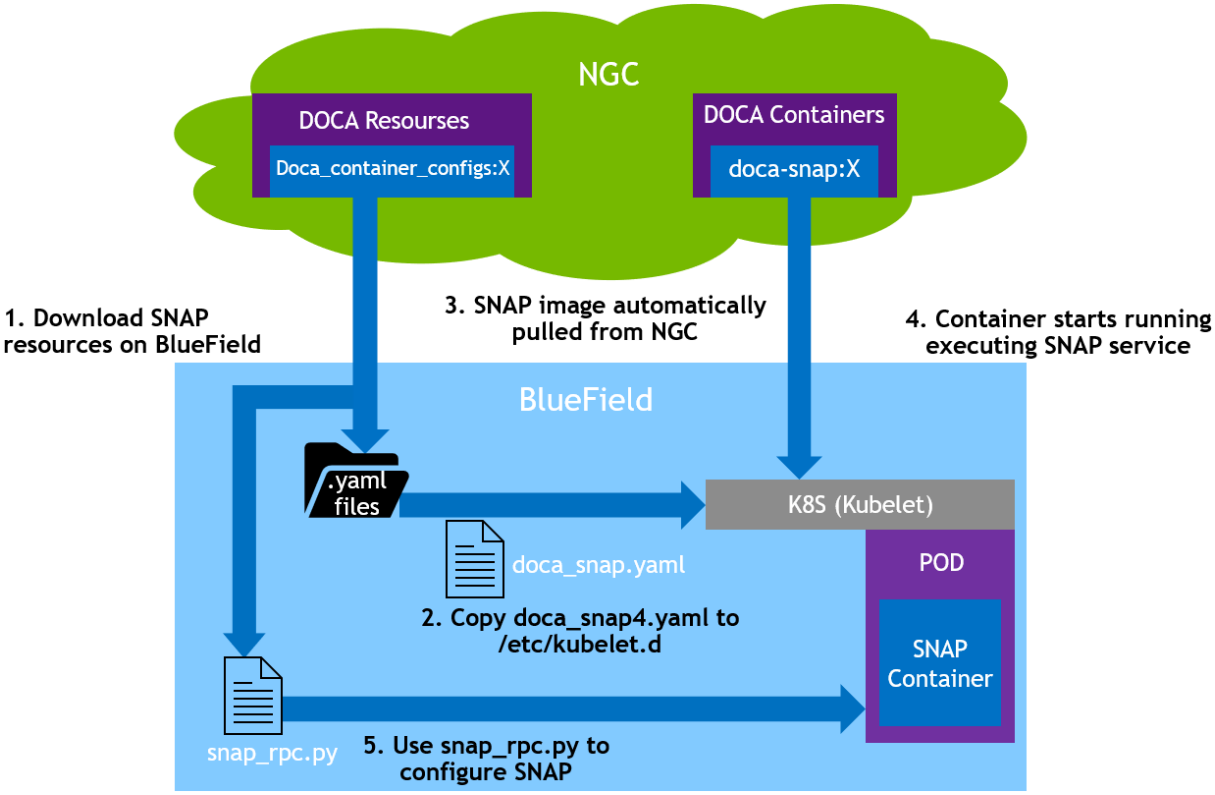
8.11.2.3.4.1 SNAP Container Deployment

SNAP container is available on the DOCA SNAP NVIDIA NGC catalog page.

SNAP container deployment on top of the BlueField DPU requires the following sequence:

1. Setup preparation and SNAP resource download for container deployment. See section "Preparation Steps" for details.
2. Adjust the `doca_snap.yaml` for advanced configuration if needed according to section "Adjusting YAML Configuration".
3. Deploy the container. The image is automatically pulled from NGC. See section "Spawning SNAP Container" for details.

The following is an example of the SNAP container setup.



8.11.2.3.4.2 Preparation Steps

Step 1: Allocate Hugepages

Allocate `4GiB` hugepages for the SNAP container according to the DPU OS's `Hugepagesize` value:

1. Query the `Hugepagesize` value:

   ```
   [dpu] grep Hugepagesize /proc/meminfo
   ```

   For Ubuntu22 and Ubuntu24, the value should be 2048KB. For Ubuntu24 with 64k page size, the value should be 524288KB.

2. Use the `doca-hugepages` to configure the requested hugepages:
   - For OS with 2048KB hugepage:

     ```
     [dpu] doca-hugepages config --app snap --size 2048 --num 2048
     ```

   - For OS with 524288KB hugepage:

     ```
     [dpu] doca-hugepages config --app snap --size 524288 --num 8
     ```

> For setups with a large size of hugepages (> 512MB), it is recommended to allocate slightly more than the requested amount (e.g., 5 GB instead of 4 GB), to ensure that SNAP has access to the required memory.

3. Reload the hugepages configuration for all applications based on the current database settings:

```
[dpu] doca-hugepages reload
```

> If live upgrade is utilized in this deployment, it is necessary to allocate twice the amount of resources listed above for the upgraded container.

> If other applications are running concurrently within the setup and are consuming hugepages, make sure to allocate additional hugepages beyond the amount described in this section for those applications.
>
> When deploying SNAP with a high scale of connections (i.e., disks 500 or more), the default allocation of hugepages (4GiB) becomes insufficient. This shortage of hugepages can be identified through error messages in the SNAP and SPDK layers. These error messages typically indicate failures in creating or modifying QPs or other objects.

Step 2: Create nvda_snap Folder

The folder `/etc/nvda_snap` is used by the container for automatic configuration after deployment.

8.11.2.3.5 Downloading YAML Configuration

The `.yaml` file configuration for the SNAP container is `doca_snap.yaml`. The download command of the `.yaml` file can be found on the DOCA SNAP NGC page.

> Internet connectivity is necessary for downloading SNAP resources. To deploy the container on DPUs without Internet connectivity, refer to appendix "Deploying Container on Setups Without Internet Connectivity".

8.11.2.3.5.1 Adjusting YAML Configuration

The `.yaml` file can easily be edited for advanced configuration.

- The SNAP `.yaml` file is configured by default to support Ubuntu setups (i.e., `Hugepagesize` = 2048 kB) by using hugepages-2Mi.
  To support other setups, edit the hugepages section according to the DPU OS's relevant `Hugepagesize` value. For example, to support CentOS 8.x configure `Hugepagesize` to 512MB:

```
limits:
   hugepages-512Mi: "<number-of-hugepages>Gi"
```

> ⚠ When deploying SNAP with a large number of controllers (500 or more), the default allocation of hugepages (4GB) may become insufficient. This shortage of hugepages can be identified through error messages, typically indicate failures in creating or modifying QPs or other objects. In these cases, more hugepages needed.

- The following example edits the `.yaml` file to request 16 CPU cores for the SNAP container and 4Gi memory and 4Gi hugepages:

```
    resources:
      requests:
        memory: "2Gi"
        hugepages-2Mi: "4Gi"
        cpu: "8"
      limits:
        memory: "4Gi"
        hugepages-2Mi: "4Gi"
        cpu: "16"
env:
  - name: APP_ARGS
    value: "-m 0xffff"
```

> ⚠ If all BlueField-3 cores are requested, the user must verify no other containers are in conflict over the CPU resources.

> ⚠ When running the Virtio-fs service with a large number of cores, it is necessary to increase the number of IO buffers in SPDK. For example, to run with 16 cores, the size of the large IO buffer pool must be set to at least 4095. This can be configured by adding the RPC command `iobuf_set_options --large-pool-count 4095` to `spdk_rpc_init.conf` under `/etc/nvda_snap`. Depending on the scale and SPDK subsystems in use other SPDK configuration parameters may need to be adjusted. Refer to SPDK documentation for more details.

- To automatically configure SNAP container upon deployment, edit the files below according to the use case. During bring-up, SNAP will forward the content of these files into the appropriate RPC script, whether SPDK RPCs or SNAP RPCs. Ensure that the required RPCs for your use case are included.
  a. Add `spdk_rpc_init.conf` file under `/etc/nvda_snap/`. The file includes the required SPDK RPCs. File example:

```
bdev_malloc_create 64 512
```

b. Add `snap_rpc_init.conf` file under `/etc/nvda_snap /`. The file includes the required SPDK RPCs.
Virtio-blk file example:

```
virtio_blk_controller_create --pf_id 0 --bdev Malloc0
```

NVMe file example:

```
nvme_subsystem_create --nqn nqn.2022-10.io.nvda.nvme:0
nvme_namespace_create -b Malloc0 -n 1 --nqn nqn.2022-10.io.nvda.nvme:0 --uuid 16dab065-
ddc9-8a7a-108e-9a489254a839
nvme_controller_create --nqn nqn.2022-10.io.nvda.nvme:0 --ctrl NVMeCtrl1 --pf_id 0 --suspended
nvme_controller_attach_ns -c NVMeCtrl1 -n 1
nvme_controller_resume -c NVMeCtrl1
```

c. Edit the `.yaml` file accordingly (uncomment):

```
env:
  - name: SPDK_RPC_INIT_CONF
    value: "/etc/nvda_snap/spdk_rpc_init.conf"
  - name: SNAP_RPC_INIT_CONF
    value: "/etc/nvda_snap/snap_rpc_init.conf"
```

It is user responsibility to make sure SNAP configuration matches firmware configuration. That is, an emulated controller must be opened on all existing (static/hotplug) emulated PCIe functions (either through automatic or manual configuration). A PCIe function without a supporting controller is considered malfunctioned, and host behavior with it is anomalous.

8.11.2.3.5.2 Spawning SNAP Container

Run the Kubernetes tool:

```
[dpu] systemctl restart containerd
[dpu] systemctl restart kubelet
[dpu] systemctl enable kubelet
[dpu] systemctl enable containerd
```

Copy the updated `doca_snap.yaml` file to the `/etc/kubelet.d` directory.

Kubelet automatically pulls the container image from NGC described in the YAML file and spawns a pod executing the container.

```
cp doca_snap.yaml /etc/kubelet.d/
```

The SNAP service starts initialization immediately, which may take a few seconds. To verify SNAP is running:

- Look for the message "SNAP Service running successfully" in the log

- Send `spdk_rpc.py spdk_get_version` to confirm whether SNAP is operational or still initializing

8.11.2.3.5.3 Debug and Log

View currently active pods, and their IDs (it might take up to 20 seconds for the pod to start):

```
crictl pods
```

Example output:

```
POD ID              CREATED              STATE         NAME
0379ac2c4f34c       About a minute ago   Ready         snap
```

View currently active containers, and their IDs:

```
crictl ps
```

View existing containers and their ID:

```
crictl ps -a
```

Examine the logs of a given container (SNAP logs):

```
crictl logs <container_id>
```

Examine the kubelet logs if something does not work as expected:

```
journalctl -u kubelet
```

The container log file is saved automatically by Kubelet under `/var/log/containers`.

The container log file is automatically saved by Kubelet to `/var/log/containers/`, using the filename format: `<pod_name>_default_snap-<container_id>.log`.

Refer to section "RPC Log History" for more logging information.

8.11.2.3.5.4 Logging Verbosity

To persist a custom log level across container restarts—or ensure it is applied during startup—add the relevant configuration command to the `snap_rpc_init.conf` file located at `/etc/nvda_snap/`.

Log level can also be modified at runtime using the `snap_log_level_set` RPC. For more details, refer to section "Log Management".

8.11.2.3.5.5 SNAP Logs (Source Package)

By default, the source package version of SNAP does not save logs automatically. To enable logging, follow the instructions in section "Run SNAP Service". For additional debugging information, refer to section "Build with Debug Prints Enabled".

To redirect SNAP output to a file, use the following command:

```
/opt/nvidia/nvda_snap/bin/snap_service > snap.log 2>&1
```

8.11.2.3.5.6 Exporting SNAP Logs (Container Only)

SNAP is integrated with SOS—a framework for consistent and structured log collection. To generate a log package:

1. Clone the SOS report tool: https://github.com/NVIDIA/doca-sosreport.
2. Follow the installation instructions in the repository.
3. Run the following command:

```
sos report --only snap_service,container_log
```

This creates a comprehensive log package. You may include additional plugins depending on the nature of the issue. For more details, refer to the "Collecting DOCA Logs for NVIDIA Inspection" page.

8.11.2.3.5.7 Stop, Start, Restart SNAP Container

SNAP binaries are deployed within a Docker container as SNAP service, which is managed as a supervisorctl service. Supervisorctl provides a layer of control and configuration for various deployment options.

- In the event of a SNAP crash or restart, supervisorctl detects the action and waits for the exited process to release its resources. It then deploys a new SNAP process within the same container, which initiates a recovery flow to replace the terminated process.
- In the event of a container crash or restart, kubeletclt detects the action and waits for the exited container to release its resources. It then deploys a new container with a new SNAP process, which initiates a recovery flow to replace the terminated process.

General Kublet Comment

After containers crash or exit, the kubelet restarts them with an exponential back-off delay (10s, 20s, 40s, etc.) which is capped at five minutes. Once a container has run for 10 minutes without an issue, the kubelet resets the restart back-off timer for that container. Restarting the SNAP service without restarting the container helps avoid the occurrence of back-off delays.

Different SNAP Termination Options

Container Termination

- To kill the container, remove the `.yaml` file form `/etc/kubelet.d/`. To start the container, `cp` the `.yaml` file back to the same path:

```
cp doca_snap.yaml /etc/kubelet.d/
```

- To restart the container (with sig-term) using `crictl`, use the `-t` (timeout) option:

```
crictl stop -t 10 <container-id>
```

SNAP Process Termination

To restart the SNAP service without restarting the entire container, user can either use the `supervictl` tool to restart the SNAP service or terminate the SNAP service process on the DPU. Different signals correspond to different termination behaviors. For example:

- Restart sends SIGTERM

```
crictl exec -it $(crictl ps -s running -q --name snap) supervisorctl restart snap
```

- Pkill sends SIGKILL

```
pkill -9 -f snap
```

SNAP service termination may take time as it releases all allocated resources. The duration depends on the scale of the use case and any other applications sharing resources with SNAP.

SNAP Process Fast Restart

The duration can be improved by configuring `supervisorctl` to give the exited SNAP process a shorter or zero termination time when using `supervisorctl restart snap`.

This causes the new process to start up while the old process' resources are still being freed by the kernel.

The user must ensure that the hugepage allocation is sufficient to accommodate both processes running in parallel. To modify the time SNAP takes to exit, the user should use the relevant environment variable `SUPERVISOR_STOPWAITSECS`.

To restart the SNAP service without restarting the container, kill the SNAP service process on the DPU. Different signals can be used for different termination options. For example:

```
pkill -9 -f snap
```

8.11.2.3.6 SNAP Source Package Deployment

8.11.2.3.6.1 System Preparation

Allocate `4GiB` hugepages for the SNAP container according to the DPU OS's `Hugepagesize` value:

1. Query the `Hugepagesize` value:

   ```
   [dpu] grep Hugepagesize /proc/meminfo
   ```

   For Ubuntu22 and Ubuntu24, the value should be 2048KB. For Ubuntu24 with 64k page size, the value should be 524288KB.

2. Use the `doca-hugepages` to configure the requested hugepages:
   - For OS with 2048KB hugepage:

     ```
     [dpu] doca-hugepages config --app snap --size 2048 --num 2048
     ```

   - For OS with 524288KB hugepage:

     ```
     [dpu] doca-hugepages config --app snap --size 524288 --num 8
     ```

     ⚠ For setups with a large size of hugepages (> 512MB), it is recommended to allocate slightly more than the requested amount (e.g., 5 GB instead of 4 GB), to ensure that SNAP has access to the required memory.

3. Reload the hugepages configuration for all applications based on the current database settings:

   ```
   [dpu] doca-hugepages reload
   ```

⚠ If live upgrade is utilized in this deployment, it is necessary to allocate twice the amount of resources listed above for the upgraded container.

⛔ If other applications are running concurrently within the setup and are consuming hugepages, make sure to allocate additional hugepages beyond the amount described in this section for those applications.

When deploying SNAP with a high scale of connections (i.e., disks 500 or more), the default allocation of hugepages (4GiB) becomes insufficient. This shortage of hugepages can be identified through error messages in the SNAP and SPDK layers. These error messages typically indicate failures in creating or modifying QPs or other objects.

8.11.2.3.6.2 Installing SNAP Source Package

Download the SNAP source package provided by NVIDIA on BlueField (BF).

Install the package:

- For Ubuntu, run:

```
dpkg -i snap-sources_<version>_arm64.*
```

- For CentOS, run:

```
rpm -i snap-sources_<version>_arm64.*
```

8.11.2.3.6.3 Build, Compile, and Install Sources

⚠ To build SNAP with a custom/legacy SPDK, see section "Replace the BFB SPDK".

1. Move to the sources folder. Run:

```
cd /opt/nvidia/nvda_snap/src/
```

2. Build the sources using `-Denable-spdk-compat=true` to ensure compatibility with SPDK, especially when using the out-of-box SPDK from a BFB. Then run:

```
meson setup /tmp/build -Denable-spdk-compat=true
```

3. Compile the sources. Run:

```
meson compile -C /tmp/build
```

4. Install the sources. Run:

```
meson install -C /tmp/build
```

8.11.2.3.6.4 Configure SNAP Environment Variables

To config the environment variables of SNAP, run:

```
source /opt/nvidia/nvda_snap/src/scripts/set_environment_variables.sh
```

8.11.2.3.6.5 Run SNAP Service

```
/opt/nvidia/nvda_snap/bin/snap_service
```

8.11.2.3.6.6 Replace the BFB SPDK (Optional)

Start with installing SPDK.

> ⚠ For legacy SPDK versions (e.g., SPDK 19.04) see appendix "Install Legacy SPDK".

To build SNAP with a custom SPDK, instead of following the basic build steps, perform the following:

1. Move to the sources folder. Run:

   ```
   cd /opt/nvidia/nvda_snap/src/
   ```

2. Build the sources with spdk-compat enabled and provide the path to the custom SPDK. Run:

   ```
   meson setup /tmp/build -Denable-spdk-compat=true -Dsnap_spdk_prefix=</path/to/custom/spdk>
   ```

3. Compile the sources. Run:

   ```
   meson compile -C /tmp/build
   ```

4. Install the sources. Run:

   ```
   meson install -C /tmp/build
   ```

5. Configure SNAP env variables and run SNAP service as explained in section "Configure SNAP Environment Variables" and "Run SNAP Service".

8.11.2.3.6.7 Build With Dynamically-linked Dependencies (Optional)

Instead of the basic build steps, perform the following:

1. Move to the sources folder. Run:

   ```
   cd /opt/nvidia/nvda_snap/src/
   ```

2. Build the sources with `-Dlibsnapemu=shared`. Run:

   ```
   meson setup /tmp/build -Denable-spdk-compat=true -Dlibsnapemu=shared /tmp/build
   ```

3. Compile the sources. Run:

   ```
   meson compile -C /tmp/build
   ```

4. Install the sources. Run:

```
meson install -C /tmp/build
```

5. Configure SNAP environment variables and run SNAP service as explained in section "Configure SNAP Environment Variables" and "Run SNAP Service".

8.11.2.3.6.8 Build with Debug Prints Enabled (Optional)

Instead of the basic build steps, perform the following:

1. Move to the sources folder. Run:

```
cd /opt/nvidia/nvda_snap/src/
```

2. Build the sources with `buildtype=debug`. Run:

```
meson --buildtype=debug /tmp/build
```

3. Compile the sources. Run:

```
meson compile -C /tmp/build
```

4. Install the sources. Run:

```
meson install -C /tmp/build
```

5. Configure SNAP env variables and run SNAP service as explained in section "Configure SNAP Environment Variables" and "Run SNAP Service".

8.11.2.3.6.9 Automate SNAP Configuration (Optional)

The script `run_snap.sh` automates SNAP deployment. Users must modify the following files to align with their setup. The configuration files are in the same format explained in the "adjust the YAML section". If different directories are utilized by the user, edits must be made to `run_snap.sh` accordingly:

1. Edit SNAP env variables in:

```
/opt/nvidia/nvda_snap/bin/set_environment_variables.sh
```

2. Edit SPDK initialization RPCs calls:

```
/opt/nvidia/nvda_snap/bin/spdk_rpc_init.conf
```

3. Edit SNAP initialization RPCs calls:

```
/opt/nvidia/nvda_snap/bin/snap_rpc_init.conf
```

4. Run the script:

```
/opt/nvidia/nvda_snap/bin/run_snap.sh
```

8.11.2.4 SNAP-4 Service Environment Variables

8.11.2.4.1 Supported Environment Variables

Name	Description	Default
`SNAP_RDMA_ZCOPY_ENABLE`	Enable/disable RDMA zero-copy transport type. For more info refer to section "Zero Copy (SNAP-direct)".	`1` (enabled)
`NVME_BDEV_RESET_ENABLE`	It is recommended that namespaces discovered from the same remote target are not shared by different PCIe emulations. If it is desirable to do that, users should set the variable `NVME_BDEV_RESET_ENABLE` to `0`. By doing so, the user must ensure that SPDK bdev always completes IOs (either with success or failure) in a reasonable time. Otherwise, the system may stall until all IOs return.	`1` (enabled)
`VBLK_RECOVERY_SHM`	Enable/disable virtio-blk recovery using shared memory files. This allows recovering without using `--force_in_order`.	`1` (enabled)
`SNAP_EMULATION_MANAGER`	The name of the RDMA device configured to have emulation management capabilities. If the variable is not defined (default), SNAP searches through all available devices to find the emulation manager (which may slow down initialization process). Unless configured otherwise, SNAP selects the first ECPF (i.e., "mlx5_0") as the emulation manager.	Unset
`VIRTIO_EMU_PROVIDER`	Configure the Virtio-blk data path Provider. Valid options: `dpu`; `dpa`.	`dpu`
`IO_CORE_DISTRIBUTION_POLICY`	Support for IO/core Multiplexer (MP) capabilities in DPA provider for NVMe. For more info refer to section "NVMe DPA multiplexer (MP) data path Provider" - options "weighted_rr", "none"	`none` (disabled)
`SUPERVISOR_STOPWAITSECS`	SNAP process termination time when using `supervisorctl restart snap`	`10` (sec)
`SNAP_LOG_FILE`	File path to redirect SNAP logs to at startup, will append/create.	Unset

8.11.2.4.2 YAML Configuration

To change the SNAP environment variables add the following to the `doca_snap.yaml` and continue from section "Adjusting YAML Configuration".

```
env:
      - name: VARIABLE_NAME
        value: "VALUE"
```

For example:

```
env:
      - name: SNAP_RDMA_ZCOPY_ENABLE
        value: "1"
```

8.11.2.4.3 Source Package Configuration

To change the SNAP environment variables:

1. Add/modify the configuration under `scripts/set_environment_variables.sh`.
2. Rerun:

   ```
   source scripts/set_environment_variables.sh
   ```

3. Rerun SNAP.

8.11.2.5 SNAP-4 Service RPC Commands

Remote procedure call (RPC) protocol is used to control the SNAP service. NVMe/virtio-blk SNAP, like other standard SPDK applications, supports JSON-based RPC protocol commands to control any resources and create, delete, query, or modify commands easily from CLI.

SNAP supports all standard SPDK RPC commands in addition to an extended SNAP-specific command set. SPDK standard commands are executed by the `spdk_rpc.py` tool while the SNAP-specific command set extension is executed by the `snap_rpc.py` tool.

Full `spdk_rpc.py` command set documentation can be found in the SPDK official documentation site.

Full `snap_rpc.py` extended commands are detailed further down in this chapter.

8.11.2.5.1 Using JSON-based RPC Protocol

The JSON-based RPC protocol can be used via the `snap_rpc.py` script that is installed inside the SNAP container and can be accessed using `crictl` tool.

> The SNAP container is CRI-compatible.

- To query the active container ID:

```
crictl ps -s running -q --name snap
```

- To post RPCs to the container using `crictl`:

```
crictl exec <container-id> snap_rpc.py <RPC-method>
```

For example:

```
crictl exec 0379ac2c4f34c snap_rpc.py emulation_function_list
```

In addition, an alias can be used:

```
alias snap_rpc.py="crictl ps -s running -q --name snap | xargs -I{} crictl exec -i {} snap_rpc.py "
alias spdk_rpc.py="crictl ps -s running -q --name snap | xargs -I{} crictl exec -i {} spdk_rpc.py "
```

- To open a bash shell to the container that can be used to post RPCs:

```
crictl exec -it <container-id> bash
```

8.11.2.5.2 Log Management

8.11.2.5.2.1 snap_log_level_set

SNAP allows dynamically changing the log level of the logger backend using the `snap_log_level_set`. Any log under the requested level is shown.

Parameter	Mandatory?	Type	Description
`level`	Yes	Number	Log level • 0 – Critical • 1 – Error • 2 – Warning • 3 – Info • 4 – Debug • 5 – Trace

8.11.2.5.3 PCIe Function Management

Emulated PCIe functions are managed through IB devices called emulation managers. Emulation managers are ordinary IB devices with special privileges to control PCIe communication and device emulations towards the host OS.

SNAP queries an emulation manager that supports the requested set of capabilities.

The emulation manager holds a list of the emulated PCIe functions it controls. PCIe functions may be approached later in 3 ways:

- `vuid` – recommended as it is guaranteed to remain constant (see appendix "PCIe BDF to VUID Translation" for details)

- `vhca_id`
- Function index (i.e., `pf_id` or `vf_id`)

8.11.2.5.3.1 emulation_function_list

`emulation_function_list` lists all existing functions.

The following is an example response for the `emulation_function_list` command:

```
[
  {
    "hotplugged": true,
    "hotplug state": "POWER_ON",
    "emulation_type": "VBLK",
    "pf_index": 0,
    "pci_bdf": "87:00.0",
    "vhca_id": 5,
    "vuid": "MT2306XZ009TVBLKS1D0F0",
    "ctrl_id": "VblkCtrl1",
    "num_vfs": 0,
    "vfs": []
  }
]
```

⚠ Use `-a` or `--all`, to show all inactive VF functions.

SNAP supports 2 types of PCIe functions:

- Static functions – PCIe functions configured at the firmware configuration stage (physical and virtual). Refer to appendix "DPU Firmware Configuration" for additional information.
- Hot-pluggable functions – PCIe functions configured dynamically at runtime. Users can add detachable functions. Refer to section "Hot-pluggable PCIe Functions Management" for additional information.

8.11.2.5.3.2 emulation_resource_list

This RPC retrieves information about the global resources available for emulated functions.

It is useful for verifying whether sufficient MSI-X or queue resources exist before creating a new hotplugged device.

The following is an example response for the `emulation_resource_list` command:

```
[
  {
    "num_available_msix_resources": 9636,
    "num_available_queue_resources": 32728
  }
]
```

⚠ NVMe queues (both Admin and I/O) consume two queue resources each, whereas virtio-blk virtqueues (vq) consume a single queue resource.

8.11.2.5.4 Hot-pluggable PCIe Functions Management

Hotplug PCIe functions are configured dynamically at runtime using RPCs. Once a new PCIe function is hot plugged, it appears in the host's PCIe device list and remains persistent until explicitly unplugged or the system undergoes a cold reboot. Importantly, this persistence continues even if the SNAP process terminates. Therefore, it is advised not to include hotplug/hotunplug actions in automatic initialization scripts (e.g., `snap_rpc_init.conf`).

> ⚠ Hotplug PFs do not support SR-IOV.

8.11.2.5.4.1 Two-step PCIe Hotplug

The following commands are designed to support modern two-step PCIe hotplug approach.

For more info about hotplug approaches, see section "Hot-pluggable PCIe Functions".

Virtio-blk Two-step PCIe Hotplug

virtio_blk_function_create

Create a new virtio-blk emulation function.

Command parameters:

Parameter	Mandatory?	Type	Description
`manager`	No	String	Emulation manager to manage hotplug function (unused)

virtio_blk_function_destroy

Delete an existing virtio-blk emulation function.

Command parameters:

Parameter	Mandatory?	Type	Description
`vuid`	Yes	String	Identifier of the hotplugged function to delete

virtio_blk_controller_hotplug

Exposes (hot plugs) the emulation function to the host OS.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller to expose to the host OS

Parameter	Mandatory?	Type	Description
`wait_for_done`	No	Bool	Block RPC until host discovers and acknowledges the new hotplug state
`mode`	No	Number	Specifies the host awareness strategy for the controller hotplug operation. Values: • `1` (host-aware): The operation takes the host system state into account to ensure safe handling. This is the recommended mode. • `2` (host-unaware): The operation ignores the host system state. ⊗ Host-unaware mode is unsafe. If this mode is used while the host is in a `not_ready` state, the RPC will return successfully (without error), but the actual hotplug behavior on the host is undefined. • `3` (host-aware + attention button): The same as host aware mode, but operation also uses PCIe Attention Button feature. ⚠ This mode causes 5-second delay of device's hotplug state change to `POWER_OFF`. It is suggested to use `emulation_functions_list` check the hotplug state have changed to `POWER_OFF` before do next step if `--wait_for_done` flag is not used. If no value is specified, the system attempts to use host-aware mode if supported. Otherwise, it reverts to the internal system default.

virtio_blk_controller_hotunplug

Removes (hot unplugs) the emulation function from the host OS.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller to expose to the host OS
`wait_for_done`	No	Bool	Specifies whether the RPC should block execution until the host system discovers and acknowledges the new hotplug state. • Enabled (True): The RPC waits synchronously for the host to acknowledge the configuration change before returning • Disabled (False): The RPC returns immediately, leaving the verification of the host state to the user When `wait_for_done` is disabled, it is the user's responsibility to verify that the host has identified the new function state. This can be done by querying the `pci_hotplug_state` parameter in the output of the `emulation_function_list` RPC.

Parameter	Mandatory?	Type	Description
`mode`	No	Number	Specifies the host awareness strategy for the controller hotunplug operation. Values: • `1` (host-aware): The operation takes the host system state into account to ensure safe handling. This is the recommended mode. • `2` (host-unaware): The operation ignores the host system state. **Host-unaware mode is unsafe. If this mode is used while the host is in a `not_ready` state, the RPC will return successfully (without error), but the actual hotunplug behavior on the host is undefined.** • `3` (host-aware + attention button): The same as host aware mode, but operation also uses PCIe Attention Button feature. **This mode will cause 5 seconds delay of device's hotplug state change to `POWER_OFF`. It is suggested to use `emulation_functions_list` check the hotplug state have changed to `POWER_OFF` before do next step if `--wait_for_done` flag is not used.** If no value is specified, the system attempts to use host-aware mode if supported. Otherwise, it reverts to the internal system default.

Virtio-blk Two-step PCIe Hotplug/Unplug Example

```
# Bringup
spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n
nqn.2022-10.io.nvda.nvme:swx-storage
snap_rpc.py virtio_blk_function_create
snap_rpc.py virtio_blk_controller_create --vuid MT2114X12200VBLKS1D0F0 --bdev nvme0n1
snap_rpc.py virtio_blk_controller_hotplug -c VblkCtrl1 --wait_for_done

# Cleanup
snap_rpc.py virtio_blk_controller_hotunplug -c VblkCtrl1 --wait_for_done
snap_rpc.py virtio_blk_controller_destroy -c VblkCtrl1
snap_rpc.py virtio_blk_function_destroy --vuid MT2114X12200VBLKS1D0F0
spdk_rpc.py bdev_nvme_detach_controller nvme0
```

NVMe Two-step PCIe Hotplug

nvme_function_create

Creates a new NVMe emulation function.

Command parameters:

Parameter	Mandatory?	Type	Description
`manager`	No	String	Emulation manager to manage hotplug function (unused)

nvme_function_destroy

Deletes an existing NVMe emulation function.

Command parameters:

Parameter	Mandatory?	Type	Description
`vuid`	Yes	String	Identifier of the hotplugged function to delete

nvme_controller_hotplug

Exposes (hot plugs) the emulation function to the host OS.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller to expose to the host OS
`wait_for_done`	No	Bool	Block RPC until host discovers and acknowledges the new hotplug state
`mode`	No	Number	Specifies the host awareness strategy for the controller hotplug operation. Values: • `1` (host-aware): The operation takes the host system state into account to ensure safe handling. This is the recommended mode. • `2` (host-unaware): The operation ignores the host system state. Host-unaware mode is unsafe. If this mode is used while the host is in a `not_ready` state, the RPC will return successfully (without error), but the actual hotplug behavior on the host is undefined. If no value is specified, the system attempts to use host-aware mode if supported. Otherwise, it reverts to the internal system default.

nvme_controller_hotunplug

Removes (hot unplugs) the emulation function from the host OS.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller to expose to the host OS
`wait_for_done`	No	Bool	Specifies whether the RPC should block execution until the host system discovers and acknowledges the new hotplug state. • Enabled (True): The RPC waits synchronously for the host to acknowledge the configuration change before returning • Disabled (False): The RPC returns immediately, leaving the verification of the host state to the user When `wait_for_done` is disabled, it is the user's responsibility to verify that the host has identified the new function state. This can be done by querying the `pci_hotplug_state` parameter in the output of the `emulation_function_list` RPC.

Parameter	Mandatory?	Type	Description
`mode`	No	Number	Specifies the host awareness strategy for the controller hotunplug operation. Values: • `1` (host-aware): The operation takes the host system state into account to ensure safe handling. This is the recommended mode. • `2` (host-unaware): The operation ignores the host system state. **Host-unaware mode is unsafe. If this mode is used while the host is in a `not_ready` state, the RPC will return successfully (without error), but the actual hotunplug behavior on the host is undefined.** If no value is specified, the system attempts to use host-aware mode if supported. Otherwise, it reverts to the internal system default.

NVMe Two-step PCIe Hotplug/Unplug Example

```
# Bringup
spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n
nqn.2022-10.io.nvda.nvme:swx-storage

spdk_rpc.py bdev_nvme_detach_controller nvme0
```

8.11.2.5.4.2 (Deprecated) PCIe Hotplug Legacy API

(Deprecated) Virtio-blk PCIe Hotplug Legacy API

Support for the legacy API ends in January 31, 2026.

Hotplug Commands

The following commands hot plug a new virtio-blk PCIe function to the system using legacy one-step interface.

virtio_blk_emulation_device_attach

Attach virtio-blk emulation function.

Command parameters:

Parameter	Mandatory?	Type	Description
`id`	No	Number	Device ID
`vid`	No	Number	Vendor ID

Parameter	Mandatory?	Type	Description
`ssid`	No	Number	Subsystem device ID
`ssvid`	No	Number	Subsystem vendor ID
`revid`	No	Number	Revision ID
`class_code`	No	Number	Class code
`num_msix`	No	Number	MSI-X table size
`total_vf`	No	Number	Maximal number of VFs allowed
`bdev`	No	String	Block device to use as backend
`num_queues`	No	Number	Number of IO queues (default 1, range 1-62). ⚠ The actual number of queues is limited by the number of queues supported by the hardware. ✓ It is recommended that the number of MSIX be greater than the number of IO queues (1 is used for the config interrupt).
`queue_depth`	No	Number	Queue depth (default 256, range 1-256) ⚠ It is only possible to modify the queue depth if the driver is not loaded.
`transitional_device`	No	Boolean	Transitional device support. See section "Virtio-blk Transitional Device Support" for more details.
`dbg_bdev_type`	No	Boolean	N/A – not supported

Hot Unplug Commands

The following commands hot-unplug a PCIe function from the system in 2 steps:

	Command	Description
1	emulation_device_detach_prepare	Prepare emulation function to be detached
2	emulation_device_detach	Detach emulation function

emulation_device_detach_prepare

This is the first step for detaching an emulation device. It prepares the system to detach a hot plugged emulation function. In case of success, the host's hotplug device state changes and you may safely proceed to the `emulation_device_detach` command.

The controller attached to the emulation function must be created and active when executing this command.

Command parameters:

Parameter	Mandatory?	Type	Description
`vhca_id`	No	Number	vHCA ID of PCIe function
`vuid`	No	String	PCIe device VUID
`ctrl`	No	String	Controller ID

⚠ At least one identifier must be provided to describe the PCIe function to be detached.

emulation_device_detach

This is the second step which completes detaching of the hotplugged emulation function. If the detach preparation times out, you may perform a surprise unplug using `--force` with the command.

⚠ The driver must be unprobed, otherwise errors may occur.

Command parameters:

Parameter	Mandatory?	Type	Description
`vhca_id`	No	Number	vHCA ID of PCIe function
`vuid`	no	String	PCIe device VUID
`force`	No	Boolean	Detach with failed preparation

⚠ At least one identifier must be provided to describe the PCIe function to be detached.

Virtio-blk Hot Plug/Unplug Example

```
// Bringup
spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n
nqn.2022-10.io.nvda.nvme:swx-storage
snap_rpc.py virtio_blk_emulation_device_attach
snap_rpc.py virtio_blk_controller_create --vuid MT2114X12200VBLKS1D0F0 --bdev nvme0n1

// Cleanup
snap_rpc.py emulation_device_detach_prepare --vuid MT2114X12200VBLKS1D0F0
snap_rpc.py virtio_blk_controller_destroy -c VblkCtrl1
snap_rpc.py emulation_device_detach --vuid MT2114X12200VBLKS1D0F0
spdk_rpc.py bdev_nvme_detach_controller nvme0
```

(Deprecated) NVMe Hotplug Legacy Commands

⛔ Support for the legacy API ends in January 31, 2027.

The following commands perform hotplug operations for a new NVMe PCIe function.

Once a PCIe function is attached, it appears immediately in the host's PCIe device list and remains there until explicitly detached or until a cold reboot occurs. It is the user's responsibility to create and activate a controller instance to manage the new function immediately after attachment. Leaving a hotplugged function unmanaged may cause anomalous behavior in the host OS driver.

nvme_emulation_device_attach

Attaches an NVMe emulation function.

Command parameters:

Parameter	Mandatory?	Type	Description
`id`	No	Number	Device ID
`vid`	No	Number	Vendor ID
`ssid`	No	Number	Subsystem device ID
`ssvid`	No	Number	Subsystem vendor ID
`revid`	No	Number	Revision ID
`class_code`	No	Number	Class code
`num_msix`	No	Number	MSI-X table size
`total_vf`	No	Number	Maximal number of VFs allowed
`num_queues`	No	Number	Number of IO queues (default 31, range 1-31). ⚠ The actual number of queues is limited by the number of queues supported by the hardware. ✓ It is recommended that the number of MSIX be greater than the number of IO queues (1 is used for the admin queue).
`version`	No	String	Specification version (currently only `1.4` is supported)

Hot Unplug Legacy Commands

The following commands hot-unplug a PCIe function from the system in 2 steps:

	Command	Description
1	emulation_device_detach_prepare	Prepare emulation function to be detached
2	emulation_device_detach	Detach emulation function

emulation_device_detach_prepare

Prepares the system to detach a hotplugged emulation function.

This is the first step in the detachment sequence. Upon success, the device enters a safe state for removal, allowing you to proceed with the `emulation_device_detach` command.

> ⚠ A controller must be active and attached to the emulation function before executing this command.

Command parameters:

Parameter	Mandatory?	Type	Description
`vhca_id`	No	Number	vHCA ID of PCIe function
`vuid`	No	String	PCIe device VUID
`ctrl`	No	String	Controller ID

> ⚠ At least one identifier must be provided to describe the PCIe function to be detached.

emulation_device_detach

Completes the detachment of a hotplugged emulation function.

If the preparation phase (`emulation_device_detach_prepare`) times out, use the `--force` option to perform a surprise unplug.

> ⚠ Ensure the driver has been properly unbound from the device before running this command, or errors may occur.

Command parameters:

Parameter	Mandatory?	Type	Description
`vhca_id`	No	Number	vHCA ID of PCIe function
`vuid`	no	String	PCIe device VUID
`force`	No	Boolean	Detach with failed preparation

> ⚠ At least one identifier must be provided to describe the PCIe function to be detached.

NVMe Hot Plug/Unplug Example

```
// Bringup
spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n nqn.2022-10.io.nvda.nvme:0
snap_rpc.py nvme_subsystem_create --nqn nqn.2022-10.io.nvda.nvme:0
```

```
snap_rpc.py nvme_namespace_create -b nvme0n1 -n 1 --nqn nqn.2022-10.io.nvda.nvme:0 --uuid 263826ad-19a3-4feb-
bc25-4bc81ee7749e
snap_rpc.py nvme_emulation_device_attach
snap_rpc.py nvme_controller_create --vuid MT240830045RNVMES1D0F0 --nqn nqn.2022-10.io.nvda.nvme:0 --suspended
snap_rpc.py nvme_controller_attach_ns -c NVMeCtrl1 -n 1
snap_rpc.py nvme_controller_resume -c NVMeCtrl1

// Cleanup
snap_rpc.py nvme_controller_detach_ns -c NVMeCtrl1 -n 1
snap_rpc.py emulation_device_detach_prepare --vuid MT240830045RNVMES1D0F0
snap_rpc.py nvme_controller_destroy -c NVMeCtrl1
snap_rpc.py emulation_device_detach --vuid MT240830045RNVMES1D0F0
snap_rpc.py nvme_namespace_destroy -n 1 --nqn nqn.2022-10.io.nvda.nvme:0
snap_rpc.py nvme_subsystem_destroy --nqn nqn.2022-10.io.nvda.nvme:0
spdk_rpc.py bdev_nvme_detach_controller nvme0
```

8.11.2.5.5 SPDK Bdev Management

8.11.2.5.5.1 bdev_list

Lists all active SNAP block devices (`bdevs`). This RPC is useful for identifying and managing custom block devices that operate outside standard SPDK `bdev` specifications.

No command parameters.

8.11.2.5.6 Virtio-blk Emulation Management

Virtio-blk emulation is a storage protocol belonging to the virtio family of devices. These devices are found in virtual environments yet by design look like physical devices to the user within the virtual machine.

Each virtio-blk device (e.g., virtio-blk PCIe entry) exposed to the host, whether it is PF or VF, must be backed by a virtio-blk controller.

⚠ Virtio-blk limitations:

- Probing a virtio-blk driver on the host without an already functioning virtio-blk controller may cause the host to hang until such controller is opened successfully (no timeout mechanism exists).
- Upon creation of a virtio-blk controller, a backend device must already exist.

8.11.2.5.6.1 Virtio-blk Emulation Management Commands

virtio_blk_controller_create

Create a new SNAP-based virtio-blk controller over a specific PCIe function on the host. To specify the PCIe function to open a controller upon must be provided as described in section "PCIe Function Management":

1. `vuid` (recommended as it is guaranteed to remain constant).
2. `vhca_id.`

3. Function index – `pf_id`, `vf_id`.

The mapping for `pci_index` can be queried by running `emulation_function_list`.

Command parameters:

Parameter	Mandatory?	Type	Description
`vuid`	No	String	PCIe device VUID
`vhca_id`	No	Number	vHCA ID of PCIe function
`pf_id`	No	Number	PCIe PF index to start emulation on
`vf_id`	No	Number	PCIe VF index to start emulation on (if the controller is meant to be opened on a VF)
`pci_bdf`	No	String	PCIe device BDF
`ctrl`	No	String	Controller ID
`num_queues`	No	Number	Number of IO queues (default 1, range 1-256). It is recommended that the number of MSIX be greater than the number of IO queues (1 is used for the config interrupt). Based on effective `num_msix` value (can be queried from `virtio_blk_controller_list` RPC), it can be later aligned using `virtio_blk_controller_modify` RPC).
`queue_size`	No	Number	Queue size (default 256, range 1- not limited). Must be a power of 2.
`size_max`	No	Number	Maximal SGE data transfer size (default 65536 bytes, range 4K - 2M) SNAP's internal memory buffer pool supports a maximum allocation size of 2 MB. This should guide the user when setting the combined value of `size_max * seg_max`. This limit is not strictly enforced. If the backend supports zero-copy datapath, users may set `size_max` beyond 2 MB based on their performance or application needs.
`seg_max`	No	Number	Maximal SGE list length (default 32, range 1-`queue_size`) `seg_max` is implicitly upper-bounded by virtio queue size in virtio-blk specification. As such, any provided `seg_max` value larger than `queue_size` will be silently clamped down to equal `queue_size` value.

Parameter	Mandatory?	Type	Description
`bdev`	No	String	SNAP SPDK block device to use as backend
`vblk_id`	No	String	Serial number for the controller
`admin_q`	No	0/1	Enables live migration and NVIDIA vDPA ⚠ This field is only applicable to controllers created through physical functions (PFs).
`dynamic_msix`	No	0/1	Dynamic MSIX for SR-IOV VFs on this PF. Only valid for PFs.
`vf_num_msix`	No	Number	Control the number of MSIX tables to associate with this controller. Valid only for VFs (whose parent PF controller is created using the `--dynamic_msix` option) and only when the dynamic MSIX management feature is enabled. Must be an even number ≥2. ⚠ This field is mandatory when the VF's MSIX is reclaimed using `virtio_blk_controller_vfs_msix_reclaim` or released using `--release_msix` on `virtio_blk_controller_destroy`.
`force_in_order`	No	0/1	Support virtio-blk crash recovery. Enabling this parameter to 1 may impact virtio-blk performance (default is 0). For more information, refer to section "Virtio-blk Crash Recovery".
`indirect_desc`	No	0/1	Enables indirect descriptors support for the controller's virt-queues. ⚠ When using the virtio-blk kernel driver, if indirect descriptors are enabled, it is always used by the driver. Using indirect descriptors for all IO traffic patterns may hurt performance in most cases.
`read_only`	No	0/1	Creates read only virtio-blk controller.
`suspended`	No	0/1	Creates controller in suspended state.
`live_update_listener`	No	0/1	Creates controller with the ability to listen for live update notifications via IPC.
`dbg_bdev_type`	No	0/1	N/A – not supported

Parameter	Mandatory?	Type	Description
`dbg_local_optimized`	No	0/1	N/A – not supported
`latency_optimized`	No	0/1	Create controller with (IO read) latency optimization. ⚠ This latency optimization applies only to non-ZCOPY flows. Using this flag may reduce bandwidth performance.

Example response:

```
{
  "jsonrpc": "2.0",
  "id": 1,
  "result": "VblkCtrl1"
}
```

virtio_blk_controller_destroy

Destroy a previously created virtio-blk controller. The controller can be uniquely identified by the controller's name as acquired from `virtio_blk_controller_create()`.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name
force	No	Boolean	Force destroying VF controller for SR-IOV

virtio_blk_controller_suspend

While suspended, the controller stops receiving new requests from the host driver and only finishes handling of requests already in flight. All suspended requests (if any) are processed after resume.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

virtio_blk_controller_resume

After the controller stops receiving new requests from the host driver (i.e., is suspended) and only finishes handling of requests already in flight, the resume command will resume the handling of IOs by the controller.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

virtio_blk_controller_bdev_attach

Attach the specified bdev into virtIO-blk SNAP controller. It is possible to change the serial ID (using the `vblk_id` parameter) if a new bdev is attached.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name
`bdev`	Yes	String	Block device name
`vblk_id`	No	String	Serial number for controller

virtio_blk_controller_bdev_detach

You may replace the bdev for virtio-blk controller. First, you should detach bdev from the controller. When bdev is detached, the controller stops receiving new requests from the host driver (i.e., is suspended) and finishes handling requests already in flight only.

At this point, you may attach a new bdev or destroy the controller.

When a new bdev is attached, the controller resumes handling all outstanding I/Os.

The block size cannot be changed if the driver is loaded.

bdev may be replaced with a different block size if the driver is not loaded.

A controller with no bdev attached to it is considered a temporary state, in which the controller is not fully operational, and may not respond to some actions requested by the driver.

If there is no imminent intention to call `virtio_blk_controller_bdev_attach`, it is advised to attach a `none` bdev instead. For example:

```
snap_rpc.py virtio_blk_controller_bdev_attach -c VblkCtrl1 --bdev none --dbg_bdev_type null
```

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

virtio_blk_controller_list

List virtio-blk SNAP controller.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	No	String	Controller name

Example response:

```
{
  "ctrl_id": "VblkCtrl2",
  "vhca_id": 38,
  "num_queues": 4,
  "queue_size": 256,
  "seg_max": 32,
  "size_max": 65536,
  "bdev": "Nvme1",
  "plugged": true,
  "indirect_desc": true,
  "num_msix": 2,
  "min configurable num_msix": 2,
  "max configurable num_msix": 32
}
```

virtio_blk_controller_modify

This function allows user to modify some of the controller's parameters in real-time, after it was already created.

Modifications can only be done when the emulated function is in idle state - thus there is no driver communicating with it.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	No	String	Controller Name
num_queues	No	int	Number of queues for the controller
num_msix	No	int	Number of MSIX to be used for a controller. Relevant only for VF controllers (when dynamic MSIX feature is enabled).

⚠ Standard virtio-blk kernel driver currently does not support PCIe FLR. As such,

virtio_blk_controller_dbg_io_stats_get

Debug counters are per-controller I/O stats that can help knowing the I/O distribution between different queues of the controller and the total I/O received on the controller.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

Example response:

```
"ctrl_id": "VblkCtrl2",
```

```
"queues": [
  {
    "queue_id": 0,
    "core_id": 0,
    "read_io_count": 19987068,
    "write_io_count": 6319931,
    "flush_io_count": 0
  },
  {
    "queue_id": 1,
    "core_id": 1,
    "read_io_count": 9769556,
    "write_io_count": 3180098,
    "flush_io_count": 0
  }
],
"read_io_count": 29756624,
"write_io_count": 9500029,
"flush_io_count": 0
    }
```

virtio_blk_controller_dbg_debug_stats_get

Debug counters are per-controller debug statistics that can help knowing the controller and queues health and status.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

Example response:

```
{
  "ctrl_id": "VblkCtrl1",
  "queues": [
    {
      "qid": 0,
      "state": "RUNNING",
      "hw_available_index": 6,
      "sw_available_index": 6,
      "hw_used_index": 6,
      "sw_used_index": 6,

}
```

virtio_blk_controller_vfs_msix_reclaim

Reclaim virtio-blk SNAP controller VFs MSIX back to the free MSIX pool. Valid only for PFs.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

8.11.2.5.6.2 Virtio-blk Configuration Examples

Virtio-blk Configuration for Single Controller

```
spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n
nqn.2022-10.io.nvda.nvme:swx-storage
snap_rpc.py virtio_blk_controller_create --vuid MT2114X12200VBLKS1D0F0 --bdev nvme0n1
```

Virtio-blk Cleanup for Single Controller

```
snap_rpc.py virtio_blk_controller_destroy -c VblkCtrl1
spdk_rpc.py bdev_nvme_detach_controller nvme0
```

Virtio-blk Dynamic Configuration For 125 VFs

1. Update the firmware configuration as described section "SR-IOV Firmware Configuration".
2. Reboot the host.
3. Run:

```
[dpu] spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n
nqn.2022-10.io.nvda.nvme:swx-storage
[dpu] snap_rpc.py virtio_blk_controller_create --ctrl VblkCtrl0 --vuid MT2114X12200VBLKS1D0F0
[dpu] for i in `seq 0 124`; do snap_rpc.py virtio_blk_controller_create --pf_id 0 --vf_id $i --bdev nvme0n1
--ctrl VblkCtrl$((i+1)); done;

[host] modprobe -v virtio-pci && modprobe -v virtio-blk
[host] echo 125 > /sys/bus/pci/devices/0000:86:00.3/sriov_numvfs
```

4. For cleanup:

```
[host] echo 0 > /sys/bus/pci/devices/0000:86:00.3/sriov_numvfs
[host] modprobe -rv virtio-pci && modprobe -rv virtio-blk

[dpu] for i in `seq 0 124`; do snap_rpc.py virtio_blk_controller_destroy -c VblkCtrl$((i+1)) -f; done;
[dpu] spdk_rpc.py bdev_nvme_detach_controller nvme0
[dpu] snap_rpc.py snap_rpc.py virtio_blk_controller_destroy -c VblkCtrl$((i+1)) -f
```

Virtio-blk Suspend, Resume Example

```
[host] // Run fio
[dpu] snap_rpc.py virtio_blk_controller_suspend -c VBLKCtrl1
[host] // IOs will get suspended
[dpu] snap_rpc.py virtio_blk_controller_resume -c VBLKCtrl1
[host] // fio will resume sending IOs
```

Virtio-blk Bdev Attach, Detach Example

```
[host] // Run fio
[dpu] snap_rpc.py virtio_blk_controller_bdev_detach -c VBLKCtrl1
[host] // Bdev will be detached and IOs will get suspended
[dpu] snap_rpc.py virtio_blk_controller_bdev_attach -c VBLKCtrl1 --bdev null2
```

```
[host] // The null2 bdev will be attached into controller and fio will resume sending IOs
```

Notes

- Virtio-blk protocol controller supports one backend device only
- Virtio-blk protocol does not support administration commands to add backends. Thus, all backend attributes are communicated to the host virtio-blk driver over PCIe BAR and must be accessible during driver probing. Therefore, backends can only be changed once the PCIe function is not in use by any host storage driver.

8.11.2.5.7 NVMe Emulation Management

8.11.2.5.7.1 NVMe Subsystem

The NVMe subsystem as described in the NVMe specification is a logical entity which encapsulates sets of NVMe backends (or namespaces) and connections (or controllers). NVMe subsystems are extremely useful when working with multiple NVMe controllers especially when using NVMe VFs. Each NVMe subsystem is defined by its serial number (SN), model number (MN), and qualified name (NQN) after creation.

The RPCs listed in this section control the creation and destruction of NVMe subsystems.

8.11.2.5.7.2 NVMe Namespace

NVMe namespaces are the representors of a continuous range of LBAs in the local/ remote storage. Each namespace must be linked to a subsystem and have a unique identifier (NSID) across the entire NVMe subsystem (e.g., 2 namespaces cannot share the same NSID even if they are linked to different controllers).

After creation, NVMe namespaces can be attached to a controller.

SNAP does not currently support shared namespaces between different controllers. So, each namespace should be attached to a single controller.

The SNAP application uses an SPDK block device framework as a backend for its NVMe namespaces. Therefore, they should be configured in advance. For more information about SPDK block devices, see SPDK bdev documentation and Appendix SPDK Configuration.

8.11.2.5.7.3 NVMe Controller

Each NVMe device (e.g., NVMe PCIe entry) exposed to the host, whether it is a PF or VF, must be backed by NVMe controller, which is responsible for all protocol communication with the host's driver.

Every new NVMe controller must also be linked to an NVMe subsystem. After creation, NVMe controllers can be addressed using either their name (e.g., `Nvmectrl1`) or both their subsystem NQN and controller ID.

8.11.2.5.7.4 Attaching NVMe Namespace to NVMe Controller

After creating an NVMe controller and an NVMe namespace under the same subsystem, the following method is used to attach the namespace to the controller.

8.11.2.5.7.5 NVMe Emulation Management Commands

nvme_subsystem_create

Create a new NVMe subsystem to be controlled by one or more NVMe SNAP controllers. An NVMe subsystem includes one or more controllers, zero or more namespaces, and one or more ports. An NVMe subsystem may include a non-volatile memory storage medium and an interface between the controller(s) in the NVMe subsystem and non-volatile memory storage medium.

Command parameters:

Parameter	Mandatory?	Type	Description
`nqn`	Yes	String	Subsystem qualified name
`serial_number`	No	String	Subsystem serial number (Max string length is 20 characters)
`model_number`	No	String	Subsystem model number
`nn`	No	Number	Maximal namespace ID allowed in the subsystem (default 0xFFFFFFFE; range 1-0xFFFFFFFE)
`mnan`	No	Number	Maximal number of namespaces allowed in the subsystem (default 1024; range 1-0xFFFFFFFE)
`single_ctrl`	No	Boolean	Subsystem is restricted to a single ctrl

Example request:

```
{
  "jsonrpc": "2.0",
  "id": 1,
  "method": "nvme_subsystem_create",
  "params": {
    "nqn": "nqn.2022-10.io.nvda.nvme:0"
  }
}
```

nvme_subsystem_destroy

Destroy (previously created) NVMe SNAP subsystem.

Command parameters:

Parameter	Mandatory?	Type	Description
`nqn`	Yes	String	Subsystem qualified name
`force`	No	Bool	Force the deletion of all the controllers and namespaces under the subsystem

nvme_subsystem_list

List NVMe subsystems.

nvme_namespace_create

Create new NVMe namespaces that represent a continuous range of LBAs in the previously configured bdev. Each namespace must be linked to a subsystem and have a unique identifier (NSID) across the entire NVMe subsystem.

Command parameters:

Parameter	Mandatory?	Type	Description
`nqn`	Yes	String	Subsystem qualified name
`bdev_name`	Yes	String	Block device to use as backend
`nsid`	Yes	Number	Namespace ID
`uuid`	No	Number	Namespace UUID ⚠ To safely detach/attach namespaces, the UUID should be provided to force the UUID to remain persistent.
`dbg_bdev_type`	No	string	Bdev plugin to be attached with the controller. Refer to section "Bdev" for more information.

nvme_namespace_destroy

Destroy a previously created NVMe namespaces.

Command parameters:

Parameter	Mandatory?	Type	Description
`nqn`	Yes	String	Subsystem qualified name
`nsid`	Yes	Number	Namespace ID

nvme_namespace_list

List NVMe SNAP namespaces.

Command parameters:

Parameter	Mandatory?	Type	Description
`nqn`	No	String	Subsystem qualified name

nvme_controller_create

Instantiates a new SNAP-based NVMe block controller over a designated host PCIe function.

Specify the target PCIe function using the `pci_index` parameter. Execute the `emulation_function_list` command to retrieve the correct `pci_index` mappings.

> ⚠ By default, the controller enables an optional NVMe command only if all namespaces attached during driver load support that specific command.

> ⚠ Explicitly set the corresponding support flag during creation to override the default behavior. For example, passing `--compare 0` disables the Compare command entirely, regardless of underlying namespace support.

Command parameters:

Parameter	Mandatory?	Type	Description
`nqn`	Yes	String	Subsystem qualified name.
`vuid`	No	Number	VUID of PCIe function.
`pf_id`	No	Number	PCIe PF index to start emulation on.
`vf_id`	No	Number	PCIe VF index to start emulation on (if the controller is destined to be opened on a VF).
`pci_bdf`	No	String	PCIe BDF to start emulation on.
`vhca_id`	No	Number	vHCA ID of PCIe function.
`ctrl`	No	Number	Controller ID.
`num_queues`	No	Number	Number of IO queues (default: 1, range: 1–31). ⚠ Limited by hardware support. ✓ Recommended for the number of MSIX to be greater than the number of IO queues.
`mdts`	No	Number	MDTS (default: 7, range: 1–7).
`fw_slots`	No	Number	Maximum number of firmware slots (default: 4).
`write_zeroes`	No	0/1	Enable the `write_zeroes` optional NVMe command.

Parameter	Mandatory?	Type	Description
`compare`	No	0/1	Set the value of the compare support bit in the controller.
`compare_write`	No	0/1	Set the value of the `compare_write` support bit in the controller. ⚠ During crash recovery, all compare and write commands are expected to fail.
`deallocate_dsm`	No	0/1	Set the value of the DSM (dataset management) support bit in the controller. Only the `deallocate` DSM request is currently supported.
`suspended`	No	0/1	Open the controller in suspended state (requires `nvme_controller_resume` to become active). Recommended for recovery scenarios or when creating the controller while the driver is loaded.
`snapshot`	No	String	Create a controller from a snapshot file path (snapshot must be taken using `nvme_controller_snapshot_get`).
`dynamic_msix`	No	0/1	Enable dynamic MSIX management for the controller (default: 0). Applies only for PFs.
`vf_num_msix`	No	Number	Number of MSIX tables to associate with this controller. Valid only for VFs whose parent PF controller was created with `--dynamic_msix`, and when dynamic MSIX management is enabled. ⚠ Mandatory if VF's MSIX is reclaimed using `nvme_controller_vfs_msix_reclaim` or released using `--release_msix` on `nvme_controller_destroy`.
`admin_only`	No	0/1	Creates NVMe controller with admin queues only (no IO queues).
`quirks`	No	Number	Bitmask to support buggy/non-compliant drivers. • Bit 0 – Send "Namespace Attribute Changed" async event, even if disabled by driver. • Bit 1 – Keep sending these events even without a "Changed Namespace List" Get Log Page request. • Bit 2 – reserved. Should not be set. • Bit 3 – Force-enable "Namespace Management capability" NVMe OACS even if unsupported. • Bit 4 – Disable Scatter-Gather Lists support. See “OS Issues” section for details.
`queue_core_alloc_policy`	No	String	Core allocation policy: `"pre-allocation"` (predictable but may be imbalanced if active queues differ from configured), or `"on-demand"` (auto-balances at runtime, unpredictable upfront). Default: `"on-demand"`. ⚠ Core-to-queue mapping is not persistent across recovery/live update/migration.

Parameter	Mandatory?	Type	Description
`admin_identify_cmd_fwd`	No	String	Enable forwarding of Identify admin commands with selected CNS values (comma-separated hex with `0x` prefix) from SNAP to the upper application. Example: `--admin_identify_cmd_fwd 0x0,0x1,0x13`
`admin_set_features_cmd_fwd`	No	String	Enable forwarding of Set Features admin commands with selected FID values (comma-separated hex with `0x` prefix) from SNAP to the upper application. Example: `--admin_set_features_cmd_fwd 0xc0,0xe4`

`queue_depth`	No	Number	Specifies the maximum IO queue size for the controller. This parameter is valid only for VFs.
			• Range: 2–4096 (inclusive).
			• If set to `0` (default), the system uses the pre-configured value based on the following hierarchy:
			  • The value last set on the emulation function since the last cold reboot (persistent across application crashes or restarts).
			  • If never set, the `NVME_EMULATION_MAX_QUEUE_DEPTH` firmware parameter.
			SR-IOV configuration modifying this parameter on a VF while the parent PF has active VFs (i.e., `sriov_numvfs` or `sriov_totalvfs` is not `0`) leads to undefined behavior.
			The actual queue depth utilized is restricted by the NVMe driver parameter `io_queue_depth` configured on the host machine.
			• Requirement: The host module's `io_queue_depth` should be configured to be at least equal to the `queue_depth` set in this RPC.
			• Persistence: To ensure this applies at boot, the parameter must be added to the host's kernel command line (`/proc/cmdline`).

Example request:

```
{
  "jsonrpc": "2.0",
  "id": 1,
  "method": "nvme_controller_create",
  "params": {
    "nqn": "nqn.2022-10.io.nvda.nvme:0",
    "pf_id": 0,
    "num_queues": 8,
  }
}
```

nvme_controller_destroy

Destroy a previously created NVMe controller. The controller can be uniquely identified by a controller name as acquired from `nvme_controller_create`.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name
`release_msix`	No	1/0	Release MSIX back to free pool. Applies only for VFs.
`force`	No	1/0	Forcefully destroy the controller (without this flag set, SNAP may block deletion in case driver is up). ⚠ After controller is destroyed with `--force` flag set, it is not guaranteed SNAP will perform a successful recovery after this. It is the user's responsibility to make sure either driver is properly cleaned up or controller is re-created with exact same configuration, before resuming SNAP controller back.

nvme_controller_suspend

While suspended, the controller stops handling new requests from the host driver. All pending requests (if any) will be processed after resume.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name
`timeout_ms`	No	Number	Suspend timeout ⚠ The maximum time in milliseconds to let the controller finish all the inflight I/Os before discarding them. If `timeout_ms` is not provided, the operation waits until the IOs complete without a timeout on the SNAP layer.
`admin_only`	No	0/1	Suspend only the admin queue
`live_update_notifier`	No	0/1	Send a live update notification via IPC

nvme_controller_resume

The resume command continues the (previously suspended) controller's handling of new requests sent by the driver. If the controller is created in suspended mode, resume is also used to start initial communication with host driver.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

nvme_controller_snapshot_get

Captures the current state of the controller and saves it to a file, which can then be used to instantiate a new controller.

> ⚠ To ensure data consistency, suspend the controller using the `nvme_controller_suspend` RPC before executing this function.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name
`filename`	Yes	String	File path

nvme_controller_vfs_msix_reclaim

Reclaims all VFs MSIX back to the PF's free MSIX pool.

This function can only be applied on PFs and can only be run when SR-IOV is not set on host side (i.e., `sriov_numvfs = 0`).

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

nvme_controller_list

Provide a list of all active (created) NVMe controllers with their characteristics.

Command parameters:

Parameter	Mandatory?	Type	Description
`nqn`	No	String	Subsystem qualified name
`ctrl`	No	String	Only search for a specific controller

nvme_controller_modify

This function allows modifying some of the controller's parameters in real-time after it was already created.

Modifications can only be made when the emulated function is in idle state (i.e., no driver is communicating with it).

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller Name
`num_queues`	No	int	Number of queues for the controller
`num_msix`	No	int	Number of MSIX to be used for a controller. Relevant only for VF controllers (when dynamic MSIX feature is enabled).
`queue_depth`	No	Number	Specifies the maximum IO queue size. This parameter is valid only for VFs. • Range: 2–4096 (inclusive). • If set to `0` (default) the system uses the pre-configured value based on the following hierarchy: a. The value last set on the emulation function since the last cold reboot (persistent across application crashes or restarts). b. If never set, the `NVME_EMULATION_MAX_QUEUE_DEPTH` firmware parameter. SR-IOV configuration modifying this parameter on a VF while the parent PF has active VFs (i.e., `sriov_numvfs` or `sriov_totalvfs` is not `0`) leads to undefined behavior.

nvme_controller_attach_ns

Attach a previously created NVMe namespace to given NVMe controller under the same subsystem.

The result in the response object returns `true` for success and `false` for failure.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name
`nsid`	Yes	Number	Namespace ID

nvme_controller_detach_ns

Detach a previously attached namespace with a given NSID from the NVMe controller.

The result in the response object returns `true` for success and `false` for failure.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name
`nsid`	Yes	Number	Namespace ID

nvme_controller_dbg_debug_stats_get

Display debug counters for NVMe controller as following:

BAR Registers

Register	Description
`CC`	Controller Configuration register.
`CSTS`	Controller Status register.

Submission Queue (SQS) Fields

Field	Description
`qid`	Queue ID.
`depth`	Queue depth.
`cqid`	Associated completion queue ID.
`state`	Current queue state.
`driver_sq_tail`	Value of the SQ Tail Doorbell register as written by the driver.
`device_sq_head`	Value of the SQ Head pointer within the device.
`Requests`	Total number of requests received on this queue.

Completion Queue (CQS) Fields

Field	Description
`qid`	Queue ID.
`depth`	Queue depth.
`state`	Current queue state.
`driver_cq_head`	Value of the CQ Head Doorbell register as written by the driver.
`device_cq_tail`	Value of the CQ Tail pointer within the device.
`Completions`	Total number of completions sent on this queue.

Command Parameters

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

nvme_controller_dbg_io_stats_get

The result in the response object returns `true` for success and `false` for failure.

Command parameters:

Parameter	Mandatory?	Type	Description
`ctrl`	Yes	String	Controller name

```
"ctrl_id": "NVMeCtrl2",
"queues": [
  {
    "queue_id": 0,
    "core_id": 0,
    "read_io_count": 19987068,
    "write_io_count": 6319931,
    "flush_io_count": 0
  },
  {
    "queue_id": 1,
    "core_id": 1,
    "read_io_count": 9769556,
    "write_io_count": 3180098,
    "flush_io_count": 0
  }
],
"read_io_count": 29756624,
"write_io_count": 9500029,
"flush_io_count": 0
    }
```

8.11.2.5.7.6 NVMe Configuration Examples

NVMe Configuration for Single Controller

On the DPU:

```
spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n
nqn.2022-10.io.nvda.nvme:swx-storage
snap_rpc.py nvme_subsystem_create --nqn nqn.2022-10.io.nvda.nvme:0
snap_rpc.py nvme_namespace_create -b nvme0n1 -n 1 --nqn nqn.2022-10.io.nvda.nvme:0 --uuid 263826ad-19a3-4feb-
bc25-4bc81ee7749e
snap_rpc.py nvme_controller_create --nqn nqn.2022-10.io.nvda.nvme:0 --pf_id 0 --suspended
snap_rpc.py nvme_controller_attach_ns -c NVMeCtrl1 -n 1
snap_rpc.py nvme_controller_resume -c NVMeCtrl1
```

⚠ It is necessary to create a controller in a suspended state. Afterward, the namespaces can be attached, and only then should the controller be resumed using the `nvme_controller_resume` RPC.

⚠ To safely detach/attach namespaces, the UUID must be provided to force the UUID to remain persistent.

NVMe Cleanup for Single Controller

```
snap_rpc.py nvme_controller_detach_ns -c NVMeCtrl2 -n 1
snap_rpc.py nvme_controller_destroy -c NVMeCtrl2
snap_rpc.py nvme_namespace_destroy -n 1 --nqn nqn.2022-10.io.nvda.nvme:0
snap_rpc.py nvme_subsystem_destroy --nqn nqn.2022-10.io.nvda.nvme:0
spdk_rpc.py bdev_nvme_detach_controller nvme0
```

NVMe and Hotplug Cleanup for Single Controller

```
snap_rpc.py nvme_controller_detach_ns -c NVMeCtrl1 -n 1
snap_rpc.py emulation_device_detach_prepare --vuid MT240830045RNVMES1D0F0
snap_rpc.py nvme_controller_destroy -c NVMeCtrl1
snap_rpc.py emulation_device_detach --vuid MT240830045RNVMES1D0F0
snap_rpc.py nvme_namespace_destroy -n 1 --nqn nqn.2022-10.io.nvda.nvme:0
snap_rpc.py nvme_subsystem_destroy --nqn nqn.2022-10.io.nvda.nvme:0
spdk_rpc.py bdev_nvme_detach_controller nvme0
```

1. Update the firmware configuration as described section "SR-IOV Firmware Configuration".
2. Reboot the host.
3. Create a dummy controller on the parent PF:

```
[dpu] # snap_rpc.py nvme_subsystem_create --nqn nqn.2022-10.io.nvda.nvme:0
[dpu] # snap_rpc.py nvme_controller_create --nqn nqn.2022-10.io.nvda.nvme:0 --ctrl NVMeCtrl1 --pf_id 0 --
admin_only
```

4. Create 125 Bdevs (Remote or Local), 125 NSs and 125 controllers:

```
[dpu] for i in `seq 0 124`; do \
   # spdk_rpc.py bdev_null_create null$((i+1)) 64 512;
   # snap_rpc.py nvme_namespace_create -b null$((i+1)) -n $((i+1)) --nqn nqn.2022-10.io.nvda.nvme:0 --uuid
3d9c3b54-5c31-410a-b4f0-7cf2afd9e$((i+100));
   # snap_rpc.py nvme_controller_create --nqn nqn.2022-10.io.nvda.nvme:0 --ctrl NVMeCtrl$((i+2)) --pf_id 0
--vf_id $i --suspended;
   # snap_rpc.py nvme_controller_attach_ns -c NVMeCtrl$((i+2)) -n $((i+1));
   # snap_rpc.py nvme_controller_resume -c NVMeCtrl$((i+2));
done
```

5. Load the driver and configure VFs:

```
[host] # modprobe -v nvme
[host] # echo 125 > /sys/bus/pci/devices/0000\:25\:00.2/sriov_numvfs
```

8.11.2.5.8 Environment Variable Management

8.11.2.5.8.1 snap_global_param_list

`snap_global_param_list` lists all existing environment variables.

The following is an example response for the `snap_global_param_list` command:

```
[
  "SNAP_ENABLE_POLL_SKIP       : set     : 0  ",
  "SNAP_POLL_CYCLE_SIZE        : not set : 16 ",
  "SNAP_RPC_LOG_ENABLE         : set     : 1  ",
  "SNAP_MEMPOOL_SIZE_MB        : set     : 1024",
  "SNAP_MEMPOOL_4K_BUFFS_PER_CORE : not set : 1024",
  "SNAP_RDMA_ZCOPY_ENABLE      : set     : 1  ",
  "SNAP_TCP_XLIO_ENABLE        : not set : 1  ",
  "SNAP_TCP_XLIO_TX_ZCOPY      : not set : 1  ",
  "MLX5_SHUT_UP_BF             : not set : 0  ",
  "SNAP_SHARED_RX_CQ           : not set : 1  ",
  "SNAP_SHARED_TX_CQ           : not set : 1  ",
...
```

8.11.2.6 SNAP-4 Service Advanced Features

8.11.2.6.1 RPC Log History

RPC log history (enabled by default) records all the RPC requests (from `snap_rpc.py` and `spdk_rpc.py`) sent to the SNAP application and the RPC response for each RPC requests in a dedicated log file, `/var/log/snap-log/rpc-log`. This file is visible outside the container (i.e., the log file's path on the DPU is `/var/log/snap-log/rpc-log` as well).

The `SNAP_RPC_LOG_ENABLE` env can be used to enable (`1`) or disable (`0`) this feature.

RPC log history is supported with SPDK version spdk23.01.2-12 and above.

When RPC log history is enabled, the SNAP application writes (in append mode) RPC request and response message to `/var/log/snap-log/rpc-log` constantly. Pay attention to the size of this file. If it gets too large, delete the file on the DPU before launching the SNAP pod.

8.11.2.6.2 SR-IOV

SR-IOV configuration depends on the kernel version and must be handled carefully to ensure device visibility and system stability across both hypervisor and DPU orchestrators.

To ensure a safe and stable SR-IOV setup, follow these steps:

1. Preconfigure VF controllers on the DPU – Before configuring SR-IOV on the host, ensure that the DPU is properly configured with all required VF controllers already created and opened.
    - VF functions are always visible and configurable on the DPU side. Use the following command to verify:

      ```
      snap_rpc.py emulation_function_list --all
      ```

    - Confirm that the configuration meets your requirements.
        - Check the number of resources allocated for the PF, specifically MSIX and queues (queried using `snap_rpc.py virtio_blk_controller_list` RPC output, field `free_queues` and `free_msix`) are enough to satisfy your needs for all underlying VFs.
        - Use dynamic MSIX if needed and supported.

- Once host-side configuration begins, further modifications may not be possible.

2. Disable autoprobing with `sriov_drivers_autoprobe=0` – In deployments with many virtual devices, autoprobing must be disabled to ensure stable device discovery. Failing to disable autoprobing may result in:
   - Incomplete device visibility
   - Missing virtual disks
   - System hangs during initialization
   - Unreliable behavior in large-scale environments (more than 100 VFs)

   > Recommended configuration for large-scale deployments:
   > - Disable autoprobe:
   >
   > ```
   > echo 0 > /sys/bus/pci/devices/<BDF>/sriov_drivers_autoprobe
   > ```
   >
   > - Manually bind the VFs to drivers using tools such as `driverctl`, or by writing to `bind` / `unbind` in `sysfs`.

3. Configure SR-IOV on the host – For small-scale deployments (fewer than 100 VFs), use the `sriov_totalvfs` entry:

   ```
   echo <number_of_vfs> > /sys/bus/pci/devices/<BDF>/sriov_totalvfs
   ```

   For newer drivers, use:

   ```
   echo <number_of_vfs> > /sys/bus/pci/devices/<BDF>/sriov_numvfs
   ```

   > After SR-IOV configuration, no disks appear in the hypervisor by default. Disks are only visible inside VMs once the corresponding PCIe VF is assigned to the VM via a virtualization manager (e.g., libvirt, VMware). To use the device directly from the hypervisor, manually bind the VF to the appropriate driver.

Additional notes:

- Hot-plugged PFs do not support SR-IOV.
- For deployments requiring more than 127 VFs, add the following kernel parameter to the host's boot command line:

  ```
  pci=assign-busses
  ```

  Without this, the host may log errors such as:

  ```
  pci 0000:84:00.0: [1af4:1041] type 7f class 0xffffff
  pci 0000:84:00.0: unknown header type 7f, ignoring device
  ```

These errors prevent the virtio driver from probing the device.

8.11.2.6.3 Hot-pluggable PCIe Functions

PCI hotplug functions allow the addition or removal of PCI devices from a running system without requiring a machine shutdown or interrupting operations. This technology relies on hardware and software support to isolate individual slots, manage power and control signals, and ensure proper power sequencing during device insertion or removal. When a device is hotplugged, the operating system's hotplug service handles quiescing the device driver, controlling the physical slot, and managing power states while the bus remains active.

SNAP enables dynamic hot-plugging and hot-unplugging of PCIe functions at runtime via dedicated RPCs (see section "Hot-pluggable PCIe Functions Management"). Once a PCIe function is hotplugged, it persists in the host's PCIe device list until it is explicitly unplugged via RPC or a firmware reset occurs. This persistence is maintained even if the SNAP process terminates.

Two-step PCIe Hotplug8.11.2.6.3.1

The two-step PCIe hotplug method divides the process into two distinct phases:

1. PCIe function creation (the function is accessible within the DPU application but remains hidden from the host OS/kernel).
2. PCIe function exposure to the host.

Symmetrically, hot-unplugging involves hiding the function from the host before destroying it.

A primary advantage of this approach is the ability to pre-configure a controller on the function prior to exposing it to the host driver. Users are required to create a controller to initiate the host exposure phase.

Sync vs. Async Hotplug Operations

Exposing a new PCIe function involves notifying the host and awaiting its response. SNAP provides two modes for this operation, controlled via the `--wait_for_done` option:

- Synchronized hotplug – The RPC blocks until the host acknowledges the action and updates its PCIe function list, or until the host is determined to be temporarily unavailable.
- Asynchronized hotplug – The RPC does not block. The user must actively validate the function's hotplug state using the `emulation_functions_list` RPC to check for host acceptance.

⚠ Synchronized operations (using `--wait_for_done`) are recommended for single hotplug/unplug actions. For multiple operations, it is more time-efficient to execute all actions asynchronously (without `--wait_for_done`) and then validate their status altogether with a single `emulation_functions_list` RPC call.

Host Awareness

During periods such as OS reboots, the host may temporarily be unable to accept new PCIe functions. SNAP offers two modes to handle these scenarios, configurable via the `--mode` parameter:

- Host-aware mode (recommended) – The device checks the host's state and takes it into consideration. If the host is unready, the firmware blocks the command and returns an RPC error. Users must manually retry the operation if a failure occurs.
- Host-unaware mode – The operation proceeds regardless of the host's state. The user is responsible for ensuring the PCI enumeration process completes successfully and avoiding undesired behaviors, as the firmware will not block the command.

Attention Button

Because the Linux Virtio PCI driver stack does not support the surprise removal of devices, ungraceful removal can cause the host PCI subsystem to repeatedly attempt device recovery (like resetting the device and reprogramming MSI-X vectors) even after it is gone.

The Attention Button feature, defined in the PCIe specification, enables a graceful hot-plug/hot-unplug sequence. When utilized via the `host_aware_ab` mode, all state transitions are intentionally delayed by 5 seconds to allow the host OS time to react to the corresponding PCIe events.

⚠ Issuing a hot-unplug RPC immediately after an async hotplug RPC without `--wait_for_done` (or vice versa) using the `host_aware_ab` mode will cause the second RPC to return a failure. However, this failure will not affect the results of the initial RPC

PCIe Hotplug8.11.2.6.3.2 Legacy ("One-step")

The deprecated legacy mechanism uses a single-step "create-and-expose" flow where the emulation function is instantiated on the DPU and immediately presented to the host in one RPC. This tight coupling means the function's lifecycle is directly bound to host enumeration without any intermediate hidden state.

This legacy approach has several structural limitations:

- The controller cannot be fully configured, tested, and bound to backing storage before being exposed to the host.
- Failures in host enumeration translate directly into RPC failures or undefined host behavior, as the operation cannot be retried on a hidden function.
- Functions cannot be hidden from the host for maintenance, migration, or gradual rollout while keeping the emulation object alive.
- It lacks options for selecting advanced host-awareness settings or the Attention Button flow.

8.11.2.6.4 Zero Copy (SNAP-direct)

⚠ Zero-copy is supported on SPDK 21.07 and higher.

SNAP-direct allows SNAP applications to transfer data directly from the host memory to remote storage without using any staging buffer inside the DPU.

SNAP enables the feature according to the SPDK BDEV configuration only when working against an SPDK NVMe-oF RDMA block device.

To enable zero copy, set the environment variable (as it is enabled by default):

```
SNAP_RDMA_ZCOPY_ENABLE=1
```

For more info refer to SNAP-4 Service Environment Variables.

8.11.2.6.5 NVMe/TCP XLIO Zero Copy

NVMe/TCP Zero Copy is implemented as a custom `NVDA_TCP` transport in SPDK NVMe initiator, and it is based on a new XLIO socket layer implementation.

The implementation is different for Tx and Rx:

- The NVMe/TCP Tx Zero Copy is similar between RDMA and TCP in that the data is sent from the host memory directly to the wire without an intermediate copy to Arm memory
- The NVMe/TCP Rx Zero Copy allows achieving partial zero copy on the Rx flow by eliminating copy from socket buffers (XLIO) to application buffers (SNAP). But data still must be DMA'ed from Arm to host memory.

To enable NVMe/TCP Zero Copy, use `SPDK v22.05.nvda --with-xlio` (`v22.05.nvda` or higher).

For more information about XLIO including limitations and bug fixes, refer to the NVIDIA Accelerated IO (XLIO) Documentation.

To enable SNAP TCP XLIO Zero Copy:

1. SNAP container: Set the environment variables and resources in the YAML file to request 6G of hugepages:

```
resources:
  requests:
    memory: "4Gi"
    cpu: "8"
  limits:
    hugepages-2Mi: "6Gi"
    memory: "6Gi"
    cpu: "16"

## Set according to the local setup
env:
  - name: APP_ARGS
    value: "--wait-for-rpc"
  - name: SPDK_XLIO_PATH
    value: "/usr/lib/libxlio.so"
```

2. SNAP sources: Set the environment variables and resources in the relevant scripts
   a. In `run_snap.sh`, edit the `APP_ARGS` variable to use the SPDK command line argument `--wait-for-rpc`:

   run_snap.sh

   ```
   APP_ARGS="--wait-for-rpc"
   ```

   b. In `set_environment_variables.sh`, uncomment the `SPDK_XLIO_PATH` environment variable:

   set_environment_variables.sh

   ```
   export SPDK_XLIO_PATH="/usr/lib/libxlio.so"
   ```

NVMe/TCP XLIO requires a BlueField Arm OS hugepage size of 4Gi. For information on configuring the hugepages, refer to sections "Step 1: Allocate Hugepages" and "Adjusting YAML Configuration".

At high scale, it is required to use the global variable `XLIO_RX_BUFS=4096` even though it leads to high memory consumption. Using `XLIO_RX_BUFS=1024` requires lower memory consumption but limits the ability to scale the workload.

For more info refer to SNAP-4 Service Environment Variables.

It is recommended to configure NVMe/TCP XLIO with the transport ack timeout option increased to 12.

```
[dpu] spdk_rpc.py bdev_nvme_set_options --transport-ack-timeout 12
```

Other `bdev_nvme` options may be adjusted according to requirements.

Expose an NVMe-oF subsystem with one namespace by using a TCP transport type on the remote SPDK target.

```
[dpu] spdk_rpc.py sock_set_default_impl -i xlio
[dpu] spdk_rpc.py framework_start_init
[dpu] spdk_rpc.py bdev_nvme_set_options --transport-ack-timeout 12
[dpu] spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t nvda_tcp -a 3.3.3.3 -f ipv4 -s 4420 -n
nqn.2023-01.io.nvmet
[dpu] snap_rpc.py nvme_subsystem_create --nqn nqn.2023-01.com.nvda:nvme:0
[dpu] snap_rpc.py nvme_namespace_create -b nvme0n1 -n 1 --nqn nqn. 2023-01.com.nvda:nvme:0 --uuid 16dab065-
ddc9-8a7a-108e-9a489254a839
[dpu] snap_rpc.py nvme_controller_create --nqn nqn.2023-01.com.nvda:nvme:0 --ctrl NVMeCtrl1 --pf_id 0 --suspended
--num_queues 16
[dpu] snap_rpc.py nvme_controller_attach_ns -c NVMeCtrl1 -n 1
[dpu] snap_rpc.py nvme_controller_resume -c NVMeCtrl1 -n 1

[host] modprobe -v nvme
[host] fio --filename /dev/nvme0n1 --rw randrw --name=test-randrw --ioengine=libaio --iodepth=64 --bs=4k --direct=1
--numjobs=1 --runtime=63 --time_based --group_reporting --verify=md5
```

For more information on XLIO, please refer to XLIO documentation.

8.11.2.6.6 Encryption

The SPDK version included with SNAP supports hardware encryption/decryption offload. To enable AES/XTS and allow the `mlx5_2` and `mlx5_3` SFs to support encryption, they must be designated as trusted.

1. Edit the configuration file `/etc/mellanox/mlnx-sf.conf`.
2. Append the following commands to configure the `VHCA_TRUST_LEVEL` and create the SFs:

   ```
   /usr/bin/mlxreg -d 03:00.0 --reg_name VHCA_TRUST_LEVEL --yes --indexes "vhca_id=0x0,all_vhca=0x1" --set
   "trust_level=0x1"
   /usr/bin/mlxreg -d 03:00.1 --reg_name VHCA_TRUST_LEVEL --yes --indexes "vhca_id=0x0,all_vhca=0x1" --set
   "trust_level=0x1"
   /sbin/mlnx-sf -action create --device 0000:03:00.0 --sfnum 0 --hwaddr 02:11:3c:13:ad:82
   /sbin/mlnx-sf -action create --device 0000:03:00.1 --sfnum 0 --hwaddr 02:76:78:b9:6f:52
   ```

3. Reboot the DPU to apply these changes.

8.11.2.6.6.1 Zero Copy (SNAP-direct) with Encryption

SNAP offers support for zero copy with encryption for `bdev_nvme` with an RDMA transport.

If another `bdev_nvme` transport or base bdev other than NVMe is used, then zero copy flow is not supported, and additional DMA operations from the host to the BlueField Arm are performed.

Refer to section "SPDK Crypto Example" to see how to configure zero copy flow with AES_XTS offload.

Command	Description
`mlx5_scan_accel_module`	Accepts a list of devices to be used for the crypto operation
`accel_crypto_key_create`	Creates a crypto key
`bdev_nvme_attach_controller`	Constructs NVMe block device
`bdev_crypto_create`	Creates a virtual block device which encrypts write IO commands and decrypts read IO commands

8.11.2.6.6.2 mlx5_scan_accel_module

Accepts a list of devices to use for the crypto operation provided in the `--allowed-devs` parameter. If no devices are specified, then the first device which supports encryption is used.

For best performance, it is recommended to use the devices with the largest InfiniBand MTU (4096). The MTU size can be verified using the `ibv_devinfo` command (look for the max and active MTU fields). Normally, the `mlx5_2` device is expected to have an MTU of 4096 and should be used as an allowed crypto device.

Command parameters:

Parameter	Mandatory?	Type	Description
`qp-size`	No	Number	QP size
`num-requests`	No	Number	Size of the shared requests pool
`allowed-devs`	No	String	Comma-separated list of allowed device names (e.g., "mlx5_2") Make sure that the device used for RDMA traffic is selected to support zero copy.
`enable-driver`	No	Boolean	Enables accel_mlx5 platform driver. Allows AES_XTS RDMA zero copy.

8.11.2.6.6.3 accel_crypto_key_create

Creates crypto key. One key can be shared by multiple bdevs.

Command parameters:

Parameter	Mandatory?	Type	Description
`cipher`	Yes	Number	Crypto protocol (AES_XTS)
`key`	Yes	Number	Key
`key2`	Yes	Number	Key2
`name`	Yes	String	Key name

8.11.2.6.6.4 bdev_nvme_attach_controller

Creates NVMe block device.

Command parameters:

Parameter	Mandatory?	Type	Description
`name`	Yes	String	Name of the NVMe controller, prefix for each bdev name
`trtype`	Yes	String	NVMe-oF target trtype (e.g., rdma, pcie)
`traddr`	Yes	String	NVMe-oF target address (e.g., an IP address or BDF)
`trsvcid`	No	String	NVMe-oF target trsvcid (e.g., a port number)
`addrfam`	No	String	NVMe-oF target adrfam (e.g., ipv4, ipv6)
`nqn`	No	String	NVMe-oF target subnqn

8.11.2.6.6.5 bdev_crypto_create

This RPC creates a virtual crypto block device which adds encryption to the base block device.

Command parameters:

Parameter	Mandatory?	Type	Description
`base_bdev_name`	Yes	String	Name of the base bdev
`name`	Yes	String	Crypto bdev name
`key-name`	Yes	String	Name of the crypto key created with `accel_crypto_key_create`

8.11.2.6.6.6 SPDK Crypto Example

The following is an example of a configuration with a crypto virtual block device created on top of `bdev_nvme` with RDMA transport and zero copy support:

```
[dpu] # spdk_rpc.py mlx5_scan_accel_module --allowed-devs "mlx5_2" --enable-driver
[dpu] # spdk_rpc.py framework_start_init
```

```
[dpu] # spdk_rpc.py accel_crypto_key_create -c AES_XTS -k 00112233445566778899001122334455 -e
11223344556677889900112233445500 -n test_dek
[dpu] # spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n
nqn.2016-06.io.spdk:cnode0
[dpu] # spdk_rpc.py bdev_crypto_create nvme0n1 crypto_0 -n test_dek
[dpu] # snap_rpc.py nvme_subsystem_create --nqn nqn.2023-05.io.nvda.nvme:0
[dpu] # snap_rpc.py nvme_controller_create --nqn nqn.2023-05.io.nvda.nvme:0 --pf_id 0 --ctrl NVMeCtrl0 --suspended
[dpu] # snap_rpc.py nvme_namespace_create -nqn nqn.2023-05.io.nvda.nvme:0 --bdev_name crypto_0 --nsid 1 --uuid
263826ad-19a3-4feb-bc25-4bc81ee7749e
[dpu] # snap_rpc.py nvme_controller_attach_ns --ctrl NVMeCtrl0 --nsid 1
[dpu] # snap_rpc.py nvme_controller_resume --ctrl NVMeCtrl0
```

8.11.2.6.7 Virtio-blk Live Migration

Live migration is a standard process supported by QEMU which allows system administrators to pass devices between virtual machines in a live running system. For more information, refer to QEMU VFIO Device Migration documentation.

Live migration is supported for SNAP virtio-blk devices in legacy and standard VFIO modes. Legacy mode uses drivers like NVIDIA's proprietary vDPA-based Live Migration Solution, while standard mode leverages the latest kernel capabilities using the `virtio-vfio-pci` kernel driver. Legacy mode can be enabled/disabled using the environment variable `VIRTIO_CTRL_VDPA_ADMIN_Q` (enabled by default).

> ⚠ In the standard virtio live migration process, the device is expected to complete all inflight I/Os, with no configurable timeout. If the remote storage is unavailable (disconnected or non-responsive), the device migration will wait indefinitely. This means migration time cannot be guaranteed, representing a degradation compared to the functionality of legacy mode.

8.11.2.6.7.1 Software Requirements for Standard VFIO

- Kernel – 6.16-rc3+ (using `virtio-vfio-pci` driver)
- QEMU – 9.2+
- libvirt – 10.6+

8.11.2.6.7.2 SNAP Configuration

1. Set the environment variable `VIRTIO_CTRL_VDPA_ADMIN_Q` to 1 (default) for legacy or 0 for standard VFIO mode.
2. Create a PF Controller with Admin Queue (common to both modes):

```
snap_rpc.py virtio_blk_controller_create --admin_q …
```

8.11.2.6.8 SNAP Container Live Upgrade

The Live Upgrade feature enables administrators to update a container's SNAP image without incurring system downtime.

Although newer releases may introduce features that alter system behavior, the upgrade architecture is engineered to maintain full backward and forward compatibility.

> **Version Compatibility**
>
> Before initiating an upgrade, consult the "Changes and New Features" section of the SNAP-4 Service Release Notes to verify the explicitly supported upgrade paths and compatibility matrices for your current version.

8.11.2.6.8.1 Live Upgrade Prerequisites

To enable live upgrade, perform the following modifications:

1. Allocate double hugepages for the destination and source containers.
2. Make sure the requested amount of CPU cores is available.
   The default YAML configuration sets the container to request a CPU core range of 8-16. This means that the container is not deployed if there are fewer than 8 available cores, and if there are 16 free cores, the container utilizes all 16.
   For instance, if a container is currently using all 16 cores and, during a live upgrade, an additional SNAP container is deployed. In this case, each container uses 8 cores during the upgrade process. Once the source container is terminated, the destination container starts utilizing all 16 cores.

   > For 8-core DPUs, the `.yaml` must be edited to the range of 4-8 CPU cores.

3. Change the name of the `doca_snap.yaml` file that describes the destination container (e.g., `doca_snap_new.yaml`) so as to not overwrite the running container `.yaml`.
4. Change the name of the new `.yaml` pod and container on lines 16 and 20, respectively (e.g., `snap-new`).
5. Deploy the the destination container by copying the new yaml (e.g., `doca_snap_new.yaml`) to kubelet.

> After deploying the destination container, until the live update process is complete, avoid making any configuration changes via RPC. Specifically, do not create or destroy hotplug functions.

> When restoring a controller in the destination container during a live update, it is recommended to use the same arguments originally used for controller creation in the source container.

User may need to update the RPC alias since the new container name has been edited.

Performing a live update disables the ML Optimizer Online service in the source container. The service in the destination container remains unaffected and operates normally.

Supported Block Devices for live_update.py

Official support for the `live_update.py` script is strictly limited to the following SPDK block devices: NVMe-oF/RDMA, Null, Malloc, and Delay `vbdev`. Although users can technically extend the script logic to accommodate other block devices, NVIDIA does not officially validate or support such configurations.

8.11.2.6.8.2 SNAP Container Live Upgrade Procedure

1. Follow the steps in section "Live Upgrade Prerequisites" and deploy the destination SNAP container using the modified `yaml` file.
2. Query the source and destination containers:

```
crictl ps -r
```

3. Check for `SNAP started successfully` in the logs of the destination container, then copy the live update from the container to your environment.

```
[dpu] crictl logs -f <dest-container-id>
[dpu] crictl exec <dest-container-id> cp /opt/nvidia/nvda_snap/bin/live_update.py /etc/nvda_snap/
```

4. Run the `live_update.py` script to move all active objects from the source container to the destination container:

```
[dpu] cd /etc/nvda_snap
[dpu] ./live_update.py -s <source-container-id> -d <dest-container-id>
```

Transition freely between a SNAP source package service and a SNAP container service in either direction.

- Use the `-s 0` flag to specify that the original process (source) is running from the SNAP source package.
- The tool does not support transitioning directly from one SNAP source package service to another

Customize the suspend timeout by passing the `-t` or `--timeout` parameter (e.g., `-t 1` sets the timeout to 1 ms). The system defaults to 20 ms.

5. After the script completes, the live update process also completes, delete the source container by removing the YAML from kubelet tool:

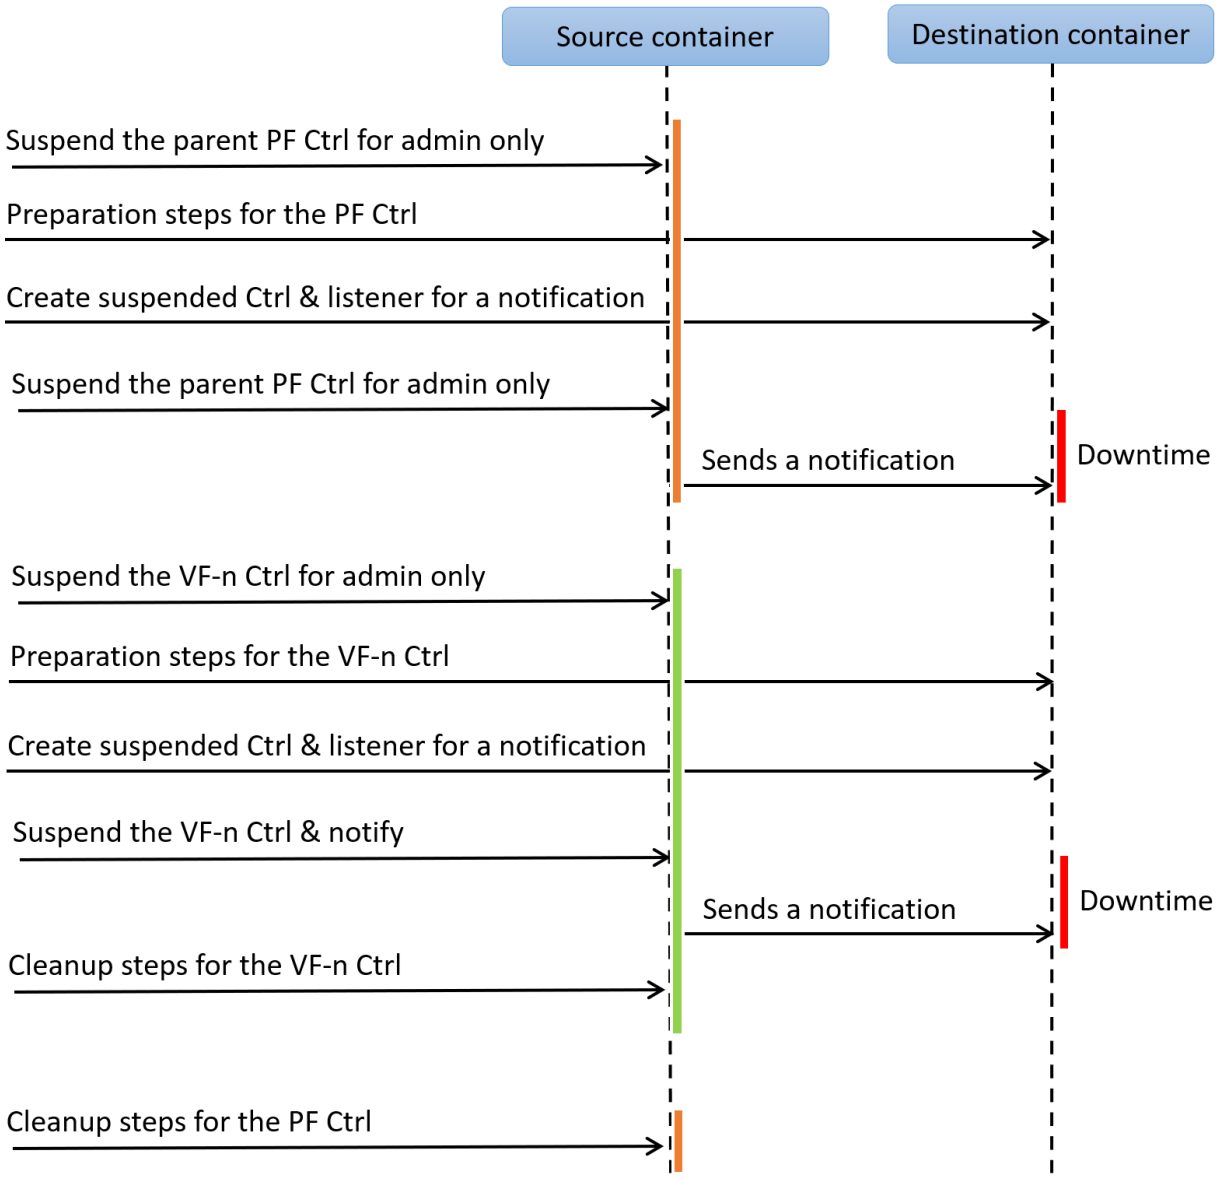
   ⚠ To post RPCs, use the `crictl` tool:

   ```
   crictl exec -it <container-id X> snap_rpc.py <RPC-method>
   crictl exec -it <container-id Y> spdk_rpc.py <RPC-method>
   ```

   ⚠ To automate the SNAP configuration (e.g., following failure or reboot) as explained in section "Automate SNAP Configuration (Optional)", `spdk_rpc_init.conf` and `snap_rpc_init.conf` must not include any configs as part of the live upgrade. Then, once the transition to the new container is done, `spdk_rpc_init.conf` and `snap_rpc_init.conf` can be modified with the desired configuration.

8.11.2.6.8.3 SNAP Container Live Upgrade Commands

The live upgrade process allows moving SNAP controllers and SPDK block devices between containers while minimizing host VM disruption.



The upgrade is done using a dedicated live update tool, which iterates over all active emulation functions and performs the following steps:

1. Suspend controller (admin only). On the source container, suspend the controller to admin-only mode. This ensures the controller no longer processes admin commands from the host driver, avoiding state changes during the handover. I/O traffic continues, so downtime has not started yet.
    - NVMe example:

      ```
      NMVe exmaple:
      ```

      ```
      snap_rpc.py nvme_controller_suspend --ctrl NVMeCtrl0VF0 --admin_only
      ```

    - Virtio-blk example:

```
Virtio-blk Example
```

```
snap_rpc.py virtio_blk_controller_suspend --ctrl [ctrl_name] --events_only
```

2. Preparation on destination container. On the destination container, create all required objects for the new controller, including attaching the backend device.
    - NVMe example:

```
NMVe exmaple:
```

```
spdk_rpc.py bdev_nvme_attach_controller ...
snap_rpc.py nvme_subsystem_create ...
snap_rpc.py nvme_namespace_create -n 1 ...
```

    - Virtio-blk example:

```
Virtio-blk Example
```

```
spdk_rpc.py bdev_nvme_attach_controller ...
```

3. Create suspended controller (as listener). On the destination container, create the controller in a suspended state and mark it as a listener for a live update notification from the source container. At this point, the controller in the source container is still handling I/O, so downtime has not started yet.
    - NVMe example:

```
NMVe exmaple:
```

```
snap_rpc.py nvme_controller_create --pf_id 0 --vf_id 0 --ctrl NVMeCtrl0VF0 --live_update_listener
--suspended ...
snap_rpc.py nvme_controller_attach_ns -c NVMeCtrl0VF0 -n 1
```

    - Virtio-blk example:

```
Virtio-blk Example
```

```
snap_rpc.py virtio_blk_controller_create  --pf_id 0 --vf_id 0 --ctrl VBLKCtrl0VF0 ...
```

4. Suspend and notify. On the source container, suspend the controller using the `--live_update_notifier` flag. This triggers the start of downtime and sends a notification to the destination container. Once suspended, the controller on the destination container resumes and starts handling I/O. This marks the end of downtime.
    - NVMe example:

```
snap_rpc.py nvme_controller_suspend --ctrl NVMeCtrl0VF0 --live_update_notifier --timeout_ms
```

    - Virtio-blk example:

```
snap_rpc.py virtio_blk_controller_suspend --ctrl [ctrl_name] --events_only
```

5. Cleanup source container. After the migration is complete, clean up any remaining controller objects on the source container.

   > ⚠ The PF controller must remain present in the source container until all related virtual functions (VFs) have been removed.

   - NVMe example:

     ```
     snap_rpc.py nvme_controller_detach_ns ...
     spdk_rpc.py bdev_nvme_detach_controller ...
     snap_rpc.py nvme_namespace_destroy ...
     snap_rpc.py nvme_controller_destroy ...
     ```

   - Virtio-blk example:

     ```
     snap_rpc.py virtio_blk_controller_suspend --ctrl [ctrl_name] --events_only
     ```

8.11.2.6.8.4 Shared Memory Pool Live Update

The Shared Memory Pool Live Update feature resolves resource constraints when a host lacks sufficient hugepages to run two full SNAP processes concurrently during a live update. By allowing the two processes to share a portion of the memory pool, this optimization significantly reduces the peak hugepage requirement.

Configuration	Total Hugepages Required	Memory Breakdown
Standard	4GB	2GB per process (1GB SNAP + 1GB SPDK)
Optimized	3GB	1GB Source SPDK + 1GB Destination SPDK + 1GB Shared SNAP

> ⚠ Although physical hugepage consumption decreases to 3GB, container orchestration layers (such as Kubernetes) may still require the memory limit set to the full 4GB to authorize the transition. The host does not need this additional 1GB physically free, and the update process will not actually consume it.

Memory Pool Architecture

To facilitate shared memory, SNAP divides its memory management into two distinct pools:

- Base mempool – The essential memory required for the process to operate.
- Extended mempool – Additional memory used for standard operation, managed dynamically during the update.

Live Update Configuration

Enable this feature by configuring specific environment variables in the `doca_vfs.yaml` file. The `SNAP_MEMPOOL_SIZE_MB` value must strictly exceed the `SNAP_MEMPOOL_BASE_SIZE_MB` value.

Configuration example:

```
env:
  - name: SNAP_MEMPOOL_SIZE_MB
    value: "1024"
  - name: SNAP_MEMPOOL_BASE_SIZE_MB
    value: "512"
```

Live Update Procedure

This optimized workflow introduces two specific RPCs: `memory_manager_deallocate_basepool` and `memory_manager_allocate_extpool`.

Execute the live update using the following strict sequence:

1. Prepare source – Issue the `memory_manager_deallocate_basepool` RPC on the source (old) container to release shared resources.
2. Deploy destination – Start the destination (new) container. It initializes using only the Base Mempool.
3. Execute handover – Run the standard live update script and wait for completion.
4. Cleanup – Destroy the source container.
5. Finalize destination – Issue the `memory_manager_allocate_extpool` RPC on the destination container to reclaim full memory capacity.

State Invalidation

If the source container's SNAP instance terminates, restarts, or recovers at any point during this process, the state becomes invalid. Completely restart the service before reattempting the live update procedure.

8.11.2.6.9 SR-IOV Dynamic MSI-X and Queues Management

Message Signaled Interrupts eXtended (MSI-X) enables devices to utilize multiple interrupt vectors, reducing CPU utilization, improving device performance, and enhancing scalability compared to traditional shared interrupts.

In SR-IOV environments, the default system behavior distributes MSI-X vectors evenly across all Virtual Functions (VFs). However, this uniform distribution is often suboptimal for heterogeneous environments where VFs attach to different VMs with varying resource requirements. Dynamic MSI-X Management allows administrators to manually override this default and explicitly control the number of MSI-X vectors allocated to each individual VF.

⚠ The configuration steps and behaviors described in this section apply to all emulation types (specifically NVMe and virtio-blk).

8.11.2.6.9.1 Lifecycle and Persistence

Dynamic MSI-X management follows a strict lifecycle for resource allocation and reclamation.

Allocation Workflow

1. Reclaim: When no VF controllers are open (`sriov_numvfs=0`), PF-related MSI-X vectors return from the VFs into the PF's global free pool.
2. Allocate: Administrators allocate MSI-X vectors from the free pool to a specific VF during controller creation.
3. Release: Resources return back to the free pool when a VF controller is destroyed.

Persistence Rules

Once configured, the MSI-X allocation for a VF remains persistent across various state changes:

State Change	Effect on MSI-X Configuration
Application restart/crash	No change
Closing/reopening PF	No change (unless dynamic support is used)
Explicit VF release	Released (returns to pool)
PF explicit reclaim	Reclaimed (returns to pool)
Arm cold boot	Reset (returns to pool)

8.11.2.6.9.2 Configuration Procedure (NVMe Example)

The following procedure demonstrates Dynamic MSI-X configuration for an NVMe controller. Apply the same logic when configuring virtio-blk.

Step 1: Reclaim Resources

Ensure no VFs are active, then reclaim all MSI-X vectors back to the PF's free pool:

```
snap_rpc.py nvme_controller_vfs_msix_reclaim <CtrlName>
```

Step 2: Query Resource Constraints

Query the controller to view the available resources currently residing in the PF's free pool:

```
snap_rpc.py nvme_controller_list -c <CtrlName>
```

Output definitions:

- `free_msix` – Total MSI-X vectors available in the PF pool (assigned via `vf_num_msix`).
- `free_queues` – Total queues (doorbells) available in the PF pool (assigned via `num_queues`).
- `vf_min_msix` / `vf_max_msix` – The valid configuration range for the `vf_num_msix` parameter.
- `vf_min_queues` / `vf_max_queues` – The valid configuration range for the `num_queues` parameter.

Step 3: Create VF and Distribute Resources

Create the VF controller and specify the exact resource allocation:

```
snap_rpc.py nvme_controller_create --vf_num_msix <n> --num_queues <m> ...
```

⚠ You must explicitly specify both `vf_num_msix` and `num_queues`. Omitting one can cause a mismatch between the MSI-X allocation and queue configuration, potentially leading to driver malfunctions.

Resource Calculation Guidelines

Allocations differ by protocol. Use the following baseline requirement (`num_queues = vf_num_msix - 1`) to determine exact values:

Protocol	Allocation Formula
NVMe	1 MSI-X per IO Queue + 1 MSI-X for the Admin Queue
Virtio	1 MSI-X per Virtqueue + 1 MSI-X for BAR configuration notifications.

Step 4: VF Teardown

When destroying the VF, ensure resources are explicitly released back to the free pool:

```
snap_rpc.py nvme_controller_destroy --release_msix ...
```

Step 5: Enable SR-IOV

Enable the VFs on the host driver:

```
echo <N> > /sys/bus/pci/devices/<BDF>/sriov_numvfs
```

8.11.2.6.9.3 Safe Configuration Methods

Strict ordering of operations is required to prevent system instability during SR-IOV configuration.

> **Host Deadlock Risk**
>
> Open all VF controllers in SNAP before binding VFs to the host driver. If VFs bind to the driver before configuration completes, the driver may attempt to use unallocated resources. Insufficient resources in this state can trigger a host deadlock that is recoverable only via a cold boot.

To configure Dynamic MSI-X safely and avoid deadlock, utilize one of the following two methods:

Method A: Disable Autoprobe (Recommended)

Disable automatic driver binding, complete the VF configuration, and manually bind them afterward:

1. Disable autoprobe to prevent immediate binding:

```
echo 0 > /sys/bus/pci/devices/<BDF>/sriov_driver_autoprobe
```

2. Perform SNAP Configuration (Execute Steps 1-5 from above).
3. Manually bind VFs to the driver:

```
echo "0000:01:00.0" > /sys/bus/pci/drivers/nvme/bind
```

Method B: Use VFIO Driver

Utilize the `vfio-pci` driver for SR-IOV configuration instead of the standard kernel driver.

1. Bind PF to the VFIO driver:

```
echo 0000:af:00.2 > /sys/bus/pci/drivers/vfio-pci/bind
```

2. Enable SR-IOV support:

```
echo 1 > /sys/module/vfio_pci/parameters/enable_sriov
```

3. Create VFs:

```
echo <N> > /sys/bus/pci/drivers/vfio-pci/0000:af:00.2/sriov_numvfs
```

8.11.2.6.10 Recovery

The recovery feature enables the restoration of controller state after the SNAP application terminates—either gracefully or unexpectedly (e.g., due to `kill -9`).

> ⚠ Recovery is only possible if the SNAP application is restarted with the exact same configuration that was active prior to the shutdown or crash.

> ⚠ **Supported Block Devices for live_update.py**
>
> Official support for the `live_update.py` script is strictly limited to the following SPDK block devices: NVMe-oF/RDMA, Null, Malloc, and Delay `vbdev`. Although users can technically extend the script logic to accommodate other block devices, NVIDIA does not officially validate or support such configurations.

8.11.2.6.10.1 NVMe Recovery

NVMe recovery enables the restoration of an NVMe controller after a SNAP application terminates, whether gracefully or due to a crash (e.g., `kill -9`).

To perform NVMe recovery:

1. Re-create the controller in a suspended state using the exact same configuration as before the crash (including the same bdevs, number of queues, namespaces, and namespace UUIDs).
2. Resume the controller only after all namespaces have been attached.

The recovery process uses shared memory files located under `/dev/shm` on the BlueField to restore the controller's internal state. These files are deleted when the BlueField is reset, meaning recovery is not supported after a BF reset.

8.11.2.6.10.2 Virtio-blk Crash Recovery

To use virtio-blk recovery, the controller must be re-created with the same configuration as before the crash (i.e. the same bdevs, num queues, etc).

The following options are available to enable virtio-blk crash recovery.

Virtio-blk Crash Recovery with --force_in_order

For virtio-blk crash recovery with `--force_in_order`, disable the `VBLK_RECOVERY_SHM` environment variable and create a controller with the `--force_in_order` argument.

In virtio-blk SNAP, the application is not guaranteed to recover correctly after a sudden crash (e.g., `kill -9`).

To enable the virtio-blk crash recovery, set the following:

```
snap_rpc.py virtio_blk_controller_create --force_in_order …
```

⚠ Setting `force_in_order` to 1 may impact virtio-blk performance as it will serve the command in-order.

⚠ If `--force_in_order` is not used, any failure or unexpected teardown in SNAP or the driver may result in anomalous behavior because of limited support in the Linux kernel virtio-blk driver.

Virtio-blk Crash Recovery without --force_in_order

For virtio-blk crash recovery without `--force_in_order`, enable the `VBLK_RECOVERY_SHM` environment variable and create a controller without the `--force_in_order` argument.

Virtio-blk recovery allows the virtio-blk controller to be recovered after a SNAP application is closed whether gracefully or after a crash (e.g., `kill -9`).

To use virtio-blk recovery without `--force_in_order` flag. `VBLK_RECOVERY_SHM` must be enabled, the controller must be recreated with the same configuration as before the crash (i.e., same bdevs, num queues, etc).

When `VBLK_RECOVERY_SHM` is enabled, virtio-blk recovery uses files on the BlueField under `/dev/shm` to recover the internal state of the controller. Shared memory files are deleted when the BlueField is reset. For this reason, recovery is not supported after BlueField reset.

8.11.2.6.10.3 SNAP Configuration Recovery

SNAP can store its configuration as defined by user RPCs and, upon restart, reload it from a configuration JSON file. This mechanism is intended for recovering a previously configured SNAP state - it cannot be used for the initial configuration.

Usage:

1. Set the environment variable `SNAP_RPC_INIT_CONF_JSON` to the directory path where the configuration file will be stored.
2. The configuration file, `snap_config.json`, is created in this directory after all changes in your script have been successfully applied.
3. If a new configuration (different from the pre-shutdown configuration) is required after restarting SNAP, delete the existing `snap_config.json` file before applying the new settings.

When this method is used, there is no need to re-run `snap` RPCs or set RPCs in init files after the initial configuration — SNAP will automatically load the saved configuration

from the `SNAP_RPC_INIT_CONF_JSON` path. This approach is recommended for fast recovery.

- When modifying controller or function configurations, ensure the controller/function is not bounded to any driver until the configuration process is complete. If the change is interrupted, recovery may fail.
- Hotplugged emulation functions persist between SNAP runs (but not across BlueField resets) and should be set only once during initial configuration. Only controllers created on these functions are stored in the saved configuration state.
- If crash recovery after a reboot is supported, store the file inside the container at `/etc/nvda_snap`. For unsupported use cases, store it in a temporary location such as `/tmp/` or `/dev/shm`.

8.11.2.6.10.4 Improving SNAP Recovery Time

The following table outlines features designed to accelerate SNAP initialization and recovery processes following termination.

Feature	Description	How to?
SPDK JSON-RPC configuration file	An initial configuration can be specified for the SPDK configuration in SNAP. The configuration file is a JSON file containing all the SPDK JSON-RPC method invocations necessary for the desired configuration. Moving from posting RPCs to JSON file improves bring-up time. For more information check SPDK JSON-RPC documentation.	To generate a JSON-RPC file based on the current configuration, run: `spdk_rpc.py save_config > config.json` The `config.json` file can then be passed to a new SNAP deployment using the environment variable in the YAML `SPDK_RPC_INIT_CONF_JSON`. If SPDK encounters an error while processing the JSON configuration file, the initialization phase fails, causing SNAP to exit with an error code.

Feature	Description	How to?
Disable SPDK accel functionality	The SPDK accel functionality is necessary when using NVMe TCP features. If NVMe TCP is not used, accel should be manually disabled to reduce the SPDK startup time, which can otherwise take few seconds. To disable all accel functionality edit the flags `disable_signature`, `disable_crypto`, and `enable_module`.	Edit the config file as follows: `{ "method": "mlx5_scan_accel_module", "params": { "qp_size": 64, "cq_size": 1024, "num_requests": 2048, "enable_driver": false, "split_mb_blocks": 0, "siglast": false, "qp_per_domain": false, "disable_signature": true, "disable_crypto": true, "enable_module": false } }`
Provide the emulation manager name	If the `SNAP_EMULATION_MANAGER` environment variable is not defined (default), SNAP searches through all available devices to find the emulation manager which may slow down initialization process. Explicitly defining the device reduces the chance of initialization delays.	Use `SNAP_EMULATION_MANAGER` to modify the the variable on the YAML. Refer to SNAP-4 Service Environment Variables for more information.
SNAP configuration recovery	SNAP configuration recovery enables restoring the SNAP state without the need to re-post SNAP RPCs. By moving from posting individual RPCs to using a pre-saved JSON configuration file, the bring-up time is significantly improved.	Set `SNAP_RPC_INIT_CONF_JSON` to a path where config file should be saved. Also use an SPDK JSON-RPC configuration file.
Hugepages allocation	SNAP allocates a mempool from hugepages. Reducing its size can impact the duration of SNAP's crash recovery.	SNAP_MEMPOOL_SIZE_MB is set to1024MB by default.

8.11.2.6.11 Watchdog and Heartbeat Monitoring

The Watchdog and Heartbeat Monitoring feature is an experimental reliability mechanism designed to enhance the robustness of the system by automatically detecting and recovering from application hangs, crashes, or unresponsive components. This mechanism minimizes service disruption by triggering recovery procedures without requiring manual intervention.

The heartbeat system functions as a periodic signal emitted by the SNAP service to indicate its operational status. These signals serve as an indicator that the service is active and functioning as expected.

A dedicated watchdog component monitors the presence and frequency of heartbeat signals. If the heartbeat is not received within a predefined timeout interval, the watchdog determines that the monitored component is unresponsive and initiates a predefined recovery action.

The typical sequence of operations is as follows:

1. A SNAP component becomes unresponsive due to a crash, hang, or other failure condition.

2. The watchdog detects the absence of the expected heartbeat signal.
3. A recovery action is automatically triggered.
4. The SNAP service is restarted, and previously configured virtual disk states are restored.
5. Normal operation resumes.

The entire recovery process is designed to complete within a few seconds, thereby minimizing downtime.

8.11.2.6.11.1 Configuring the Watchdog

The behavior of the Watchdog and Heartbeat Monitoring system is configurable through environment variables. These variables allow the user to specify parameters such as heartbeat intervals, timeouts, and recovery policies without requiring changes to the application code.

Environment Variable	Impact on Recovery	Default Value
`SNAP_HEARTBEAT_INTERVAL_MS`	Interval (in milliseconds) between heartbeat signals from SNAP	`0` (disabled)
`SNAP_HEARTBEAT_THREAD_ID`	ID of the thread responsible for processing heartbeat signals	`1`

For more configuration options, check the `snap_watchdog.py` script.

8.11.2.6.11.2 Running the Watchdog

To initiate the watchdog service while the SNAP application is running, execute the following command:

```
./snap_watchdog.py --daemon
```

This command launches the watchdog in the background, where it continuously monitors the health of the SNAP service and initiates recovery procedures as necessary.

snap_watchdog.py requires using python 3.7 or above.
If SNAP is running in a BFB that only contains an older version of python (i.e. Anolis 8), user must also run the command:

```
pip install dataclasses
```

8.11.2.6.12 IO/Core Multiplexer

The I/O Core Multiplexer (MP) is a configurable mechanism that determines how I/O requests from a single source are distributed across the available DPU cores. This feature is critical for optimizing performance based on application-specific needs, particularly in scenarios involving high I/O workloads.

The multiplexer offers two policy modes:

- None (Default) – All I/O operations originating from a single source are processed by a single DPU core. I/O sources are distributed across DPU cores in a balanced manner.
  - Recommended for: Low-latency environments
  - Optimization focus: I/O latency
- (Weighted) Round Robin – I/O requests from a single source are distributed across multiple DPU cores in a round-robin sequence. If the backend supports per-core weight configuration (e.g., SPDK NVMe-oF bdev), the distribution follows those weights. Otherwise, the I/Os are spread evenly.
  - Recommended for: Bandwidth-intensive environments or systems with low per-core backend throughput (e.g., TCP-based backends)
  - Optimization focus: I/O bandwidth

To configure the IO/Core Multiplexer policy, users need to set the `IO_CORE_DISTRIBUTION_POLICY` environment variable. The available options are:

- `none` – Refers to the default policy where all I/Os from a single source are handled by a single DPU core
- `weighted_rr` – Refers to the (Weighted) Round Robin policy, distributing I/Os across multiple cores

> ⚠ `weighted_rr` policy is not supported for virtio-blk.

8.11.2.6.13 DPA Execution Unit Management

The DPA is an auxiliary processor designed to accelerate data-path operations. Its architecture comprises a cluster of 16 cores, each containing 16 execution units (EUs).

- Total SNAP capacity – 171 EUs (index range: 0–170).
- Supported protocols – SNAP utilizes DPA applications to accelerate NVMe and virtio-blk protocols.
- Hardware constraint – The hardware enforces a strict limit of 128 queues (threads) per DPA EU.

By default, the system shares all EUs (0–170) across NVMe, virtio-blk, and other system DPA applications (such as virtio-net).

> **Resource Conflict**
>
> If other DPA applications run concurrently with SNAP, configure a DPA resource YAML file to explicitly allocate EUs and prevent resource overlaps. For further details, consult the Single Point of Resource Distribution documentation

8.11.2.6.13.1 Method 1: YAML-based Resource Management (Recommended)

The YAML-based tool serves as the primary method for controlling DPA EUs, providing a centralized and consistent approach to allocating resources across applications.

Configuration Requirements

Requirement	Details
Partitioning	Run SNAP DPA applications exclusively on the `ROOT` partition. EUs configured in other partitions are inaccessible.
Valid range	Allocate only EUs 0–170 for SNAP operations
Allocation rules	• At least 1 EU must be allocated per application instance. • EU allocations must not overlap across different applications. • EU groups are not supported.
Application names	Match the YAML configuration to SNAP's internal application names exactly: • `dpa_helper` : Used for virtio-blk and NVMe (DPU mode) ⚠ Match instances to the number of allocated Arm cores/EUs. • `dpa_virtq_split` : Used for virtio-blk (DPA mode) • `dpa_nvme` : Used for NVMe (DPA mode)

Multi-Container Configuration

When deploying multiple SNAP containers, enforce unique application naming:

1. Set the environment variable `SNAP_DPA_INSTANCE_ID_ENV` to a unique ID inside each container.
2. Update the YAML file to reflect the instance names using the `<APP_NAME>_<ID>` format.

Example of two virtio-blk DPU containers:

```
---
version: 25.04
---
DPA_APPS:
  dpa_helper_1:
    - partition: ROOT
      affinity_EUs: [1-16]
  dpa_helper_2:
    - partition: ROOT
      affinity_EUs: [17-32]
```

Deployment Workflow

1. Define your configuration in a source file (e.g., `~/DPA_RESOURCE_INPUT.yaml`).
2. Execute the management tool to generate the final system configuration:

```
dpa-resource-mgmt config -d mlx5_0 -f ~/DPA_RESOURCE_INPUT.yaml
```

> Never manually edit the output YAML file generated by the `dpa-resource-mgmt` tool.

3. Point SNAP to the generated configuration file:

```
export SNAP_DPA_YAML_PATH=~/ROOT.YAML
```

> **Container Implementations**
>
> Ensure the generated YAML file path is properly mounted into the container, such as mapped to `/etc/nvda_snap`).

Default Configuration Reference

For reference, the standard default configuration is as follows:

```
---
version: 25.04
---
DPA_APPS:
  dpa_helper:
    - partition: ROOT
      affinity_EUs: [1-16]
  dpa_virtq_split:
    - partition: ROOT
      affinity_EUs: [0-169]
  dpa_nvme:
    - partition: ROOT
      affinity_EUs: [0-169]
```

8.11.2.6.13.2 Method 2: Core Mask (Specific Use Case)

The Core Mask method provides an alternative approach for EU allocation.

> **Use Case Restriction**
>
> This method is the default, preconfigured approach strictly for running SNAP-4 concurrently with the SNAP virtio-fs service. For all other scenarios requiring DPA EU modifications, utilize the YAML-based method described above.

Configuration

To assign a specific set of EUs via a mask, set the corresponding environment variable using a hexadecimal string.

Application	Environment Variable
Virtio-blk / NVMe (DPU Mode)	`dpa_helper_core_mask=0x<EU_mask>`
NVMe (DPA Mode)	`dpa_nvme_core_mask=0x<EU_mask>`
Virtio-blk (DPA Mode)	`dpa_virtq_split_core_mask=0x<EU_mask>`

Mask Logic

The system parses the core mask from right to left, utilizing valid hexadecimal digits.

Example: `dpa_virtq_split_core_mask=0xff00`

- The hexadecimal `ff00` sets 8 bits high (specifically bits 8–15).
- Result: The system allocates 8 EUs (EUs 8 through 15) to the virtio-blk application.

8.11.2.6.14 SNAP ML Optimizer Online

The SNAP ML Online Optimizer is a dynamic performance-tuning utility that continuously adjusts polling parameters within the SNAP I/O subsystem. It maximizes controller throughput by identifying the optimal configuration based on real-time hardware conditions, workload patterns, and system constraints.

8.11.2.6.14.1 Operational Workflow

The optimizer utilizes predictive modeling to converge on an optimal setup efficiently, eliminating the need to exhaustively test all possible parameter combinations. It operates using the following iterative loop:

1. Execute actions: Iteratively modifies internal configuration parameters (actions) during runtime.
2. Measure rewards: Measures the resulting system performance (reward) after each configuration change. Currently, the optimizer explicitly targets and maximizes IOPS as the primary reward metric.
3. Predict next state: Uses predictive models to determine the most promising configuration to evaluate next.

8.11.2.6.14.2 Background Optimization Behavior

The SNAP ML Optimizer continuously analyzes active workloads and applies optimization actions in the background. It dynamically learns workload profiles and adapts rapidly when it recognizes returning traffic patterns.

Once the optimizer characterizes a workload and applies the optimal parameters, it transitions into an idle state. It resumes active tuning only when it detects a significant change in the underlying traffic pattern.

Configuring SNAP ML Online Optimizer

The ML Optimizer can be enabled using one of two methods:

1. Environment variable – Set `SNAP_ML_OPTIMIZER_ENABLED=1` when launching SNAP.
2. Runtime RPC – Execute the `snap_ml_optimizer_create` RPC.

ML Optimizer RPCs

The following Remote Procedure Calls (RPCs) are used to manage the optimizer at runtime.

snap_ml_optimizer_create

The `snap_ml_optimizer_create` initializes or recreates the ML Optimizer, which will immediately begin analyzing and optimizing the system.

> ⚠ Enabling the ML Optimizer will override any system parameters previously applied via `snap_actions_set`, environment variables, or default settings.

snap_ml_optimizer_destroy

The `snap_ml_optimizer_destroy` command tops the ML Optimizer service.

- Once stopped, the system restores the default SNAP parameters.
- All workload data collected by the optimizer is discarded. Any future instances of the optimizer will begin the learning process from scratch.

snap_ml_optimizer_is_running

The `snap_ml_optimizer_is_running` command queries the current operational status of the ML Optimizer.

snap_ml_optimizer_current_parameters

The `snap_ml_optimizer_current_parameters` command retrieves the currently active internal parameters. This command returns the active configuration regardless of whether it was applied by the ML Optimizer or manually configured by the user.

snap_actions_set

The `snap_actions_set` command is used to dynamically adjust SNAP parameters (known as "actions") that control polling behavior. This command is a core feature of SNAP-AI tools, enabling both automated optimization for specific environments and workloads, as well as manual adjustment of polling parameters.

Command parameters:

Parameter	Mandatory ?	Type	Description
`poll_size`	No	Number	Maximum number of IOs SNAP passes in a single polling cycle (integer; 1-256)

Parameter	Mandatory ?	Type	Description
`poll_ratio`	No	Number	The rate in which SNAP poll cycles occur (float; 0< `poll_ratio` ≤1)
`max_inflights`	No	Number	Maximum number of in-flight IOs per core (integer; 1-65535)
`max_iog_batch`	No	Number	Maximum fairness batch size (integer; 1-4096)
`max_new_ios`	No	Number	Maximum number of new IOs to handle in a single poll cycle (integer; 1-4096)

`snap_actions_set` cannot be used when ML Optimizer Online is enabled

snap_reward_get

The `snap_reward_get` command retrieves performance counters, specifically completion counters (or "reward"), which are used by the optimizer to monitor and enhance SNAP performance.

No parameters are required for this command.

snap_observations_get

The `snap_observations_get` returns the current state of SNAP as a set of predefined parameters.

No parameters are required for this command.

8.11.2.6.15 SNAP ML Optimizer Offline (DEPRECATED)

8.11.2.6.15.1 SNAP ML Optimizer Preparation Steps

Machine Requirements

The device should be able to SSH to the BlueField:

- Python 3.10 or above
- At least 6 GB of free storage

Setting Up SNAP ML Optimizer

To set up the SNAP ML optimizer:

1. Copy the `snap_ml` folder from the container to the shared `nvda_snap` folder and then to the requested machine:

```
crictl exec -it $(crictl ps -s running -q --name snap) cp -r /opt/nvidia/nvda_snap/bin/snap_ml /etc/
nvda_snap/
```

2. Change directory to the `snap_ml` folder:

```
cd tools/snap_ml
```

3. Create a virtual environment for the SNAP ML optimizer.

```
python3 -m venv snap_ml
```

This ensures that the required dependencies are installed in an isolated environment.

4. Activate the virtual environment to start working within this isolated environment:

```
source snap_ml/bin/activate
```

5. Install the Python package requirements:

```
pip3 install --no-cache-dir -r requirements.txt
```

This may take some time depending on your system's performance.

6. Run the SNAP ML Optimizer.

```
python3 snap_ml.py --help
```

Use the `--help` flag to see the available options and usage information:

```
--version Show the version and exit.
-f, --framework <TEXT> Name of framework (Recommended: ax , supported: ax, pybo).
-t, --total-trials <INTEGER> Number of optimization iterations. The recommended range is 25-60.
--filename <TEXT> where to save the results (default: last_opt.json).
--remote <TEXT> connect remotely to the BlueField card, format: <bf_name>:<username>:<password>
--snap-rpc-path <TEXT> Snap RPC prefix (default: container path).
--log-level <TEXT> CRITICAL | ERROR | WARN | WARNING | INFO | DEBUG
--log-dir <TEXT> where to save the logs.
```

8.11.2.6.15.2 Run the Offline ML Optimizer

To optimize SNAP's parameters for your environment, use the following command:

```
python3 snap_ml.py --framework ax --total-trials 40 --filename example.json --remote
<bf_hostname>:<username>:<password> --log-dir <log_directory>
```

Results and Post-optimization Actions

Once the optimization process is complete, the tool automatically applies the optimized parameters. These parameters are also saved in a `example.json` file in the following format:

```
{
    "poll_size": 30,
    "poll_ratio": 0.6847347955107689,
    "max_inflights": 32768,
    "max_iog_batch": 512,
    "max_new_ios": 32
```

```
}
```

Additionally, the tool documents all iterations, including the actions taken and the rewards received, in a timestamped file named `example_<timestamp>.json`.

Applying Optimized Parameters Manually

Users can apply the optimized parameters on fresh instances of SNAP service by explicitly calling the `snap_actions_set` RPC with the optimized parameters as follows:

```
snap_rpc.py snap_actions_set -poll_size 30 -poll_ratio 0.6847 --max_inflights 32768 -max_iog_batch 512 -max_new_ios
32
```

It is only recommended to use the optimized parameters if the system is expected to behave similarly to the system on which the SNAP ML optimizer is used.

Deactivating Python Environment

Once users are done using the SNAP ML Optimizer, they can deactivate the Python virtual environment by running:

```
deactivate
```

8.11.2.6.16 Plugins

Plugins are modular components or add-ons that enhance the functionality of the SNAP application. They integrate seamlessly with the main software, allowing additional features without requiring changes to the core codebase. Plugins are designed for use only with the source package, as it allows customization during the build process, such as enabling or disabling plugins as needed.

In containerized environments, the SNAP application is shipped as a pre-built binary with a fixed configuration. Since the binary in the container is precompiled, adding or removing plugins is not possible. The containerized software only supports the plugins included during its build. For environments requiring plugin flexibility, such as adding custom plugins, the source package must be used.

To build a SNAP source package with a plugin, perform the following instead of following the basic build steps:

1. Move to the sources folder. Run:

   ```
   cd /opt/nvidia/nvda_snap/src/
   ```

2. Build the sources with plugin to be enabled. Run:

   ```
   meson setup /tmp/build -Denable-bdev-null=true -Denable-bdev-malloc=true
   ```

3. Compile the sources. Run:

```
meson compile -C /tmp/build
```

4. Install the sources. Run:

```
meson install -C /tmp/build
```

5. Configure the SNAP environment variables and run SNAP service as explained in sections "Configure SNAP Environment Variables" and "Run SNAP Service".

8.11.2.6.16.1 Bdev

SNAP supports various block device (`bdev`) plugins to emulate storage backends without modifying core software. SPDK serves as the default `bdev` plugin; SNAP routes block device operations through SPDK unless an alternative is explicitly specified. For detailed SPDK documentation, refer to spdk_bdev.

The following plugins provide specific storage emulation capabilities:

Asynchronous I/O Block Device

The AIO plugin uses the Linux asynchronous I/O (`libaio`) interface to support block devices backed by regular files or raw Linux block devices. It routes SPDK storage operations through the kernel instead of user-space drivers.

- Use cases: Testing, development, and environments lacking direct hardware access. It also enables UEFI boot (including read-only boot images) by exposing a bootable disk before initializing hardware drivers.
- Constraints: Introduces higher latency than native SPDK drivers due to kernel overhead.
- Build option: Enable via `--enable-bdev-aio` .

AIO configuration example:

1. Create a file-backed AIO `bdev` :

```
fallocate -l 10G test
spdk_rpc.py bdev_aio_create test aio_test 512
```

2. Create an AIO `bdev` backed by a disk image and attach it to an NVMe controller:

```
spdk_rpc.py bdev_aio_create /path/to/disk.img aio_test 512
snap_rpc.py nvme_subsystem_create --nqn nqn.2022-10.io.nvda.nvme:0
snap_rpc.py nvme_namespace_create -b aio_test -n 1 --nqn nqn.2022-10.io.nvda.nvme:0 --uuid
263826ad-19a3-4febbc25-4bc81ee7749e
snap_rpc.py nvme_controller_create --nqn nqn.2022-10.io.nvda.nvme:0 --pf_id 0 --suspended
snap_rpc.py nvme_controller_attach_ns -c NVMeCtrl1 -n 1
snap_rpc.py nvme_controller_resume -c NVMeCtrl1
```

3. Delete the AIO `bdev` :

```
spdk_rpc.py bdev_aio_delete aio_test
```

Malloc

The Malloc plugin creates a memory-backed block device by allocating a buffer in RAM.

- Use cases: Performance analysis and debugging.
- Constraints: Not for production. Data is volatile and permanently lost upon system shutdown or device resizing.
- Build option: Enable via `--enable-bdev-malloc`.

Malloc configuration example:

1. Create a Malloc `bdev` and attach it to an NVMe controller:

```
snap_rpc.py snap_bdev_malloc_create --bdev test 64 512
snap_rpc.py nvme_subsystem_create -s nqn.2020-12.mlnx.snap
snap_rpc.py nvme_namespace_create -s nqn.2020-12.mlnx.snap -t malloc -b test -n 1
snap_rpc.py nvme_controller_create --pf_id=0 -s nqn.2020-12.mlnx.snap --mdts=7
snap_rpc.py nvme_controller_attach_ns -c NVMeCtrl1 -n 1
```

2. Resize a Malloc `bdev`:

```
snap_rpc.py snap_bdev_malloc_resize test 32
```

> This destroys the existing device and creates a new one; all data is lost.

3. Delete the Malloc `bdev`:

```
snap_rpc.py snap_bdev_malloc_destroy test
```

NULL

The NULL plugin acts as a dummy block device that accepts I/O requests without performing actual physical storage operations.

- Use cases: Benchmarking and testing scenarios that require minimal system resources and no real storage hardware.
- Constraints: Not for production. Strictly for performance analysis and debugging.
- Build option: Enable via `--enable-bdev-null`.

NULL configuration example:

1. Create a NULL `bdev` and attach it to an NVMe controller:

```
snap_rpc.py snap_bdev_null_create_dbg test 1 512
snap_rpc.py nvme_subsystem_create -s nqn.2020-12.mlnx.snap
snap_rpc.py nvme_namespace_create -s nqn.2020-12.mlnx.snap -t malloc -b test -n 1
snap_rpc.py nvme_controller_create --pf_id=0 -s nqn.2020-12.mlnx.snap --mdts=7
snap_rpc.py nvme_controller_attach_ns -c NVMeCtrl1 -n 1
```

2. Delete the NULL `bdev`:

```
snap_rpc.py snap_bdev_null_destroy_dbg test
```

8.11.2.6.17 Single Protocol Mode

Single Protocol Mode restricts a SNAP instance to a single designated storage protocol (NVMe or virtio-blk). This configuration facilitates strict resource isolation and enables parallel container deployments.

8.11.2.6.17.1 System Behaviors

When operating in this mode, the system enforces the following behaviors:

- Initialization checks – During startup, SNAP verifies that the underlying hardware supports the configured protocol. If a capability mismatch occurs, the service fails to start and outputs a critical log detailing the missing hardware requirements.
- Function filtering – The `emulation_function_list` RPC response strictly filters its output, displaying only the functions associated with the configured protocol.
- Strict rejection – The system immediately rejects any hotplug or controller creation requests targeting an unsupported protocol, returning an explicit error message to the user.

8.11.2.6.17.2 Configuration

Enable and define the protocol restriction using the `SNAP_SUPPORTED_PROTOCOL` environment variable.

Parameter Value	Supported Protocol	Description
0 (or unset)	All protocols	Default behavior: The SNAP instance supports all available storage protocols.
1	NVMe only	Restricts the instance strictly to NVMe protocol operations.
2	Virtio-blk only	Restricts the instance strictly to virtio-blk protocol operations.

8.11.2.6.17.3 Deployment Guidelines and Constraints

When deploying multiple parallel SNAP containers, adhere to the following best practices to prevent resource contention and system conflicts:

- Protocol separation: Deploy concurrent containers using different protocols (e.g., one NVMe container alongside one virtio-blk container). Running multiple containers configured for the exact same protocol can cause severe conflicts when sharing firmware protocol objects.
- Resource partitioning: Running two parallel containers requires doubling the total hugepage allocation. Ensure other system resources, such as CPU cores and RAM, are explicitly partitioned between the instances.

- Object isolation: Do not share identical operational objects across different containers. For example, avoid connecting two separate containers to the exact same remote block device (`bdev`).

8.11.2.6.18 UEFI Boot Configuration Walkthrough

This section provides a step-by-step guide for configuring SNAP NVMe and virtio-blk devices as UEFI boot targets. The workflow encompasses firmware configuration, SNAP backend preparation, and host BIOS/UEFI integration.

8.11.2.6.18.1 Prerequisites

Before initiating the configuration, ensure the environment meets the following baseline requirements:

- Software: BlueField must run a full DOCA image with SNAP-4 deployed (either as a container or a source-package service).
- Firmware: Storage emulation must be enabled in the firmware for NVMe and/or virtio-blk Physical Functions (PFs). Static PFs are strongly recommended for boot configurations.
- Storage backend: A bootable backend must exist and be reachable (e.g., a local NVMe SSD, a remote NVMe-oF RDMA target, or another supported SPDK `bdev`). This backend must contain a pre-installed OS or an accessible installer ISO.

8.11.2.6.18.2 Step 1: Configure UEFI Expansion ROM in Firmware

UEFI boot requires the activation of NVIDIA's UEFI expansion ROM drivers on the DPU. This allows the platform firmware to utilize NVIDIA's driver during the UEFI boot phase instead of relying on the vendor's default BIOS implementation.

1. Ensure the device operates in the internal CPU model and that storage emulation is active.
   - `INTERNAL_CPU_MODEL=1`
   - `PF_BAR2_ENABLE=0`

     ⚠ This parameter is deprecated and must strictly be set to `0` .
   - `NVME_EMULATION_ENABLE=1` and/or `VIRTIO_BLK_EMULATION_ENABLE=1` (with at least one PF configured).
2. Execute the following `mlxconfig` command to enable the UEFI expansion ROMs for x86 hosts:

```
mlxconfig -d /dev/mst/mt41692_pciconf0 s \
    EXP_ROM_VIRTIO_BLK_UEFI_x86_ENABLE=1 \
    EXP_ROM_NVME_UEFI_x86_ENABLE=1
```

3. Perform a complete power cycle of both the host and the DPU to apply the firmware configuration.

8.11.2.6.18.3 Step 2: Prepare SNAP Backend and Controller on the DPU

The UEFI stack strictly requires boot devices to be fully configured before the boot phase initiates. The SNAP PCIe function must be visible, and the backend disk must be attached to the emulated controller prior to the host reaching the UEFI boot sequence.

> **Hotplug Constraints**
>
> If utilizing hotplug PFs instead of static PFs, the hotplug operation must finalize before the BIOS begins the UEFI boot sequence. This limits hotplug boot support exclusively to warm reboot or external DPU power scenarios.

Option A: NVMe Configuration (Recommended Pattern)

To utilize NVMe for the system disk, create the controller in a suspended state, attach the namespace, and then resume operations. This guarantees the namespace is available upon initialization.

1. Attach the remote backend:

```
spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma \
    -a <target_ip> -f ipv4 -s 4420 -n <subnqn>
```

2. Create the subsystem and namespace:

```
snap_rpc.py nvme_subsystem_create \
    --nqn nqn.2025-01.com.nvda:nvme:boot0

snap_rpc.py nvme_namespace_create \
    -b nvme0n1 -n 1 \
    --nqn nqn.2025-01.com.nvda:nvme:boot0 \
    --uuid <boot_ns_uuid>
```

3. Create the controller in a suspended state:

```
snap_rpc.py nvme_controller_create \
    --nqn nqn.2025-01.com.nvda:nvme:boot0 \
    --pf_id 0 \
    --ctrl NVMeBoot0 \
    --suspended \
    --num_queues 2
```

4. Attach the namespace and resume the controller:

```
snap_rpc.py nvme_controller_attach_ns -c NVMeBoot0 -n 1
snap_rpc.py nvme_controller_resume -c NVMeBoot0
```

> **Queue Requirements**
>
> The UEFI NVMe expansion ROM strictly requires a minimum of 2 I/O queues. Always configure `--num_queues=2` or higher on the boot controller.

Option B: virtio-blk Configuration

Configure a single system disk using the virtio-blk protocol:

1. Attach the remote backend:

```
spdk_rpc.py bdev_nvme_attach_controller -b nvme0 -t rdma \
    -a <target_ip> -f ipv4 -s 4420 -n <subnqn>
```

2. Create the virtio-blk controller:

```
snap_rpc.py virtio_blk_controller_create \
    --pf_id 0 \
    --ctrl VBLKBoot0 \
    --bdev nvme0n1
```

Validation

After executing either option, run `snap_rpc.py emulation_function_list` or `{nvme,virtio_blk}_controller_list` to verify the emulation function is present and successfully bound to the correct controller.

8.11.2.6.18.4 Step 3: Host BIOS/UEFI Configuration

With the firmware and SNAP environment fully configured, map the host BIOS/UEFI to boot from the SNAP-provided disk.

1. Access BIOS: Reboot the host into the BIOS/UEFI setup utility. Ensure the DPU remains powered and the SNAP service is fully active during this process.
2. Identify the device: Navigate to the UEFI boot menu and verify the SNAP emulated device appears as a bootable NVMe or virtio-blk disk.

   > ⚠ Exact name and vendor strings depend on the specific firmware configuration.

3. Set boot priority: Select the emulated disk as the primary boot option. Alternatively, boot from an installer ISO, install the OS to the SNAP-provided disk, and subsequently set it as the primary system disk.

> ℹ **Troubleshooting: Boot Stalls**
>
> UEFI boot times over SNAP should parallel non-SNAP, bare-metal configurations. If the boot process stalls significantly (e.g., exceeding 1 minute), investigate the deployment for backend connectivity failures or configuration mismatches.

8.11.2.7 SNAP-4 Service Appendixes

8.11.2.7.1 Appendix – DPU Firmware Configuration

Before configuring SNAP, the user must ensure that all firmware configuration requirements are met. By default, SNAP is disabled and must be enabled by running both common SNAP configurations and additional protocol-specific configurations depending on the expected usage of the application (e.g., hot-plug, SR-IOV, UEFI boot, etc).

After configuration is finished, the host must be power cycled for the changes to take effect.

⚠ To verify that all configuration requirements are satisfied, users may query the current/next configuration by running the following:

```
mlxconfig -d /dev/mst/mt41692_pciconf0 -e query
```

8.11.2.7.1.1 System Configuration Parameters

Parameter	Description	Possible Values
`INTERNAL_CPU_MODEL`	Enable BlueField to work in internal CPU model ⚠ Must be set to `1` for storage emulations.	0/1
`SRIOV_EN`	Enable SR-IOV	0/1
`PCI_SWITCH_EMULATION_ENABLE`	Enable PCIe switch for emulated PFs	0/1
`PCI_SWITCH_EMULATION_NUM_PORT`	The maximum number of hotplug emulated PFs which equals `PCI_SWITCH_EMULATION_NUM_PORT` –1. For example, if `PCI_SWITCH_EMULATION_NUM_PORT=32`, then the maximum number of hotplug emulated PFs would be 31. ⚠ One switch port is reserved for all static PFs.	[0,2-32]

⚠ `SRIOV_EN` is valid only for static PFs.

8.11.2.7.1.2 RDMA/RoCE Configuration

By default, BlueField's RDMA/RoCE communication is blocked for its primary OS interfaces (known as ECPFs, typically `mlx5_0` and `mlx5_1`).

If RoCE traffic is required, you must create additional network functions (scalable functions) that support RDMA/RoCE.

> ⚠ This configuration is not required when working over TCP or RDMA/IB.

To enable RoCE interfaces, run the following from within the DPU:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PER_PF_NUM_SF=1
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0.1 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
```

8.11.2.7.1.3 NVMe Configuration

Parameter	Description	Possible Values
`NVME_EMULATION_ENABLE`	Enable NVMe device emulation	0/1
`NVME_EMULATION_NUM_PF`	Number of static emulated NVMe PFs	[0-2]
`NVME_EMULATION_NUM_MSIX`	Number of MSIX assigned to emulated NVMe PFs ⚠ Firmware treats this value as a best effort value. The effective number of MSI-X given to the function should be queried as part of the nvme_controller_list RPC command.	[0-63]
`NVME_EMULATION_NUM_VF_MSIX`	Number of MSIX per emulated NVMe VF ⚠ Firmware treats this value as a best effort value. The effective number of MSI-X given to the function should be queried as part of the nvme_controller_list RPC command. ⚠ This value should match the maximum number of queues assigned to a VF's NVMe SNAP controller through the nvme_controller_create `num_queues` parameter, as each queue requires one MSIX interrupt.	[0-4095]
`NVME_EMULATION_NUM_VF`	Number of VFs per emulated NVMe PF ⚠ If not 0, overrides `NUM_OF_VFS`; valid only when `SRIOV_EN=1`.	[0-256]

Parameter	Description	Possible Values
`EXP_ROM_NVME_UEFI_x86_ENABLE`	Enable NVMe UEFI exprom driver ⚠ Used for UEFI boot process.	0/1
`NVME_EMULATION_MAX_QUEUE_DEPTH`	Defines the default maximum queue depth for NVMe I/O queues for Physical and Virtual Functions. The value should be set to the binary logarithm of the desired maximum queue size. • A value of `0` (default) limits the queue size to 64. • The recommended value is `12`, which allows for a queue size of 4096.	[0-12]

8.11.2.7.1.4 Virtio-blk Configuration

Due to virtio-blk protocol limitations, using bad configuration while working with static virtio-blk PFs may cause the host server OS to fail on boot.

Before continuing, make sure you have configured:

- A working channel to access Arm even when the host is shut down. Setting such channel is out of the scope of this document. Please refer to NVIDIA BlueField DPU BSP documentation for more details.
- Add the following line to `/etc/nvda_snap/snap_rpc_init.conf`:

```
virtio_blk_controller_create -pf_id 0
```

For more information, please refer to section "Virtio-blk Emulation Management".

Parameter	Description	Possible Values
`VIRTIO_BLK_EMULATION_ENABLE`	Enable virtio-blk device emulation	0/1
`VIRTIO_BLK_EMULATION_NUM_PF`	Number of static emulated virtio-blk PFs ⚠ See warning above.	[0-4]
`VIRTIO_BLK_EMULATION_NUM_MSIX`	Number of MSIX assigned to emulated virtio-blk PFs ⚠ The firmware treats this value as a best effort value. The effective number of MSI-X given to the function should be queried as part of the virtio_blk_controller_list RPC command.	[0-63]

Parameter	Description	Possible Values
`VIRTIO_BLK_EMULATION_NUM_VF_MSIX`	Number of MSIX per emulated virtio-blk VF ⚠ The firmware treats this value as a best effort value. The effective number of MSI-X given to the function should be queried as part of the virtio_blk_controller_list RPC command. ⚠ This value should match the maximum number of queues assigned to a VF's NVMe SNAP controller through the nvme_controller_create `num_queues` parameter, as each queue requires one MSIX interrupt.	[0-4095]
`VIRTIO_BLK_EMULATION_NUM_VF`	Number of VFs per emulated virtio-blk PF ⚠ If not 0, overrides `NUM_OF_VFS`; valid only when `SRIOV_EN=1`	[0-2047]
`EXP_ROM_VIRTIO_BLK_UEFI_x86_ENABLE`	Enable virtio-blk UEFI exprom driver ⚠ Used for UEFI boot process.	0/1

8.11.2.7.2 Appendix – Configure Persistent Network Interfaces

To configure persistent network interfaces so they are not lost after reboot. Under `/etc/sysconfig/network-scripts` modify the following four files, or create them if do not exist, then perform a reboot:

```
# cd /etc/sysconfig/network-scripts/
# cat ifcfg-p0
  NAME="p0"
  DEVICE="p0"
  NM_CONTROLLED="no"
  DEVTIMEOUT=30
  PEERDNS="no"
  ONBOOT="yes"
  BOOTPROTO="none"
  TYPE=Ethernet
  MTU=9000

# cat ifcfg-p1
  NAME="p1"
  DEVICE="p1"
  NM_CONTROLLED="no"
  DEVTIMEOUT=30
  PEERDNS="no"
  ONBOOT="yes"
  BOOTPROTO="none"
  TYPE=Ethernet
  MTU=9000

# cat ifcfg-enp3s0f0s0
  NAME="enp3s0f0s0"
  DEVICE="enp3s0f0s0"
  NM_CONTROLLED="no"
  DEVTIMEOUT=30
  PEERDNS="no"
  ONBOOT="yes"
  BOOTPROTO="static"
  TYPE=Ethernet
  IPADDR=1.1.1.1
  PREFIX=24
  MTU=9000

# cat ifcfg-enp3s0f1s0
  NAME="enp3s0f1s0"
  DEVICE="enp3s0f1s0"
  NM_CONTROLLED="no"
  DEVTIMEOUT=30
```

```
PEERDNS="no"
ONBOOT="yes"
BOOTPROTO="static"
TYPE=Ethernet
IPADDR=1.1.1.2
PREFIX=24
MTU=9000
```

8.11.2.7.3 Appendix – Building SNAP Container with Custom SPDK

The SNAP source package contains the files necessary for building a container with a custom SPDK.

To build the container:

1. Download and install the SNAP sources package:

   ```
   [dpu] # dpkg -i /path/snap-sources_<version>_arm64.deb
   ```

2. Navigate to the `src` folder and use it as the development environment:

   ```
   [dpu] # cd /opt/nvidia/nvda_snap/src
   ```

3. Copy the following to the container folder:
   - SNAP source package – required for installing SNAP inside the container
   - Custom SPDK – to `container/spdk`. For example:

     ```
     [dpu] # cp /path/snap-sources_<version>_arm64.deb  container/
     [dpu] # git clone -b v23.01.1 --single-branch --depth 1 --recursive --shallow-submodules https://
     github.com/spdk/spdk.git container/spdk
     ```

4. Modify the `spdk.sh` file if necessary as it is used to compile SDPK.
5. To build the container:
   - For Ubuntu, run:

     ```
     [dpu] # ./container/build_public.sh --snap-pkg-file=snap-sources_<version>_arm64.deb
     ```

   - For CentOS, run:

     ```
     [dpu] # rpm -i snap-sources-<version>.el8.aarch64.rpm
     [dpu] # cd /opt/nvidia/nvda_snap/src/
     [dpu] # cp /path/snap-sources_<version>_arm64.deb container/
     [dpu] # git clone -b v23.01.1 --single-branch --depth 1 --recursive --shallow-submodules https://
     github.com/spdk/spdk.git container/spdk
     [dpu] # yum install docker-ce docker-ce-cli
     [dpu] # ./container/build_public.sh --snap-pkg-file=snap-sources_<version>_arm64.deb
     ```

6. Transfer the created image from the Docker tool to the crictl tool. Run:

   ```
   [dpu] # docker save doca_snap:<version> doca_snap.tar
   [dpu] # ctr -n=k8s.io images import doca_snap.tar
   ```

   ⚠ To transfer the container image to other setups, refer to appendix "Deploying Container on Setups Without Internet Connectivity".

7. To verify the image, run:

```
[DPU] #  crictl images
IMAGE                                TAG                 IMAGE ID            SIZE
docker.io/library/doca_snap          <version>           79c503f0a2bd7       284MB
```

8. Edit the image filed in the `container/doca_snap.yaml` file. Run:

```
image: doca_snap:<version>
```

9. Use the YAML file to deploy the container. Run:

```
[dpu] # cp doca_snap.yaml /etc/kubelet.d/
```

⚠ The container deployment preparation steps are required.

8.11.2.7.4 Appendix – Deploying Container on Setups Without Internet Connectivity

When Internet connectivity is not available on a DPU, Kubelet scans for the container image locally upon detecting the SNAP YAML. Users can load the container image manually before the deployment.

To accomplish this, users must download the necessary resources using a DPU with Internet connectivity and subsequently transfer and load them onto DPUs that lack Internet connectivity.

1. To download the `.yaml` file:

```
[bf] # wget --content-disposition https://api.ngc.nvidia.com/v2/resources/nvidia/doca/
doca_container_configs/versions/<path-to-yaml>/doca_snap.yaml
```

⚠ Access the latest download command on NGC. The `doca_snap:4.1.0-doca2.0.2` tag is used in this section as an example, and the latest tag is also available on NGC.

2. To download SNAP container image:

```
[bf] # crictl pull nvcr.io/nvidia/doca/doca_snap:4.1.0-doca2.0.2
```

3. To verify that the SNAP container image exists:

```
[bf] # crictl images

IMAGE                                TAG                 IMAGE ID            SIZE
nvcr.io/nvidia/doca/doca_snap        4.1.0-doca2.0.2     9d941b5994057       267MB
k8s.gcr.io/pause                     3.2                 2a060e2e7101d       251kB
```

⚠ `k8s.gcr.io/pause` image is required for the SNAP container.

4. To save the images as a `.tar` file:

```
[bf] # mkdir images
[bf] # ctr -n=k8s.io image export images/snap_container_image.tar nvcr.io/nvidia/doca/doca_snap:4.1.0-
doca2.0.2
[bf] # ctr -n=k8s.io image export images/pause_image.tar k8s.gcr.io/pause:3.2
```

5. Transfer the `.tar` files and run the following to load them into Kubelet:

```
[bf] # sudo ctr --namespace k8s.io image import images/snap_container_image.tar
[bf] # sudo ctr --namespace k8s.io image import images/pause_image.tar
```

6. Now, the image exists in the tool and is ready for deployment.

```
[bf] # crictl images
IMAGE                                TAG                 IMAGE ID            SIZE
nvcr.io/nvidia/doca/doca_snap        4.1.0-doca2.0.2     9d941b5994057       267MB
k8s.gcr.io/pause                     3.2                 2a060e2e7101d       251kB
```

8.11.2.7.5 Appendix – Install Legacy SPDK

To build SPDK-19.04 for SNAP integration:

1. Cherry-pick a critical fix for SPDK shared libraries installation (originally applied on upstream only since v19.07).

```
[spdk.git] git cherry-pick cb0c0509
```

2. Configure SPDK:

```
[spdk.git] git submodule update --init
[spdk.git] ./configure --prefix=/opt/mellanox/spdk --disable-tests --without-crypto --without-fio --with-
vhost --without-pmdk --without-rbd --with-rdma --with-shared --with-iscsi-initiator --without-vtune
[spdk.git] sed -i -e 's/CONFIG_RTE_BUILD_SHARED_LIB=n/CONFIG_RTE_BUILD_SHARED_LIB=y/g' dpdk/build/.config
```

⚠ The flags `--prefix`, `--with-rdma`, and `--with-shared` are mandatory.

3. Make SPDK (and DPDK libraries):

```
[spdk.git] make && make install
[spdk.git] cp dpdk/build/lib/* /opt/mellanox/spdk/lib/
[spdk.git] cp dpdk/build/include/* /opt/mellanox/spdk/include/
```

8.11.2.7.6 Appendix – PCIe BDF to VUID Translation

PCIe BDF (Bus, Device, Function) is a unique identifier assigned to every PCIe device connected to a computer. By identifying each device with a unique BDF number, the computer's OS can manage the system's resources efficiently and effectively.

PCIe BDF values are determined by host OS and are hence subject to change between different runs, or even in a single run. Therefore, the BDF identifier is not the best fit for permanent configuration.

To overcome this problem, NVIDIA devices add an extension to PCIe attributes, called VUIDs. As opposed to BDF, VUID is persistent across runs which makes it useful as a PCIe function identifier.

PCI BDF and VUID can be extracted one out of the other, using `lspci` command:

1. To extract VUID out of BDF:

```
[host] lspci -s <BDF> -vvv | grep -i VU | awk '{print $4}'
```

2. To extract BDF out of VUID:

```
[host] ./get_bdf.py <VUID>
[host] cat ./get_bdf.py
#!/usr/bin/python3

import subprocess
import sys

vuid = sys.argv[1]

# Split the output into individual PCI function entries
lspci_output = subprocess.check_output(['lspci']).decode().strip().split('\n')

# Create an empty dictionary to store the results
pci_functions = {}

# Loop through each PCI function and extract the BDF and full info
for line in lspci_output:
    bdf = line.split()[0]
    if vuid in subprocess.check_output(['lspci', '-s', bdf, '-vvv']).decode():
        print(bdf)
        exit(0)

print("Not Found")
```

8.11.2.7.7 Appendix – SNAP Memory Consumption

This appendix explains how SNAP consumes memory and how to manage memory allocation.

The user must allocate the DPA hugepages memory according to the section "Step 1: Allocate Hugepages". It is possible to use use a portion of the DPU memory allocation in the SNAP container as described in section "Adjusting YAML Configuration". This configuration includes the following minimum and maximum values:

- The minimum allocation which the SNAP container consumes:

```
resources:
  requests:
    memory: "4Gi"
```

- The maximum allocation that the SNAP container is allowed to consume:

```
resources:
  limits:
    hugepages-2Mi: "4Gi"
```

Hugepage memory is used by the following:

- SPDK `mem-size` global variable which controls the SPDK hugepages consumption (configurable in SPDK, 1GB by default)
- SNAP `SNAP_MEMPOOL_SIZE_MB` – used with non-ZC mode as IO buffers staging buffers on the Arm. By default, the SNAP mempool consumes 1G from the SPDK `mem-size` hugepages allocation. SNAP mempool may be configured using the `SNAP_MEMPOOL_SIZE_MB` global variable (minimum is 64 MB).

  > ⚠ If the value assigned is too low, with non-ZC, a performance degradation could be seen.

- SNAP and SPDK internal usage – 1G should be used by default. This may be reduced depending on the overall scale (i.e., VFs/num queues/QD).
- XLIO buffers – allocated only when NVMeTCP XLIO is enabled.

The following is the limit of the container memory allowed to be used by the SNAP container:

```
resources:
  limits:
    memory: "6Gi"
```

> ℹ This includes the hugepages limit (in this example, additional 2G of non-hugepages memory).

The SNAP container also consumes DPU SHMEM memory when NVMe recovery is used (described in section "NVMe Recovery"). In addition, the following resources are used:

```
limits:
  memory:
```

8.11.2.7.8 Appendix – Host OS Configuration

With Linux environment on host OS, additional kernel boot parameters may be required to support SNAP related features:

- To use SR-IOV:
  - For Intel, `intel_iommu=on iommu=pt` must be added
  - For AMD, `amd_iommu=on iommu=pt` must be added
- To use PCIe hotplug, `pci=realloc` must be added
- `modprobe.blacklist=virtio_blk,virtio_pci` for non-built-in `virtio-blk` driver or `virtio-pci` driver

To view boot parameter values, run:

```
cat /proc/cmdline
```

It is recommended to use the following with virtio-blk:

```
[dpu] cat /proc/cmdline BOOT_IMAGE … pci=realloc modprobe.blacklist=virtio_blk,virtio_pci
```

To enable VFs (virtio_blk/NVMe):

```
echo 125 > /sys/bus/pci/devices/0000\:27\:00.4/sriov_numvfs
```

8.11.2.7.8.1 Intel Server Performance Optimizations

```
cat /proc/cmdline
BOOT_IMAGE=(hd0,msdos1)/vmlinuz-5.15.0_mlnx root=UUID=91528e6a-b7d3-4e78-9d2e-9d5ad60e8273 ro crashkernel=auto
resume=UUID=06ff0f35-0282-4812-894e-111ae8d76768 rhgb quiet iommu=pt intel_iommu=on pci=realloc
modprobe.blacklist=virtio_blk,virtio_pci
```

8.11.2.7.8.2 AMD Server Performance Optimizations

```
cat /proc/cmdline
cat /proc/cmdline BOOT_IMAGE=(hd0,msdos1)/vmlinuz-5.15.0_mlnx root=UUID=91528e6a-b7d3-4e78-9d2e-9d5ad60e8273 ro
crashkernel=auto resume=UUID=06ff0f35-0282-4812-894e-111ae8d76768 rhgb quiet iommu=pt amd_iommu=on pci=realloc
modprobe.blacklist=virtio_blk,virtio_pci
```

8.11.2.7.9 Appendix – SPDK Configuration

The SPDK `bdev_nvme` module utilizing RDMA transport does not support Completion Queue (CQ) resizing.

This constraint limits the number of SPDK NVMe RDMA IO queues that can be created per core. Consequently, this restricts the maximum number of supported PCI functions (including VFs, static PFs, and hot-plug PFs).

The actual limit depends on several factors, including the maximum queue depth configured on the NVMf RDMA target and the number of paths to the target. For example, with a max queue depth of 128 (the default for SPDK NVMe-oF targets) and a single path per NVMe-oF subsystem, the default CQ size supports only up to 16 IO queues per core. There are two options how to support larger scale deployments: enable SRQ or configure bigger CQ size

8.11.2.7.9.1 Enable SRQ

The `bdev_nvme` module can be configured to use a Shared Receive Queue (SRQ). This allows multiple connections to share receive buffers, significantly increasing scalability. This is the recommended approach, but it may result in a small IOPS reduction (around 5%) at large scales (more than 500 qpairs/core)

Enable SRQ by setting the `rdma-srq-size` option via the `bdev_nvme_set_options` RPC:

```
spdk_rpc.py bdev_nvme_set_options --rdma-srq-size <RDMA_SRQ_SIZE>
```

The SRQ size must be sufficiently large to minimize Receiver Not Ready (RNR) events. If the size is too small, RNR events will occur, leading to performance degradation. The optimal value depends on the specific traffic profile of the workload.

Parameter	Value / Limit	Notes
Minimum Recommended	`4096`	Setting the size smaller than 4096 is not recommended.
Maximum Supported	`32767`	The hard limit for the SRQ size.
Disable SRQ	`0`	Setting the size to 0 disables SRQ usage.

8.11.2.7.9.2 Configure CQ size

The `bdev_nvme_set_options` RPC provides 2 parameters which set the initial and maximum CQ size: `rdma-initial-cq-size` and `rdma-max-cq-size`. **IMPORTANT:** to avoid CQ resize, both parameters must be equal.

The CQ size must be sufficiently large to accommodate all CQEs for all qpairs. The maximum number of outstanding CQEs can be estimated using this formula: `target_max_queue_depth * 2 * connections_per_core`

IMPORTANT: if the CQ is not large enough or the application does not poll it often enough, some CQEs may be lost, meaning some I/O operations will never complete unless an I/O timeout is enabled. That is why enabling SRQ is the recommended and safer approach.

RPC usage example:

```
spdk_rpc.py bdev_nvme_set_options --rdma-initial-cq-size <RDMA_CQ_SIZE> --rdma-max-cq-size <RDMA_CQ_SIZE>
```

Parameter	Value / Limit	Notes
Minimum Recommended	`4096`	Setting the size smaller than 4096 is not recommended.
Maximum Supported	`4194303`	The hard limit for the CQ size.

8.11.2.7.10 Appendix – Custom Bdev Modules

This section explains how to extend the SNAP service with custom SPDK Bdev modules. The guide provides two distinct workflows:

1. Production Build: Creating a new container image that permanently includes the custom module.
2. Development Build: Manually building and running inside a container for rapid iteration and testing.

⚠ The examples provided below utilize the external `passthru` bdev module included with SPDK (`spdk/test/external_code/passthru`). You should adapt these paths and commands to suit your specific custom module and deployment environment.

8.11.2.7.10.1 Method 1: Building a Production Container (Recommended)

This method generates a standalone container image with the SNAP service and your custom functionality built-in, making it suitable for deployment via Kubernetes.

Environment Preparation

Create a working directory and clone the SPDK source code corresponding to your SNAP version.

```
# Create working directory (example: /opt/build)
mkdir -p /opt/build
cd /opt/build

# Clone SPDK sources
git clone https://github.com/Mellanox/spdk --branch v25.05.2.nvda

# Verify directory structure
ls -F
# Output should show: Dockerfile  spdk/
```

Create the Dockerfile

Create a `Dockerfile` in your working directory with the following content. This multi-stage build compiles the module and then copies it into the final SNAP image.

```
# Stage 1: Builder
FROM nvcr.io/nvstaging/doca/doca_snap:4.9.0-6-doca3.2.0 as builder

# Install build dependencies
RUN apt-get update && apt-get install -y \
    autoconf libtool python3-pyelftools libaio-dev \
    libncurses-dev libfuse3-dev patchelf libcmocka-dev make

# Copy external code source
COPY spdk/test/external_code /external_code

# Build the custom module
WORKDIR /external_code
ENV SPDK_HEADER_DIR=/opt/mellanox/spdk/include
ENV SPDK_LIB_DIR=/opt/mellanox/spdk/lib
ENV DPDK_LIB_DIR=/opt/mellanox/spdk/include

RUN make passthru_shared

# Stage 2: Final Image
FROM nvcr.io/nvstaging/doca/doca_snap:4.9.0-6-doca3.2.0

# Copy compiled shared object
COPY --from=builder /external_code/passthru/libpassthru_external.so /opt/nvidia/spdk/lib/
ENV SNAP_LD_PRELOAD=/opt/nvidia/spdk/lib/libpassthru_external.so

# Copy RPC python script
COPY --from=builder /external_code/passthru/bdev_passthru.py /usr/lib/python3/dist-packages/spdk/rpc/
ENV SPDK_RPC_PLUGIN="spdk.rpc.bdev_passthru"
```

Build and Deploy

1. Build the container image:

```
docker build -t doca_snap_custom_bdev:latest -f Dockerfile .
```

2. Import to Kubernetes (Kubelet):

```
# Export image to tarball
docker save doca_snap_custom_bdev:latest > doca_snap_custom_bdev.tar

# Import into containerd
ctr -n=k8s.io images import doca_snap_custom_bdev.tar
```

3. Edit `/etc/kubelet.d/doca_snap.yaml` to use the new image:

```
image: doca_snap_custom_bdev:latest
```

Configuration Example

Once the container is running, you can configure the custom bdev module via RPC.

```
# Identify the running SNAP container ID
SNAP_ID=$(crictl ps -s running -q --name snap)

# Create a base Malloc bdev
crictl exec $SNAP_ID spdk_rpc.py bdev_malloc_create 32 4096 -b Malloc0

# Construct the custom passthru bdev on top of Malloc0
crictl exec $SNAP_ID spdk_rpc.py construct_ext_passthru_bdev -b Malloc0 -p TestPT

# Create NVMe Subsystem and Controller
crictl exec $SNAP_ID snap_rpc.py nvme_subsystem_create --nqn nqn.2023-05.io.nvda.nvme:0
crictl exec $SNAP_ID snap_rpc.py nvme_controller_create --nqn nqn.2023-05.io.nvda.nvme:0 --pf_id 0 --ctrl NVMeCtrl0
--suspended

# Create Namespace using the custom bdev (TestPT)
crictl exec $SNAP_ID snap_rpc.py nvme_namespace_create --nqn nqn.2023-05.io.nvda.nvme:0 --bdev_name TestPT --nsid 1

# Attach Namespace and Resume Controller
crictl exec $SNAP_ID snap_rpc.py nvme_controller_attach_ns --ctrl NVMeCtrl0 --nsid 1
crictl exec $SNAP_ID snap_rpc.py nvme_controller_resume --ctrl NVMeCtrl0
```

8.11.2.7.10.2 Manual Development Workflow

This approach sets up an interactive development container, ideal for workflows requiring frequent code changes, recompilation, and testing.

Environment Preparation

Prepare the working directory and clone sources (same as the Production method).

```
mkdir -p /opt/build
cd /opt/build
git clone https://github.com/Mellanox/spdk --branch v25.05.2.nvda
```

Create Development Dockerfile

Create a simplified `Dockerfile` that installs dependencies and provides a shell.

```
FROM nvcr.io/nvstaging/doca/doca_snap:4.9.0-6-doca3.2.0 as builder

RUN apt-get update && apt-get install -y \
    autoconf libtool python3-pyelftools libaio-dev \
    libncurses-dev libfuse3-dev patchelf libcmocka-dev make

ENTRYPOINT /bin/bash
```

Build and Run Interactive Container

1. Build the dev image:

```
docker build -t doca_snap_custom_bdev_dev:latest -f Dockerfile .
```

2. Run interactively. Mount the necessary system volumes and your source code directory:

```
docker run -ti --privileged --net=host \
    --volume /dev/hugepages:/dev/hugepages \
    --volume /dev/shm:/dev/shm \
    --volume /dev/infiniband:/dev/infiniband \
    --volume /etc/nvda_snap:/etc/nvda_snap \
    --volume ${PWD}/spdk/test/external_code:/external_code \
    doca_snap_custom_bdev_dev:latest
```

Build and Test Inside Container

Once inside the container shell, perform the following steps:

1. Compile the module:

```
cd /external_code/
export SPDK_HEADER_DIR=/opt/mellanox/spdk/include
export SPDK_LIB_DIR=/opt/mellanox/spdk/lib
export DPDK_LIB_DIR=/opt/mellanox/spdk/include

make passthru_shared
```

2. Launch the service manually, preloading your compiled shared object:

```
# Copy RPC definition
cp /external_code/passthru/bdev_passthru.py /usr/bin/

# Load environment variables
source /opt/nvidia/nvda_snap/bin/set_environment_variables.sh

# Start Service with LD_PRELOAD
LD_PRELOAD=/external_code/passthru/libpassthru_external.so \
/opt/nvidia/nvda_snap/bin/snap_service -m 0xff &
```

3. Configure and test:

```
# Create base Malloc bdev
spdk_rpc.py bdev_malloc_create 32 4096 -b Malloc0

# Create custom Passthru bdev (explicitly specifying plugin)
spdk_rpc.py --plugin bdev_passthru construct_ext_passthru_bdev -b Malloc0 -p TestPT

# Setup NVMe Controller logic
snap_rpc.py nvme_subsystem_create --nqn nqn.2023-05.io.nvda.nvme:0
snap_rpc.py nvme_controller_create --nqn nqn.2023-05.io.nvda.nvme:0 --pf_id 0 --ctrl NVMeCtrl0 --suspended
snap_rpc.py nvme_namespace_create --nqn nqn.2023-05.io.nvda.nvme:0 --bdev_name TestPT --nsid 1
snap_rpc.py nvme_controller_attach_ns --ctrl NVMeCtrl0 --nsid 1
snap_rpc.py nvme_controller_resume --ctrl NVMeCtrl0
```

8.11.3 DOCA SNAP-3 User Guide

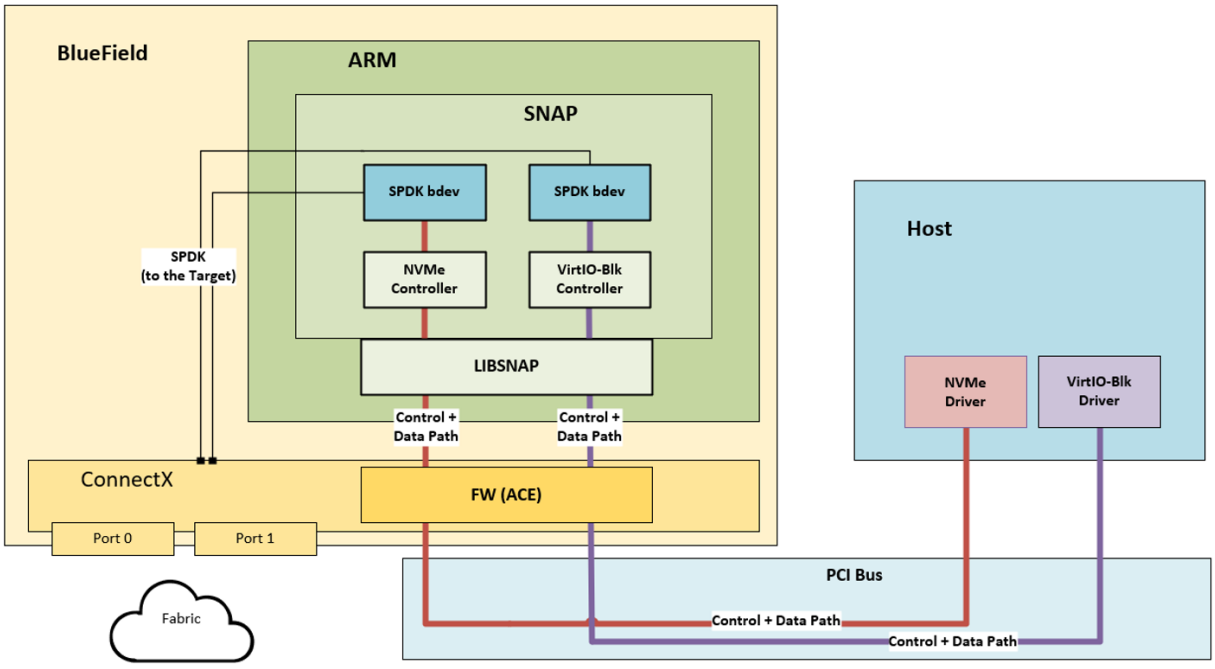
This guide details the configuration and usage of the SNAP to emulate NVMe and virtio-blk storage devices on NVIDIA® BlueField®-2 DPUs.

8.11.3.1 Introduction

8.11.3.1.1 SNAP

NVIDIA® BlueField® SNAP and virtio-blk SNAP (Storage-defined Network Accelerated Processing) technology enables hardware-accelerated virtualization of local storage. NVMe/virtio-blk SNAP presents networked storage as a local block-storage-device such as an SSD, emulating a local drive on the PCIe bus. The host OS/hypervisor uses its standard storage driver, unaware that communication is done, not with a physical drive, but with NVMe/virtio-blk SNAP framework. Any logic may be applied to the I/O requests or to the data via the NVMe/virtio-blk SNAP framework prior to redirecting the request and/or data over a fabric-based network to remote or local storage targets.

NVMe/virtio-blk SNAP is based on BlueField-2 DPU family technology and combines unique hardware-accelerated storage virtualization with the advanced networking and programmability capabilities of the DPU. NVMe/virtio-blk SNAP together with the BlueField DPU enable a world of applications addressing storage and networking efficiency and performance.



The traffic from a host-emulated PCIe device is redirected to its matching storage controller opened on the `mlnx_snap` service. The controller, from its side, holds at least one open backend device (usually SPDK block device). When a command is received, the controller executes it. Admin commands are answered immediately, while I/O commands are redirected to the backend device for processing. The request handling pipeline is completely asynchronous and the workload is distributed across all Arm cores (allocated to SPDK application) to achieve the best performance.

The following are key concepts for SNAP:

- Full flexibility in fabric/transport/protocol (e.g. NVMe-oF/iSCSI/other, RDMA/TCP, ETH/IB)
- NVMe and virtio-blk emulation support
- Easy data manipulation
- Using Arm cores for data path

> ⚠ BlueField SNAP/virtio-blk SNAP are licensed software. Users must purchase a license per BlueField device to use them.

8.11.3.1.2 Libsnap

Libsnap is a common library designed to assist in common tasks for applications wishing to interact with emulated hardware over BlueField DPUs and take the most advantage from the hardware capabilities. As such, libsnap exposes a simple API for the upper layer application to create, modify, query, and destroy different emulation objects, such PCIe BAR management, emulated queues etc.

In addition, the library provides a set of helper functions to perform efficient DMA transactions between host and DPU memory.

SNAP application makes extensive usage of the libsnap library for resource management and efficient DMA operations required by the storage controllers.

8.11.3.2 SNAP Installation

8.11.3.2.1 SNAP Installation Process

8.11.3.2.1.1 DPU Image Installation

The BlueField OS image (BFB) includes all needed packages for mlnx_snap to operate: MLNX_OFED, RDMA-CORE libraries, and the supported SPDK version, libsnap and mlnx-snap headers, libraries and binaries.

To see which operating systems are supported, refer to the BlueField Software Documentation under Release Notes → Supported Platforms and Interoperability → Supported Linux Distributions.

RShim must be installed on the host to connect to the NVIDIA® BlueField® DPU. To install RShim, please follow the instructions described in the BlueField Software Documentation → BlueField DPU SW Manual → DPU Operation → DPU Bring-up and Driver Installation → Installing Linux on DPU → Step 1: Set up the RShim Interface.

Use RShim interface from the x86 host machine to install the desired image:

```
BFB=/<path>/latest-bluefield-image.bfb
cat $BFB > /dev/rshim0/boot
```

Optionally, it is possible to connect to the remote console of the DPU and watch the progress of the installation process. Using the `screen` tool, for example:

```
screen /dev/rshim0/console
```

8.11.3.2.1.2 Post-installation Configuration

Firmware Configuration

Refer to Firmware Configuration to confirm the firmware configuration matches the SNAP application's requirements (SR-IOV support, MSI-X resources, etc).

Network Configuration

Before enabling `mlnx_snap` or configuring it, users must first verify that uplink ports are configured correctly, and that network connectivity toward the remote target works properly.

By default, two SF interfaces are opened—one over each PF as configured in `/etc/mellanox/mlnx-sf.conf` —which match RDMA devices `mlx5_2` and `mlx5_3` respectively. As mentioned, only these interfaces may support RoCE/RDMA transport for the remote storage.

If working with an InfiniBand link, an active InfiniBand port must be made available to allow for InfiniBand support. Once an active IB port is available, users must configure the port RDMA device in the JSON configuration file (see `rdma_device` under "Configuration File Examples" for `mlnx_snap` to work on that port).

If working with bonding, it is transparent to MLNX SNAP configuration, and no specific configuration is necessary on NVMe/virtio-blk SNAP level.

8.11.3.2.1.3 Out-of-box Configuration

NVMe/virito-blk SNAP is disabled by default. Once enabled (see section "Firmware Configuration"), the out-of-box configuration of NVMe/virtio-blk SNAP includes a single NVMe controller, backed by a 64MB RAM-based SPDK block device (e.g. RAM drive) in non-offload mode. Out-of-box configuration does not include virtio-blk devices.

A sample configuration file for the out-of-box NVMe controller is located in `/etc/mlnx_snap/mlnx_snap.json`. For additional information about its values, please see section "Non-offload Mode".

The default initialization command set is described in `/etc/mlnx_snap/spdk_rpc_init.conf` and `/etc/mlnx_snap/snap_rpc_init.conf`, as follows:

- spdk_rpc_init.conf

```
bdev_malloc_create 64 512
```

- snap_rpc_init.conf

```
subsystem_nvme_create  Mellanox_NVMe_SNAP "Mellanox NVMe SNAP Controller"
controller_nvme_create mlx5_0 --subsys_id 0 --pf_id 0
controller_nvme_namespace_attach -c NvmeEmu0pf0 spdk Malloc0 1
```

⚠ BlueField out-of-box configuration is slightly different than BlueField-2. For a clean out-of-box experience, `/etc/mlnx_snap/snap_rpc_init.conf` is a symbolic link pointing to the relevant hardware-oriented configuration.

⚠ To make any other command set persistent, users may update and modify `/etc/mlnx_snap/spdk_rpc_init.conf` and `/etc/mlnx_snap/snap_rpc_init.conf` for according to their needs. Refer to section "SNAP Commands" for more information.

8.11.3.2.2 SNAP Service Control (systemd)

To enable, start, stop, or check the status of SNAP service, run:

```
systemctl {start | stop | status} mlnx_snap
```

8.11.3.2.3 Logging

The mlnx_snap application output is captured by the SystemD and stored in the internal database. Users are able to get the output from the service console by using the following SystemD commands:

- `systemctl status mlnx_snap`
- `journalctl -u mlnx_snap`

SystemD keeps logs in a binary format under the `/var/run/log/journal/` directory, which is stored on the tmpfs (i.e. it is not persistent).

SystemD redirects log messages into the `rsyslog` service. Configuration of `rsyslog` is default to CentOS/RHEL, so users may find all those messages in the `/var/log/messages` directory.

The `rsyslog` daemon may be configured to send messages to a remote (centralized) syslog server if desired.

8.11.3.3 SNAP Commands

8.11.3.3.1 RPC Command Interface

Remote Procedure Call (RPC) protocol is a very simple protocol defining a few data types and commands. NVMe/virtio-blk SNAP, like other standard SPDK applications, supports JSON-based RPC protocol commands, to control any resources create/delete/query/modify commands easily from CLI.

The mlnx_snap application supports executing all standard SPDK RPC commands, in addition to an extended SNAP-specific command set. SPDK standard commands are executed by the standard `spdk_rpc.py` tool, while the SNAP-specific command set extension is executed by an equivalent `snap_rpc.py` tool.

Full `spdk_rpc.py` command set documentation can be found in the SPDK official documentation site.

Full `snap_rpc.py` extended command is detailed later in this chapter.

8.11.3.3.2 PCIe Function Management Commands

8.11.3.3.2.1 Emulation Managers Discovery

Emulated PCIe functions are managed through IB devices called "emulation managers". The emulation managers are ordinary IB devices (e.g. mlx5_0, mlx5_1, etc.) with special privileges to also control PCIe communication and device emulations towards the host operating system. Numerous emulation managers may co-exist, each with its own set of capabilities.

The list of emulation managers with their capabilities can be queried using the following command:

```
snap_rpc.py emulation_managers_list
```

Appendix SPDK Configuration includes additional information.

8.11.3.3.2.2 Emulation Devices Configuration (Hotplug)

As mentioned above, each emulation manager holds a list of the emulated PCI functions it controls. The PCI functions may be approached later by either their function index (in emulation manager's list) or their PCIe BDF number (e.g. 88:00.2) as enumerated by the

host OS. Some PCIe functions configured at the FW configuration stage are considered "static" (i.e. always present).

In addition, users can dynamically add detachable functions to that list at runtime (and to the host's PCIe devices list accordingly). These functions are called "Hotplugged" PCIe functions.

After a new PCIe function is plugged, it is shown on host PCIe devices list until either explicitly unplugged or the system goes through a cold reboot. Hot-plugged PCIe function will remain persistent even after SNAP process termination.

Some OSs automatically start to communicate with the new function after it is plugged. Some continue to communicate with the function (for a certain time) even after it is signaled to be unplugged. Therefore, users must always keep an open controller (of a matching type) over any existing configured PCIe function (see NVMe Controller Management and Virtio-blk Controller Management for more details).

The following command hotplugs a new PCIe function to the system:

```
snap_rpc.py emulation_device_attach emu_manager {nvme,virtio_blk} [--id ID] [--vid VID] [--ssid SSID] [--ssvid
SSVID] [--revid REVID] [--class_code CLASS_CODE] [--bdev_type {spdk,none}] [--bdev BDEV] [--num_queues NUM_QUEUES]
[--queue_depth QUEUE_DEPTH][--total_vf TOTAL_VF] [--num_msix NUM_MSIX]
```

The following command hot-unplugs a new PCIe function from the system:

```
snap_rpc.py emulation_device_detach <emu_manager> {nvme,virtio_blk} [-d PCI_BDF / -i PCI_INDEX / --vuid VUID]
```

Mandatory parameters:

- `emu_manager` – emulation manager
- `{nvme,virtio_blk}` – device type

Optional arguments:

- `--pci_bdf` – PCIe BDF identifier
- `--pci_index` – PCIe index identifier
- `--vuid` – PCIe VUID identifier
- `--force` – forcefully remove device (not recommended)

> ⚠ At least one identifier must be provided to describe the PCIe function to be detached.

> ⚠
> - Before calling `emulation_device_detach`, you need to uninstall or disable the controller from the Windows side (Device Manager → Storage Controllers).
> - Once a PCIe function is unplugged from the host system (when calling `emulation_device_detach`), its controller will be deleted implicitly also.

The following command lists all existing functions (either static or hotplugged):

```
snap_rpc.py emulation_functions_list
```

8.11.3.3.3 NVMe Emulation Management Commands

8.11.3.3.3.1 NVMe Subsystem

The NVMe subsystem, as described in the NVMe specification, is a logical entity which encapsulates sets of NVMe backends (or namespaces) and connections (or controllers). NVMe subsystems are extremely useful when working with multiple NVMe controllers, and especially when using NVMe virtual functions.

Each NVMe subsystem is defined by its serial number (SN), model number (MN), and qualified name (NQN). After creation, each subsystem also gets a unique index number.

The following example creates a new NVMe subsystem with a default generated NQN:

```
snap_rpc.py subsystem_nvme_create <serial_number> <model_number>
```

Mandatory parameters:

- `serial_number` – subsystem serial number
- `model_number` – subsystem model number

Optional arguments:

- `--nqn` – subsystem qualified name (auto-generated if not provided)
- `--nn` – maximal namespace ID allowed in the subsystem (default 0xFFFFFFFE; range 1-0xFFFFFFFE)
- `--mnan` – maximal number of namespaces allowed in the subsystem (default 1024; range 1-0xFFFFFFFE)

The following command deletes an NVMe subsystem:

```
snap_rpc.py subsystem_nvme_delete <NQN>
```

Where `<NQN>` is the subsystem's NQN.

The following command lists all NVMe subsystems:

```
snap_rpc.py subsystem_nvme_list
```

8.11.3.3.3.2 NVMe Controller

Each NVMe device (e.g. NVMe PCIe entry) exposed to the host, whether it is a PF or VF, must be backed by NVMe controller, which is responsible for all protocol communication with the host's driver. Every new NVMe controller must also be linked to NVMe subsystem. After creation, NVMe controllers can be addressed using either their name (e.g., "NvmeEmu0pf0") or both their subsystem NQN and controller ID.

The following command opens a new NVMe controller:

```
snap_rpc.py controller_nvme_create mlx5_0 [--pf_id ID / --pci_bdf / --vuid VUID] [--subsys_id ID / --nqn NQN]
```

Mandatory parameters:

- `emu_manager` – emulation manager

Optional parameters:

- `--vf_id VF_ID` – PCIe VF index to start emulation on (if the controller is destined to be opened on a VF). `--pf_id` must also be set for the command to take effect.
- `--conf` – JSON configuration file path to be used to provide an extended set of configuration parameters. Full information concerning the different parameters of the configuration file can be found under appendix "JSON File Format".
- `--nr_io_queues` – I/O queues maximal number (default 32, range 0-32)
- `--mdts` – maximum data transfer size (default 4, range 1-6)
- `--max_namespaces` – maximum number of namespaces for this controller (default 1024, range 1-0xFFFFFFFE)
- `--quirks` – bitmask to enable specific NVMe driver quirks to work with non-NVMe spec compliant drivers. For more information, refer to appendix "JSON File Format".
- `--mem {static,pool}` – use memory from a global pool or from dedicated buffers. See "Mem-pool" for more information.

The following command deletes an existing NVMe controller:

```
snap_rpc.py controller_nvme_delete [--name NAME / --subnqn SUBNQN --cntlid ID / --vuid VUID]
```

Optional arguments:

- `-c NAME`, `--name NAME` – controller Name. Must be set if `--nqn` and `--cntlid` are not set.
- `-n SUBNQN`, `--subnqn SUBNQN` – NVMe subsystem (NQN). Must be set if `--name` is not set.
- `-i CNTLID`, `--cntlid CNTLID` – controller identifier in NVMe subsystem. Must be set if `--name` is not set.

The following command lists all NVMe controllers:

```
snap_rpc.py controller_list --type nvme
```

Optional arguments:

- `-t {nvme,virtio_blk,virtio_net}`, `--type {nvme,virtio_blk,virtio_net}` – controller type

8.11.3.3.3.3 NVMe Backend (Namespace)

NVMe Namespaces are the representors of a continuous range of LBAs in the local/ remote storage device (previously configured in "Backend Configuration" section). Each Namespace must be linked to a controller and have a unique identifier (NSID) across the entire NVMe subsystem (e.g. 2 namespaces cannot share the same NSID, even though linked to different controllers).

SNAP application uses SPDK block device framework as backends for its NVMe namespaces. Therefore, they should be configured in advance. For more information about SPDK block devices, see SPDK BDEV documentation and appendix "SPDK Configuration".

The following command attaches a new namespace to an existing NVMe controller:

```
snap_rpc.py controller_nvme_namespace_attach [--ctrl CTRL / --subnqn SUBNQN --cntlid ID] <bdev_type> <bdev> <nsid>
```

Mandatory parameters:

- `bdev_type` – block device type
- `bdev` – block device to use as backend
- `nsid` – namespace ID

Optional parameters:

- `-c CTRL`, `--ctrl CTRL` – controller name. Must be set if `--nqn` and `--cntlid` are not set.
- `-n SUBNQN`, `--subnqn SUBNQN` – NVMe subsystem (NQN). Must be set if `--ctrl` is not set.
- `-i CNTLID`, `--cntlid CNTLID` – controller identifier in NVMe subsystem. Must be set if `--ctrl` is not set.
- `-q QN`, `--qn QN` – QN of remote target which provides this namespace
- `-p PROTOCOL`, `--protocol PROTOCOL` – protocol used
- `-g NGUID`, `--nguid NGUID` – namespace globally unique identifier
- `-e EUI64`, `--eui64 EUI64` – namespace EUI-64 identifier
- `-u UUID`, `--uuid UUID` – namespace UUID

⚠ In full-offload mode, backends are acquired from the remote storage automatically and no manual configuration is required.

The following command detaches a namespace from a controller:

```
snap_rpc.py controller_nvme_namespace_detach [--ctrl CTRL / --subnqn SUBNQN --cntlid ID] <nsid>
```

Mandatory parameters:

- `nsid` – namespace ID

Optional parameters:

- `-c CTRL`, `--ctrl CTRL` – controller name. Must be set if `--nqn` and `--cntlid` are not set.
- `-n SUBNQN`, `--subnqn SUBNQN` – NVMe subsystem (NQN). Must be set if `--ctrl` is not set.
- `-i CNTLID`, `--cntlid CNTLID` – controller identifier in NVMe subsystem. Must be set if `--ctrl` is not set.

The following command lists a namespace of a controller:

```
snap_rpc.py controller_nvme_namespace_list [--ctrl CTRL / --subnqn SUBNQN --cntlid ID]
```

Optional parameters:

- `-c CTRL`, `--ctrl CTRL` – controller name. Must be set if `--nqn` and `--cntlid` are not set.
- `-n SUBNQN`, `--subnqn SUBNQN` – NVMe subsystem (NQN). Must be set if `--ctrl` is not set.
- `-i CNTLID`, `--cntlid CNTLID` – controller identifier in NVMe subsystem. Must be set if `--ctrl` is not set.

8.11.3.3.4 Virtio-blk Emulation Management Commands

8.11.3.3.4.1 Virtio-blk Controller

Each virtio-blk device (e.g. virtio-blk PCI entry) exposed to the host, whether it is PF or VF, must be backed by a virtio-blk controller. Virtio-blk is considered a limited storage protocol (compared to NVMe, for instance).

Due to protocol limitations:

- Trying to use a virtio-blk device (e.g. probe virtio-blk driver on host) without an already functioning virtio-blk controller, may cause the host server to hang until such controller is opened successfully (no timeout mechanism exists)
- Upon creation of a virtio-blk controller, a backend device must already exist

The following command creates a new virtio-blk controller:

```
snap_rpc.py controller_virtio_blk_create <emu_manager> [-d PCI_BDF / --pf_id PF_ID / --vuid VUID]
```

Mandatory parameters:

- `emu_manager` – emulation manager

Optional parameters:

- `--vf_id` – PCIe VF index to start emulation on, if controller is destined to be opened on VF
- `--num_queues` – number of queues (default 64, range 2-256)
- `--queue_depth` – queue depth (default 128, range 1-256)
- `--size_max` –- maximal SGE data transfer size (default 4096, range 1 – MAX_UINT16). See virtio specification for more information.
- `--seg_max` – maximal SGE list length (default 1, range 1-queue_depth). See virtio specification for more information.
- `--bdev_type` – block device type (spdk/none). Note that opening a controller with `none` backend means to open it with a backend of size of 0.
- `--bdev` – SPDK block device to use as backend
- `--serial` – serial number for the controller
- `--force_in_order` - force I/O in-order completions. Note that this value is required to ensure future virtio-blk controllers always successfully recover after an application crash.
- `--suspend` – create controller is in a SUSPENDED state (must be explicitly resumed later)
- `--mem {static,pool}` – use memory from a global pool or from dedicated buffers. See "Advanced Features" for more information.

The following command deletes a virtio-blk controller:

```
snap_rpc.py controller_virtio_blk_delete [-c NAME / --vuid VUID]
```

Mandatory arguments:

- `name` – controller name

Optional arguments:

- `--f` , `--force` – force controller deletion

The following command lists all virtio-blk controllers:

```
snap_rpc.py controller_list --type virtio_blk
```

Optional arguments:

- `-t {nvme,virtio_blk,virtio_net}`, `--type {nvme,virtio_blk,virtio_net}` – controller type

Virtio-blk controllers can also be suspended and resumed. While suspended, the controller stops receiving new requests from the host driver and only finishes handling of requests already in flight (without prompting any IO errors back to the driver).

The following command suspends/resumes virtio-blk controller:

```
snap_rpc.py controller_virtio_blk_suspend <name>
snap_rpc.py controller_virtio_blk_resume <name>
```

Mandatory arguments:

- `name` – controller name

8.11.3.3.4.2 Virtio-blk Backend Management

Like NVMe, virtio-blk also uses SPDK block devices framework as its backend devices, but since virtio-blk is a limited storage protocol as opposed to NVMe, whose backend management abilities are limited as well:

- Virtio-blk protocol supports only one backend device
- Virtio-blk protocol does not support administration commands to add backends, thus all backend attributes are communicated to the host virtio-blk driver over PCIe BAR and must be accessible during driver probing. For that reason, backends can only be changed when PCIe function is not in use by any host storage driver.

For these reasons, when the host driver is active, all backend management operations must occur only when the controller is in suspended state.

The following command attaches a new backend to a controller:

```
snap_rpc.py controller_virtio_blk_bdev_attach <ctrl_name> {spdk} <bdev_name>
```

Mandatory arguments:

- `name` – controller name
- `{spdk}` – block device type
- `bdev` – block device to use as backend

Optional arguments:

- `--size_max` – maximal SGE data transfer size (no hard limit). See Virtio specification for more information.

- `--seg_max` – maximal SGE list length (no hard limit). See Virtio specification for more information.

The following command detaches a backend from a controller:

```
snap_rpc.py controller_virtio_blk_bdev_detach <ctrl_name>
```

Mandatory arguments:

- `ctrl_name` – controller name

> ⚠ Destruction of SPDK block devices using SPDK block devices' API is considered a `controller_virtio_blk_bdev_detach` and is bound to the same limitations.

The following command lists a backend detail of a controller:

```
snap_rpc.py controller_virtio_blk_bdev_list <name>
```

Mandatory arguments:

- `name` – controller name

8.11.3.3.5 Debug and Statistics

BlueField and virito-blk SNAP provide a set of commands which help customers retrieve performance and debug statistics about the opened emulated devices. The statistics are provided at the SNAP controller level (whether for NVMe or Virtio-blk).

8.11.3.3.5.1 IO Statistics

The following commands are available to measure how many successful/failed IO operations were executed by the controller.

These commands have minimal effect on BlueField SNAP performance and can therefore be used to sample statistics while the controller performs high bandwidth IO operations.

```
snap_rpc.py controller_nvme_get_iostat [-c CTRL_NAME]
snap_rpc.py controller_virtio_blk_get_iostat [-c CTRL_NAME]
```

> ⚠ These commands have minimal effect on BlueField SNAP performance and can therefore be used to sample statistics while the controller performs high-bandwidth IO operations.

Mandatory arguments:

- `CTRL_NAME` – controller name

NVMe/Virtio IO statistics:

- `read_ios` – number of read commands handled
- `completed_read_ios` – number of read commands completed successfully
- `err_read_ios` – number of read commands completed with error
- `write_ios` – number of write commands handled
- `completed_write_ios` – number of write commands completed successfully
- `err_write_ios` – number of write commands completed with error
- `flush_ios` – number of flush commands handled
- `completed_flush_ios` – number of flush commands completed successfully
- `err_flush_ios` – number of flush commands completed with error

Virtio IO specific statistics:

- `fatal_ios` – number of commands dropped and never completed
- `outstanding_in_ios` – number of outstanding IOs at a given moment
- `outstanding_in_bdev_ios` – number of outstanding IOs at a given moment, pending backend handling
- `outstanding_to_host_ios` – number of outstanding IOs at a given moment, pending DMA handling

8.11.3.3.5.2 Debug Statistics

The following commands are available to examine the controller and queues with more detailed status and information.

When queried frequently, these commands may impact performance and should therefore be called for debug purposes only.

```
snap_rpc.py controller_nvme_get_debugstat [-c NAME]
snap_rpc.py controller_virtio_blk_get_debugstat [-c NAME]
```

8.11.3.3.6 Initialization Scripts

The default initialization scripts `/etc/mlnx_snap/spdk_rpc_init.conf` and `/etc/mlnx_snap/snap_rpc_init.conf` allow users to control the startup configuration.

These scripts, which are used for the out-of-box configuration, may be modified by the user to control the SNAP initialization:

- The `spdk_rpc_init.conf` may be modified with the SPDK commands listed under the SPDK Configuration appendix.

- The `snap_rpc_init.conf` may be modified with the `snap_rpc` commands described throughout this chapter (SNAP Commands).

8.11.3.4 Advanced Features

8.11.3.4.1 Performance Optimization

⚠ Tuning MLNX SNAP for the best performance may require additional resources from the system (CPU, memory) and may affect SNAP controller scalability.

8.11.3.4.1.1 Increasing Number of Used Arm Cores

By default, MLNX SNAP uses 4 Arm cores, with core mask 0xF0. The core mask is configurable in `/etc/default/mlnx_snap` (parameter `CPU_MASK`) for best performance (i.e., `CPU_MASK=0xFF`).

⚠ As SNAP is an SPDK based application, it constantly polls the CPU and therefore occupies 100% of the CPU it runs on.

8.11.3.4.1.2 Disabling Mem-pool

When mem-pool is enabled, that reduces the memory footprint but decreases the overall performance.

To configure the controller to not use mem-pool, set `MEM_POOL_SIZE=0` in `/etc/default/mlnx_snap`.

See section "Mem-pool" for more information.

8.11.3.4.1.3 Maximizing Single IO Transfer Data Payload

Increasing datapath staging buffer sizes improves performance for larger block sizes (>4K):

- For NVMe, this can be controlled by increasing the MDTS value either in the JSON file or the RPC parameter. For more information regarding MDTS, refer to the NVMe specification. The default value is 4 (64K buffer), and the maximum value is 6 (256K buffer).
- For virtio-blk, this can be controlled using the `seg_max` and `size_max` RPC parameters. For more information regarding these parameters, refer to the VirtIO-blk specification. No hard-maximum limit exists.

8.11.3.4.1.4 Increasing Emulation Manager MTU

The default MTU for the emulation manager network interface is 1500. Increasing MTU to over 4K on the emulation manager (e.g., MTU=4200) also enables the SNAP application to transfer larger amount of data in a single Host→DPU memory transactions, which may improve performance.

8.11.3.4.1.5 Optimizing Number of Queues and MSIX Vector (virtio-blk only)

SNAP emulated queues are spread evenly across all configured PFs (static and dynamic) and defined VFs per PF (whether functions are being used or not). This means that the larger the total number of functions SNAP is configured with (either PFs or VFs), the less queues and MSIX resources each function will be assigned which would affect its performance accordingly. Therefore, it is recommended to configure in Firmware Configuration the minimal number of PFs and VFs per PF desired for that specific system.

Another consideration is matching between MSIX vector size and the desired number of queues. The standard virtio-blk kernel driver uses an MSIX vector to get events on both control and data paths. When possible, it assigns exclusive MSIX for each virtqueue (e.g., per CPU core) and reserves an additional MSIX for configuration changes. If not possible, it uses a single MSIX for all virtqueues. Therefore, to ensure best performance with virtio-blk devices, the condition `VIRTIO_BLK_EMULATION_NUM_MSIX` > `virtio_blk_controller.num_queues` must be applied.

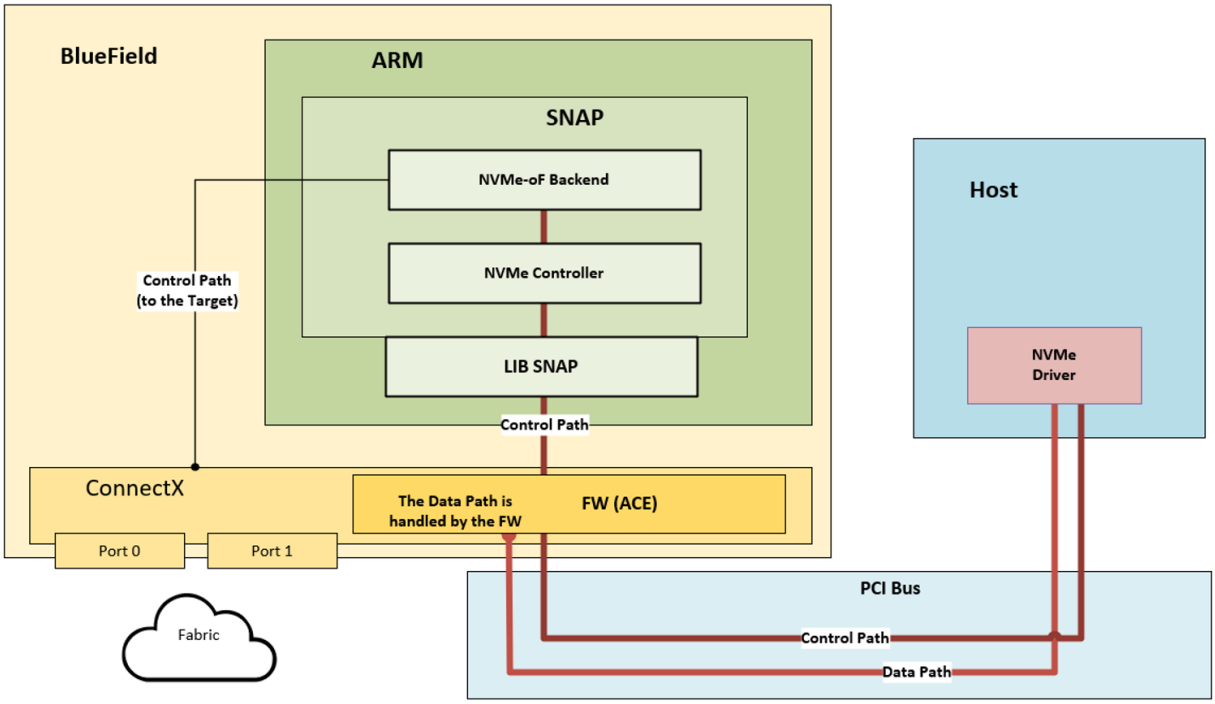
> ⚠ The total number of MSIXs is limited on BlueField-2 cards, so MSIX reservation considerations may apply when running with multiple devices. For more information, refer to this FAQ.

8.11.3.4.2 NVMe-RDMA Full Offload Mode

The NVMe-RDMA full offload mode allows reducing the Arm cores CPU cost by offloading the data-path directly to the firmware/hardware. If the user needs to control the data plane or the backend this mode does not allow it.

In full offload mode the control plane is handled at the SW level, while the data plane is being handled at the FW level and requires no SW interaction. For that reason, the user has no control over the backend devices. Thus they are detected automatically and no namespace management commands are required.

The NVMe-RDMA architecture:



> ⚠ In this mode, a remote target parameter must be provided using a JSON configuration file (a JSON file example can be found in `/etc/mlnx_snap/mlnx_snap_offload.json.example`) and the NVMe controller can detect and connect to the relevant backends by itself.

As the SNAP application does not participate in the datapath and needs fewer resources, it is recommended to reduce CPU_MASK to a single core (i.e., `CPU_MASK=0x80`). Refer to "Increasing Number of Used Arm Cores" for `CPU_MASK` configuration.

After configuration is done, users must create the NVMe subsystem and (offloaded) controller. Note that `snap_rpc.py controller_nvme_namespace_attach` is not required and `--rdma_device mlx5_2` is provided to mark the relevant RDMA interface for the connection.

The following example creates an NVMe full-offload controller:

```
# snap_rpc.py subsystem_nvme_create  "Mellanox_NVMe_SNAP" "Mellanox NVMe SNAP Controller"
# snap_rpc.py controller_nvme_create mlx5_0 --subsys_id 0 --pci_bdf 88:00.2 --nr_io_queues 32 --mdts 4 -c /etc/
mlnx_snap/mlnx_snap.json --rdma_device mlx5_2
```

This is the matching JSON file example:

```
{
  "ctrl": {
    "offload": true,
  },
  "backends": [
    {
      "type": "nvmf_rdma",
      "name": "testsubsystem",
      "paths": [
        {
```

```
            "addr": "1.1.1.1",
            "port": 4420,
            "ka_timeout_ms": 15000,
            "hostnqn": "r-nvmx03"
          }
        ]
      }
    ]
}
```

> ⚠ Full offload mode requires that the provided RDMA device (given in `--rdma_device` parameter) supports RoCE transport (typically SF interfaces). Full offload mode for virtio-blk is not supported.

> ⚠ The discovered namespace ID may be remapped to get another ID when exposed to the host in order to comply with firmware limitations.

8.11.3.4.3 SR-IOV

SR-IOV configuration depends on the kernel version:

- Optimal configuration may be achieved with a new kernel in which the `sriov_drivers_autoprobe sysfs` entry exists in `/sys/bus/pci/devices/<BDF>/`
- Otherwise, the minimal requirement may be met if the `sriov_totalvfs sysfs` entry exists in `/sys/bus/pci/devices/<BDF>/`

SR-IOV configuration needs to be done on both the host and DPU side, marked in the following example as [HOST] and [ARM] respectively. This example assumes that there is 1 VF on static virtio-blk PF 86:00.3 (NVMe flow is similar), and that a `Malloc0` SPDK BDEV exists.

8.11.3.4.3.1 Optimal Configuration

```
[ARM] snap_rpc.py controller_virtio_blk_create mlx5_0 -d 86:00.3 --bdev_type none
[HOST] modprobe -v virtio-pci && modprobe -v virtio-blk
[HOST] echo 0 > /sys/bus/pci/devices/0000:86:00.3/sriov_drivers_autoprobe
[HOST] echo 1 > /sys/bus/pci/devices/0000:86:00.3/sriov_numvfs [ARM] snap_rpc.py controller_virtio_blk_create
mlx5_0 --pf_id 0 --vf_id 0 --bdev_type spdk --bdev Malloc0
\* Continue by binding the VF PCIe function to the desired VM. *\
```

> ⚠ After configuration is finished, no disk is expected to be exposed in the hypervisor. The disk only appears in the VM after the PCIe VF is assigned to it using the virtualization manager. If users want to use the device from the hypervisor, they simply need to bind the PCIe VF manually.

8.11.3.4.3.2 Minimal Requirement

```
[ARM] snap_rpc.py controller_virtio_blk_create mlx5_0 -d 86:00.3 --bdev_type none
[HOST] modprobe -v virtio-pci && modprobe -v virtio-blk
[HOST] echo 1 > /sys/bus/pci/devices/0000:86:00.3/sriov_numvfs
```

```
\* the host now hangs until configuration is performed on the DPU side *\ [ARM] snap_rpc.py
controller_virtio_blk_create mlx5_0 --pf_id 0 --vf_id 0 --bdev_type spdk --bdev Malloc0
\* Host is now released *\
\* Continue by binding the VF PCIe function to the desired VM. *\
```

Hotplug PFs do not support SR-IOV.

It is recommended to add `pci=assign-busses` to the boot command line when creating more than 127 VFs.

Without this option, the following errors may appear from host, and the virtio driver will not probe these devices.

```
pci 0000:84:00.0: [1af4:1041] type 7f class 0xffffff
pci 0000:84:00.0: unknown header type 7f, ignoring device
```

8.11.3.4.4 Zero Copy (SNAP-direct)

Zero-copy is supported on SPDK 21.07 and higher.

The SNAP-direct feature allows SNAP applications to transfer data directly from the host memory to remote storage without using any staging buffer inside the DPU.

SNAP enables the feature according to the SPDK BDEV configuration only when working against an SPDK NVMe-oF RDMA block device.

To configure the controller to use Zero Copy, set the following in `/etc/default/mlnx_snap`:

- For virtio-blk:

```
VIRTIO_BLK_SNAP_ZCOPY=1
```

- For NVMe:

```
NVME_SNAP_ZCOPY=1
```

8.11.3.4.5 NVMe/TCP Zero Copy

NVMe/TCP Zero Copy is implemented as a custom NVDA_TCP transport in SPDK NVMe initiator and it is based on a new XLIO socket layer implementation.

The implementation is different for Tx and Rx:

- The NVMe/TCP Tx Zero Copy is similar between RDMA and TCP in that the data is sent from the host memory directly to the wire without an intermediate copy to Arm memory
- The NVMe/TCP Rx Zero Copy allows achieving partial zero copy on the Rx flow by eliminating copy from socket buffers (XLIO) to application buffers (SNAP). But data still must be DMA'ed from Arm to host memory.

To enable NVMe/TCP Zero Copy, use `SPDK v22.05.nvda --with-xlio`.

> ⚠ For more information about XLIO including limitations and bug fixes, refer to the NVIDIA Accelerated IO (XLIO) Documentation.

To configure the controller to use NVMe/TCP Zero Copy, set the following in `/etc/default/mlnx_snap`:

```
EXTRA_ARGS="-u -mem-size 1200 -wait-for-rpc"
NVME_SNAP_TCP_RX_ZCOPY=1
SPDK_XLIO_PATH=/usr/lib/libxlio.so
MIN_HUGEMEM=4G
```

To connect using NVDA_TCP transport:

- If `/etc/mlnx_snap/spdk_rpc_init.conf` is not being used, add the following at the start of the file in the given order:

  ```
  sock_set_default_impl -i xlio
  framework_start_init
  ```

  When the `mlnx_snap` service is started, run the following command:

  ```
  [ARM] spdk_rpc.py bdev_nvme_attach_controller -b <NAME> -t NVDA_TCP -f ipv4 -a <IP> -s <PORT> -n <SUBNQN>
  ```

- If `/etc/mlnx_snap/spdk_rpc_init.conf` is not being used, once the service is started, run the following commands in the given order:

  ```
  [ARM] spdk_rpc.py sock_set_default_impl -i xlio
  [ARM] spdk_rpc.py framework_start_init
  [ARM] spdk_rpc.py bdev_nvme_attach_controller -b <NAME> -t NVDA_TCP -f ipv4 -a <IP> -s <PORT> -n <SUBNQN>
  ```

> ⚠ NVDA_TCP transport is fully interoperable with other implementations based on the NVMe/TCP specifications.

> ⚠ NVDA_TCP limitations:
>
> - SPDK multipath is not supported
> - NVMe/TCP data digest is not supported

- SR-IOV is not supported

8.11.3.4.6 Robustness and Recovery

As SNAP is a standard user application running on the DPU OS, it is vulnerable to system interferences, like closing SNAP application gracefully (i.e., stopping mlnx_snap service), killing SNAP process brutally (i.e., running `kill -9`), or even performing full OS restart to DPU. If there are exposed devices already in use by host drivers when any of these interferences occur, that may cause the host drivers/application to malfunction.

To avoid such scenarios, the SNAP application supports a "Robustness and Recovery" option. So, if the SNAP application gets interrupted for any reason, the next instance of the SNAP application will be able to resume where the previous instance left off.

This functionality can be enabled under the following conditions:

- Only virtio-blk devices are used (this feature is currently not supported for NVMe protocol)
- By default, SNAP application is programmed to survive any kind of "graceful" termination, including controller deletion, service restart, and even (graceful) Arm reboot. If extended protection against brutal termination is required, such as sending SIGKILL to SNAP process or performing brutal Arm shutdown, the `--force_in_order` flag must be added to the `snap_rpc.py controller_virtio_blk_create` command.

  > ⚠ The `force_in_order` flag may impact performance if working with remote targets as it may cause high rates of out-of-order completions or if different queues are served in different rates.

- It is the user's responsibility to open the recovered virtio-blk controller with the exact same characteristics as the interrupted virtio-blk controller (same remote storage device, same BAR parameters, etc.)

8.11.3.4.7 Mem-pool

By default, SNAP application pre-allocates all required memory buffers in advance.

A great amount of allocated memory may be required when using:

- Large number of controllers (as with SR-IOV)
- Large number of queues per controller
- High queue-depth
- Large mdfs (for NVMe) or `seg_max` and `size_max` (for virtio-blk)

To reduce the memory footprint of the application, users may choose to use mem-pool (a shared memory buffer pool) instead. However, using mem-pool may decrease overall performance.

To configure the controller to use mem-pool rather than private ones:

1. In `/etc/default/mlnx_snap`, set the parameter `MEM_POOL_SIZE` to a non-zero value. This parameter accepts K/M/G notations (e.g., `MEM_POOL_SIZE=100M`). If K/M/G notation is not specified, the value defaults to bytes.
2. Users must choose the right value for their needs—a value too small may cause longer starvations, while a value too large consumes more memory. As a rule of thumb, typical usage may choose to set it as a minimum (num_devices*4MB, 512MB).
3. Upon controller creation, add the option `--mempool`. For example:

```
snap_rpc.py controller_nvme_create mlx5_0 –subsys_id 0 –pf_id 0 --mem pool
```

> ⚠ The per controller mem-pool configuration is independent from all others. Users can set some controllers to work with mem-pool and other controllers to work without it.

8.11.3.4.8 Virtio-blk Transitional Device (0.95)

SNAP supports virtio-blk transitional devices. Virtio transitional devices refer to devices supporting drivers conforming to modern specification and legacy drivers (conforming to legacy 0.95 specifications).

To configure virtio-blk PCIe functions to be transitional devices, special firmware configuration parameters must be applied:

- `VIRTIO_BLK_EMULATION_PF_PCI_LAYOUT` (0: MODERN / 1: TRANSITIONAL) – configures transitional device support for PFs

  > ⚠ This parameter is currently not supported.

- `VIRTIO_BLK_EMULATION_VF_PCI_LAYOUT` (0: MODERN / 1: TRANSITIONAL) – configures transitional device support for underlying VFs

  > ⚠ This parameter is currently not supported.

- `VIRTIO_EMULATION_HOTPLUG_TRANS` (True/False) – configures transitional device support for hot-plugged virtio-blk devices

To use virtio-blk transitional devices, Linux boot parameters must be set on the host:

- If the kernel version is older than 5.1, set the following Linux boot parameter on the host OS:

```
intel_iommu=off
```

- If `virtio_pci` is built-in from host OS, set the following Linux boot parameter:

```
virtio_pci.force_legacy=1
```

- If `virtio_pci` is a kernel module rather than built-in from host OS, use force legacy to load the module:

```
modprobe -rv virtio_pci
modprobe -v virtio_pci force_legacy=1
```

For hot-plugged functions, additional configuration must be applied during SNAP hotplug operation:

```
# snap_rpc.py emulation_device_attach mlx5_0 virtio_blk -- transitional_device --bdev_type spdk --bdev BDEV
```

8.11.3.4.9 Virtio-blk Live Migration

Live migration is a standard process supported by QEMU which allows system administrators to pass devices between virtual machines in a live running system. For more information, refer to QEMU VFIO device Migration documentation.

Live migration is supported for SNAP virtio-blk devices. It can be activated using a driver with proper support (e.g., NVIDIA's proprietary VDPA-based Live Migration Solution). For more info, refer to TBD.

If the physical function (PF) has been removed, for instance, using vDPA provisioning virtio-blk PF with the command:

```
python ./app/vfe-vdpa/vhostmgmt mgmtpf -a 0000:af:00.3
```

It is advisable to confirm and restore the presence of controllers in SNAP before attempting to re-add them using the command:

```
python dpdk-vhost-vfe/app/vfe-vdpa/vhostmgmt vf -v /tmp/sock-blk-0 -a 0000:59:04.5
```

8.11.3.5 Appendix – Live Upgrade

The following procedure is designed for live deployment of small software bug fixes or modifications made in the SNAP application. Using this procedure for other purposes (e.g., bumping SNAP service to a new version on top of an older BFB image) may cause SNAP to malfunction.

To live upgrade SNAP, 2 SNAP processes must be opened in parallel.

All system resources (e.g., hugepages, memory) must be sufficient to temporarily support 2 SNAP application instances operating in parallel during the upgrade procedure.

8.11.3.5.1 Passing virtio-blk Controller's Management Between SNAP Processes

1. Open 2 SNAP processes simultaneously on the Arm.

   This requires changing the SPDK RPC server path.

   For lower downtime, it is highly recommended to run each process on a different CPU mask.

   For SNAP Process 1, run:

   ```
   ./mlnx_snap_emu -m 0xf0 -r /var/tmp/spdk.sock1
   ```

   For SNAP Process 2, run:

   ```
   ./mlnx_snap_emu -m 0x0f -r /var/tmp/spdk.sock2
   ```

2. Connect to the same bdev with both processes (i.e., with Malloc device).
   For SNAP Process 1, run:

   ```
   spdk_rpc.py -s /var/tmp/spdk.sock1 bdev_malloc_create -b Malloc1 1024 512
   ```

   For SNAP Process 2, run:

   ```
   spdk_rpc.py -s /var/tmp/spdk.sock2 bdev_malloc_create -b Malloc1 1024 512
   ```

3. Open a virtio-blk controller on the SNAP Process 1:

```
snap_rpc.py -s /var/tmp/spdk.sock1 controller_virtio_blk_create mlx5_0 --pf_id 0 --bdev_type spdk --bdev
Malloc1 --num_queues 16
```

4. Load virtio-blk driver on the host side and start using it.
5. Delete the virtio-blk controller instance from SNAP Process 1 and immediately open a virtio-blk controller on SNAP Process 2:

```
snap_rpc.py -s /var/tmp/spdk.sock1 controller_virtio_blk_delete VblkEmu0pf0 --force &&  snap_rpc.py -s /
var/tmp/spdk.sock2 controller_virtio_blk_create mlx5_0 --pf_id 0 --bdev_type spdk --bdev Malloc1  --
num_queues 16
```

8.11.3.5.2 Full "Live Upgrade" Procedure

Assuming there exists a fully configured SNAP service is already running on the system:

1. Create a local copy of SNAP binary file (e.g., under `/tmp` folder):

```
cp /usr/bin/mlnx_snap_emu /tmp/
```

2. For all active virtio-blk controllers, follow management passing procedure as described in section "Passing virtio-blk Controller's Management Between SNAP Processes".
3. Stop original SNAP service.

```
systemctl stop mlnx_snap
```

4. Upgrade SNAP service.
   - If installed from binary, use Linux official installation framework (`apt` / `yum`)
   - If installed from sources, follow the same installation process as done originally
5. Repeat management passing procedure, this time to move back control from the local copy into the official (updated) version of SNAP service.

8.11.3.6 Appendix – Host OS Configuration

With Linux environment on host OS, additional kernel boot parameters may be required to support SNAP related features:

- To use SR-IOV, `intel_iommu=on iommu=ptmust` be added
- To use PCIe hotplug, `pci=realloc` must be added
- When using SR-IOV, `pci=assign-busses` must be added

To view boot parameter values, use the command `cat /proc/cmdline` .

8.11.3.7 Appendix – SPDK Configuration

SPDK backend (BDEV) management commands:

```
spdk_rpc.py bdev_nvme_attach_controller -b <name> -t rdma -a <ip> -f ipv4 -s <port> -n <nqn>
spdk_rpc.py bdev_nvme_detach_controller <name>
spdk_rpc.py bdev_null_create <name> <size_mb> <blk_size>
spdk_rpc.py bdev_null_delete <name>
spdk_rpc.py bdev_aio_create <filepath> <name> <blk_size>
spdk_rpc.py bdev_aio_delete <name>
```

For more information, please refer to SPDK BDEV documentation.

8.11.3.8 Appendix – Firmware Configuration

Before configuring mlnx_snap, the user must ensure all FW configuration requirements are met. By default, mlnx_snap is disabled, and needs to be enabled by running both common mlnx-snap configuration, and additional protocol-specific configuration depending on the expected usage of the application (e.g. Hotplug, SR-IOV, UEFI boot, etc).

After all configuration is finished, power-cycling the host is required for these changes to take effect.

To verify that all configuration requirements are satisfied, users may query the current/next configuration by running the following:

```
mlxconfig -d /dev/mst/mt41686_pciconf0 -e query
```

8.11.3.8.1 Basic Configuration

1. (Optional) Reset all previous configuration.

   ```
   [dpu] mst start
   [dpu] mlxconfig -d /dev/mst/mt41686_pciconf0 reset
   ```

   This will return your product to its default configurations. Do this only if you were not able to get SNAP to work.

2. Set general basic parameters.
   On BlueField-2:

   ```
   [dpu] mlxconfig -d /dev/mst/mt41686_pciconf0 s INTERNAL_CPU_MODEL=1
   ```

   On BlueField:

```
[dpu] sudo mlxconfig -d /dev/mst/mt41682_pciconf0 s INTERNAL_CPU_MODEL=1 PF_BAR2_ENABLE=1 PF_BAR2_SIZE=1
```

3. When using RDMA/RoCE transport, additional parameters must be configured:

```
[dpu] mlxconfig -d /dev/mst/mt41686_pciconf0 s PER_PF_NUM_SF=1
[dpu] mlxconfig -d /dev/mst/mt41686_pciconf0 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
[dpu] mlxconfig -d /dev/mst/mt41686_pciconf0.1 s PF_SF_BAR_SIZE=8 PF_TOTAL_SF=2
```

8.11.3.8.2 System Configuration Parameters

Parameter	Description	Possible Values	Comments
SRIOV_EN	Enable SR-IOV	0/1	
NUM_OF_VFS	Number of VFs per emulated PF	[0-127]	
NUM_PF_MSIX	Number of MSIX assigned to emulated PF	[0-63]	
NUM_VF_MSIX	Number of MSIX assigned to emulated VF	[0-63]	
PCI_SWITCH_EMULATION_ENABLE	Enable PCIe switch for emulated PFs	0/1	
PCI_SWITCH_EMULATION_NUM_PORT	Max number of emulated PFs	[0-32]	Single port is reserved for all static PFs

SRIOV_EN is valid only for static PFs

8.11.3.8.3 NVMe Configuration

Parameter	Description	Possible Values	Comments
NVME_EMULATION_ENABLE	Enable NVMe device emulation	0/1	
NVME_EMULATION_NUM_PF	Number of static emulated NVMe PFs	[0-2]	
NVME_EMULATION_NUM_MSIX	Number of MSIX assigned to emulated NVMe PF/VF	[0-63]	
NVME_EMULATION_NUM_VF	Number of VFs per emulated NVMe PF	[0-127]	If not 0, overrides NUM_OF_VFS; valid only when SRIOV_EN=1

Parameter	Description	Possible Values	Comments
`EXP_ROM_NVME_UEFI_x86_ENABLE`	Enable NVMe UEFI exprom driver	0/1	Used for UEFI boot process

8.11.3.8.4 Virtio-blk Configuration

Due to virtio-blk protocol limitations, using bad configuration while working with static virtio-blk PFs may cause the host server OS to fail on boot.

Before continuing, make sure you have configured:

- A working channel to access Arm even when the host is shut down. Setting such channel is out of the scope of this document. Please refer to "NVIDIA BlueField BSP documentation" for more details.
- Add the following line to `/etc/mlnx_snap/snap_rpc_init.conf`:

```
controller_virtio_blk_create mlx5_0 --pf_id 0 --bdev_type none
```

For more information, please refer to section "Virtio-blk Controller Management".

Parameter	Description	Possible Values	Comments
`VIRTIO_BLK_EMULATION_ENABLE`	Enable virtio-blk device emulation	0/1	
`VIRTIO_BLK_EMULATION_NUM_PF`	Number of static emulated virtio-blk PFs	[0-2]	See WARNING above
`VIRTIO_BLK_EMULATION_NUM_MSIX`	Number of MSIX assigned to emulated virtio-blk PF/VF	[0-63]	
`VIRTIO_BLK_EMULATION_NUM_VF`	Number of VFs per emulated virtio-blk PF	[0-127]	If not 0, overrides `NUM_OF_VFS`; valid only when `SRIOV_EN=1`
`EXP_ROM_VIRTIO_BLK_UEFI_x86_ENABLE`	Enable virtio-blk UEFI exprom driver	0/1	Used for UEFI boot process

8.11.3.9 Appendix – JSON File Format

This section is relevant only for the following cases:

- Using legacy mode in which the user prefers to not use the recommended SNAP commands, but to use the JSON file format
- NVMe-RDMA full offload mode in which the configuration is only possible with the JSON file format

The configuration parameters are divided into two categories: Controller and backends.

8.11.3.9.1 Configuration File Examples

8.11.3.9.1.1 Legacy Mode Configuration

> ⚠ For the non-full offload mode, it is recommended to use the SNAP RPC commands (described in SNAP Commands) and not the legacy mode of the JSON file format described in this section.

```
{
  "ctrl": {
    "func_num": 0,
    "rdma_device": "mlx5_2",
    "sqes": 0x6,
    "cqes": 0x4,
    "cq_period": 3,

      "paths": [
        {
          "addr": "1.1.1.1",
          "port": 4420,
          "ka_timeout_ms": 15000,
          "hostnqn": "r-nvmx03"
        }
      ]
    }
  ]
}
```

8.11.3.9.2 Configuration Parameters

8.11.3.9.2.1 Controller Parameters

Parameters in SNAP JSON configuration file. Default file is located in `/etc/mlnx_snap/mlnx_snap.json`.

Parameter	Description	Legal Values	Default
`rpc_server`	Describes the RPC server socket for passing through RPC commands. Relevant only when using vendor-specific RPC commands from host.	Any	`""`
`offload`	Enable full-offload mode	`true`, `false`	`false`
`nr_io_queues`	Maximum number of I/O queues. ⚠ The actual number of queues is limited by number of queues supported by FW.	≥0	`32`
`mn`	Model number	String (up to 40 chars)	`"MLX NVMe Ctrl"`
`sn`	Serial number	String (up to 20 chars)	`"MNC12"`
`nn`	Number of namespaces (NN) indicates the maximum value of a valid NSID for the NVM subsystem. If the `mnan` field is cleared to `0h`, then this field also indicates the maximum number of namespaces supported by the NVM subsystem.	0-0xFFFFFFFE	`0xFFFFFFFE`
`mnan`	Maximum number of allowed namespaces (MNAN) supported by the NVM subsystem	1-0xFFFFFFFE	`1024`
`mdts`	Max data transfer size. This value is in units of the minimum memory page size (CAP.MPSMIN) and is reported as a power of two (2^n). A value of 0h indicates that there is no maximum data transfer size.	1-6	`4`

Parameter	Description	Legal Values	Default
`quirks`	Bitmask for enabling specific NVMe driver quirks in order to work with non-NVMe spec compliant drivers. • Bit 0 – send namespace change async events even if driver does not explicitly request them via the SET_FTRS command ⚠ Enable this if the NVMe driver knows to handle namespace change but does not use SET_FTRS. CentOS 7.5 inbox driver does this. • Bit 1 – send new namespace change events even if previous ones are not yet cleared by the driver ⚠ CentOS 7.5 inbox driver requires this. • Bit 2 – force Number of Namespaces (NN) on Identify controller to dynamically track and indicate both the maximum value of a valid NSID and the maximum number of namespaces supported by the NVM controller. There is no limitation on namespaces NSIDs on controller level. • Bit 3 – force OACS to enable namespace management bit ⚠ VMWare driver requires this bit to be set.	`0x0` - `0x3`	`0x0`
`max_namespaces`	Limit number of available namespaces	Any	`1024`

8.11.3.9.2.2 Backend Parameters

Theses parameters are used to define the backend server.

⚠ Even though a list of backends can be configured, currently only a single backend is supported.

Parameter	Description	Legal Values	Default
`type`	Backend type: • `"memdisk"` – RAM based local storage • `"nvmf_rdma"` – NVMe-oF over RDMA remote storage • `"posix_io"` – file-based storage • `"spdk_bdev"` – SPDK block devices	`nvmf_rdma`, `spdk_bdev`	`"spdk_bdev"`
`name`	Depends on backend type: • `"nvmf_rdma"` – remote subsystem name • `"memdisk"` / `"spdk_bdev"` – unused • `"posix_io"` – backend filename	Any	Null

Parameter	Description	Legal Values	Default
`size_mb`	Represents the desired size (in MB) of the opened backend ⚠ Relevant only for `memdisk` / `posix_io` backends.	Any	Unused
`block_order`	Represents the desired block size (in logarithmic scale) of the opened backend ⚠ Relevant only for `memdisk` / `posix_io` backends.	9, 12	Unused

Path Section

This section is relevant only if backend type is set to `nvmf_rdma`. For each backend, a list of paths can be specified using the following parameters:

Parameter	Description	Legal Values	Default
`addr`	Target IPv4 address	String in `a.b.c.d` format	`"192.168.101.2"`
`port`	Target port number	1024-65534	`4420`
`ka_timeout_ms`	Keepalive timeout in msec	>0	`15000`
`Nqn`	Host NQN	String up to 223-char long	`"nqn.2014-08.org.nvmexpress:uuid:11111111-2222-3333-4444-555555555555"`

8.11.3.10 Appendix – Frequently Asked Questions

8.11.3.10.1 How do I enable SNAP?

Please refer to section "SNAP Installation".

8.11.3.10.2 How do I configure SNAP to support VirtIO-blk?

Please refer to section "Virtio-blk Configuration".

8.11.3.10.3 How do I configure SNAP to work with both ports (for the same or for multiple targets)?

Assumptions:

- The remote target is configured with nqn "Test" and 1 namespace, and it exposes it through the 2 RDMA interfaces 1.1.1.1/24 and 2.2.2.1/24
- The RDMA interfaces are 1.1.1.2/24 and 2.2.2.2/24

Non-offload mode configuration:

1. Create the SPDK BDEVS. Run:

```
spdk_rpc.py bdev_nvme_attach_controller -b Nvme0 -t rdma -a 1.1.1.1 -f ipv4 -s 4420 -n Test
spdk_rpc.py bdev_nvme_attach_controller -b Nvme1 -t rdma -a 2.2.2.1 -f ipv4 -s 4420 -n Test
```

2. Create NVMe controller. Run:

```
snap_rpc.py controller_nvme_create mlx5_0 --subsys_id 0 -c /etc/mlnx_snap/mlnx_snap.json --rdma_device
mlx5_2
```

3. Attach the namespace twice, one through each port. Run:

```
snap_rpc.py controller_nvme_namespace_attach -c NvmeEmu0pf0 spdk Nvme0n1 1
snap_rpc.py controller_nvme_namespace_attach -c NvmeEmu0pf0 spdk Nvme1n1 2
```

At this stage, you should see `/dev/nvme0n1` and `/dev/nvme0n2` on the host "nvme list", both of which are mapped to the same remote disk via 2 different ports.

Full-offload mode configuration:

> ⚠ Full-offload mode currently allows users to connect to multiple remote targets in parallel (but not to the same remote target through different paths).

1. Create 2 separate JSON full-offload configuration files (see section "NVMe-RDMA Full Offload Mode Configuration"). Each describe a connection to remote target via different RDMA interface.
2. Configure 2 separate NVMe device entries to be exposed to the host either as hot-plugged PCIe functions or “static” ones (see section "Firmware Configuration").
3. Create 2 NVMe controllers, one per RDMA interface. Run:

```
snap_rpc.py subsystem_nvme_create Mellanox_NVMe_SNAP "Mellanox NVMe SNAP Controller"
snap_rpc.py controller_nvme_create mlx5_0 --subsys_id 0 --pf_id 0 -c /etc/mlnx_snap/mlnx_snap_p0.json --
rdma_device mlx5_2
snap_rpc.py subsystem_nvme_create  Mellanox_NVMe_SNAP "Mellanox NVMe SNAP Controller"
snap_rpc.py controller_nvme_create mlx5_0 --subsys_id 1 --pf_id 1 -c /etc/mlnx_snap/mlnx_snap_p1.json --
rdma_device mlx5_3
```

> ⚠ NVMe controllers may also share the same NVMe subsystem. In this case, users must make sure all namespaces in all remote targets have a distinct NSID.

At this stage, you should see `/dev/nvme0n1` and `/dev/nvme1n1` on the host `nvme list`.

8.11.3.10.4 How do I configure offload mode? Which protocols are supported?

Please refer to section "NVMe-RDMA Full Offload Mode Configuration".

For more information on full offload, please refer to section "NVMe-RDMA Full Offload Mode".

8.11.3.10.5 How do I configure Firmware for SNAP?

Please refer to section "Firmware Configuration".

8.11.3.10.6 Can I work with custom SPDK on Arm?

MLNX SNAP is natively compiled against NVIDIA's internal branch of SPDK. It is possible to work with different SPDK versions, under the following conditions:

- mlnx-snap sources must be recompiled against the new SPDK sources
- The new SPDK version changes do not break any external SPDK APIs

Integration process:

1. Build SPDK (and DPDK) with shared libraries.

```
[spdk.git] ./configure --prefix=/opt/mellanox/spdk-custom --disable-tests --disable-unit-tests --without-crypto --without-fio --with-vhost --without-pmdk --without-rbd --with-rdma --with-shared --with-iscsi-initiator --without-vtune --without-isal
[spdk.git] make && sudo make install
[spdk.git] cp -r dpdk/build/lib/* /opt/mellanox/spdk-custom/lib/
[spdk.git] cp -r dpdk/build/include/* /opt/mellanox/spdk-custom/include/
```

> ⚠ It is also possible to install DPDK in that directory but copying suffices.

> ⚠ Only the flag `with-shared` is mandatory

2. Build SNAP against the new SPDK.

```
[mlnx-snap.src] ./configure --with-snap --with-spdk=/opt/mellanox/spdk-custom --without-gtest --prefix=/usr
[mlnx-snap.src] make -j8 && sudo make install
```

3. Append additional custom libraries to the mlnx-snap application.
   Set `LD_PRELOAD="/opt/mellanox/spdk/lib/libspdk_custom_library.so"`.

   ⚠ Additional SPDK/DPDK libraries required by `libspdk_custom_library.so` might also need to be attached to `LD_PRELOAD`.

   ⚠ `LD_PRELOAD` setting can be added to `/etc/default/mlnx_snap` for persistent work with the mlnx_snap system service.

4. Run application.

8.11.3.10.7 Can I replace my backend storage at runtime?

NVMe protocol has an embedded support for backends (namespaces) attach/detach at runtime.

To change backend storage during runtime for NVMe, run:

```
snap_rpc.py controller_nvme_namespace_detach -c NvmeEmu0pf0 1
snap_rpc.py controller_nvme_namespace_attach -c NvmeEmu0pf0 spdk nvme0n1 1
```

Virtio-blk does not have similar support in its protocol's specification. Therefore, detaching while running IO results in error on any IO received between the request to detach and attach.

To change backend storage at runtime for virtio-blk, run:

```
snap_rpc.py controller_virtio_blk_bdev_detach VblkEmu0pf0
snap_rpc.py controller_virtio_blk_bdev_attach VblkEmu0pf0 spdk nvme0n1
```

8.11.3.10.8 I'm suffering from low performance after updating to latest mlnx-snap. How can I fix it?

After adding the option to work with a large number of controllers, resource considerations had to be considered. It was necessary to pay special attention to the MSIX resource, which is limited to ~1K across the whole BlueField-2 card. Therefore, new PCI functions are now opened with limited resources by default (specifically, MSIX is set to 2).

User may choose to assign more resources for a specific function, as detailed in the following:

1. Increase the number of MSIX allowed to be assigned to a function (power-cycle may be required for changes to take effect):

```
[dpu] mlxconfig -d /dev/mst/mt41686_pciconf0 s VIRTIO_BLK_EMULATION_NUM_MSIX=63
```

2. Hotplug virtio-blk PF with the increased value of MSIX.

```
[dpu] snap_rpc.py emulation_device_attach mlx5_0 virtio_blk --num_msix=63
```

3. Open the controller with increased number of queues (1 queue per MSIX, and leave another free MSIX for configuration interrupts):

```
[dpu] snap_rpc.py controller_virtio_blk_create mlx5_0 --pf_id 0 --bdev_type spdk --bdev Null0 --
num_queues=62
```

For more information, please refer to section "Performance Optimization".

8.11.3.11 SNAP-3 Release Notes

The release note pages provide information for NVIDIA® BlueField®-2 SNAP software such as changes and new features, software known issues, and bug fixes.

8.11.3.11.1 Changes and New Features

- N/A

8.11.3.11.2 Known Issues

The following are known limitations of this NVMe/virtio-blk SNAP software version.

Ref #	Issue
4712565	Description: Windows2019 is not supported on the OpenEuler BFB in SNAP 3.8.0-13.
	Workaround: N/A
	Keywords: Windows 19; OpenEuler BFB
	Discovered in version: 3.8.0-13
–	Description: NVMeTCP XLIO is currently not supported when running 64K page size kernels on the DPU Arm cores (as is the case for CentOS 8.x, Rocky 8.x, or openEuler 20.x).
	Workaround: N/A
	Keywords: 64K page size; NVMeTCP XLIO
	Discovered in version: 3.6.0
–	Description: When running with virtio-blk and virtio-net protocols in parallel, performance may be negatively impacted.

Ref #	Issue
	Workaround: N/A
	Keywords: Performance
	Discovered in version: 3.7.2
2957317	Description: Due to an upstream kernel bug that exists in some Linux kernel distributions, the command `emulation_device_detach` times out, which causes any inflight traffic to hang.
	Workaround: It is recommended to ensure that all inflight traffic on the device is stopped before performing a hotunplug.
	Keywords: PCIe Hotplug
	Discovered in version: 3.6.0
3046440	Description: NVMe full-offload mode does not work properly over the first generation of BlueField SoCs
	Workaround: N/A
	Keywords: NVMe full-offload mode
	Discovered in version: 3.6.0
2879262	Description: Due to a kernel bug that exists in some Linux kernel distributions, configuring large number of virtio queues along with a small number of MSIX may lead the kernel to a soft lock-up (on top of causing significant performance degradation).
	Workaround: It is recommended that to keep virtio-blk controller's `--num_queues` value in `snap_rpc.py controller_virtio_blk_create` is smaller than the value of `VIRTIO_BLK_EMULATION_NUM_MSIX` (which is configured through `mlxconfig`).
	Keywords: Virtio-blk; kernel hang
	Discovered in version: 3.6.0
–	Description: SPDK multipath is supported only with NVMe over RDMA (and not with NVMe over TCP).
	Workaround: N/A
	Keywords: SPDK; NVMe
	Discovered in version: 3.6.0
3055119	Description: Windows driver does not work with Virtio-blk SNAP-Direct feature.
	Workaround: To disable the feature when working with Windows OS, user must set `VIRTIO_BLK_SNAP_ZCOPY=0` in `/etc/default/mlnx_snap`.
	Keywords: Windows
	Discovered in version: 3.5.0
–	Description: NVMe multipath features cannot be obtained when using SNAP in full-offload mode configuration
	Workaround: N/A
	Keywords: NVMe full-offload mode; multipath
	Discovered in version: 3.4.0

Ref #	Issue
–	Description: After each PCIe device hot-plug, a matching controller must be immediately opened. Specifically, hot-unplugging the device before a controller is created may cause the host kernel driver to malfunction on some Linux distributions.
	Workaround: N/A
	Keywords: Hot-plug; controller
	Discovered in version: 3.3.0
–	Description: SR-IOV on hot-plugged PFs is not supported
	Workaround: N/A
	Keywords: PCIe Hotplug
	Discovered in version: 3.2.0
–	Description: Any PCIe emulated device exposed to the host must have a matching controller opened on it in mlnx_snap service prior to loading its kernel driver. This includes virtio-net devices too.
	Workaround: N/A
	Keywords: VF; PF; virtio-net; kernel driver
	Discovered in version: 3.1.0

–	Description: It is not possible to attach block devices using the same nsid to different NVMe controllers which are linked to the same NVMe subsystem. For example, the following commands will result with an error as both controllers are attached with NSID 1:
	`snap_rpc.py controller_nvme_namespace_attach NvmeEmu2pf0 spdk Null0 1`
	`snap_rpc.py controller_nvme_namespace_attach NvmeEmu2pf1 spdk Null1 1`

	Workaround: N/A
	Keywords: Block device; controller
	Discovered in version: 3.0.0
–	Description: mlnx_snap NVMe controller supports an admin queue with a maximum size of 1024 towards the host.
	Workaround: N/A
	Keywords: Admin queue; controller
	Discovered in version: 3.0.0
–	Description: The DPU expansion ROM includes NVMe and virtio-blk UEFI drivers certified by NVIDIA, which should be used by the BIOS. Any other BIOS drivers are not guaranteed to work properly.
	Workaround: N/A
	Keywords: BIOS; certified drivers
	Discovered in version: 3.0.0
–	Description: Legacy interrupts are not supported.
	Workaround: N/A
	Keywords: Block device; controller
	Discovered in version: 3.0.0

8.11.3.11.2.1 Windows OS Known Issues

⚠ The following are not BlueField SNAP limitations.

Ref #	Issue
3543249	Description: When using hotplugged PCIe devices, after all devices are plugged, the host must be rebooted for Windows to detect all devices.
	Workaround: N/A
	Keywords: Hotplug
	Discovered in version: 3.7.4
3521378	Description: For a successful `emulation_device_detach` RPC command, it is recommended to use `directio=1` (`O_DIRECT`) with virtio-blk controller created on hot-plugged emulation. ⚠ If `directio=0` is used, the IO must be stopped manually. Otherwise, `emulation_device_detach` may fail.
	Workaround: N/A
	Keywords: Virtio-blk; RPC
	Discovered in version: 3.7.4
2957317	Description: Setting virtio-blk emulation on bare metal will end with server crash.
	Workaround: Set the `seg_max` flag of the virtio-blk controller to at least 16 (default is 1) using the following RPC: `controller_virtio_blk_create … --seg_max 16`
	Keywords: Virtio-blk; bare-metal; seg_max
	Discovered in version: 3.7.2
3056533	Description: When using NVMe driver in Windows, if I/O is not completed for more than 120 seconds, Windows starts ignoring the NVMe device and its disks disappear.
	Workaround: N/A
	Keywords: NVMe device disappears
	Discovered in version: 3.6.1
N/A	Description: There is a Windows driver known issue that it may crash when attaching multiple namespaces simultaneously. Users must attach namespaces one-by-one, and verify each namespace is discovered by the OS before attaching a new one.
	Workaround: N/A
	Keywords: Attaching multiple namespaces simultaneously
	Discovered in version: 3.4.0

Ref #	Issue
N/A	Description: There is a known Windows NVMe driver bug which causes Windows initiators to crash if the NVMe driver is started and no target is up and ready. Therefore, if users work with Windows OS on top of the emulated NVMe device, they must make sure that mlnx_snap NVMe controller is connected to the remote target before running the driver on the host side.
	Workaround: N/A
	Keywords: Windows initiators crash
	Discovered in version: 3.1.0
N/A	Description: There is a known Windows driver bug in which namespaces hotplug is not supported. On newer Windows builds, NVMe controller quirks must be set to 0x5. For more information, please see section "Controller Parameters".
	Workaround: N/A
	Keywords: Namespaces hotplug
	Discovered in version: 3.1.0

8.11.3.11.2.2 NVMe Linux Driver Limitations

Ref #	Issue
-	Description: When using SRIOV with VFs sharing the same driver as their PF (sriov_driver_autoprobe=1) - unprobing the driver may take a long time, and some admin commands might get timeout
	Workaround: N/A
	Keywords: SRIOV; driver.
	Discovered in version: 3.8.0-8

8.11.3.11.2.3 Virtio-blk Linux Driver Limitations

Ref #	Issue
3066750	Description: Driver does not support PCIe function level reset (FLR). Running FLR during IO causes the IO (and kernel) to hang.
	Workaround: N/A
	Keywords: PCIe function; hang
	Discovered in version: 3.6.1
2879262	Description: When working with a large number of virtqueues (≥ 64) over a single MSIX, the host kernel might experience soft lockup. Specifically, setting `--num_queues` to a high number, which is also higher than the configured `--num_msix` value, might cause this issue.
	Workaround:
	Keywords: Kernel; hang; virtqueues
	Discovered in version: 3.6.1
2957317	Description: In Linux kernel version 5.4.0-91-generic and above, the command `emulation_device_detach` times out if I/O traffic is running.

Ref #	Issue
	Workaround: N/A
	Keywords: Command time out
	Discovered in version: 3.6.1

8.11.3.11.2.4 Virtio-blk Transitional Device Limitations

Ref #	Issue
3231721	Description: When using `emulation_device_attach` RPC to hot plug a virtio-blk transitional device, the capacity and block size attributes must be provided for this hot-plugged virtio-blk transitional device.
	Workaround: Use the `--bdev_type spdk` and `--bdev spdk_bdev` options to provide a bdev to the hot-plugged virtio-blk transitional device when using `emulation_device_attach` RPC.
	Keywords: Hot plugging virtio-blk transitional device
	Discovered in version: 3.7.0
–	Description: Legacy/transitional drivers do not require syncing with the device upon driver initialization. Therefore, it is highly recommended that the SNAP controller is opened on the PCIe function before the driver becomes operational. If the driver becomes operational before the controller, controller configuration options would be very limited.
	Workaround: N/A
	Keywords: Legacy; SNAP controller; SNAP driver
	Discovered in version: 3.7.0
–	Description: Legacy/transitional device support naturally includes backends with 512B block size. Using backends with any other block size (e.g., 4K) can only be achieved when SNAP controller is opened before driver is activated.
	Workaround: N/A
	Keywords: Legacy; backend block size
	Discovered in version: 3.7.0

8.12 DOCA Telemetry Service Guide

This guide provides instructions on how to use the DOCA Telemetry Service (DTS) container on top of hosts or NVIDIA® BlueField® DPU.

8.12.1 Release Notes

8.12.1.1 New Features

- Extended the OpenTelemetry exporter to support gRPC transport, as well as TLS/mTLS encryption across both HTTP and gRPC transports.
- Added support for the new SDK APIs (via IPC to DTS), specifically the Metrics API and the OTLP logs API.
- Enabled `dpeserver` support on RPM-based operating systems for BlueField deployments.

8.12.1.2 Bug Fixes

- BlueField inventory collection:
  - Resolved an issue that caused corrupted data points with identical timestamps (e.g., "data0", "data1") when inventory collection was enabled.
  - Corrected IPv4 data collection to reliably target the `oob_net0` network interface.
- `ppcc_eth` provider: Implemented automatic detection for the `libmlxreg_sdk.so` library location on the host. This resolves pathing failures in Arm images caused by recent directory changes.

8.12.2 Introduction

The DOCA Telemetry Service (DTS) delivers real-time system and workload metrics for BlueField platforms and supported host systems. It aggregates data from both built-in telemetry providers and external applications utilizing the DOCA Telemetry Exporter API library.

8.12.2.1 Supported Providers

DTS collects and aggregates metrics through the following supported providers:

8.12.2.1.1 Data Providers

- `sysfs`

⚠ Enabled by default on BlueField platforms

- `ethtool`
- Advanced monitoring and bringup errors (`amber`)
- Port programmable congestion control (`ppcc_eth`)
- Diagnostic data
- `ifconfig`
- RDMA notifications
- Data Center GPU Manager (DCGM)
- NVIDIA System Management Interface (`nvidia-smi`)
- BlueField performance (`bfperf`)
- Traffic control (`tc`)

8.12.2.1.2 Aggregation Providers

- Fluent aggregator
- Prometheus aggregator

8.12.2.2 Data Export Options

DTS supports multiple mechanisms for exporting and storing collected telemetry data.

8.12.2.2.1 Export Mechanisms

- Prometheus endpoint (Pull)
- Fluent Bit (Push)
- OpenTelemetry (Push)
- Prometheus Remote Write (Push)

8.12.2.2.2 Local Storage Export

DTS can store collected telemetry as binary files in the `/opt/mellanox/doca/services/telemetry/data` directory.

- Default state: Data writing is disabled by default.
- Data retrieval: Use the `clx_read` binary (included in the `collectx-clxapidev` Linux package) to parse and read these binary files.

Managing Telemetry Volume

Because DTS can generate a massive volume of telemetry data, strictly filter the output using the `fieldset` or `counterset` options to optimize performance and storage. For specific configuration details, refer to the Counterset and Fieldset Files documentation.

8.12.3 Service Deployment

DTS is available as a built-in service on BlueField DPUs and as a container image on NVIDIA NGC for hosts.

Since DTS does not monitor all changes related to firmware, networking, firewall settings, or other system components, it is strongly recommended (and in some cases required) to restart DTS after any server configuration changes to ensure proper operation.

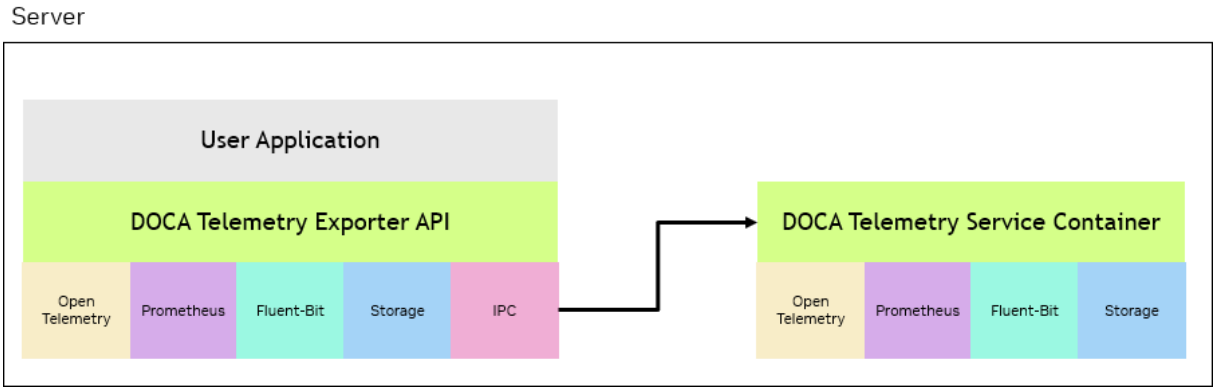
8.12.3.1 Built-in DOCA Service Image (BlueField)

DOCA Telemetry Service is included by default in the BlueField DPU image. Each DPU image ships with a fixed version of the service, providing out-of-the-box support for applications using the DOCA Telemetry Exporter library.

8.12.3.2 DOCA Telemetry Exporter Integration

Applications using the DOCA Telemetry Exporter API can leverage DTS Inter-Process Communication (IPC) to export collected telemetry data through DTS.

The export modules available in DTS are also integrated into the DOCA Telemetry Exporter. Both solutions support decoupling telemetry collection from export configuration and allow data to be exported either directly from the library (e.g., to Prometheus or OpenTelemetry) or indirectly via DTS using IPC.



8.12.3.3 DOCA Service on NGC

In addition to the built-in image, updated DTS versions are available on NVIDIA NGC. This is useful if you need to upgrade to a newer version than the one bundled with the BlueField OS. Refer to the container's NGC page for service-specific configuration and deployment steps.

> For more information about the deployment of DOCA containers on top of the BlueField DPU, refer to NVIDIA DOCA Container Deployment Guide.

8.12.3.4 DPU Deployment

On BlueField DPUs, DTS starts automatically during boot using the configuration defined in:

```
/etc/kubelet.d/doca_telemetry_standalone.yaml
```

- To disable auto-start, remove the YAML file from this path
- Changes to the YAML file are applied on system restart

DTS file location: `/opt/mellanox/doca/services/telemetry/`

- Container volume mounts:
  - `config/`
  - `data/`
  - `ipc_sockets/`
- Backup artifacts:
  - `doca_telemetry_service_${version}_arm64.tar.gz` – DTS container image
  - `doca_telemetry_standalone.yaml` – backup of the default boot YAML

8.12.3.5 Host Deployment

DTS supports deployment on `x86_64` and `aarch64` host architectures. All exporters and providers run from a single Docker container.

1. Initialize and configure host DTS with the desired DTS version:

```
export DTS_IMAGE=nvcr.io/nvidia/doca/doca_telemetry:<desired-DTS-host-version>
docker run -v "/opt/mellanox/doca/services/telemetry/config:/config" --rm --name doca-telemetry-init -it
$DTS_IMAGE /bin/bash -c "DTS_CONFIG_DIR=host /usr/bin/telemetry-init.sh"
```

NGC does not support the `latest` tag. You must specify a full versioned tag (e.g., `1.23.4-doca3.2.0-host`).

```
export DTS_IMAGE=nvcr.io/nvidia/doca/doca_telemetry:1.23.4-doca3.2.0-host
```

The purpose of `telemetry-init.sh` is to populate the `config/` directory. If this directory already contains configuration files, the script is a no-op. When upgrading, mount an alternate directory to add new configuration files as needed.

2. Launch the DTS container:

```
docker run -d --net=host --uts=host --ipc=host \
           --privileged \
           --device=/dev/mst/ \
           --device=/dev/infiniband/ \
           --gpus all \
           -v "/opt/mellanox/doca/services/telemetry/config:/config" \
           -v "/opt/mellanox/doca/services/telemetry/ipc_sockets:/tmp/ipc_sockets" \
           -v "/opt/mellanox/doca/services/telemetry/data:/data" \
           -v "/opt/mellanox/doca/services/telemetry/log:/var/log" \
           -v "/usr/lib64/mft:/usr/lib64/mft" \
           --rm --name doca-telemetry -it $DTS_IMAGE /usr/bin/telemetry-run.sh
```

If the `--gpus all` parameter causes the command to fail and DTS GPU providers are not needed, remove the parameter from the command.

If GPU providers are required but the GPU driver is not available, install the `nvidia-container-toolkit` package and restart the container runtime.

Required mounts per service:

Service Component	Required Flags
GPU providers (`nvidia_smi` , `dcgm`)	`--gpus all`
`amber` , `ppcc_eth`	`--device=/dev/mst/` `-v "/usr/lib64/mft:/usr/lib64/mft"`
UCX/RDMA modes	`--device=/dev/infiniband/`

8.12.3.6 Deployment with Grafana Monitoring

For information on integrating DTS with Grafana dashboards, refer to the section "Deploying with Grafana Monitoring".

8.12.4 DTS Configuration

DTS configuration is located at `/opt/mellanox/doca/services/telemetry/config`.

This directory is initialized during service startup. It contains the main configuration file (`dts_config.ini`) and a folder for Fluent Bit configuration (`fluent_bit_configs`). The `dts_config.ini` file is used to control telemetry provider behavior, exporter settings, sampling rates, and data output. Fluent Bit integration is discussed separately in the Fluent Bit section.

> ⚠ Any changes to `dts_config.ini` automatically trigger a DTS restart within 60 seconds to apply updates.

8.12.4.1 Initialization Scripts (BlueField Deployment)

The DTS container's `initContainers` section of the `.yaml` file executes two initialization scripts:

- `/usr/bin/telemetry-init.sh` – Generates default configuration files only if the `config` directory is empty
- `/usr/bin/enable-fluent-forward.sh` – Configures the Fluent Bit forwarding destination (host and port). This script only runs when both parameters are provided and will overwrite the `fluent_bit_configs` directory with a new `.exp` configuration file.

8.12.4.2 Enabling Fluent Bit Forwarding

To enable Fluent Bit forwarding, add the destination IP and port to the command line in the `initContainers` section of your deployment YAML:

```
command: ["/bin/bash", "-c", "/usr/bin/telemetry-init.sh && /usr/bin/enable-fluent-forward.sh -i=127.0.0.1
-p=24224"]
```

> ⚠ The IP and port shown above are examples. See the "Fluent Bit" section for manual configuration guidance.

8.12.4.3 Generating Configuration

The `config` directory starts empty by default. The initialization process will generate default configuration files during first launch.

8.12.4.4 Resetting Configuration

To reset DTS to its default state:

1. Delete all files from `/opt/mellanox/doca/services/telemetry/config/`.
2. Restart the DTS container to regenerate default configuration files.

8.12.4.5 Sampling Interval

The sampling interval for most telemetry providers is controlled by the `update` parameter in `dts_config.ini`:

```
# Sampling interval for providers (milliseconds)
update=1000
```

⚠ Export frequency may differ due to internal buffer logic. Data is exported once a page of counters is filled. You can enforce a time-based flush using the `sync-time-limit` parameter:

```
# Timeout for forced page rotation in seconds
sync-time-limit=10000
```

8.12.4.6 Enabling Providers

To enable a telemetry provider, uncomment its `enable-provider` line in `dts_config.ini`. For example:

```
enable-provider=ethtool
```

⚠ See the "Providers" section for a full list of available telemetry providers.

8.12.4.6.1 Remote Collection (BlueField Only)

Some providers may not function correctly within a container and require remote execution. Enable this mode as follows:

1. Start the DOCA privileged executor (DPE):

```
systemctl start dpe
```

2. Prefix the provider name with `grpc.`. For example, the following line configures remote collection of the `sysfs.fw_pages` component:

```
enable-provider=grpc.sysfs.fw_pages
```

3. For provider-specific configuration, apply the same prefix. Building upon the previous example:

```
grpc.sysfs.fw_pages.mlx5_1=ignore
```

8.12.4.7 Enabling Data Output

To enable writing collected data to disk, uncomment the following line in `dts_config.ini`:

```
output=/data
```

8.12.4.8 Enabling IPC with External Applications

To enable inter-process communication (IPC) between DTS and a non-containerized application, refer to the section "Using IPC with Non-container Application" in DOCA Telemetry Exporter.

8.12.4.9 Level Labels

DTS supports metadata static labels for telemetry exporters such as Prometheus and OpenTelemetry. Labels can be configured globally or per device, and are defined in `/opt/mellanox/doca/services/telemetry/config/level_labels.ini`.

8.12.4.9.1 Sample `level_labels.ini`

The following is an example `level_labels.ini` file, defining global and per-device labels:

```
# lines starting with hash are ignored
# 2 level labels are supported - global and device
# global labels will be added to all metrics
# device labels will be added to metrics matching the device description

[global_labels]
# global labels to be added to all metrics
# format:
# label_name=label_value
hostname=myhost
ip=127.127.127.127

[device_labels]
# device labels will be added to metrics related to the device
# format:
# device_index_label=device_label_name1|device_label_value1|device_label_name2|device_label_value2
# where device_index_label is either an RDMA device name or PCI address
mlx5_0=rail|0|network|compute
mlx5_1=rail|1|network|compute
mlx5_2=rail|2|network|storage

[device_mapping]
# optional: mapping of device names to network interfaces and mst devices
# this is done internally by DTS, but can be overridden here
# add clear_auto_detected_mapping=true to clear the auto-detected mapping
# format:
# device_name=mst_device_name|net_interface_names
# in case of multiple net interfaces, separate them with comma

[data_types_mapping]
# internal data types, don't change this section if you don't know what you are doing
# format:
# data_type|index|device_type_name
ethtool_event=device_name|netif
ppcc_eth=device_name|mst
ifconfig_event=device_name|netif
amber_event=device_name|mst
```

8.12.4.9.2 Enabling Level Labels

1. Confirm that `level_labels.ini` is properly configured.
2. Add the following line to `dts_config.ini`:

```
level-labels-file=/config/level_labels.ini
```

8.12.4.9.3 Monitoring and Reloading

DTS continuously monitors `level_labels.ini`. When a change is detected:

- The current telemetry process exits automatically
- DTS restarts within 60 seconds and loads the updated labels

This ensures label changes take effect without requiring manual restarts.

8.12.5 Description

8.12.5.1 Providers

DTS supports on-board data collection from `sysf`, `ethtool`, and `tc` providers. Fluent and Prometheus aggregator providers can collect the data from other applications.

Other providers are available based on different conditions (e.g., specific container mounts or host only such as `amber`, `ppcc_eth`, etc). Such providers are described with their dependencies in their corresponding sections.

8.12.5.1.1 Sysfs

The `sysfs` provider includes several components: `ib_port`, `hw_port`, `devices`, `ib_mr_cache`, `eth`, `hwmon`, and `bf_ptm`. The schema for `sysfs` counters defines the exact counters available for each component.

By default, the following components are disabled when the `sysfs` provider is enabled:

- `ib_mr_cache`
- `rate`
- `bf_ptm`

You can enable the provider and selectively disable components. For example, to disable `eth`:

```
enable-provider=sysfs
disable-provider=sysfs.eth
```

⚠ `ib_port` and `ib_hw` are state counters collected per port and are only collected when the port is in an active state.

⚠ The `hwmon` component is supported only on BlueField-2 and BlueField-3.

To filter which counters are collected, you may use a `.cset` (counterset) file. This file must not contain aliases. Place the `.cset` file in the config directory (or any accessible directory in the container), and specify the path in the configuration:

```
sysfs-cset-path=/config/path/to/my.cset
```

8.12.5.1.1.1 Counters List

- `ib_port` counters:

```
{hca_name}:{port_num}:ib_port_state
{hca_name}:{port_num}:VL15_dropped
{hca_name}:{port_num}:excessive_buffer_overrun_errors
{hca_name}:{port_num}:link_downed
{hca_name}:{port_num}:link_error_recovery
{hca_name}:{port_num}:local_link_integrity_errors
{hca_name}:{port_num}:multicast_rcv_packets
{hca_name}:{port_num}:multicast_xmit_packets
{hca_name}:{port_num}:port_rcv_constraint_errors
{hca_name}:{port_num}:port_rcv_data
{hca_name}:{port_num}:port_rcv_errors
{hca_name}:{port_num}:port_rcv_packets
{hca_name}:{port_num}:port_rcv_remote_physical_errors
{hca_name}:{port_num}:port_rcv_switch_relay_errors
{hca_name}:{port_num}:port_xmit_constraint_errors
{hca_name}:{port_num}:port_xmit_data
{hca_name}:{port_num}:port_xmit_discards
{hca_name}:{port_num}:port_xmit_packets
{hca_name}:{port_num}:port_xmit_wait
{hca_name}:{port_num}:symbol_error
{hca_name}:{port_num}:unicast_rcv_packets
{hca_name}:{port_num}:unicast_xmit_packets
```

- `ib_hw` counters:

```
{hca_name}:{port_num}:hw_state
{hca_name}:{port_num}:hw_duplicate_request
{hca_name}:{port_num}:hw_implied_nak_seq_err
{hca_name}:{port_num}:hw_lifespan
{hca_name}:{port_num}:hw_local_ack_timeout_err
{hca_name}:{port_num}:hw_out_of_buffer
{hca_name}:{port_num}:hw_out_of_sequence
{hca_name}:{port_num}:hw_packet_seq_err
{hca_name}:{port_num}:hw_req_cqe_error
{hca_name}:{port_num}:hw_req_cqe_flush_error
{hca_name}:{port_num}:hw_req_remote_access_errors
{hca_name}:{port_num}:hw_req_remote_invalid_request
{hca_name}:{port_num}:hw_resp_cqe_error
{hca_name}:{port_num}:hw_resp_cqe_flush_error
{hca_name}:{port_num}:hw_resp_local_length_error
{hca_name}:{port_num}:hw_resp_remote_access_errors
{hca_name}:{port_num}:hw_rnr_nak_retry_err
{hca_name}:{port_num}:hw_rx_atomic_requests
{hca_name}:{port_num}:hw_rx_dct_connect
{hca_name}:{port_num}:hw_rx_icrc_encapsulated
{hca_name}:{port_num}:hw_rx_read_requests
{hca_name}:{port_num}:hw_rx_write_requests
```

- `ib_mr_cache` counters:

```
{hca_name}:mr_cache:size_{n}:cur
{hca_name}:mr_cache:size_{n}:limit
{hca_name}:mr_cache:size_{n}:miss
{hca_name}:mr_cache:size_{n}:size
```

⚠ Where `n` ranges from 0 to 24.

- `eth` counters:

```
{hca_name}:{device_name}:eth_collisions
{hca_name}:{device_name}:eth_multicast
{hca_name}:{device_name}:eth_rx_bytes
{hca_name}:{device_name}:eth_rx_compressed
{hca_name}:{device_name}:eth_rx_crc_errors
{hca_name}:{device_name}:eth_rx_dropped
{hca_name}:{device_name}:eth_rx_errors
{hca_name}:{device_name}:eth_rx_fifo_errors
{hca_name}:{device_name}:eth_rx_frame_errors
{hca_name}:{device_name}:eth_rx_length_errors
{hca_name}:{device_name}:eth_rx_missed_errors
{hca_name}:{device_name}:eth_rx_nohandler
{hca_name}:{device_name}:eth_rx_over_errors
{hca_name}:{device_name}:eth_rx_packets
{hca_name}:{device_name}:eth_tx_aborted_errors
{hca_name}:{device_name}:eth_tx_bytes
{hca_name}:{device_name}:eth_tx_carrier_errors
{hca_name}:{device_name}:eth_tx_compressed
```

```
{hca_name}:{device_name}:eth_tx_dropped
{hca_name}:{device_name}:eth_tx_errors
{hca_name}:{device_name}:eth_tx_fifo_errors
{hca_name}:{device_name}:eth_tx_heartbeat_errors
{hca_name}:{device_name}:eth_tx_packets
{hca_name}:{device_name}:eth_tx_window_errors
```

- `devices` counters

```
{hca_name}:current_link_width
{hca_name}:current_link_speed
{hca_name}:max_link_speed
{hca_name}:max_link_width
```

- BlueField-2 `hwmon` counters:

```
{hwmon_name}:{l3cache}:CYCLES
{hwmon_name}:{l3cache}:HITS_BANK0
{hwmon_name}:{l3cache}:HITS_BANK1
{hwmon_name}:{l3cache}:MISSES_BANK0
{hwmon_name}:{l3cache}:MISSES_BANK1
{hwmon_name}:{pcie}:IN_C_BYTE_CNT
{hwmon_name}:{pcie}:IN_C_PKT_CNT
{hwmon_name}:{pcie}:IN_NP_BYTE_CNT
{hwmon_name}:{pcie}:IN_NP_PKT_CNT
{hwmon_name}:{pcie}:IN_P_BYTE_CNT
{hwmon_name}:{pcie}:IN_P_PKT_CNT
{hwmon_name}:{pcie}:OUT_C_BYTE_CNT
{hwmon_name}:{pcie}:OUT_C_PKT_CNT
{hwmon_name}:{pcie}:OUT_NP_BYTE_CNT
{hwmon_name}:{pcie}:OUT_NP_PKT_CNT
{hwmon_name}:{pcie}:OUT_P_PKT_CNT
{hwmon_name}:{tile}:MEMORY_READS
{hwmon_name}:{tile}:MEMORY_WRITES
{hwmon_name}:{tile}:MSS_NO_CREDIT

{hwmon_name}:{mss}:SKYLIB_DDN_TX_FLITS
{hwmon_name}:{mss}:SKYLIB_DDN_RX_FLITS
```

- BlueField-3 `bf_ptm` counters:

```
bf:ptm:active_power_profile
bf:ptm:atx_power_available
bf:ptm:core_temp
bf:ptm:ddr_temp
bf:ptm:error_state
bf:ptm:power_envelope
bf:ptm:power_throttling_event_count
bf:ptm:power_throttling_state
bf:ptm:thermal_throttling_event_count
bf:ptm:thermal_throttling_state
bf:ptm:throttling_state
bf:ptm:total_power
bf:ptm:vr0_power
bf:ptm:vr1_power
```

- `rate` counters – calculated counters showing the rate of raw counters of other components. Such counters are identified by a `_rate` suffix which correspond to the original raw counter name they track.

8.12.5.1.1.2 Port Counters

The following parameters are located in `/sys/class/infiniband/mlx5_0/ports/1/counters`.

Counter	Description	InfiniBand Spec Name	Group
`port_rcv_data`	The total number of data octets, divided by 4, (counting in double words, 32 bits), received on all VLs from the port.	`PortRcvData`	Informative
`port_rcv_packets`	Total number of packets (this may include packets containing Errors. This is 64 bit counter.	`PortRcvPkts`	Informative
`port_multicast_rcv_packets`	Total number of multicast packets, including multicast packets containing errors.	`PortMultiCastRcvPkts`	Informative
`port_unicast_rcv_packets`	Total number of unicast packets, including unicast packets containing errors.	`PortUnicastRcvPkts`	Informative
`port_xmit_data`	The total number of data octets, divided by 4, (counting in double words, 32 bits), transmitted on all VLs from the port.	`PortXmitData`	Informative
`port_xmit_packets` `port_xmit_packets_64`	Total number of packets transmitted on all VLs from this port. This may include packets with errors. This is 64 bit counter.	`PortXmitPkts`	Informative
`port_rcv_switch_relay_errors`	Total number of packets received on the port that were discarded because they could not be forwarded by the switch relay.	`PortRcvSwitchRelayErrors`	Error
`port_rcv_errors`	Total number of packets containing an error that were received on the port.	`PortRcvErrors`	Informative
`port_rcv_constraint_errors`	Total number of packets received on the switch physical port that are discarded.	`PortRcvConstraintErrors`	Error
`local_link_integrity_errors`	The number of times that the count of local physical errors exceeded the threshold specified by `LocalPhyErrors`.	`LocalLinkIntegrityErrors`	Error
`port_xmit_wait`	The number of ticks during which the port had data to transmit but no data was sent during the entire tick (either because of insufficient credits or because of lack of arbitration).	`PortXmitWait`	Informative
`port_multicast_xmit_packets`	Total number of multicast packets transmitted on all VLs from the port. This may include multicast packets with errors.	`PortMultiCastXmitPkts`	Informative
`port_unicast_xmit_packets`	Total number of unicast packets transmitted on all VLs from the port. This may include unicast packets with errors.	`PortUnicastXmitPkts`	Informative

Counter	Description	InfiniBand Spec Name	Group
`port_xmit_discards`	Total number of outbound packets discarded by the port because the port is down or congested.	`PortXmitDiscards`	Error
`port_xmit_constraint_errors`	Total number of packets not transmitted from the switch physical port.	`PortXmitConstraintErrors`	Error
`port_rcv_remote_physical_errors`	Total number of packets marked with the EBP delimiter received on the port.	`PortRcvRemotePhysicalErrors`	Error
`symbol_error`	Total number of minor link errors detected on one or more physical lanes.	`SymbolErrorCounter`	Error
`VL15_dropped`	Number of incoming VL15 packets dropped due to resource limitations (e.g., lack of buffers) of the port.	`VL15Dropped`	Error
`link_error_recovery`	Total number of times the Port Training state machine has successfully completed the link error recovery process.	`LinkErrorRecoveryCounter`	Error
`link_downed`	Total number of times the Port Training state machine has failed the link error recovery process and downed the link.	`LinkDownedCounter`	Error

8.12.5.1.1.3 Hardware Counters

The hardware counters, found under `/sys/class/infiniband/mlx5_0/ports/1/hw_counters/`, are counted per function and exposed on the function. Some counters are not counted per function. These counters are commented with a relevant comment.

Counter	Description	Group
`duplicate_request`	Number of received packets. A duplicate request is a request that had been previously executed.	Error
`implied_nak_seq_err`	Number of times the requested decided an ACK. with a PSN larger than the expected PSN for an RDMA read or response.	Error
`lifespan`	The maximum period in ms which defines the aging of the counter reads. Two consecutive reads within this period might return the same values	Informative
`local_ack_timeout_err`	The number of times QP's ack timer expired for RC, XRC, DCT QPs at the sender side. The QP retry limit was not exceeded, therefore it is still recoverable error.	Error
`np_cnp_sent`	The number of CNP packets sent by the Notification Point when it noticed congestion experienced in the RoCEv2 IP header (ECN bits).	Informative

Counter	Description	Group
np_ecn_marked_roce_packets	The number of RoCEv2 packets received by the notification point which were marked for experiencing the congestion (ECN bits where '11' on the ingress RoCE traffic) .	Informative
out_of_buffer	The number of drops occurred due to lack of WQE for the associated QPs.	Error
out_of_sequence	The number of out of sequence packets received.	Error
packet_seq_err	The number of received NAK sequence error packets. The QP retry limit was not exceeded.	Error
req_cqe_error	The number of times requester detected CQEs completed with errors.	Error
req_cqe_flush_error	The number of times requester detected CQEs completed with flushed errors.	Error
req_remote_access_errors	The number of times requester detected remote access errors.	Error
req_remote_invalid_request	The number of times requester detected remote invalid request errors.	Error
resp_cqe_error	The number of times responder detected CQEs completed with errors.	Error
resp_cqe_flush_error	The number of times responder detected CQEs completed with flushed errors.	Error
resp_local_length_error	The number of times responder detected local length errors.	Error
resp_remote_access_errors	The number of times responder detected remote access errors.	Error
rnr_nak_retry_err	The number of received RNR NAK packets. The QP retry limit was not exceeded.	Error
rp_cnp_handled	The number of CNP packets handled by the Reaction Point HCA to throttle the transmission rate.	Informative
rp_cnp_ignored	The number of CNP packets received and ignored by the Reaction Point HCA. This counter should not raise if RoCE Congestion Control was enabled in the network. If this counter raise, verify that ECN was enabled on the adapter. See HowTo Configure DCQCN (RoCE CC) values for ConnectX-4 (Linux).	Error

Counter	Description	Group
`rx_atomic_requests`	The number of received ATOMIC request for the associated QPs.	Informative
`rx_dct_connect`	The number of received connection request for the associated DCTs.	Informative
`rx_read_requests`	The number of received READ requests for the associated QPs.	Informative
`rx_write_requests`	The number of received WRITE requests for the associated QPs.	Informative
`rx_icrc_encapsulated`	The number of RoCE packets with ICRC errors.	Error
`roce_adp_retrans`	Counts the number of adaptive retransmissions for RoCE traffic	Informative
`roce_adp_retrans_to`	Counts the number of times RoCE traffic reached timeout due to adaptive retransmission	Informative
`roce_slow_restart`	Counts the number of times RoCE slow restart was used	Informative
`roce_slow_restart_cnps`	Counts the number of times RoCE slow restart generated CNP packets	Informative
`roce_slow_restart_trans`	Counts the number of times RoCE slow restart changed state to slow restart	Informative
`roce_slow_restart`	Counts the number of times RoCE traffic reached timeout due to adaptive retransmission	Informative

8.12.5.1.1.4 Debug Status Counters

The following parameters are located in `/sys/class/net/<interface>/debug`.

Parameter	Description	Default

`lro_timeout`	Sets the LRO timer period value in usecs which will be used as LRO session expiration time. For example:
	`# cat /sys/class/net/eth2/debug/lro_timeout`
	`Actual timeout: 32`
	`Supported timeout: 8 16 32 1024`
		32

Parameter	Description	Default

`link_down_reason`	Link down reason will allow the user to query the reason which is preventing the link from going up. For example:
	`$ cat /sys/class/net/ethXX/debug/link_down_reason`
	`monitor_opcode: 0x0`
	`status_message: The port is Active.`
	Refer to *NVIDIA's Adapters Programmer's Reference Manual (PRM)* for all possible options (PDDR register).
		N/A

8.12.5.1.1.5 Power Thermal Counters

The `bf_ptm` component collects BlueField-3 power thermal counters using remote collection. It is disabled by default and can be enabled as follows:

1. Load kernel module `mlxbf-ptm`:

```
modprobe -v mlxbf-ptm
```

2. Enable component using remote collection:

```
enable-provider=grpc.sysfs.bf_ptm
```

> ⚠ DPE server should be active before changing the `dts_config.ini` file. See section "Remote Collection" for details.

8.12.5.1.2 Ethtool Counters

Ethtool counters deliver a comprehensive, per-device list of hardware and software statistics generated by the Ethtool utility. Administrators rely on these counters to monitor traffic flow, measure hardware offload efficiency, and identify network or device errors.

8.12.5.1.2.1 Counter Groups

The system categorizes counters based on their origin location within the datapath:

- Ring: Software ring counters.
- Software port: An aggregation of all software ring counters for a given port.
- vPort: Traffic and drop counters related to internal steering or buffer availability.
  - Scope: Includes standard Ethernet traffic (including raw) and RDMA/RoCE traffic.
  - Troubleshooting: Errors in this group typically indicate issues internal to the BlueField DPU.

- Physical port: Counters for the physical port connecting the BlueField DPU to the external network.
  - Standards Tracking: Includes IEEE 802.3, RFC 2863, RFC 2819, RFC 3635, flow control, and Forward Error Correction (FEC) counters.
  - Troubleshooting: Errors here generally indicate physical link issues (e.g., defective cables or transceivers) or external network switch issues.

    > ⚠ The system does not expose physical port counters to virtual machines.
- Priority port: A specialized subset of physical port counters, broken down by priority level per port.

8.12.5.1.2.2 Counter Types

Within each group, counters fall into three functional classifications:

- Traffic informative: Tracks general traffic volume. Use these counters for load estimation and high-level debugging.
- Traffic acceleration `[A]`: Tracks traffic processed specifically by NVIDIA hardware offloads or drivers.

  > ⚠ Acceleration tracking adds an additional layer to the informative set. The system counts the identical packet in both the informative and acceleration counters. Acceleration counters always feature the `[A]` designation.
- Error counters: Tracks dropped packets or malformed frames. Increments in these counters serve as primary indicators of network or device problems.

8.12.5.1.2.3 Acceleration Mechanism Counters

Specific hardware offload mechanisms utilize dedicated counters to verify operational efficiency:

- TCP segmentation offload (TSO): Tracks outbound throughput improvements where the kernel aggregates multiple packets into a single large buffer, which the BlueField hardware subsequently splits into individual packets.
- Large receive offload (LRO): Tracks inbound throughput improvements where the hardware aggregates multiple incoming packets from a single stream into a single buffer.
- CQE compress: Tracks the compression of Completion Queue Events (CQE). This mechanism spares PCIe bandwidth and improves overall performance.
- CHECKSUM: Tracks TCP checksum calculations performed by the BlueField hardware. Status indicators include:

- `CHECKSUM_UNNECESSARY` : No checksum required.
- `CHECKSUM_NONE` : No acceleration applied.
- `CHECKSUM_COMPLETE` : The device successfully verified the checksum for the entire packet.
- `CHECKSUM_PARTIAL` : The device provided partial checksum validation.

  > Consult the Linux skbuff.h header file for detailed definitions of these states

8.12.5.1.2.4 Configuration Parameters

Configure which interfaces to monitor and exactly what data to collect using the parameters below in the DTS configuration file.

Interface Selection

Define the network interfaces to monitor using a comma-separated list. By default, the system uses a "contains" matching method (any interface name containing the specified string matches).

```
ethtool-interfaces=enp1s0f0,enp1s0f1,enp1s0f2
```

To force a strict, exact match for the interface names, configure the following parameter:

```
ethtool-interfaces-match-method=exact
```

Fieldset Customization (Filtering)

To customize exactly which fields the service collects, point the configuration to a specific fieldset file (`.fset`). Ensure this file resides in the DTS configuration folder.

```
ethtool-fieldset-file=/config/ethtool.fset
```

Example `.fset` filtering for Receive (Rx) and Transmit (Tx) pause control counters:

```
[ethtool_event_*]
rx_pause_ctrl_phy
tx_pause_ctrl_phy
```

8.12.5.1.2.5 Ring and Software Port Counters

The counters listed in the subsequent table supply detailed information regarding the volume of traffic accelerated by the BlueField DPU. Keep in mind that these counters tally the accelerated traffic *in addition* to the standard informative counters (accelerated traffic counts twice).

The counter names apply to both ring and software port counters depending on the presence of an index:

- Ring counters: Include the specific `[i]` index number (e.g., `rx0_packets` for ring 0).
- Software port counters: Aggregate the rings and omit the index entirely (e.g., `rx_packets` for the entire software port).

Counter Name	Description	Status / Type
`rx[i]_packets`	The number of packets received on ring *i*.	Informative
`rx[i]_bytes`	The number of bytes received on ring *i*.	Informative
`tx[i]_packets`	The number of packets transmitted on ring *i*.	Informative
`tx[i]_bytes`	The number of bytes transmitted on ring *i*.	Informative
`tx[i]_tso_packets`	The number of TCP Segmentation Offload (TSO) packets transmitted on ring *i* `[A]`.	Acceleration
`tx[i]_tso_bytes`	The number of TSO bytes transmitted on ring *i* `[A]`.	Acceleration
`tx[i]_tso_inner_packets`	The number of TSO packets carrying internal encapsulation transmitted on ring *i* `[A]`.	Acceleration
`tx[i]_tso_inner_bytes`	The number of TSO bytes carrying internal encapsulation transmitted on ring *i* `[A]`.	Acceleration
`rx[i]_lro_packets`	The number of Large Receive Offload (LRO) packets received on ring *i* `[A]`.	Acceleration
`rx[i]_lro_bytes`	The number of LRO bytes received on ring *i* `[A]`.	Acceleration
`rx[i]_csum_unnecessary`	Packets received with a `CHECKSUM_UNNECESSARY` status on ring *i* `[A]`.	Acceleration
`rx[i]_csum_none`	Packets received with a `CHECKSUM_NONE` status on ring *i* `[A]`.	Acceleration
`rx[i]_csum_complete`	Packets received with a `CHECKSUM_COMPLETE` status on ring *i* `[A]`.	Acceleration
`rx[i]_csum_unnecessary_inner`	Packets received with inner encapsulation and a `CHECKSUM_UNNECESSARY` status on ring *i* `[A]`.	Acceleration

Counter Name	Description	Status / Type
`tx[i]_csum_partial`	Packets transmitted with a `CHECKSUM_PARTIAL` status on ring *i* `[A]`.	Acceleration
`tx[i]_csum_partial_inner`	Packets transmitted with inner encapsulation and a `CHECKSUM_PARTIAL` status on ring *i* `[A]`.	Acceleration
`tx[i]_csum_none`	Packets transmitted with no hardware checksum acceleration on ring *i*.	Informative
`tx[i]_stopped` *(Global: `tx_queue_stopped`)*	Events where the Send Queue (SQ) was full on ring *i*. If this counter increases, check the number of buffers allocated for transmission.	Error
`tx[i]_wake` *(Global: `tx_queue_wake`)*	Events where the SQ was full and has subsequently become not full on ring *i*.	Error
`tx[i]_dropped` *(Global: `tx_queue_dropped`)*	Transmitted packets dropped due to a DMA mapping failure on ring *i*. If this counter increases, check the number of buffers allocated for transmission.	Error
`rx[i]_wqe_err`	The number of wrong opcodes received on ring *i*.	Error
`tx[i]_nop`	Tracks the number of empty Work Queue Elements (NOP WQEs) inserted into the Send Queue (SQ) for ring *i*. The driver inserts these empty WQEs when nearing the end of the cyclic buffer to prevent a single WQE from wrapping around the queue boundary.	Informative
`rx[i]_mpwqe_frag`	The number of WQEs that failed to allocate a compound page, resulting in the use of fragmented MPWQEs (multi-packet WQEs) on ring *i*. An increase indicates insufficient memory for large pages. ℹ This is not an abnormal condition	Informative
`rx[i]_mpwqe_filler_cqes`	The number of filler CQE events issued on ring *i*. ℹ Prior to kernel 4.19, this counter was named `rx[i]_mpwqe_filler`.	Informative
`rx[i]_cqe_compress_blks`	The number of receive blocks utilizing CQE compression on ring *i* `[A]`.	Acceleration

Counter Name	Description	Status / Type
`rx[i]_cqe_compress_pkts`	The number of receive packets utilizing CQE compression on ring *i* `[A]`.	Acceleration
`rx[i]_cache_reuse`	Events involving the successful reuse of a page from the driver's internal page cache.	Acceleration
`rx[i]_cache_full`	Events where the internal page cache is full. The driver cannot return a page to the cache for recycling (the page is freed instead).	Acceleration
`rx[i]_cache_empty`	Events where the cache is empty (no page available). The driver must allocate a new page.	Acceleration
`rx[i]_cache_busy`	Events where the cache head is busy and cannot be recycled. The driver must allocate a new page.	Acceleration
`rx[i]_xmit_more`	The number of packets sent with the `xmit_more` indication set on the `skbuff` (no doorbell).	Acceleration
`tx[i]_cqes`	The number of completions received on the Completion Queue (CQ) of the TX ring.	Informative
`ch[i]_poll`	The number of invocations of the NAPI poll for the channel.	Informative
`ch[i]_arm`	The number of times the NAPI poll function completed and armed the completion queues on the channel. Supported from kernel 4.19.	Informative
`ch[i]_aff_change`	The number of times the NAPI poll function explicitly stopped execution on a CPU due to an affinity change on the channel.	Informative
`rx[i]_congst_umr`	The number of times an outstanding UMR request is delayed due to congestion on the ring. Supported from kernel 4.19.	Error
`ch[i]_events`	The number of hard interrupt events on the completion queues of the channel.	Informative
`rx[i]_mpwqe_filler_strides`	The number of strides consumed by filler CQEs on the ring.	Informative
`rx[i]_xdp_tx_xmit`	The number of packets forwarded back to the port due to the XDP program's `XDP_TX` action (bouncing). These are counted by physical port and vPort counters, but not by other software counters.	Informative
`rx[i]_xdp_tx_full`	The number of packets intended for port forwarding via `XDP_TX` but dropped due to a full TX queue. To resolve, open more RX queues, spread traffic across all queues, or increase the RX ring size.	Error

Counter Name	Description	Status / Type
`rx[i]_xdp_tx_err`	The number of times an `XDP_TX` error (such as frame too long/short) occurred on the `XDP_TX` ring of the RX ring.	Error
`rx[i]_xdp_tx_cqes` *(Global: `rx_xdp_tx_cqe`)*	The number of completions received on the CQ of the `XDP_TX` ring.	Informative
`rx[i]_xdp_drop`	The number of packets dropped due to the XDP program's `XDP_DROP` action.	Informative
`rx[i]_xdp_redirect`	The number of times an XDP redirect action triggered on the ring.	Acceleration
`tx[i]_xdp_xmit`	The number of packets redirected to the interface via XDP redirect.	Informative
`tx[i]_xdp_full`	The number of packets redirected to the interface but dropped due to a full TX queue. To resolve, enlarge the TX queues.	Informative
`tx[i]_xdp_err`	The number of packets redirected to the interface but dropped due to an error (e.g., frame too long/short).	Error
`tx[i]_xdp_cqes`	The number of completions received on the CQ for packets redirected to the interface via XDP redirect.	Informative
`rx[i]_cache_waive`	The number of cache evacuations. This occurs if a page moves to another NUMA node or if a page was `pfmemalloc`-ed and requires immediate freeing.	Acceleration

8.12.5.1.2.6 vPort Counters

These counters reside on the eSwitch port connected to the vNIC. They are critical for monitoring traffic steering between the DPU and the host or virtual machines.

Counter Name	Description	Status / Type
`rx_vport_unicast_packets`	Unicast packets received and steered to a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`rx_vport_unicast_bytes`	Unicast bytes received and steered to a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`tx_vport_unicast_packets`	Unicast packets transmitted and steered from a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`tx_vport_unicast_bytes`	Unicast bytes transmitted and steered from a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative

Counter Name	Description	Status / Type
`rx_vport_multicast_packets`	Multicast packets received and steered to a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`rx_vport_multicast_bytes`	Multicast bytes received and steered to a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`tx_vport_multicast_packets`	Multicast packets transmitted and steered from a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`tx_vport_multicast_bytes`	Multicast bytes transmitted and steered from a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`rx_vport_broadcast_packets`	Broadcast packets received and steered to a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`rx_vport_broadcast_bytes`	Broadcast bytes received and steered to a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`tx_vport_broadcast_packets`	Broadcast packets transmitted and steered from a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`tx_vport_broadcast_bytes`	Broadcast bytes transmitted and steered from a port. Includes raw Ethernet QP/DPDK traffic; excludes RDMA traffic.	Informative
`rx_vport_rdma_unicast_packets`	RDMA unicast packets received and steered to a port. Counts RoCE (UD/RC) traffic `[A]`.	Acceleration
`rx_vport_rdma_unicast_bytes`	RDMA unicast bytes received and steered to a port. Counts RoCE (UD/RC) traffic `[A]`.	Acceleration
`tx_vport_rdma_unicast_packets`	RDMA unicast packets transmitted and steered from a port. Counts RoCE (UD/RC) traffic `[A]`.	Acceleration
`tx_vport_rdma_unicast_bytes`	RDMA unicast bytes transmitted and steered from a port. Counts RoCE (UD/RC) traffic `[A]`.	Acceleration
`rx_vport_rdma_multicast_packets`	RDMA multicast packets received and steered to a port. Counts RoCE (UD/RC) traffic `[A]`.	Acceleration
`rx_vport_rdma_multicast_bytes`	RDMA multicast bytes received and steered to a port. Counts RoCE (UD/RC) traffic `[A]`.	Acceleration
`tx_vport_rdma_multicast_packets`	RDMA multicast packets transmitted and steered from a port. Counts RoCE (UD/RC) traffic `[A]`.	Acceleration
`tx_vport_rdma_multicast_bytes`	RDMA multicast bytes transmitted and steered from a port. Counts RoCE (UD/RC) traffic `[A]`.	Acceleration
`rx_steer_missed_packets`	Packets received by the NIC but discarded because they did not match any flow in the NIC flow table. Supported from kernel 4.16.	Error

Counter Name	Description	Status / Type
`rx_packets`	Representor Only: Packets received that were handled by the hypervisor. Supported from kernel 4.18.	Informative
`rx_bytes`	Representor Only: Bytes received that were handled by the hypervisor. Supported from kernel 4.18.	Informative
`tx_packets`	Representor Only: Packets transmitted that were handled by the hypervisor. Supported from kernel 4.18.	Informative
`tx_bytes`	Representor Only: Bytes transmitted that were handled by the hypervisor. Supported from kernel 4.18.	Informative

8.12.5.1.2.7 Physical Port Counters

These counters monitor the external interface connecting the adapter to the network. They include standardized metrics (IEEE 802.3, RFCs) and hardware-specific indicators for Flow Control and FEC.

Counter Name	Description	Status / Type
`rx_packets_phy`	Total packets received on the physical port. Excludes discards due to FCS, frame size, or similar errors.	Informative
`tx_packets_phy`	Total packets transmitted on the physical port.	Informative
`rx_bytes_phy`	Total bytes received, including Ethernet header and FCS.	Informative
`tx_bytes_phy`	Total bytes transmitted.	Informative
`rx_multicast_phy`	Total multicast packets received.	Informative
`tx_multicast_phy`	Total multicast packets transmitted.	Informative
`rx_broadcast_phy`	Total broadcast packets received.	Informative

Counter Name	Description	Status / Type
`tx_broadcast_phy`	Total broadcast packets transmitted.	Informative
`rx_crc_errors_phy`	Packets dropped due to Frame Check Sequence (FCS) errors. **Troubleshooting** If this rate is high, monitor `rx_symbol_err_phy` and `rx_corrected_bits_phy` to assess link quality.	Error
`rx_in_range_len_errors_phy`	Packets dropped due to length/type errors.	Error
`rx_out_of_range_len_phy`	Packets dropped because length exceeded the allowed maximum. **Troubleshooting** Indicates the peer has a larger MTU configured. Align MTU settings to resolve.	Error
`rx_oversize_pkts_phy`	Packets dropped because they exceed the MTU size. **Troubleshooting** Indicates an MTU mismatch with the connected peer.	Error
`rx_symbol_err_phy`	Packets dropped due to physical coding (symbol) errors.	Error
`rx_mac_control_phy`	Total MAC control packets received.	Informative
`tx_mac_control_phy`	Total MAC control packets transmitted.	Informative
`rx_pause_ctrl_phy`	Link-layer pause packets received. **Troubleshooting** High counts imply the network is congested and cannot absorb traffic from the adapter.	Informative
`tx_pause_ctrl_phy`	Link-layer pause packets transmitted. **Troubleshooting** High counts imply the NIC is congested and cannot absorb traffic from the network.	Informative
`rx_unsupported_op_phy`	MAC control packets received with an unsupported opcode.	Error

Counter Name	Description	Status / Type
`rx_discards_phy`	Packets dropped due to a lack of buffers. **Troubleshooting** Indicates the adapter is congested and cannot absorb incoming network traffic.	Error
`tx_discards_phy`	Packets discarded during transmission despite no detected errors. May be caused by link-down state, Head-of-Line (HoL) blocking, or network pause frames.	Error
`tx_errors_phy`	Transmitted packets dropped because they exceed the MTU size.	Error
`rx_undersize_pkts_phy`	Packets dropped because they are shorter than 64 bytes. **Troubleshooting** Indicates a non-standard MTU on the peer or malformed packets.	Error
`rx_fragments_phy`	Packets shorter than 64 bytes with FCS errors. **Troubleshooting** Often implies a non-standard MTU on the connected peer.	Error
`rx_jabbers_phy`	Packets longer than 64 bytes with FCS errors.	Error
`rx_64_bytes_phy`	Packets received with a size of exactly 64 bytes.	Informative
`rx_65_to_127_bytes_phy`	Packets received with a size of 65–127 bytes.	Informative
`rx_128_to_255_bytes_phy`	Packets received with a size of 128–255 bytes.	Informative
`rx_256_to_511_bytes_phy`	Packets received with a size of 256–511 bytes.	Informative
`rx_512_to_1023_bytes_phy`	Packets received with a size of 512–1023 bytes.	Informative
`rx_1024_to_1518_bytes_phy`	Packets received with a size of 1024–1518 bytes.	Informative
`rx_1519_to_2047_bytes_phy`	Packets received with a size of 1519–2047 bytes.	Informative
`rx_2048_to_4095_bytes_phy`	Packets received with a size of 2048–4095 bytes.	Informative
`rx_4096_to_8191_bytes_phy`	Packets received with a size of 4096–8191 bytes.	Informative

Counter Name	Description	Status / Type
`rx_8192_to_10239_bytes_phy`	Packets received with a size of 8192–10239 bytes.	Informative
`link_down_events_phy`	Number of times the link state changed to "Down." **Troubleshooting** Frequent increments indicate port flapping; consider replacing the cable or transceiver.	Error
`rx_out_of_buffer`	Number of times the receive queue lacked software buffers for incoming traffic.	Error
`module_bus_stuck`	Number of times an I2C bus short-wire (Data or Clock) was detected. *(Supported from kernel 4.10).*	Error
`module_high_temp`	Number of times module temperature exceeded safe limits. Check ambient cooling or replace the module. *(Supported from kernel 4.10).*	Error
`module_bad_shorted`	Number of times module cables were shorted. *(Supported from kernel 4.10).*	Error
`module_unplug`	Number of times the module was ejected. *(Supported from kernel 4.10).*	Informative
`rx_buffer_passed_thres_phy`	Events where the port receive buffer exceeded 85% capacity. *(Supported from kernel 4.14).*	Informative
`tx_pause_storm_warning_events`	Number of times the device sent pause frames for an extended duration. *(Supported from kernel 4.15).*	Informative
`tx_pause_storm_error_events`	Number of times a pause storm reached a timeout, causing the device to disable pause frame transmission. Drops may occur during this period. *(Supported from kernel 4.15).*	Error
`rx[i]_buff_alloc_err` *(Global:* `rx_buff_alloc_err` *)*	Failed to allocate a buffer (or SKB) for received packets.	Error
`rx_bits_phy`	Total traffic that could have been received. Use this as a baseline to calculate error ratios for `rx_pcs_symbol_err_phy` and `rx_corrected_bits_phy`.	Informative
`rx_pcs_symbol_err_phy`	Symbol errors not corrected by the Forward Error Correction (FEC) algorithm. **Troubleshooting** High BER (Bit Error Rate) indicates a failing link. The error rate is calculated as `rx_pcs_symbol_err_phy` / `rx_bits_phy`.	Error

Counter Name	Description	Status / Type
`rx_corrected_bits_phy`	Bits corrected by active FEC (RS/FC). High counts indicate a poor link quality (high BER).	Error
`phy_raw_errors_lane[l]`	Physical raw errors per lane index `[l]` before FEC correction. **Troubleshooting** Use this to isolate issues to specific hardware lanes. Supported from kernel 4.20.	Error

8.12.5.1.2.8 Priority Port Counters

These counters are a specialized subset of physical port metrics, indexed by priority `[p]`.

Counter Name	Description	Status / Type
`rx_prio[p]_bytes`	Total bytes received with priority *p* on the physical port.	Informative
`rx_prio[p]_packets`	Total packets received with priority *p* on the physical port.	Informative
`tx_prio[p]_bytes`	Total bytes transmitted on priority *p* on the physical port.	Informative
`tx_prio[p]_packets`	Total packets transmitted on priority *p* on the physical port.	Informative
`rx_prio[p]_pause`	Link-layer pause packets received with priority *p*. **Troubleshooting** Increasing values imply the network is congested and cannot absorb adapter traffic. Requires PFC to be enabled on priority *p*. Refer to HowTo Configure PFC on ConnectX-4.	Informative
`rx_prio[p]_pause_duration`	Total duration (in microseconds) that priority *p* was paused by the receiver. High values indicate the network is heavily congested. Requires PFC to be enabled on priority *p*. Refer to HowTo Configure PFC on ConnectX-4.	Informative
`rx_prio[p]_pause_transition`	Number of transitions from `Xoff` (Stop) to `Xon` (Start) on priority *p*. Requires PFC to be enabled on priority *p*. Refer to HowTo Configure PFC on ConnectX-4.	Informative

Counter Name	Description	Status / Type
`tx_prio[p]_pause`	Link-layer pause packets transmitted on priority *p*. **Troubleshooting** Increasing values imply the adapter is congested and cannot absorb network traffic. Requires PFC to be enabled on priority *p*. Refer to HowTo Configure PFC on ConnectX-4.	Informative
`tx_prio[p]_pause_duration`	Total duration (in microseconds) the adapter transmitted pause frames for priority *p*. Requires PFC to be enabled on priority *p*. Refer to HowTo Configure PFC on ConnectX-4.	Informative
`rx_prio[p]_buf_discard`	Packets discarded by the device due to a lack of per-host receive buffers. Supported from kernel 5.3.	Informative
`rx_prio[p]_cong_discard`	Packets discarded by the device due to per-host congestion. Supported from kernel 5.3.	Informative
`rx_prio[p]_marked`	Packets marked with Explicit Congestion Notification (ECN) due to per-host congestion. Supported from kernel 5.3.	Informative
`rx_prio[p]_discard`	Total packets discarded by the device due to a general lack of receive buffers. Supported from kernel 5.6.	Informative

8.12.5.1.2.9 Device Counters

Device counters monitor the health and performance of the PCIe subsystem. High error rates here typically indicate physical hardware issues or bus-level bottlenecks rather than network problems.

Counter Name	Description	Status / Type
`rx_pci_signal_integrity`	Counts physical layer PCIe signal integrity errors, including transitions to recovery caused by Framing errors and CRC (DLP and TLP). **Troubleshooting** If this counter increases, move the adapter to a different PCIe slot and ensure the latest firmware and server BIOS are installed.	Error
`tx_pci_signal_integrity`	Counts physical layer PCIe signal integrity errors where recovery was initiated by the peer (triggered by TS/EIEOS). **Troubleshooting** If this counter increases, move the adapter to a different PCIe slot and ensure the latest firmware and server BIOS are installed.	Error
`outbound_pci_buffer_overflow`	Number of packets dropped due to PCIe buffer overflow. **Troubleshooting** High rates indicate that the receive traffic volume exceeds the PCIe bus bandwidth, causing congestion. Supported from kernel 4.14.	Informative
`outbound_pci_stalled_rd`	The percentage (0–100%) of time within the last second that the NIC had outbound non-posted read requests but stalled due to insufficient posted credits. Supported from kernel 4.14.	Informative
`outbound_pci_stalled_wr`	The percentage (0–100%) of time within the last second that the NIC had outbound posted write requests but stalled due to insufficient posted credits. Supported from kernel 4.14.	Informative
`outbound_pci_stalled_rd_events`	The total number of seconds where `outbound_pci_stalled_rd` exceeded 30%. Supported from kernel 4.14.	Informative
`outbound_pci_stalled_wr_events`	The total number of seconds where `outbound_pci_stalled_wr` exceeded 30%. Supported from kernel 4.14.	Informative
`dev_out_of_buffer`	Number of times the device-owned queue lacked sufficient allocated buffers.	Error

8.12.5.1.3 Traffic Control Info

The following TC objects are supported and reported regarding the ingress filters:

- Filters
    - flower
- Actions
    - mirred
    - tunnel_key

The info is provided as one of the following events:

- Basic filter event
- Flower/IPv4 filter event
- Flower/IPv6 filter event
- Basic action event
- Mirred action event
- Tunnel_key/IPv4 action event
- Tunnel_key/IPv6 action event

General notes:

- Actions always belong to a filter, so action events share the filter event's ID via the `event_id` data member
- Basic filter event only contains textual *kind* (so users can see which real life objects' support they are lacking)
- Basic action event only contains textual *kind* and some basic common statistics if available

8.12.5.1.4 Amber Provider

Amber data for both InfiniBand and Ethernet MST devices in amBER format.

MST device names can be found under `/dev/mst/`.

`/dev/mst` should be accessible within DTS container.

The following configuration parameters are optional:

```
amber_devices=mt41692_pciconf0,mt41692_pciconf0.1   # Default:all, or a comma-separated list of devices under /dev/
mst
amber_update_interval_sec=30                        # Sample rate for collection amber counters
```

8.12.5.1.5 PPCC_ETH Provider

Programmable congestion control counters are based on algorithms defined by the user, although default algorithms are also available.

Counters are collected per MST device and algorithm parameters.

MST device names can be found under `/dev/mst/`.

Ensure `/dev/mst` is accessible within the DTS container.

The counter list depends on the installed MFT version.

`/usr/lib64/mft` or `/usr/lib/mft` must be mounted to the DTS container to retrieve the counter list corresponding to the installed MFT version. If not mounted, DTS uses its internal version of the counter list.

The provider supports automatic detection of available Ethernet MST devices for collection. To override this behavior, specify a comma-separated list of device names:

```
ppcc_eth_devices=mt41692_pciconf0,mt41692_pciconf0.1
```

When correctly configured, the `ppcc_eth` provider operates in read-only mode and does not write to device registers. The following parameter enforces this behavior:

```
ppcc_read_only=1
```

The following algorithm parameters use default values and typically do not require changes:

```
ppcc_algo_slot=1
ppcc_algo_param_index=0
ppcc_local_port=1
ppcc_pnat=0
```

```
ppcc_lp_msb=0
```

For more details, consult the official PPCC documentation.

Some `algo_slots` are not implemented. Devices with no counters are ignored. If no valid devices are detected, the provider is disabled.

8.12.5.1.6 Fluent Aggregator

`fluent_aggr` listens on a port for Fluent Bit Forward protocol input connections. Received data can be streamed via a Fluent Bit exporter.

The default port is 42442. This can be changed by updating the following option:

```
fluent-aggr-port=42442
```

8.12.5.1.7 Prometheus Aggregator

`prometheus_aggr` polls data from a list of Prometheus endpoints.

Each endpoint is listed in the following format:

```
prometheus_aggr_endpoint.{N}={host_name},{host_port_url},{poll_inteval_msec}
```

Where N starts from 0.

Aggregated data can be exported via a Prometheus Aggr Exporter endpoint.

8.12.5.1.8 Network Interfaces

`ifconfig` collects network interface data. To enable, set:

```
enable-provider=ifconfig
```

If the Prometheus endpoint is enabled and autodetection of fset indexes is disabled, add the following configuration to cache every collected network interface and arrange the index according to their names:

```
prometheus-fset-indexes=name
```

Metrices are collected for each network interface as follows:

```
name
rx_packets
tx_packets
rx_bytes
tx_bytes
rx_errors
tx_errors
rx_dropped
tx_dropped
multicast
collisions
rx_length_errors
rx_over_errors
rx_crc_errors
rx_frame_errors
rx_fifo_errors
rx_missed_errors
tx_aborted_errors
tx_carrier_errors
tx_fifo_errors
tx_heartbeat_errors
tx_window_errors
rx_compressed
tx_compressed
rx_nohandler
```

8.12.5.1.9 NVIDIA System Management Interface

The `nvidia-smi` provider collects GPU and GPU process information provided by the NVIDIA system management interface.

This provider is supported only on hosts with installed GPUs. All GPU cards supported by `nvidia-smi` are supported by this provider.

The counter list is GPU dependent. Additionally, per-process information is collected for the first 20 (by default) `nvidia_smi_max_processes` processes.

Counters can be either collected as string data "as is" in `nvidia-smi` or converted to numbers when `nvsmi_with_numeric_fields` is set.

To enable `nvidia-smi` provider and change parameters, set:

```
enable-provider=nvidia_smi

# Optional parameters:
#nvidia_smi_max_processes=20
#nvsmi_with_numeric_fields=1
```

8.12.5.1.10 NVIDIA Data Center GPU Manager

The `dcgm` provider collects GPU information provided by the NVIDIA data center GPU manager (DCGM) API.

This provider is supported only on hosts with installed GPUs, and requires running the `nv-hostengine` service (refer to DCGM documentation for details).

DCGM counters are split into several groups by context:

- GPU – basic GPU information (always)
- COMMON – common fields that can be collected from all devices
- PROF – profiling fields

- ECC – ECC errors
- NVLINK / NVSWITCH / VGPU – fields depending on the device type

To enable DCGM provider and counter groups, set:

```
enable-provider=dcgm

dcgm_events_enable_common_fields=1
#dcgm_events_enable_prof_fields=0
#dcgm_events_enable_ecc_fields=0
#dcgm_events_enable_nvlink_fields=0
#dcgm_events_enable_nvswitch_fields=0
#dcgm_events_enable_vgpu_fields=0
```

8.12.5.1.11 BlueField Performance

The `bfperf` provider collects calculated performance counters of BlueField Arm cores. It requires the executable `bfperf_pmc`, which is integrated in the DOCA BFB bundle of BlueField-3, as well as an active DPE.

To enable BlueField performance provider, set:

```
enable-provider=bfperf
```

When running, the `bfperf` provider is expected to recurrently reset the counters of the `sysfs.hwmon` component. Consider disabling it if `bfperf` is enabled.

8.12.5.1.12 Diagnostic Data

Diagnostic data is comprised of two providers which gather diagnostic data counters from network interface cards (NICs). These providers support the same counters (as defined in a YAML file), but they differ in usage and collection frequency:

- Low frequency provider is defined in `dts_config.ini` and is controlled by DTS collection loop.
- High frequency provider is expected to run ad-hoc remotely (via REST API) or from `dts_ad_hoc_runner_config.ini`, and operates in a distinct flow for a limited duration.

Both providers get the counter set from a YAML file - see below.

Prerequisites:

- Firmware version 28.43.1000 onwards for ConnectX-7 or 32.43.1000 onwards for BlueField-3.

- `fwctl` driver should be installed and loaded (see instructions in NVIDIA MLNX_OFED Documentation v24.07-0.6.1.0), which is packaged in doca-ofed profile. Ensure that `fwctl` and `mlx5_fwctl` drivers are loaded with:

```
lsmod | grep fwctl
```

8.12.5.1.12.1 Diagnostic Data Low Frequency

To enable the diagnostic data low frequency provider, set:

```
enable-provider=diagnostic_data_low_freq
```

Configure the counter set YAML file (all default files are available in the mounted folder host `/opt/mellanox/doca/services/telemetry/config/diagnostic_data_configs`).

If there is no such folder, you must update the config folder by running `telemetry-init.sh`. See "DTS Deployment" section for information.

```
diagnostic-data-yml-file=/config/diagnostic_data_configs/all-single-port.yml
```

To configure the diagnostic data timestamp collection type, set the following:

```
diagnostic-data-timestamp-collection-type=<method>
```

Where `<method>` can be one of the following:

- `no_counters` – Do not collect timestamp counters. This is the default method.
- `start_and_end` – Collect sample start and end timestamps
- `per_counter` – Collect every counter collection timestamp

To configure the clock firmware should use when collecting time stamps, set the following:

```
diagnostic-data-timestamp-source=<clock>
```

Where `<clock>` can be one of the following:

- `RTC` – Real-time clock (default clock used)
- `RFC` – Free-running clock

8.12.5.1.12.2 Diagnostic Data High Frequency

The Diagnostic Data High Frequency provider supports higher sampling frequencies with sub-millisecond resolution, enabling detailed and precise telemetry collection. Due to the large volume of collected data, this provider is designed to run ad-hoc for limited

periods, unlike standard DTS providers configured via the DTS configuration file at `/opt/mellanox/doca/services/telemetry/config/dts_config.ini`.

While the standard DTS flow functions as an endless collect-export loop, High Frequency Telemetry (HFT) operates as an external flow triggered by an HFT HTTP API or by HFT configuration file.

8.12.5.1.12.3 Providers Compatibility

Both low and high frequency providers can run concurrently. The low frequency provider samples at the DTS standard frequency (defined in `dts_config.ini`), and the high frequency provider samples counters based on the HFT configuration file (`dts_ad_hoc_runner_config.ini`).

To allow both providers to run concurrently, verify that the counters, the timestamp collection type, and the timestamp collection source are identical. Otherwise, when the high frequency provider starts sampling, the low frequency provider hangs until the end of the HFT session.

8.12.5.1.12.4 HFT HTTP API

The HFT HTTP API allows to start and stop remotely high frequency sampling sessions at scale on devices running DTS, it also allows to get and delete the data as needed.

The API is disabled by default. To enable it, add the following parameter to DTS configuration file `/opt/mellanox/doca/services/telemetry/config/dts_config.ini`.

```
enable-http-api=true
```

The default port is 9117. To modify it, set the `http-port` option with the desired port number.

The general expected API usage is:

1. Start an HFT ad hoc collection, wait for it to stop or manually stop it. By default, the collected telemetry is stored locally to binary files in the filesystem.
2. Get the binary data files. The binary data can be read using the `/opt/mellanox/collectx/bin/clx_read` app, packaged in `collectx-clxapidev`, a DOCA dependency package.
3. Delete the collection from DTS host. In any case, DTS runs a configurable retention policy for the collected data files:

```
# by size - set the max size limit of the collection files in bytes. Default is 1GB
ad-hoc-runner-max-size-bytes=1073741824
# by time - set the max age of collection files in seconds. Default is 1 week
ad-hoc-runner-max-age-seconds=604800
# set the minimum time for collection files to exist. Default is 10 minutes
ad-hoc-runner-min-age-seconds=600
```

Summary

Method	URL	Description	Query Parameters	Has Request Body
`POST`	`/ad-hoc-collection/start`	Start an ad hoc collection session. Returns collection ID.	-	Yes
`POST`	`/ad-hoc-collection/stop`	Stop active ad hoc collection session	-	No
`POST`	`/ad-hoc-collection/hft-counterset`	Post an HFT counter set	`filename`	Yes
`GET`	`/ad-hoc-collection`	Get compressed folder with collection data	`collection_id`, `delta`	No
`GET`	`/ad-hoc-collection/list`	List collection folders	-	No
`GET`	`/ad-hoc-collection/status`	Show status of collections	`collection_id`	No
`DELETE`	`/ad-hoc-collection`	Remove collection data permanently	`collection_id`	No

Query parameters are key-value pairs appended to the URL using `?` and separated by `&`. Example: `/URL?key1=value1&key2=value2`.

Request body is a JSON object containing key-value pairs passed in the body of the request. Example: `{"key1": "value1", "key2": "value2"}`.

Response body is the JSON-formatted reply returned by the server. The Success Response section of each endpoint specifies the expected response format.

Status code:

- `200` indicates a successful request
- Other status codes indicate errors

POST /ad-hoc-collection/start

Start ad hoc collection.

Request Body

> Without a request body, this call will trigger an HFT collection for 30 seconds, in resolution of 10K samples per second, and will write the telemetry to binary data files.

Request body is passed as JSON with key-value pairs. all JSON values must be of string type.

The following table describes supported parameters in the request body:

Key	Default Value	Description
`sample-time-us`	`100000`	Sampling time in microseconds for SW iteration. one SW iteration collects all FW samples
`num-iterations`	`300`	Number of iterations
`start-time`	Current time	Start time for collection. UTC epoch timestamp (in microseconds)
`end-time`	Calculated based on `start-time`, `num-iterations`, and `sample-time-us`	End time for collection. UTC epoch timestamp (in microseconds)
`file-write`	`true`	Whether to write binary files
`busy-wait-sampling`	`false`	Whether to use busy wait sampling instead of sleep
`prometheus-endpoint`	-	Prometheus endpoint URL
`fluentbit-config-dir`	-	Fluentbit configuration directory
`open-telemetry-receiver`	-	OpenTelemetry receiver URL
`remote-write-receiver`	-	Prometheus Remote write receiver URL
`hft-counterset`	-	Counterset to use. Should be The filename provided to /ad-hoc-collection/hft-counterset.
`provider.diagnostic-data-num-samples`	`1000`	Number of diagnostic data samples (FW parameter)
`provider.diagnostic-data-sample-period-nsec`	`100000`	Sample period in nanoseconds (FW parameter)
`provider.diagnostic-data-yml-file`	`/config/diagnostic_data_configs/all-single-port.yml`	Configuration file path. Conflicts with hft-counterset

Key	Default Value	Description
`provider.diagnostic-data-timestamp-collection-type`	`start_and_end`	Type of timestamp collection: [`no_counters` , `start_and_end` , `per_counter`]
`provider.diagnostic-data-timestamp-source`	`RTC`	Source for timestamps: [`RTC` , `FRC`]

Success Response

```
{
  "status": "success",
  "message": "Collection created",
  "collection_id": 2
}
```

The `collection_id` parameter is generated automatically by this API and used in the GET and DELETE requests.

POST /ad-hoc-collection/stop

Stop active collection.

Success Response

```
{
  "status": "success",
  "message": "Collection stopped successfully"
}
```

POST /ad-hoc-collection/hft-counterset

Posts an HFT counterset that can later be used by the `POST /ad-hoc-collection/start` endpoint via the `hft-counterset` parameter.

Two methods are supported for posting a counterset to this endpoint:

- By providing a JSON payload
- By uploading a YAML file (using the format used by the diagnostic data high-frequency provider)

YAML File Request

The request is expected to be a multipart/form-data containing a valid counterset YAML file.

```
curl -X POST localhost:9117/ad-hoc-collection/hft-counterset?filename=my_cx7_hft_cset -F
"file=@my_cx7_hft_cset.yml"
```

JSON Request

JSON of key-value strings pairs, keys are the counter names and the value is a string representation of the hexadecimal data ID of that counter.

For example, the following JSON contains two counters

```
curl -X POST localhost:9117/ad-hoc-collection/hft-counterset?filename=my_cx7_hft_cset -d '{"port_rx_bytes_0":
"0x1020000100000000", "port_rx_packets_0": "0x1020000300000000"}'
```

Query Parameters

Parameter	Description
filename	Name to assign to the requested counterset

Success Response

```
{
  "status": "success",
  "message": "HFT counterset saved successfully",
  "filename": "my_cset_filename",
  "overriden": false
}
```

`overriden` is `true` if there was already a counterset with this name and it was replaced.

GET /ad-hoc-collection

This request is feasible for collections that were made with `file-write: true` and were not removed from the system (by DELETE /ad-hoc-collection or the retention policy).

Query Parameters

Parameter	Description
`collection_id`	Required collection ID
`delta`	When `delta=true`, the response contains only the delta—that is, the difference in data files written since the previous call with `delta=true`, using the same `collection_id` and `X-Client-ID` header. This option is applicable only when a collection is in progress. The data schema is provided in the first call with `delta=true` and remains consistent across subsequent delta requests.

Success Response

Content of `tar.gz` file. when extracted, a `collection_data` folder should appear in the working directory. Example with bash:

```
$ curl -s localhost:9117/ad-hoc-collection?collection_id=2 -o response.tar.gz
$ tar xf response.tar.gz
$ tree collection_data
collection_data/
    2025
        0401
            c-237-169-100-103
                diagnostic_data_1743529761189538.bin
                diagnostic_data_1743529761802460.bin
```

```
                diagnostic_data_1743529762402948.bin
                diagnostic_data_1743529763003488.bin
                diagnostic_data_1743529763604078.bin
                diagnostic_data_1743529764204606.bin
                diagnostic_data_1743529764805022.bin
                diagnostic_data_1743529765405535.bin
                diagnostic_data_1743529766005931.bin
    schema
        schema_c4d0317ee6cecbab995bfbcc237c76b2.json
```

Example with `delta=true`:

```
$ curl -s -H "X-Client-ID: my_app" "localhost:9117/ad-hoc-collection?collection_id=3&delta=true" -o
response1.tar.gz
$ curl -s -H "X-Client-ID: my_app" "localhost:9117/ad-hoc-collection?collection_id=3&delta=true" -o
response2.tar.gz
$ curl -s -H "X-Client-ID: my_app" "localhost:9117/ad-hoc-collection?collection_id=3&delta=true" -o
response3.tar.gz
$ tar xf response1.tar.gz
$ tar xf response2.tar.gz
$ tar xf response3.tar.gz
$ tree collection_data/
collection_data/
    2025
        0709
            swx-ray02
                diagnostic_data_1752050796207691.bin
                diagnostic_data_1752050796512800.bin
                diagnostic_data_1752050796949445.bin
                diagnostic_data_1752050797235709.bin
                diagnostic_data_1752050797524730.bin
                diagnostic_data_1752050797826312.bin
    schema
        schema_300a8aceac1d63c968ae837f366c9db4.json
```

GET /ad-hoc-collection/list

List the collections available on the file system, to be gathered by GET /ad-hoc-collection.

Success Response

```
{
  "status": "success",
  "num_collections": 3,
  "collection_ids": [1,2,3]
}
```

DELETE /ad-hoc-collection

Delete data of an ad-hoc collection. Note that in addition to this API there is a configurable retention policy.

Query Parameters

Parameter	Description	Notes
`collection_id`	The collection ID to delete	0 means delete all

Success Response

```
{
  "status": "success",
  "message": "Collection removed"
}
```

8.12.5.1.12.5 HFT Configuration File

The configuration file is mounted to DTS container, the host path is `/opt/mellanox/doca/services/telemetry/config/clx_ad_hoc_runner_config.ini`

This configuration file specifies the HFT session's timing parameters, provider settings, and export configurations. HFT allows data export to endpoints or protocols distinct from those used in the standard DTS collection loop. The DTS configuration references the HFT configuration file as an "ad hoc runner," enabling DTS to monitor its status via the following directive:

```
ad-hoc-runner-file=/config/clx_ad_hoc_runner_config.ini
```

The HFT configuration file serves as both the trigger and definition for HFT sessions. Modifying the file stops the current session and applies the new configuration for the next session. Deleting the file stops any pending HFT sessions entirely.

HFT File Parameters

This table provides the details of the HFT parameters. Refer to section "HFT Configuration File Example" for more helpful tips.

Option	Description
`start-time`	HFT session start time. If not used, the session starts immediately. UTC epoch timestamp (in microseconds) or human readable format: HH:MM:SS / HH:MM
`end-time`	HFT session end time. Ignored if `start-time` is missing. If not used, `end-time` is calculated using `num-iterations`. UTC epoch timestamp (in microseconds). or human readable format: HH:MM:SS / HH:MM
`num-iterations`	Number of iterations. If not used, `start-time` and `end-time` are required, and the number of iterations is calculated.
`sample-time-us`	Time interval between iterations (in microseconds)
`provider`	Provider to use. Should be `diagnostic_data_high_freq`.
`file-write`	Whether to write collected telemetry to files. If enabled, could potentially write several MB of data every second.
`data-root`	Root folder for file writing. Ignored if `file-write=false`.
`open-telemetry-receiver`	Enables export to specified open telemetry receiver
`remote-write-receiver`	Enables export to specified open telemetry receiver

Option	Description
`fluentbit-config-dir`	Enables export to fluentbit receivers. By default the folder is the same fluent bit configs folder used by DTS. Users can specify different folder, as long as it is available in DTS container, according to container volumes.
`prometheus-endpoint`	Enables in process HTTP server with data cache in prometheus, json and csv format. This is not recommended for HFT data collection due to high update rate of the data cache
`busy-wait-sampling`	Set busy wait between iterations (instead of sleep, which is less accurate).
`provider.diagnostic-data-num-samples`	Number of samples to collect in one iteration. Affects the buffer used by the firmware for diagnostic data.
`provider.diagnostic-data-sample-period`	Sample period between samples (in nanoseconds). This option specifies the sample interval per iteration, as the provider collects N samples during each iteration.
`provider.diagnostic-data-yml-file`	The diagnostic data counters YAML file to use
`provider.diagnostic-data-timestamp-collection-type`	`no_counters`, `start_and_end`, or `per_counter`. Same option as in low frequency provider.
`provider.diagnostic-data-timestamp-source`	`RTC` or `FRC`. Same option as in low frequency provider.

HFT Configuration File Example

```
## DTS configuration file for ad-hoc high frequency collection
## When modified, the file is parsed and applied.
## Note that the folders path is the container path, not the host path.

## Each section defines a collection. A file may have several sections, each one defines a high frequency
collection.
## Section names must be unique and will be used as collection name by clx.
[collection-session]

### Time between samples in microseconds
sample-time-us=100000

### Start time of high frequency collection. Can be in the format HH:MM:SS or HH:MM or as epoch timestamp in
microseconds
### Note - in container, the time is in UTC
start-time=18:00:00

### End time of high frequency collection. Can be in the format HH:MM:SS or HH:MM or as epoch timestamp in
microseconds
### Note - in container, the time is in UTC
end-time=18:01:00
### Alternatively, you can set the number of iterations. This and start_time field will determine the end time
#num-iterations=300

### Data provider to use
provider=diagnostic_data_high_freq

### Write data to file system. Could potentially fill up the disk
file-write=false

### Root directory to store the data
# Ignored if file-write is set to false
data-root=/data

### Enable busy wait between iterations, for a more accurate sample time (default is false)
#busy-wait-sampling=true

### Set prometheus endpoint to enable http endpoint
#prometheus-endpoint=http://0.0.0.0:9112
```

```
### Set fluentbit config dir to enable fluentbit export
#fluentbit-config-dir=/config/fluent_bit_configs

### Set open telemetry receiver to enable open telemetry export
#open-telemetry-receiver=http://0.0.0.0:9502/v1/metrics

### Set remote write receiver to enable remote write export
#remote-write-receiver=http://0.0.0.0:9090/api/v1/write

### Provider specific parameters. Format is 'provider.$KEY=$VALUE'.
### The options below are specific to the diagnostic data high frequency provider

# Number of samples to collect on each iteration
provider.diagnostic-data-num-samples=1000

# The time period (in nanoseconds) between samples
provider.diagnostic-data-sample-period-nsec=100000

# The YAML file with the configuration for the diagnostic data provider
provider.diagnostic-data-yml-file=/config/diagnostic_data_configs/all-single-port.yml

# Diagnostic Data timestamp collection type. Options are ['no_counters', 'start_and_end', 'per_counter']. default:
'no_counters'
#provider.diagnostic-data-timestamp-collection-type=start_and_end

# Diagnostic Data timestamp source. Options are ['RTC', 'FRC']. default: 'RTC'
#provider.diagnostic-data-timestamp-source=FRC
```

8.12.5.1.12.6 Diagnostic Data YAML File

For compatibility with other related tools, the counter set is defined in YAML format.

There are 4 YAML files within a DTS container (one per permutation of BlueField-3 and ConnectX-7 with dual or single ports). The path to the YAMLs folder is `/opt/mellanox/doca/services/telemetry/config/diagnostic_data_configs` which is mounted to `/config/diagnostic_data_configs`.

By default, YAML files include a counter set that is not device-specific. This implies that the same counter set is utilized across all devices by default.

It is possible to assign a specific device within a YAML file; however, this requires maintaining a separate copy of the YAML file for each device. To manage multiple devices, use the `diagnostic-data-yml-dir` option to specify a directory for YAML files, where each `.yml` / `.yaml` file is utilized. This folder should be available to the container under `/opt/mellanox/doca/services/telemetry/config`.

The following list describes the expected entries in the YAML file:

- `counters` – sequence of counters to collect
  - `id` – counter data ID
  - `desc` – counter description (optional)
  - `unit` – name of unit to collect from (optional)
  - `name` – name of counter to use (optional). If not specified, the generated name is based on the counter description. Otherwise, it is based on the data ID.
- `device` – name of the mlx devices to collect, comma separated (optional). If not used, the provider requires a single file containing a list of counters, which it then applies to all available devices on the host.

YAML File Example

The following is the content of the `all-dual-port.yml` file provided by DTS:

```
counters:
  - id: 0x1020000100000000
    name: port_rx_bytes_0
  - id: 0x1020000100000001
    name: port_rx_bytes_1
  - id: 0x1020000300000000
    name: port_rx_packets_0
  - id: 0x1020000300000001
    name: port_rx_packets_1
  - id: 0x1140000100000000
    name: port_tx_bytes_0
  - id: 0x1140000100000001
    name: port_tx_bytes_1
  - id: 0x1140000300000000
    name: port_tx_packets_0
  - id: 0x1140000300000001
    name: port_tx_packets_1
  - id: 0x1100000100000000
    name: port_tx_transport_cnp_sent_packets_0
  - id: 0x1100000100000001
    name: port_tx_transport_cnp_sent_packets_1
  - id: 0x1080000500000000
    name: port_rx_transport_cnp_handled_packets_0
  - id: 0x1080000500000001
    name: port_rx_transport_cnp_handled_packets_1
  - id: 0x1080000400000000
    name: port_rx_transport_ecn_packets_0
  - id: 0x1080000400000001
    name: port_rx_transport_ecn_packets_1
  - id: 0x1160000b00000000
    name: pcie_link_latency_total_read_ns
  - id: 0x1160000c00000000
    name: pcie_link_latency_total_read_packets
  - id: 0x1160000d00000000
    name: pcie_link_latency_max_read_ns
  - id: 0x1160000e00000000
    name: pcie_link_latency_min_read_ns
  - id: 0x1180000100000000
    name: global_icmc_request
  - id: 0x1180000200000000
    name: global_icmc_hit
  - id: 0x1180000300000000
    name: global_icmc_miss
```

The NVIDIA Adapters Programmer's Reference Manual (PRM) "Diagnostic Data" section defines the rules for data IDs as well as the counter set.

8.12.5.1.13 RDMA Notifications

The RDMA Notifications events provider collects notifications from the RDMA firmware and converts them into DTS events for telemetry purposes.

To enable the RDMA notifications provider, add the following line to the DTS configuration file (`/opt/mellanox/doca/services/telemetry/config/dts_config.ini`):

```
enable-provider=rdma_notifications
```

8.12.5.1.13.1 Prerequisites

- RDMA device(s) configured to operate in Ethernet protocol
- OFED installed
- ConnectX-7 or BlueField-3 and later
- Firmware version x.44.0820 or newer

8.12.5.1.13.2 Options

Name	Description	Type	Default	Notes
`rdma-notifications-hca`	HCA used for receive QP, comma separated for multiple HCAs	String	`mlx5_0`	
`rdma-notifications-num-event-indexes`	Number of event indexes	Integer	`1`	This option is relevant for Prometheus Export, in case user wants to store last N events of each type. For proper indexing of Prometheus export, in case the autodetection of fset indexes is disabled, add the configuration option `prometheus-fset-indexes=device_name,idx,syndrome`.
`rdma-notifications-num-buffers`	Number of buffers used by QP	Integer	`1000`	
`rdma-notifications-buffer-size`	Size of every buffer used by QP	Integer	`256`	
`rdma-notifications-syndrome-counter-event-interval-sec`	Interval in seconds to export syndrome counter events	Integer	`30`	See "counter event" in event types section.
`rdma-notifications-include-syndrome-zero-counters`	Export syndrome counter events if no events are found	Boolean	`false`	There are potentially 2^7 event types. If enabled, an event per syndrome will be sent every `rdma-notifications-syndrome-counter-event-interval-sec`.
`rdma-notifications-rt-all-vports`	Set the corresponding field in RDMA telemetry object	Boolean	`true`	
`rdma-notifications-rt-num-vport-ranges`	Number of vport ranges	Integer	`0`	May conflict with `rdma-notifications-rt-all-vports` option.
`rdma-notifications-rt-vport-range-[0-3]-max-id`	Vport range maximal ID (inclusive) in RDMA telemetry object	Integer	`0`	This row is for 4 different options. Use one index in every line. Example: `rdma-notifications-rt-vport-range-0-max-id`

Name	Description	Type	Default	Notes
`rdma-notifications-rt-vport-range-[0-3]-min-id`	Vport range maximal ID (inclusive) in RDMA telemetry object	Integer	`0`	This row is for 4 different options. Use one index in every line. Example: `rdma-notifications-rt-vport-range-0-min-id`
`rdma-notifications-qkey`	QKey used for firmware registration	Hexadecimal Integer	`0x100`	

8.12.5.1.13.3 Events List

There are two types of events provided by the RDMA notifications:

- Notification Event – A direct translation of an RDMA notification into one of four possible event types, based on the notification content
- Counter Event – A periodic aggregation event that reports the total number of events collected for each syndrome

For additional details, refer to the "RDMA Telemetry Notifications" section in the NVIDIA Adapters Programmer's Reference Manual (PRM).

Currently, the CQE with error is the only supported type of RDMA notification.

Notification Events

Additional fields are provided for convenience:

- `guid` – A globally unique identifier for the device
- `idx` – The event index, determined by the provider option `rdma-notifications-num-event-indexes`
- `device_name` – The name of the RDMA device, based on the devices listed in `rdma-notifications-hca`

These fields are not specified in the NVIDIA Adapters PRM but are included in the event data to enhance usability.

```

8.12.5.1.14 vNIC Provider

To enable the virtual NIC counters provider:

```
enable-provider=vnic
```

Operation and retrieval:

- Counters are automatically provided for all valid Ethernet devices listed in the `devlink dev` output.
- The service retrieves these metrics by executing:

  ```
  devlink health diagnose <device_name> reporter vnic
  ```

- The exact set of available counters is dynamic and depends on the specific driver version currently in use.

The following is an example of a counter list:

```
total_error_queues
send_queue_priority_update_flow
comp_eq_overrun
async_eq_overrun
cq_overrun
invalid_command
quota_exceeded_command
generated_pkt_steering_fail
handled_pkt_steering_fail
```

8.12.5.1.15 Adaptive Retx Provider

The `doca_telemetry_adp_retx` provider exposes real-time statistics for the Adaptive Retransmission (ADP-RETX) algorithm configured on supported NVIDIA BlueField DPUs and ConnectX network adapters.

Adaptive Retransmission optimizes RDMA performance by dynamically adjusting retransmit timers based on network conditions. The provider collects this telemetry in a histogram format, organizing retransmit counts into specific time-range bins. This allows administrators to visualize the distribution of network latency and recovery efficiency.

To enable the Adaptive Retx events provider, add the following line to your configuration:

```
enable-provider=apt_retx
```

8.12.5.2 Data Outputs

DTS can send the collected data to the following outputs:

- Data writer (saves binary data to disk)
- Prometheus endpoint (keeps the most recent data to be pulled)
- Fluent Bit (push-model streaming)
- Open Telemetry exporter (push-model streaming)

- Prometheus Remote write exporter (push-model streaming)

8.12.5.2.1 Data Writer

The data writer is disabled by default to save space on BlueField. Steps for activating data write during debug can be found under section Enabling Data Output.

The schema folder contains JSON-formatted metadata files which allow reading the binary files containing the actual data. The binary files are written according to the naming convention shown in the following example (`apt install tree`):

```
tree /opt/mellanox/doca/services/telemetry/data/
/opt/mellanox/doca/services/telemetry/data/
    {year}
        {mmdd}
            {hash}
                {source_id}
                    {source_tag}{timestamp}.bin
                {another_source_id}
                    {another_source_tag}{timestamp}.bin
    schema
        schema_{MD5_digest}.json
```

New binary files appears when the service starts or when binary file age/size restriction is reached. If no schema or no data folders are present, refer to the Troubleshooting section.

> ⚠ `source_id` is usually set to the machine hostname. `source_tag` is a line describing the collected counters, and it is often set as the provider's name or name of user-counters.

Reading the binary data can be done from within the DTS container using the following command:

```
crictl exec -it <Container ID> /opt/mellanox/collectx/bin/clx_read -s /data/schema /data/path/to/datafile.bin
```

> ⚠ The path to the data file must be an absolute path.

Example output:

```
{
    "timestamp": 1634815738799728,
    "event_number": 0,
    "iter_num": 0,
    "string_number": 0,
    "example_string": "example_str_1"
}
{
    "timestamp": 1634815738799768,
    "event_number": 1,
    "iter_num": 0,
    "string_number": 1,
    "example_string": "example_str_2"
}
…
```

8.12.5.2.2 Prometheus Exporter

The Prometheus endpoint maintains a buffer of the most recent telemetry data for pull-based collection by a Prometheus server. This mechanism is enabled by default, allowing external monitoring systems to scrape BlueField metrics at defined intervals.

8.12.5.2.2.1 Data Retrieval and Verification

To verify that the Prometheus exporter is active and providing data, execute the following command on the BlueField DPU:

```
curl -s http://0.0.0.0:9100/metrics
```

This command returns each counter in the format `counter_name {list of meta fields} counter_value timestamp`.

The endpoint also supports alternative output formats:

- JSON: `curl -s http://0.0.0.0:9100/json/metrics`
- CSV: `curl -s http://0.0.0.0:9100/csv/metrics`

8.12.5.2.2.2 Schema Metadata

DTS provides schema metadata to help users understand the structure and origin of specific counters.

- Retrieve all schema IDs:

  ```
  curl -s http://0.0.0.0:9100/management/schema
  ```

- Fetch a specific schema:

  ```
  curl -s http://0.0.0.0:9100/management/schema?schema_id=xxx
  ```

- View all available schemas:

  ```
  curl -s http://0.0.0.0:9100/management/schema?schema_id=all
  ```

8.12.5.2.2.3 Configuration Details

The Prometheus exporter is managed via `dts_config.ini`. By default, the HTTP endpoint listens on port 9100.

Standard vs. Secure Configuration

To disable the exporter, comment out the `prometheus` line. To enable HTTPS, provide the certificate and key paths:

```
# For standard HTTP
```

```
prometheus=http://0.0.0.0:9100

# For Secure HTTPS (Requires certs in DTS config volume)
prometheus=https://0.0.0.0:9100
prometheus-cert=/config/certs/server.crt
prometheus-key=/config/certs/server.key
```

Filtering and Indexing

- Name filtering: Ignore specific counters by providing a comma-separated list to `prometheus-ignore-names`.
- Tag filtering: Ignore data sources by tag. By default, streaming metrics (like `FI_metrics`) are disabled as the pull-based exporter is not suitable for high-frequency streaming.

```
prometheus-ignore-tags=FI_metrics
```

- Custom indexing: Users can override default indexing to preserve multiple records with different index values. These index fields are automatically converted into Prometheus labels.

```
# Manual override for fset indexes (Autodetected in version 1.22+)
prometheus-fset-indexes=idx1,idx2
```

8.12.5.2.2.4 Prometheus Aggregator Exporter

The Prometheus Aggregator Exporter creates a specialized endpoint that maintains the latest aggregated data from multiple sources. It labels data according to its origin (endpoint name), allowing for centralized viewing of distributed telemetry.

The following configuration example enables aggregation from two distinct endpoints with different sampling intervals (1000ms and 3000ms) and exports the combined data on port 33333.

```
# Enable the aggregator provider
enable-provider=prometheus_aggr

# Define aggregation endpoints: [Name],[URL],[Interval_ms]
prometheus_aggr_endpoint.0=AAA,http://0.0.0.0:9000,1000
prometheus_aggr_endpoint.1=BBB,http://0.0.0.0:9002/metrics,3000

# Configure the aggregated exporter endpoint
prometheus-aggr-exporter-host=0.0.0.0
prometheus-aggr-exporter-port=33333
```

In this example, metrics from the first source will include the label `ep_name=AAA`, while the second will feature `ep_name=BBB`.

Fluent Bit

Fluent Bit allows streaming to multiple destinations. Destinations are configured in `.exp` files that are documented in-place and can be found under:

```
/opt/mellanox/doca/services/telemetry/config/fluent_bit_configs
```

Fluent Bit allows exporting data via "Forward" protocol which connects to the Fluent Bit/FluentD instance on customer side.

Export can be enabled manually:

1. Uncomment the line with `fluent_bit_configs=…` in `dts_config.ini`.
2. Set `enable=1` in required `.exp` files for the desired plugins.
3. Additional configurations can be set according to instructions in the `.exp` file if needed.
4. Restart the DTS.
5. Set up receiving instance of Fluent Bit/FluentD if needed.
6. See the data on the receiving side.

Export file destinations are set by configuring `.exp` files or creating new ones. It is recommended to start by going over documented example files. Documented examples exist for the following supported plugins:

- forward
- file
- stdout
- kafka
- es (elastic search)
- influx

All `.exp` files are disabled by default if not configured by `initContainer` entry point through `.yaml` file.

To forward the data to several destinations, create several `forward_{num}.exp` files. Each of these files must have their own destination host and port.

8.12.5.2.2.5 Export File Configuration Details

Each export destination has the following fields:

- `name` – configuration name
- `plugin_name` – Fluent Bit plugin name
- `enable` – 1 or 0 values to enable/disable this destination
- `host` – the host for Fluent Bit plugin
- `port` – port for Fluent Bit plugin
- `msgpack_data_layout` – the msgpacked data format. Default is `flb_std`. The other option is custom. See section Msgpack Data Layout for details.
- `plugin_key=val` – key-value pairs of Fluent Bit plugin parameter (optional)

- `counterset` / `fieldset` – file paths (optional). See details in section Cset/Fset Filtering.
- `source_tag=source_tag1,source_tag2` – comma-separated list of data page source tags for filtering. The rest tags are filtered out during export. Event tags are event provider names. All counters can be enabled/disabled only simultaneously with a `counters` keyword.

⚠ Use `#` to comment a configuration line.

8.12.5.2.2.6 Msgpack Data Layout

Data layout can be configured using `.exp` files by setting `msgpack_data_layout=layout`. There are two available layouts: Standard and Custom.

The standard `flb_std` data layout is an array of 2 fields:

- timestamp double value
- a plain dictionary (key-value pairs)

The standard layout is appropriate for all Fluent Bit plugins. For example:

```
[timestamp_val, {"timestamp"->ts_val, type=>"counters/events", "source"=>"source_val", "key_1"=>val_1,
"key_2"=>val_2,...}]
```

The custom data layout is a dictionary of meta-fields and counter fields. Values are placed into a separate plain dictionary. Custom data format can be dumped with `stdout_raw` output plugin of Fluent-Bit installed or can be forwarded with `forward` output plugin.

Counters example:

```
{"timestamp"=>timestamp_val, "type"=>"counters", "source"=>"source_val", "values"=> {"key_1"=>val_1,
"key_2"=>val_2,...}}
```

Events example:

```
{"timestamp"=>timestamp_val, "type"=>"events", "type_name"=>"type_name_val", "source"=>" source_val",
"values"=>{"key_1"=>val_1, "key_2"=>val_2,...}}
```

8.12.5.2.2.7 Cset/Fset Filtering

Each export file can optionally use one `cset` and one `fset` file to filter DTS counters and events data.

- `cset` contains tokens per line to filter data with `"type"="counters"`.

- `fset` contains several blocks started with the header line `[event_type_name]` and tokens under that header. An Fset file is used to filter data with `"type"="events"`.

  > ⚠ Event type names could be prefixed to apply the same tokens to all fitting types. For example, to filter all ethtool events, use `[ethtool_event_*]`.

If several tokens must be matched simultaneously, use `<tok1>+<tok2>+<tok3>`. Exclusive tokens are available as well. For example, the line `<tok1>+<tok2>-<tok3>-<tok4>` filters names that match both tok1 and tok2 and do not match tok3 or tok4.

The following are the details of writing `cset` files:

```
# Put tokens on separate lines
# Tokens are the actual name 'fragments' to be matched
# port$ # match names ending with token "port"
# ^port # match names starting with token "port"
# ^port$ # include name that is exact token "port
# port+xmit # match names that contain both tokens "port" and "xmit"
# port-support # match names that contain the token "port" and do not match the "-" token "support"
#
# Tip: To disable counter export put a single token line that fits nothing
```

The following are the details of writing `fset` files:

```
# Put your events here
# Usage:
#
# [type_name_1]
# tokens
# [type_name_2]
# tokens
# [type_name_3]
# tokens
# ...
# Tokens are the actual name 'fragments' to be matched
# port$ # match names ending with token "port"
# ^port # match names starting with token "port"
# ^port$ # include name that is exact token "port
# port+xmit # match names that contain both tokens "port" and "xmit"
# port-support # match names that contain the token "port" and do not match the "-" token "support"

# The next example will export all the "tc" events and all events with type prefix "ethtool_" "ethtool" are
filtered with token "port":
# [tc]
#
# [ethtool_*]
# packet

# To know which event type names are available check export and find field "type_name"=>"ethtool_event_p0"
# ...
# Corner cases:
# 1. Empty fset file will export all events.
# 2. Tokens written above/without [event_type] will be ignored.
# 3. If cannot open fset file, warning will be printed, all event types will be exported.
```

8.12.5.2.3 NetFlow Exporter

NetFlow exporter must be used when data is collected as NetFlow packets from the telemetry client applications. In this case, DOCA Telemetry Exporter NetFlow API sends NetFlow data packages to DTS via IPC. DTS uses NetFlow exporter to send data to the NetFlow collector (3rd party service).

To enable NetFlow exporter, set `netflow-collector-ip` and `netflow-collector-port` in `dts_config.ini`. `netflow-collector-ip` could be set either to IP or an address.

For additional information, refer to the `dts_config.ini` file.

8.12.5.2.4 OpenTelemetry Exporter

DTS) can stream telemetry data to an OpenTelemetry (OTel) receiver using the OpenTelemetry Protocol (OTLP). This exporter is disabled by default and supports both HTTP and gRPC transports with robust security options.

> Reference documentation:
> - Open Telemetry Metrics Service API
> - OTLP Specification 1.3.0

8.12.5.2.4.1 Transport and Security

- Protocols: Supports OTLP over HTTP (JSON encoded) and OTLP over gRPC (Protobuf).
- Security: Supports both insecure connections and mutual TLS (mTLS) using client certificates, keys, and CA bundles.
- Compatibility: Optimized for the OTLP Specification 1.3.0.

8.12.5.2.4.2 Configuration Examples (`dts_config.ini`)

Set the `open-telemetry-receiver` parameter to define your destination.

OTLP over HTTP

```
# Insecure HTTP (JSON)
open-telemetry-receiver=http://0.0.0.0:9502/v1/metrics

# Secure HTTP with TLS
open-telemetry-receiver=https://0.0.0.0:9504/v1/metrics
open-telemetry-cert-file=certs/client.pem
open-telemetry-key-file=certs/client.key
open-telemetry-ca-file=certs/ca.pem
```

This example expects the running Open Telemetry receiver to be bound to port 9502 on the host running the DTS instance. Section "Open Telemetry Metrics Receiver Sample Configuration" provides an example of the Open Telemetry receiver configuration.

8.12.5.2.4.3 OTLP over gRPC

```
# Insecure gRPC
open-telemetry-transport=grpc
open-telemetry-receiver=0.0.0.0:9501

# Secure gRPC with TLS
open-telemetry-transport=grpc
open-telemetry-receiver=0.0.0.0:9503
open-telemetry-cert-file=certs/client.pem
```

```
open-telemetry-key-file=certs/client.key
open-telemetry-ca-file=certs/ca.pem
```

8.12.5.2.4.4 Advanced Streaming Controls

You can fine-tune how OTel handles your data attributes and throughput:

- Filtering: Apply `counter-set` or `field-set` to the stream to limit data volume (see Counterset and Fieldset section for more details).

```
open-telemetry-counter-set=slow_counters
open-telemetry-field-set=slow_counters
```

- Attribute mapping: By default, DTS uses space-efficient hierarchical attributes. For compatibility with backends like Prometheus DB, enable per-data-point attributes.

```
open-telemetry-with-data-point-attributes=true
```

- Performance tuning: Adjust the bulk size for combining data bursts (default is 100).

```
open-telemetry-bulk-size=20
```

- Serialization: To use the official Protobuf serializer instead of the default JSON encoder:

```
open-telemetry-fast-serializer=false
open-telemetry-binary-protobuf=true
```

- Aggregation temporality: To ensure all "Sum" metrics (like packet counters) are treated as Cumulative values (which is the standard for high-reliability monitoring) configure this parameter:

```
# Ensures Sum metrics are marked as Cumulative (Industry Standard)
open-telemetry-sum-is-always-cumulative=off
```

8.12.5.2.4.5 OpenTelemetry Receiver: Sample Collector Configuration

To receive data from DTS, configure your OpenTelemetry Collector (`collector-config.yaml`) as follows:

```
receivers:
  otlp/insecure:
    protocols:
      grpc:
        endpoint: 0.0.0.0:9501
      http:
        endpoint: 0.0.0.0:9502

  # Secure endpoints with TLS
  otlp/secure:
    protocols:
      grpc:
        endpoint: 0.0.0.0:9503
        tls:
          cert_file: /etc/otel/tls/server.crt
          key_file: /etc/otel/tls/server.key
      http:
        endpoint: 0.0.0.0:9504
        tls:
```

```
          cert_file: /etc/otel/tls/server.crt
          key_file: /etc/otel/tls/server.key

exporters:
  debug:
    verbosity: detailed

service:
  pipelines:
    traces:
      receivers: [otlp/insecure, otlp/secure]
      exporters: [debug]
    metrics:
      receivers: [otlp/insecure, otlp/secure]
      exporters: [debug]
    logs:
      receivers: [otlp/insecure, otlp/secure]
      exporters: [debug]
```

Run the Collector via Docker

```
docker run --rm --name "otel_collector" \
    -p 9501:9501 -p 9502:9502 -p 9503:9503 -p 9504:9504 \
    -v $(pwd)/collector-config.yaml:/etc/otelcol/config.yaml \
    -v $(pwd)/certs:/etc/otel/tls \
    otel/opentelemetry-collector
```

8.12.5.2.5 Prometheus Remote Write Exporter

DTS can stream the telemetry data towards an external Prometheus service with an enabled metrics receiver. If enabled, the DTS data exporter acts as a Prometheus remote write protocol "Sender", streaming telemetry data towards a Prometheus server using remote write protocol.

> Refer to Prometheus Remote Write Specification for more information.

To enable telemetry data streaming:

```
remote-write-receiver=http://0.0.0.0:9090/api/v1/write
```

This example assumes the running Prometheus remote write receiver to be bound to port 9090 on the host running the DTS instance.

For example, a Prometheus remote write receiver could be run using the following command:

```
docker run -p 9090:9090 prom/prometheus --config.file=/etc/prometheus/prometheus.yml \
    --storage.tsdb.path=/prometheus --web.console.libraries=/usr/share/prometheus/console_libraries \
    --web.console.templates=/usr/share/prometheus/consoles --web.enable-remote-write-receiver
```

The Prometheus remote write exporter can be configured to apply counter-set or field-set to the data stream, similar to the Open Telemetry exporter:

```
remote-write-counter-set=slow_counters
remote-write-field-set=slow_counters
```

The Prometheus remote write exporter sends data in bulk, combining bursts when possible. By default, the size of the bulk is up to 100 data points. If necessary, the size of the bulk can be altered using the bulk-size configuration parameter. For example:

```
remote-write-bulk-size=20
```

8.12.5.2.6 Load Balancer Exporter

The load balancer exporter is an exporter which distributes or copies data between multiple instances of another (secondary) exporter.

For example, the number of instances may be set as follows depending on the use case:

Variable	Description	Default	Example	Required	Notes
`loadbalancer-exporter-name`	Name of the secondary exporter to load: `open_telemetry`, `remote_write`	N/A	`open_telemetry`	Yes	
`loadbalancer-num-instances`	Number of instances to create of the secondary exporter	N/A	`2`	Yes	Inferred when using `loadbalancer-INDEX-KEY` parameters
`loadbalancer-mode`	Balancing mode. Possible values: `distribution`; `replication`.	`distribution`	`replication`	No	
`loadbalancer-INDEX-KEY`	General prefix for key-value parameters to specific export instance	N/A	`loadbalancer-0-open-telemetry-receiver=http://0.0.0.0:9502/v1/metrics`	No	Index is 0-based. KEY expected be an option supported of the used exporter. See exporter description for list of options.
`loadbalancer-exporter-config-var`	Variable name to substitute for instances of the secondary exporter	N/A	`open-telemetry-receiver`	No	Will be deprecated. Use `loabalancer-INDEX-KEY` instead.

If any of the required variables is missing, the load balancer will not start.

When `loadbalancer-INDEX-KEY` and `loadbalancer-exporter-config-var` are not used, all instances are created equal, and their configuration is done according to other available configuration. If none of the instance configuration variables exist, that instance is created with other available configuration.

For example, the following is a section of the `dts_config.ini` configuration file which provides a sample of enabling load balancer to run 2 OTLP exporter instances:

```
loadbalancer-exporter-name=open_telemetry
```

```
loadbalancer-mode=replication
loadbalancer-0-open-telemetry-receiver=http://10.141.160.210:9502/v1/metrics
loadbalancer-1-open-telemetry-receiver=http://10.141.160.211:9502/v1/metrics
```

The default behavior is to export the entire collected data. To restrict the export interval of different instances (multirate export), add the required interval in seconds:

```
loadbalancer-0-open-telemetry-export-interval=30
loadbalancer-1-open-telemetry-export-interval=60
```

8.12.5.2.7 Distributed Real Time Analysis Exporter

The Real Time Analysis (RTA) Exporter is a powerful tool designed to export real-time analytics data from DTS. It provides seamless integration with various data sources and destinations, allowing you to efficiently collect, process, and export analytics information in real-time. One of its key features is the ability to run an HTTP server at a preconfigured port, allowing for remote management of Lua scripts used in data processing.

It allows to get relevant insights based on telemetry data without the overhead of aggregation and central analysis. Potential use cases can be running link health tests (by analyzing L1 data) before executing an AI job (saving cluster time by avoiding starting a job on a bad link), or any other custom logic that is able to run on-demand \ on-going and uses telemetry data as input.

To enable this exporter, the lua scripts folder path (in DTS container filesystem) should be specified in DTS config file

```
lua-script-dir=/config/rta/lua_scripts
```

The default DTS configuration folder contains several Lua scripts that can be used as an example. The section below describes the API

> ⚠ This provider can run an HTTP server for RESTful interface of Lua scripts management.
>
> Below are the parameters that can be modified to change the default logic:
>
> ```
> rta-enable-http-api=true
> rta-http-port=1812
> ```

8.12.5.2.7.1 Additional Configuration Parameters

Option Name	Description	Example
`rta-inqueue`	Size of the inbound data page processing queue. Default is 10.	`5`

`rta-outqueue`	Size of the outgoing Prometheus write queue. Default is 1000.	`5000`
`rta-threads`	Number of threads to run the remote write exporter. Default is 1.	`2`
`rta-counter-set`	Name of the counter set to apply to the data stream.	`low_freq`
`rta-field-set`	Name of the field set to apply to the data stream.	`low_freq`
`rta-metrics-capacity`	Defines the default maximum size of the buffer that stores the most recent metric values.	`16`
`rta-max-metrics-capacity`	Maximum capacity for metrics storage	`10000`
`rta-enable-http-api`	Enables RTA HTTP API requests.	`true`
`rta-http-port`	RTA HTTP server port.	`1814`
`rta-ufm-events-endpoint`	(In case UFM is running) URL of the UFM events endpoint for posting external events.	`https://r-ufm114/ufmRestV3/app/events/external_events`
`rta-ufm-access-token`	(In case UFM is running) Access token used for authentication when posting events to UFM.	`fJiq6mvCjMiQn6ZFwmKJxWygd8O2pX` Corresponds to `r-ufm114`
`rta-skip-unchanged-data-points`	Skips unchanged data points during processing if set to `true`.	`true`
`rta-script-log-lines-size`	Maximum number of log lines to keep per script	`1000`
`rta-lua-disallow-list`	Comma-separated list of forbidden Lua functions	`io.open,io.popen,os.execute,dofile,loadfile,require`
`rta-lua-allow-functions-list`	Comma-separated list of allowed Lua functions for scripts	`print,ipairs,pairs,type,tostring,tonumber`
`rta-lua-allow-libraries-list`	Comma-separated list of allowed Lua libraries for scripts	`math,string,table`

8.12.5.2.7.2 Lua Script Requirements

- If the script implements the `isEnabled()` function, it must return `true` for the script to be enabled. If this function is not implemented, the script will be disabled by default.

- Scripts must provide a set of metric names to be filtered for processing by implementing the `getMetricNames()` function.
- If a script is disabled, doesn't implement `getMetricNames()`, or returns an empty set of metric names, it will not be loaded.

8.12.5.2.7.3 Lua Scripts Workflow

The RTA Exporter plugin processes data in two ways:

a. Periodic:
   - At the end of each data page, the plugin calls the `processDataPageCompleted()` Lua function.
   - This function allows the Lua script to process the collected data.

b. On demand via http server - see <link>

8.12.5.2.7.4 Lua Script Examples

Lua scripts for RTA Exporter are available in `/opt/mellanox/doca/services/telemetry/config/rta/lua_scripts`. The following are examples for analyzing `sysfs` provider counters:

- `sysfs_normalized_cbw.lua` – Calculates the percentage of theoretical maximum bandwidth lost due to congestion on InfiniBand ports
- `sysfs_check_link_state.lua` – Monitors six key InfiniBand link metrics to verify that links are properly configured and operational

8.12.5.2.7.5 Lua Scripts API

There are 2 directions of function calls:

- DTS calls Lua script functions
- Lua script calls DTS functions

Lua Script Functions

2 functions are required - `isEnabled` and `getMetricNames`

isEnabled()

Determines if the script should be loaded.

```
function isEnabled()
    return true -- or false
end
```

getMetricNames()

Provides a set of metric names to be filtered for processing.

```
function getMetricNames()
    return {"metric1", "metric2", "metric3"}
end
```

processDataPageCompleted()

Processes collected data at the end of each data page.

```
function processDataPageCompleted()
    -- Implementation for processing data
end
```

getMetricsCapacity()

Defines the maximum size of the buffer that stores the most recent metric values.

```
function getMetricsCapacity()
    return 20 -- Example: Set the buffer size to 20 entries
end
```

processChangedMetricsOnly()

This function instructs the host application (CLX) to provide only metrics that have changed since the last time the script accessed them.

```
function processChangedMetricsOnly()
    return true -- Receive only updated metrics data
end
```

- Purpose: Optimizes data processing by instructing the host application to provide only metrics with new values since the script last accessed them. This can significantly improve performance and reduce unnecessary data transfer.
- Return value:
    - `true` : The host application will provide only metrics that have changed since the last access by the script.
    - `false` : The host application will provide all metrics, regardless of whether they've changed.

processDataMinPeriodMs()

Returns the minimum delay in milliseconds between calls to `processDataPageCompleted()` . This function helps reduce the frequency of calls if data pages are completed too quickly.

```
function processDataMinPeriodMs()
    return 5000 -- Example: Ensure processDataPageCompleted() is called at least 5 seconds apart
end
```

- Purpose: This function allows you to control maximum frequency at which `processDataPageCompleted()` is called when multiple data pages are completed in rapid succession.
- Note: The frequency of data pages becoming ready for processing is controlled by the CLX configuration. If the `processDataMinPeriodMs()` value is lower than the

interval at which data pages are completed (as set by CLX), `processDataPageCompleted()` will be called on each data page completion, as the delay condition will always be met.
- If data pages are completed more frequently than the specified delay, `processDataPageCompleted()` will be called less often to prevent excessive processing.

processData()

Processes data on demand when requested via the HTTP API.

```
function processData()
    -- Your logic here to process data
    -- For example, let's assume a simple response
    return "Data processed successfully","text/plain; charset=utf-8"
end
```

The `processData()` function is an optional function in Lua scripts that is only required when the script is executed on demand. It processes data and returns a response. When implemented, it must return two values:

1. `Response Content` (string): The actual data or message to be sent back
2. `Content Type` (string): Specifies how the response should be interpreted

Return Values

- `First Value`: The response content as a string
- `Second Value`: The content type as a string (e.g., `"text/plain; charset=utf-8"`)

Content Type Examples

- `"text/plain; charset=utf-8"` - For plain text responses
- `"text/html; charset=utf-8"` - For HTML responses
- `"application/json"` - For JSON responses

- Purpose: This function allows scripts to handle on-demand data processing requests initiated through the RTA HTTP API.
- Note: The `processData()` function is called independently of the regular data page processing cycle and is used for ad-hoc data processing tasks.

DTS functions that can be called from Lua script

The RTA Exporter plugin provides several functions implemented by DTS that allow Lua scripts to interact with metrics data. These functions are prefixed with `clx_` and are designed to be called from within the `processDataPageCompleted()` and `processData()` functions in your Lua scripts.

clx_get_updated_metric_names(metricNames)

This function returns a list of metric names that have been updated since the last access.

```
function clx_get_updated_metric_names(metricNames)
```

- Parameters:
  - `metricNames`: A table of metric names to check for updates.
- Returns:
  - A table containing the names of metrics that have been updated.

clx_create_label_sets_iterator(metric_name, skip_unchanged)

This function creates an iterator for label sets associated with a given metric.

```
for label_set_index, labels in clx_create_label_sets_iterator(metric_name, skip_unchanged) do
    -- Process data
end
```

- Parameters:
  - `metric_name`: The name of the metric to iterate over.
  - `skip_unchanged`: A boolean indicating whether to skip label sets that haven't changed.
- Returns:
  - An iterator that yields pairs of `label_set_index` and `labels` for the specified metric.

clx_get_last_data_points(metric_name, label_set_index)

Retrieves both timestamps and corresponding values for a specific metric and label set index.

```
local timestamps, values = clx_get_last_data_points(metric_name, label_set_index)
```

- Parameters:
  - `metric_name`: The name of the metric.
  - `label_set_index`: The index of the label set associated with the metric.
- Returns:
  - `timestamps`: A table of timestamps corresponding to the data points.
  - `values`: A table of values corresponding to the timestamps.

clx_get_last_metric_values_by_index(metric_name, label_set_index, n)

Retrieves the last `n` values for a specific metric and label set index.

```
local values = clx_get_last_metric_values_by_index(metric_name, label_set_index, n)
```

- Parameters:

- `metric_name`: The name of the metric.
- `label_set_index`: The index of the label set associated with the metric.
- `n`: The number of last values to retrieve.

- Returns:
  - A table containing the last `n` values for the specified metric and label set index.

clx_get_labels_set(label_set_index)

Retrieves the labels set for a given label set index.

```
local labels = clx_get_labels_set(label_set_index)
```

- Parameters:
  - `label_set_index`: The index of the label set to retrieve.
- Returns:
  - A table containing the labels set for the specified index.

clx_get_last_metric_values(metric_name, labels, n)

This function retrieves the last `n` values for a specific metric and label set.

```
function clx_get_last_metric_values(metric_name, labels, n)
```

- Parameters:
  - `metric_name`: The name of the metric.
  - `labels`: The label set associated with the metric.
  - `n`: The number of last values to retrieve.
- Returns:
  - A table containing the last `n` values for the specified metric and label set.

clx_get_all_metrics_data_points(label_set_index, n)

This function retrieves historical data points for a set of metrics

```
local timestamps, values = clx_get_all_metrics_data_points(label_set_index, n)
```

- Parameters:
  - `label_set_index`: number - Index of the label set to get data for
  - `n`: number - Maximum number of data points to retrieve per metric
- Returns:
  - `timestamps_table`: table - Array of timestamps for each metric
  - `values_table`: table - Array of values for each metric
- Usage: Used to access historical metric data for analysis
- Example:

```
local timestamps, values = clx_get_all_metrics_data_points(label_set_index, 2)
if timestamps and values then
    for i, metric_name in ipairs(metricNames) do
        if values[i] and #values[i] > 0 then
            local last_value = values[i][#values[i]]
            -- Process the value
        end
    end
end
```

clx_post_ufm_event(event_dictionary)

Posts a UFM external event and returns the response. (This is relevant in case UFM is running).

```
local response = clx_post_ufm_event(event_dictionary)
```

- Parameters:
  - `event_dictionary`: A table containing the event details to be posted. (See: Trigger External Events)
- Returns:
  - The UFM external event response if successful, or an error string if the operation fails.

clx_log_info(...)

Logs an informational message.

```
clx_log_info("Informational message %s %d", "Additional context", 123)
```

- **Parameters**:
  - `...`: Variable number of arguments to log. These can be strings, numbers, or other types that can be converted to strings.

clx_log_warning(...)

Logs a warning message.

```
clx_log_warning("Warning message %s %d", "Additional context", 456)
```

- **Parameters**:
  - `...`: Variable number of arguments to log.

clx_log_error(...)

Logs an error message.

```
clx_log_error("Error message %s %d", "Additional context", 789)
```

- **Parameters**:
  - `...`: Variable number of arguments to log.

clx_log_debug(...)

Logs a debug-level message, useful during development and troubleshooting.

```
clx_log_debug("Debugging details %s %d", "Additional context", 101112)
```

- **Parameters**:
  - `...`: Variable number of arguments to log.

Alternative Logging Functions

The following functions provide logging capabilities similar to Lua's `print()` function. They accept variadic arguments and automatically concatenate them into a single string for logging:

- `clx_log_print_info(...)`: Logs informational messages.
- `clx_log_print_warning(...)`: Logs warning messages.
- `clx_log_print_error(...)`: Logs error messages.
- `clx_log_print_debug(...)`: Logs debug-level messages.

Expected Arguments:

- These functions accept a variable number of arguments (`...`) without requiring modifiers for formatting.
- Arguments can be strings, numbers, or other types convertible to strings, and they are concatenated into a single log message.

Usage Example #1

Here's how you might use these logging functions within your Lua script:

```
function processDataPageCompleted()
  clx_log_info("Data page processing started with %s %s", #getMetricNames(), "metrics.")
end
```

Usage Example #2

Here's an updated example of how these functions should be used within the `processDataPageCompleted()` function:

```
function processDataPageCompleted()
  local metricNames = getMetricNames()
  local updatedMetrics = clx_get_updated_metrics_names(metricNames)
  for _, metric_name in ipairs(updatedMetrics) do
    for label_set_index, labels in clx_create_label_sets_iterator(metric_name, true) do
      local lastValues = clx_get_last_metric_values_by_index(metric_name, label_set_index, 5)
      -- Process the last 5 values and labels for this metric and label set
    end
  end
end
```

This example demonstrates the correct usage of the updated and new host application functions within `processDataPageCompleted()`. It shows how to:

1. Iterate over updated metrics and their label sets.

2. Retrieve the last 5 values for each metric and label set combination using the label set index.

Best Practices

Remember to call these functions only within `processDataPageCompleted()` to ensure access to the most recent and consistent metrics data.

1. It's recommended to return `true` from `processChangedMetricsOnly()` in most cases to receive only updated metrics data, improving efficiency.
2. Use `false` only when your script specifically needs to process all metrics on each data page completion, regardless of changes.
3. Ensure your script's logic can handle receiving and processing only a subset of metrics when this function returns `true`.
4. Be aware that returning `true` may result in receiving fewer metrics per processing cycle, but these metrics will always be the most recently updated ones.
5. Use `getMetricsCapacity()` to control memory usage and performance by limiting the number of stored metric values.
6. Use `processData()` to handle on-demand data processing tasks initiated via the HTTP API's *Run Script* command.
7. Ensure your script's logic can handle both regular data page processing and on-demand requests independently.
8. Be aware that `processData()` is called outside of regular processing cycles, so it should be designed for standalone execution.

8.12.5.2.7.6 HTTP REST API

List

- **Purpose**: Retrieves a list of available Lua scripts.
- **Method**: POST
- **Request Body**: A JSON object with the `scriptCommand` set to `"list"`.

```
{
  "scriptCommand": "list"
}
```

- **Response**: A JSON array containing the base file names (without path or extension) of the available Lua scripts.

Add

- **Purpose**: Submits a request to add a new Lua script to the system. The actual addition is performed at the earliest opportunity, typically at the beginning of the next incoming data page processing cycle.
- **Method**: POST

- **Request Body**: A JSON object with the `scriptCommand` set to `"add"`, `scriptName`, and `scriptContent`.

```
{
  "scriptCommand": "add",
  "scriptName": "example_script", // Optional
  "scriptContent": "Lua script content here"
}
```

  - If `scriptName` is provided, the script will be saved with that name to the directory containing your Lua scripts.
  - If `scriptName` is not provided (or empty), the script content will be saved to a temporary file. The lifecycle of such scripts will be tied to the RTA Exporter's lifecycle, meaning they will be automatically removed when the RTA Exporter terminates.
- **Response**: A success message indicating that the request has been queued for processing.

Remove

- **Purpose**: Submits a request to remove an existing and enabled Lua script from the system. The actual removal is performed at the earliest opportunity, typically at the beginning of the next incoming data page processing cycle.
- **Method**: POST
- **Request Body**: A JSON object with the `scriptCommand` set to `"remove"` and `scriptName`.

```
{
  "scriptCommand": "remove",
  "scriptName": "example_script"
}
```

  Important: Only enabled (active and running) Lua scripts that exist within the configured Lua scripts directory can be removed using this command. Attempts to remove scripts outside of this directory or scripts that are not enabled will be disregarded.
- **Response**: A success message indicating that the request has been queued for processing.

Run

- **Purpose**: Submits a request to execute a Lua script immediately. The script is executed directly.
- **Method**: POST
- **Request Body**: A JSON object with the `scriptCommand` set to `"run"`, optionally `scriptName`, and `scriptContent`.

```
{
  "scriptCommand": "run",
  "scriptName": "example_script", // Optional
  "scriptContent": "Lua script content here"  // Used if scriptName is not provided
}
```

  - If `scriptName` is provided, the existing script with that name will be executed.
  - If `scriptName` is not provided (or empty), the script content specified in `scriptContent` will be executed directly.

- **Response**: Returns the result of the `processData()` function execution if successful, or an error message if any error condition occurs during execution.
- **Note**: The Lua script must implement a function named `processData()` which is called by this `Run` request during execution. If this function is not present, execution will fail.

Reload Scripts

- **Purpose**: Submits a request to reload all Lua scripts from the configured scripts directory. This command does not perform reload immediately but queues it for execution at the earliest opportunity, typically at the beginning of the next incoming data page processing cycle.
- **Method**: POST
- **Request Body**: A JSON object with the `scriptCommand` set to `"reloadScripts"`.

```
{
  "scriptCommand": "reloadScripts"
}
```

- **Response**: A success message indicating that the reload request has been queued for processing, or an error message if any issue occurs during queuing.

Show Script Log

- **Purpose**: Retrieves the log entries for a specified Lua script.
- **Method**: POST
- **Request Body**: A JSON object with the `scriptCommand` set to `"log"` and `scriptName`.

```
{
  "scriptCommand": "log",
  "scriptName": "example_script"
}
```

  - **Important**: Only existing and enabled Lua scripts can be queried using this command. Attempts to query non-existent or disabled scripts will return an empty log.
- **Response**: A JSON object containing the log entries for the specified script, or an empty log if the script does not exist, is not enabled, or if there are no log entries.

Alternative Endpoints

In addition to the `/rta/lua/scripts/cmd` endpoint, the following endpoints provide a simpler way to perform common operations:

- **Add Script**:
  bash
  `curl -X POST http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/script/add/example_script \ -H "Content-Type: text/plain" \ -d 'print("Hello, Lua!")'`
- **Remove Script**:
  bash
  `curl -X DELETE http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/script/remove/example_script`
- **Show Script Log**:
  bash
  `curl -X GET http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/script/showlog/example_script`
- **Run Script (by Name)**:
  bash
  `curl -X GET http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/script/run/example_script`
- **Run Script (with Content)**:
  bash
  `curl -X POST http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/script/run \ -H "Content-Type: text/plain" \ -d 'function processData() print("Processing Data") end'`
- **List Scripts**:
  bash
  `curl -X GET http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/scripts/list`
- **Reload Scripts**:
  bash
  `curl -X GET http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/scripts/reload`

Execution Timing

Note that commands like `add`, `remove`, and `reloadScripts` are not executed immediately. Instead, they are queued and performed at the earliest opportunity, typically at the beginning of the next incoming data page processing cycle. This ensures that script management operations do not interfere with ongoing data processing tasks. The `run` command executes scripts immediately.

Error Handling

- Invalid or Missing Command: If an unsupported `scriptCommand` is provided or if `scriptCommand` is not specified, the endpoint will return an error message indicating that the command is not recognized.
- Missing Arguments: If required arguments are missing for any command, the endpoint will return an error message specifying the missing fields.
- Script Existence: For the `add` command, if a script with the same name already exists, the endpoint will overwrite the existing script.
- Script Removal: For the `remove` command, if the specified script does not exist within the configured Lua scripts directory or is not enabled, the request will be disregarded without error.
- Script Execution: For the `run` command:
    - If execution fails due to missing or invalid code (e.g., missing `processData()` function), an error message will be returned.
- Script Reload Request:
    - If any issue occurs during queuing of reload requests (e.g., invalid configuration), an error message will be returned.

Security Considerations

- Authentication: Ensure that appropriate authentication mechanisms are in place to restrict access to this endpoint.
- Input Validation: Always validate the input data to prevent potential security vulnerabilities such as script injection.

Example Usage

- List Scripts:

```
curl -X POST http://localhost:1814/rta/lua/scripts/cmd \
        -H "Content-Type: application/json" \
        -d '{"scriptCommand": "list"}'
```

- Add Script:

```
curl -X POST http://localhost:1814/rta/lua/scripts/cmd \
        -H "Content-Type: application/json" \
        -d '{"scriptCommand": "add", "scriptName": "example", "scriptContent": "print(\"Hello, Lua!\")"}'
```

- Remove Script:

```
curl -X POST http://localhost:1814/rta/lua/scripts/cmd \
        -H "Content-Type: application/json" \
        -d '{"scriptCommand": "remove", "scriptName": "example"}
```

- Run Script:

```
curl -X POST http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/scripts/cmd \
        -H "Content-Type: application/json" \
        -d '{"scriptCommand": "run", "scriptContent": "function processData() print(\"Processing Data\")
end processData()"}'
```

- Reload Scripts Request:

```
curl -X POST http://localhost:$CLX_RTA_HTTP_PORT/rta/lua/scripts/cmd \
      -H "Content-Type: application/json" \
      -d '{"scriptCommand": "reloadScripts"}'
```

- Show Script Log:

```
curl -X POST http://localhost:1814/rta/lua/scripts/cmd \
       -H "Content-Type: application/json" \
       -d '{"scriptCommand": "log", "scriptName": "example"}
```

8.12.6 Counterset and Fieldset Files

Counterset and fieldset files are configuration files used by DTS exporters to define which telemetry data fields to export and how to transform them. These files provide fine-grained control over data export, allowing you to select specific counters or fields and assign aliases for better readability.

They are primarily used by exporters to filter the telemetry data being exported.

The default folder for DTS counterset and fieldset files is: `/opt/mellanox/doca/services/telemetry/config/prometheus_configs/cset/`.

8.12.6.1 Difference Between .cset and .fset Files

Internally, DTS uses two types of schemas: counters and events. Each provider defines its own schema type.

- Most DTS providers use the events schema, which corresponds to `.fset` files.
- A few providers (e.g., `sysfs`, `diagnostic_data_low_freq`) use the counters schema, which corresponds to `.cset` files.

The main difference:

- A `.cset` file is a flat list of counter names or patterns.
- An `.fset` file groups fields under specific event types, which add an additional layer of hierarchy.

Schemas can be viewed in the data folder or retrieved via the HTTP endpoint: `http://<host>:9100/management/schema`.

8.12.6.2 Counterset (.cset) File Format

Counterset files follow a simple, comment-friendly key-value format. They support:

- Direct counter name selection
- Substring pattern matching
- Aliases for field renaming

```
# Lines starting with '#' are comments
# Select specific counters
port_xmit_bytes
_rcv_

# Field aliases
infiniband_link_downed_events=LinkDownedCounterExtended
infiniband_port_xmit_data_bytes=PortXmitDataExtended
normalized_cbw=normalized_CBW
```

8.12.6.3 Fieldset (.fset) File Format

Fieldset files define event-specific fields grouped under event type headers:

```
[ethtool_event_*]
rx_queue_0_xdp_packets
rx_queue_1_xdp_packets
tx_queue_0_xdp_packets

[dcgm_events_gpu]
DCGM_FI_DEV_GPU_TEMP
DCGM_FI_DEV_GPU_UTIL
DCGM_FI_DEV_MEM_CLOCK
```

8.12.6.4 Best Practices

File organization:

- Use descriptive filenames that reflect the file's purpose
- Group related counters or fields together
- Apply consistent naming conventions

Performance considerations:

- Keep files reasonably sized to avoid overhead
- Use patterns to minimize manual effort
- Cache frequently used configurations when possible

Maintainability:

- Add comments to clarify complex patterns or logic
- Use consistent formatting and indentation
- Document custom patterns or transformations

Testing:

- Start with small datasets
- Validate that patterns match expected fields
- Check the exported data format and structure

Security:

- Avoid exposing sensitive information in field names
- Use aliases to mask internal names if needed
- Set appropriate file and directory permissions

8.12.6.5 Common Issues

- Files not found: Check file paths and permissions.
- Fields not exported: Ensure the fields exist in the data schema and are referenced in the configuration.
- Performance issues: Review file size and pattern complexity.

8.12.7 DOCA Privileged Executor

When running on a BlueField, the DOCA Privileged Executer (DPE) is a daemon that enables specific DOCA services, including DTS, to access BlueField information that would otherwise be inaccessible from a container due to technology limitations or restricted permissions. By granting access to privileged system information, DPE enriches the data collected by DTS, providing additional insights and metrics. However, DTS can still operate independently without DPE, as the daemon is disabled by default.

DPE is available on Debian based operation systems only.

8.12.7.1 DPE Usage

DPE is controlled by systemd, and can be used as follows:

- To check DPE status:

```
sudo systemctl status dpe
```

- To start DPE:

```
sudo systemctl start dpe
```

- To stop DPE:

```
sudo systemctl stop dpe
```

DPE logs can be found in `/var/log/doca/telemetry/dpe.log`.

8.12.7.2 DPE Configuration File

DPE can be configured by the user. This section covers the syntax and implications of its configuration file.

> ⚠ The DPU telemetry collected by DTS does not require for this configuration file to be used.

The DPE configuration file allows users to define the set of commands that DPE should support. This may be done by passing the `-f` option in the following line of `/etc/systemd/system/dpe.service`:

```
ExecStart=/opt/mellanox/doca/services/telemetry/dpe/bin/dpeserver -vvv
```

To use the configuration file:

```
ExecStart=/opt/mellanox/doca/services/telemetry/dpe/bin/dpeserver -vvv -f /path/to/dpe_config.ini
```

The configuration file supports the following sections:

- `[server]` - list of key=value lines for general server configuration. Allowed keys: `socket`.
- `[commands]` - list of bash command lines that are not using custom RegEx
- `[commands_regex]` - list of bash command lines that are using custom RegEx
- `[regex_macros]` - custom RegEx definitions used in the `commands_regex` section

Consider the following example configuration file:

```
[server]
socket=/tmp/dpe.sock

[commands]
hostname
cat /etc/os-release

[commands_regex]
crictl inspect $HEXA       # resolved as "crictl inspect [a-f0-9]+"
lspci $BDF                 # resolved as "lspci ([0-9a-f]{4}\:|)[0-9a-f]{2}\:[0-9a-f]{2}\.[0-9a-f]"

[regex_macros]
HEXA=[a-f0-9]+
BDF=([0-9a-f]{4}\:|)[0-9a-f]{2}\:[0-9a-f]{2}\.[0-9a-f]
```

> ⚠ DPE is shipped with a preconfigured file that matches the commands used by the standalone DTS version included in the same DOCA installation. The file is located in `/opt/mellanox/doca/services/telemetry/dpe/etc/dpe_config.ini`.

Using a DPE configuration file allows for a fine-grained control over the interface exposed by it to the rest of the DOCA services. However, even when using the pre-supplied configuration file mentioned above, one should remember that it has been configured to match a fixed DTS version. That is, replacing the standalone DTS version with a new one downloaded from NGC means that the used configuration file might not cover additional features added in the new DTS version.

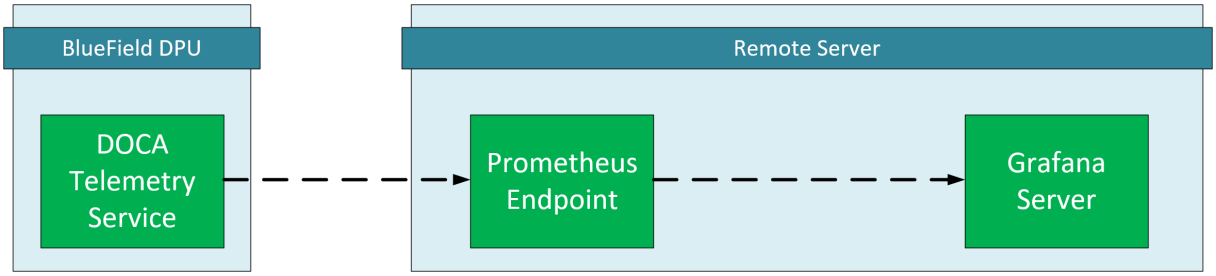
8.12.8 Deploying with Grafana Monitoring

This chapter provides an overview and deployment configuration of DOCA Telemetry Service with Grafana.

8.12.8.1 Grafana Deployment Prerequisites

- BlueField DPU running DOCA Telemetry Service.
- Optional remote server to host Grafana and Prometheus.
- Prometheus installed on the host machine. Please refer to the Prometheus website for more information.
- Grafana installed on the host machine. Please refer to Grafana Labs website for more information.

8.12.8.2 Grafana Deployment Configuration



8.12.8.2.1 DTS Configuration (DPU Side)

Configuring DTS to export the sysfs counter using the Prometheus plugin:

Sysfs is used as an example, other counters are available.

1. Make sure the sysfs counter is enabled.

```
vim /opt/mellanox/doca/services/telemetry/config/dts_config.ini
enable-provider=sysfs
```

2. Enable Prometheus exporter by setting the `prometheus` address and port.

```
vim /opt/mellanox/doca/services/telemetry/config/dts_config.ini
prometheus=http://0.0.0.0:9100
```

> In this example, the Prometheus plugin exports data on localhost port 9100, this is an arbitrary value and can changed.

> DTS must be restarted to apply changes.

8.12.8.2.2 Prometheus Configuration (Remote Server)

Please download Prometheus for your platform.

Prometheus is configured via command-line flags and a configuration file, `prometheus.yml`.

1. Open the `prometheus.yml` file and configure the DPU as the endpoint target.

```
vim prometheus.yml
# metrics_path defaults to '/metrics'
# scheme defaults to 'http'.

static_configs:
- targets: ["<dpu-ip>:<prometheus-port>"]
```

Where:

- `<dpu-ip>` is the DPU IP address. Prometheus reaches to this IP to pull data.
- `<prometheus-port>` the exporter port that set in DTS configuration.

2. Run Prometheus server:

```
./prometheus --config.file="prometheus.yml"
```

> Prometheus services are available as Docker images. Please refer to Using Docker in Prometheus' Installation guide.

8.12.8.2.3 Grafana Configuration (Remote Server)

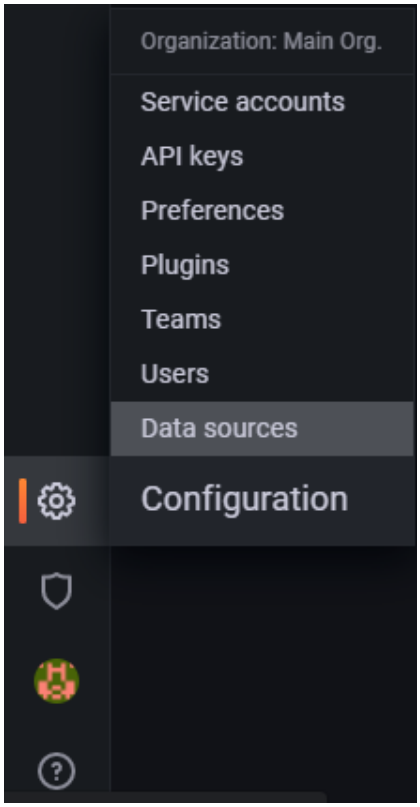
Please download and install Grafana for your platform.

1. Setup Grafana. Please refer to Install Grafana guide in Grafana documentation.

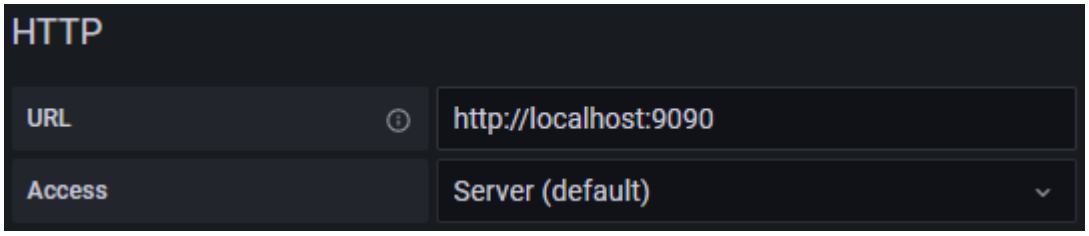
2. Log into the Grafana dashboard at http://localhost:3000.

> ⚠ Port 3000 is the default port number set by Grafana. This can be changed if needed. The default credentials are admin/admin.

3. Add Prometheus as data source by navigating to Settings → Data sources → Add data source → Prometheus.



4. Configure the Prometheus data source. Under the HTTP section, set the Prometheus server address.



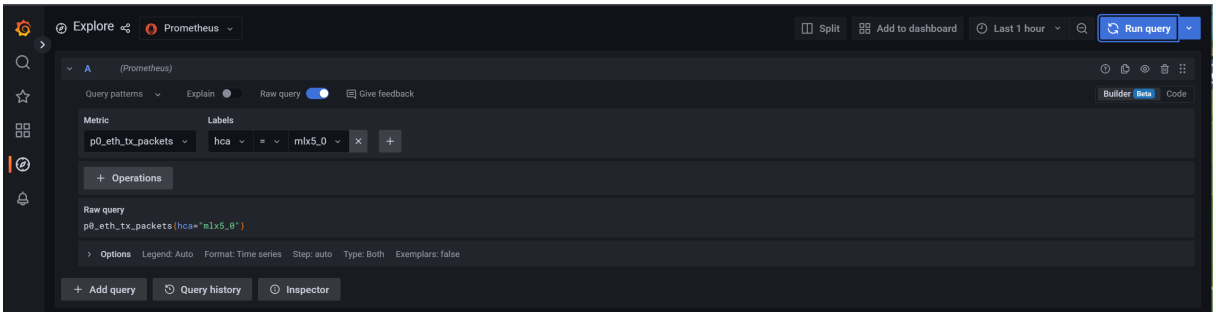
> ⚠ The Prometheus server's default listen port is 9090. Prometheus and Grafana are both running on the same server, thus the address is localhost.

5. Save and test.

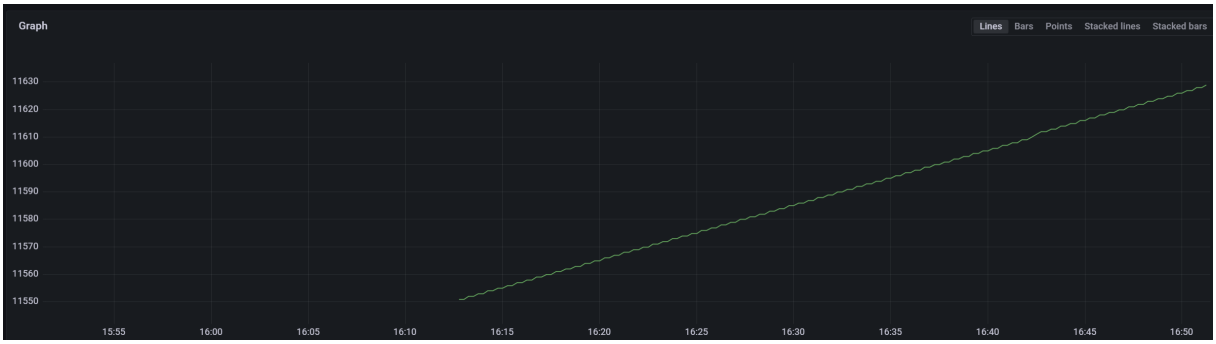
8.12.8.3 Exploring Telemetry Data

Go to the Explore page on the left-hand side, and choose a Prometheus provider.

Choose a metric to display and specify a label. The label can be used to filter out data based on the source and HCA devices.



Graph display after selecting a metric and specifying a label to filter by:



8.12.9 Troubleshooting

On top of the Troubleshooting section in the NVIDIA DOCA Container Deployment Guide, here are additional troubleshooting tips for DTS:

- For general troubleshooting, refer to the DOCA Troubleshooting.
- If the pod's state fails to be marked as "Ready", refer to `/var/log/syslog`.
- Check if the service is configured to write data to the disk as this may cause the system to run out of disk space.
- If a PIC bus error occurs, configure the following files inside the container:

```
crictl exec -it <container-id> /bin/bash
# Add to /config/clx.env the following line:
"
export UCX_TLS=tcp
"
```

- If a wrong hostname is set in the `source` / `source_id` label of DTS exports, this may indicate that the container is not running on the host network. In such cases,

usually the hostname is based on the container name `doca-telemetry`. To fix this, update the docker command/YAML file accordingly.

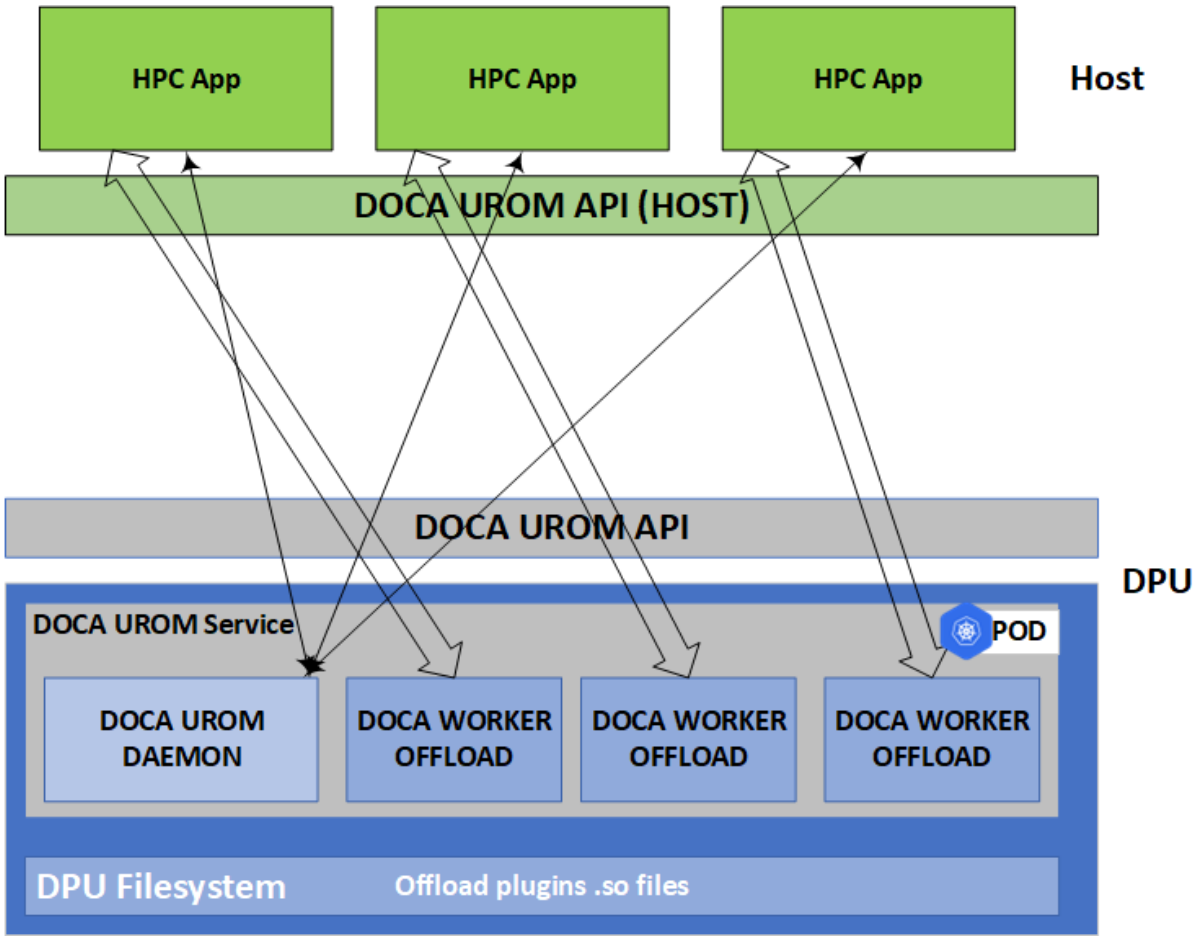
8.13 DOCA UROM Service Guide

This guide provides instructions on how to use the DOCA UROM Service on top of the NVIDIA® BlueField® networking platform.

8.13.1 Introduction

The DOCA UROM service provides a framework for offloading significant portions of HPC software stack directly from the host and to the BlueField device.

Using a daemon, the service handles the discovery of resources, the coordination between the host and BlueField, and the spawning, management, and teardown of the BlueField workers themselves.



The first step in initiating an offload request involves the UROM host application establishing a connection with the UROM service. Upon receiving the plugin discovery command, the UROM service responds by providing the application with a list of plugins available on the BlueField. The application then attaches the plugin IDs that correspond to the desired workers to their network identifiers. Finally, the service triggers UROM worker plugin instances on the BlueField to execute the parallel computing tasks. Within the service's Kubernetes pod, workers are spawned by the daemon in response to these offload requests. Each computation can utilize either a single library or multiple computational libraries.

8.13.2 Requirements

Before deploying the UROM service container, ensure that the following prerequisites are satisfied:

- Allocate huge pages as needed by DOCA:

```
$ echo '2048' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

8.13.3 Service Deployment

For information about the deployment of DOCA containers on top of the BlueField, refer to the NVIDIA BlueField Container Deployment Guide.

Service-specific configuration steps and deployment instructions can be found under the service's container page.

8.13.4 Description

8.13.4.1 Plugin Discovery and Reporting

When the application initiates a connection request to the DOCA UROM Service, the daemon reads the `UROM_PLUGIN_PATH` environment variable. This variable stores directory paths to `.so` files for the plugins with multiple paths separated by semicolons. The daemon scans these paths sequentially and tries loading each `.so` file. Once the daemon finishes the scan, it reports the available BlueField plugins to the host application.

The host application gets the list of available plugins as a list of `doca_urom_service_plugin_info` structures:

```
struct doca_urom_service_plugin_info {
    uint64_t id;         // Unique ID to send commands to the plugin
    uint64_t version;    // Plugin version
    char plugin_name[DOCA_UROM_PLUGIN_NAME_MAX_LEN]; // .so filename
};
```

The UROM daemon is responsible for generating unique identifiers for the plugins, which are necessary to enable the worker to distinguish between different plugin tasks.

8.13.4.2 Loading Plugin in Worker

During the spawning of UROM workers by the UROM daemon, the daemon attaches a list of desired plugins in the worker command line. Each plugin is passed in a format of `so_path:id`.

As part of worker bootstrapping, the flow iterates all `.so` files and tries to load them by using `dlopen` system call and look for `urom_plugin_get_iface()` symbol to get the plugin operations interface.

8.13.4.3 Yaml File

The `.yaml` file downloaded from NGC can be easily edited according to users' needs:

```
 env:
      # Service-Specific command line arguments
      - name: SERVICE_ARGS
        value: "-l 60 -m 4096"
      - name: UROM_PLUGIN_PATH
        value: "/opt/mellanox/doca/samples/doca_urom/plugins/worker_sandbox/;/opt/mellanox/doca/samples/doca_urom/
plugins/worker_graph/"
```

- The `SERVICE_ARGS` are the runtime arguments received by the service:
  - `-l`, `--log-level <value>` – sets the (numeric) log level for the program `<10=DISABLE, 20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>`
  - `--sdk-log-level` – sets the SDK (numeric) log level for the program `<10=DISABLE, 20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>`
  - `-m`, `--max-msg-size` – specify UROM communication channel maximum message size
- The `UROM_PLUGIN_PATH` is an env variable that stores directory paths to `.so` files for the plugins

For each plugin on the BlueField, it is necessary to add a volume mount inside the service container. For example:

```
volumes:
  - name: urom-sandbox-plugin
    hostPath:
```

```
      path: /opt/mellanox/doca/samples/doca_urom/plugins/worker_sandbox
      type: DirectoryOrCreate
...
volumeMounts:
    - mountPath: /opt/mellanox/doca/samples/doca_urom/plugins/worker_sandbox
      name: urom-sandbox-plugin
```

8.13.5 Troubleshooting

When troubleshooting a container deployment issues, it is highly recommended to follow the deployment steps and tips found in the "Review Container Deployment" section of the DOCA Container Deployment Guide.

One could also check the `/var/log/doca/urom` log files for more details about the running cycles of service components (daemon and workers).

The log file name for workers is `urom_worker_<pid>_dev.log` and for the daemon it is `urom_daemon_dev.log`.

8.13.5.1 Pod is Marked as "Ready" and No Container is Listed

8.13.5.1.1 Error

When deploying the container, the pod's STATE is marked as `Ready` and an image is listed, however, no container can be seen running:

```
$ sudo crictl pods
POD ID              CREATED             STATE               NAME
NAMESPACE           ATTEMPT             RUNTIME
3162b71e67677       4 seconds ago       Ready               doca-urom-my-dpu                                  default
0                   (default)

$ sudo crictl images
IMAGE                                 TAG                 IMAGE ID            SIZE
k8s.gcr.io/pause                      3.2                 2a060e2e7101d       487kB
nvcr.io/nvidia/doca/doca_urom         1.0.0-doca2.7.0     2af1e539eb7ab       86.8MB

$ sudo crictl ps
CONTAINER           IMAGE               CREATED             STATE               NAME                ATTEMPT
POD ID              POD
```

8.13.5.1.2 Solution

In most cases, the container did start but immediately exited. This could be checked using the following command:

```
$ sudo crictl ps -a
CONTAINER           IMAGE               CREATED             STATE               NAME                ATTEMPT
POD ID              POD
556bb78281e1d       2af1e539eb7ab       6 seconds ago       Exited              doca-urom           1
          3162b71e67677       doca-urom-my-dpu
```

Should the container fail (i.e., reporting a state of `Exited`), it is recommended to examine the UROM's main log at `/var/log/doca/urom/urom_daemon_dev.log`.

In addition, for a short period of time after termination, the container logs could also be viewed using the container's ID:

```
$ sudo crictl logs 556bb78281e1d
...
```

8.13.5.2 Pod is Not Listed

8.13.5.2.1 Error

When placing the container's YAML file in the Kubelet's input folder, the service pod is not listed in the list of pods:

```
$ sudo crictl pods
POD ID              CREATED             STATE               NAME
NAMESPACE           ATTEMPT             RUNTIME
```

8.13.5.2.2 Solution

In most cases, the pod has not started because of the absence of the requested hugepages. This can be verified using the following command:

```
$ sudo journalctl -u kubelet -e. . .
Oct 04 12:12:19 <my-dpu> kubelet[2442376]: I1004 12:12:19.905064 2442376 predicate.go:103] "Failed to admit pod,
unexpected error while attempting to recover from admission failure" pod="default/doca-urom-service-<my-dpu>"
 err="preemption: error finding a set of pods to preempt: no set of running pods found to reclaim resources: [(res:
hugepages-2Mi, q: 104563999874), ]"
```

8.14 DOCA Virtio-net Service Guide

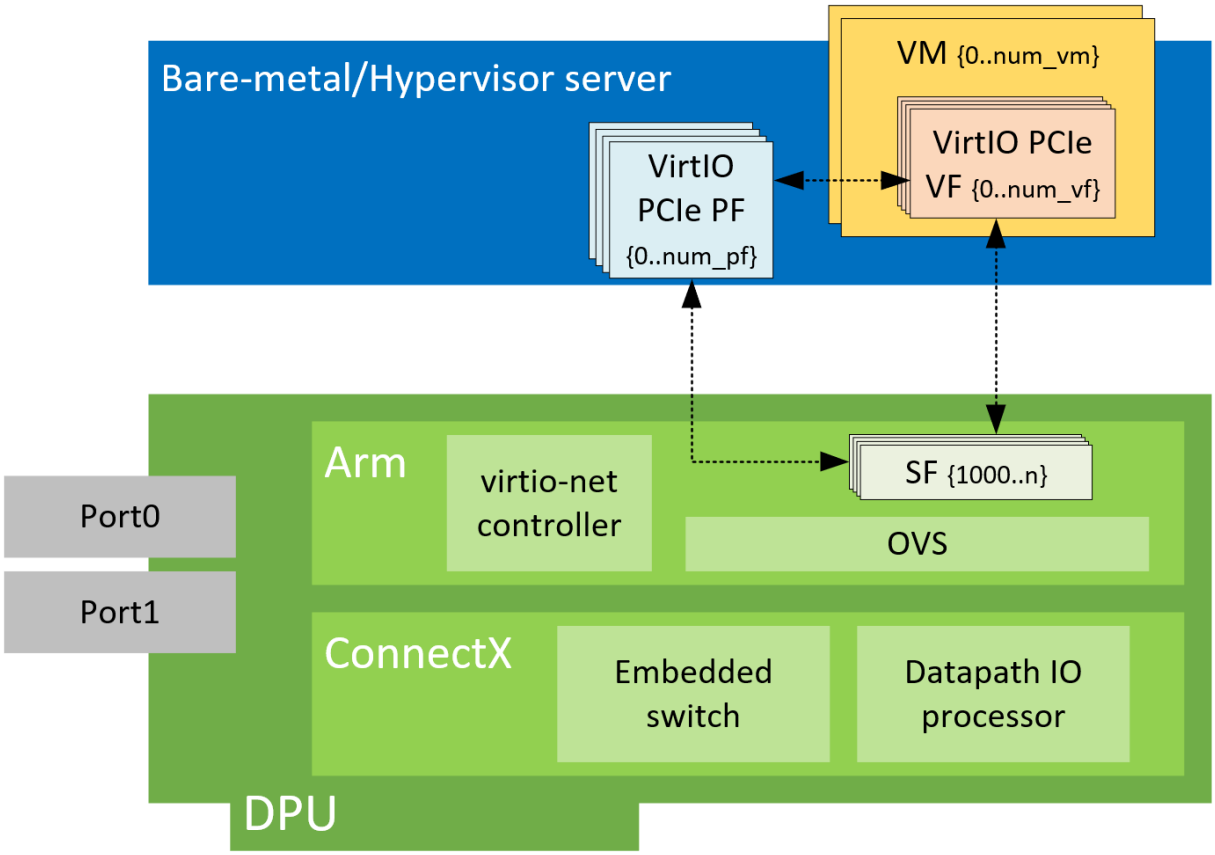
This guide provides instructions on how to use the DOCA virtio-net service container on top of NVIDIA® BlueField®-3 networking platform.

8.14.1 Introduction

NVIDIA® BlueField® virtio-net enables users to create virtio-net PCIe devices in the system where the BlueField is connected. In a traditional virtualization environment, virtio-net devices can be emulated by QEMU from the hypervisor, or offloading part of the work (e.g., dataplane) to the NIC (e.g., vDPA). Compared to those solutions, virtio-net

PCIe devices offload both data and control plane to the BlueField networking device. The PCIe virtio-net devices exposed to the hypervisor do not depend on QEMU or other software emulators/vendor drivers from the guest OS.

The solution is based on BlueField family technology on top of virtual switch and OVS, so that virtio-net devices can benefit from the full SDN and hardware offload methodologies.

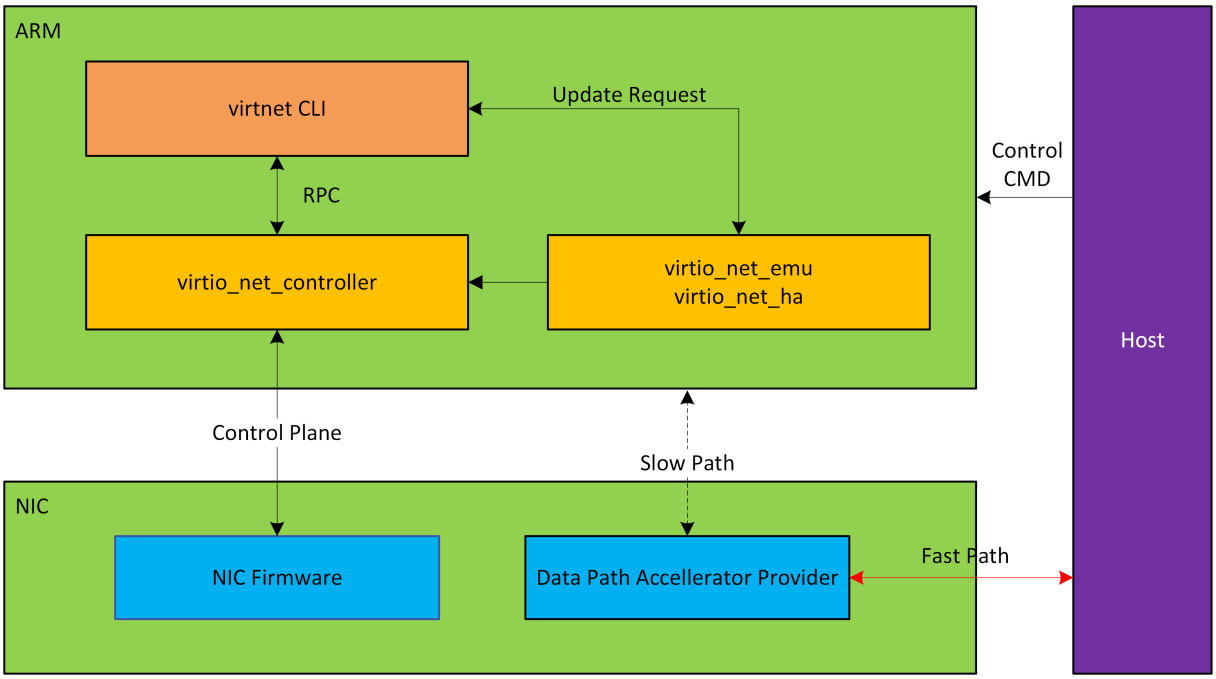


8.14.2 Virtio-net Controller SystemD Service

Virtio-net-controller is a `systemd` service which runs the BlueField with a command-line interface (CLI) frontend to communicate with the service running in the background. The controller `systemd` service is enabled by default and runs automatically after certain firmware configurations are deployed.

> Refer to "Virtio-net Deployment" for more information.

The processes `virtio_net_emu` and `virtio_net_ha` are created to manage live update and high availability.



8.14.3 Virtio-net Deployment

8.14.3.1 Updating OS Image on BlueField

To install the BFB bundle on the NVIDIA® BlueField®, run the following command from the Linux hypervisor:

```
[host]# sudo bfb-install --rshim <rshimN> --bfb <image_path.bfb>
```

For more information, refer to section "Deploying BlueField Software Using BFB from Host" in the *NVIDIA BlueField DPU BSP* documentation.

8.14.3.2 Updating NIC Firmware

From the BlueField networking platform, run:

```
[dpu]# sudo /opt/mellanox/mlnx-fw-updater/mlnx_fw_updater.pl --force-fw-update
```

For more information, refer to section "Upgrading Firmware" in the *NVIDIA DOCA Installation Guide for Linux*.

8.14.3.3 Configuring NIC Firmware

As default, DPU should be configured in DPU mode. A simple way to confirm DPU is running at DPU mode is to log into the BlueField Arm system and check if `p0` and `pf0hpf` both exists by running command below.

```
[dpu]# ip link show
```

Virtio-net full emulation only works in DPU mode. For more information about DPU mode configuration, please refer to BlueField Modes of Operation.

Before enabling the virtio-net service, configure firmware via `mlxconfig` tool is required. There are examples on typical configurations, the table listed relevant `mlxconfig` entry descriptions.

> ⚠ For `mlxconfig` configuration changes to take effect, perform a BlueField system-level reset.

Mlxconfig Entries	Description
`VIRTIO_NET_EMULATION_ENABLE`	Must be set to `TRUE`, for virtio-net to be enabled
`VIRTIO_NET_EMULATION_NUM_PF`	Total number of PCIe functions (PFs) exposed by the device for virtio-net emulation. Those functions are persistent along with host/BlueField power cycle.
`VIRTIO_NET_EMULATION_NUM_VF`	The max number of virtual functions (VFs) that can be supported for each virtio-net PF
`VIRTIO_NET_EMULATION_NUM_MSIX`	Number of MSI-X vectors assigned for each PF of the virtio-net emulation device, minimal is `4`.
`VIRTIO_NET_EMULATION_NUM_VF_MSIX`	Number of MSI-X vectors assigned for each VF of the virtio-net emulation device, minimal is `4`. Relevant for BlueField-3 devices only.
`PCI_SWITCH_EMULATION_ENABLE`	When `TRUE`, the device exposes a PCIe switch. All PF configurations are applied on the switch downstream ports. In such case, each PF gets a different PCIe device on the emulated switch. This configuration allows exposing extra network PFs toward the host which can be enabled for virtio-net hot-plug devices.

Mlxconfig Entries	Description
`PCI_SWITCH_EMULATION_NUM_PORT`	The maximum number of emulated switch ports. Each port can hold a single PCIe device (emulated or not). This determines the supported maximum number of hot-plug virtio-net devices. The maximum number depends on hypervisor PCIe resource and cannot exceed 31. ⚠ Check system PCIe resource. Changing this entry to a big number may result in the host not booting up, which would necessitate disabling the BlueField device and clearing the host NVRAM.
`PER_PF_NUM_SF`	When `TRUE`, the SFs configuration is defined by `TOTAL_SF` and `SF_BAR_SIZE` for each PF individually. If they are not defined for a PF, device defaults are used.
`PF_TOTAL_SF`	The total number of scalable function (SF) partitions that can be supported for the current PF. Valid only when `PER_PF_NUM_SF` is set to `TRUE`. This number should be greater than the total number of virtio-net PFs (both static and hotplug) and VFs. ⚠ This entry differs between the BlueField and host side `mlxconfig`. It is also a system wide value, which is shared by virtio-net and other users. The DPU normally creates 1 SF as default per port. Consider this default SF into account when reserving the `PF_TOTAL_SF`.
`PF_SF_BAR_SIZE`	Log (base 2) of the BAR size of a single SF, given in KB. Valid only when `PF_TOTAL_SF` is non-zero and `PER_PF_NUM_SF` is set to `TRUE`.
`PF_BAR2_ENABLE`	When `TRUE`, BAR2 is exposed on all external host PFs (but not on the embedded Arm PFs/ECPFs). The BAR2 size is defined by the `log_pf_bar2_size`.
`SRIOV_EN`	Enable single-root I/O virtualization (SR-IOV) for virtio-net and native PFs
`EXP_ROM_VIRTIO_NET_PXE_ENABLE`	Enable expansion ROM option for PXE for virtio-net functions ⚠ All virtio `EXP_ROM` options should be configured from host side other than the BlueField platform's side, only static PF is supported.
`EXP_ROM_VIRTIO_NET_UEFI_ARM_ENABLE`	Enable expansion ROM option for UEFI for Arm based host for virtio-net functions
`EXP_ROM_VIRTIO_NET_UEFI_x86_ENABLE`	Enable expansion ROM option for UEFI for x86 based host for virtio-net functions

The maximum number of supported devices is listed below. It does not apply when there are hot-plug and VF created at the same time.

Static PF	Hot-plug PF	VF
31	31	1008

The maximum supported number of hotplug PFs depends on the host PCI resource, it may support less or none on specific systems. Refer to host BIOS specification.

8.14.3.3.1 Static PF

Static PF is defined as virtio-net PFs which are persistent even after DPU or host power cycle. It also supports creating SR-IOV VFs.

The following is an example for enabling the system with 4 static PFs (`VIRTIO_NET_EMULATION_NUM_PF`) only:

10 SFs (`PF_TOTAL_SF`) are reserved to take into account other application using the SFs.

```
[dpu]# mlxconfig -d 03:00.0 s \
VIRTIO_NET_EMULATION_ENABLE=1 \
VIRTIO_NET_EMULATION_NUM_PF=4 \
VIRTIO_NET_EMULATION_NUM_VF=0 \
VIRTIO_NET_EMULATION_NUM_MSIX=64 \
PCI_SWITCH_EMULATION_ENABLE=0 \
PCI_SWITCH_EMULATION_NUM_PORT=0 \
PER_PF_NUM_SF=1 \
PF_TOTAL_SF=64 \
PF_BAR2_ENABLE=0 \
PF_SF_BAR_SIZE=8 \
SRIOV_EN=0
```

8.14.3.3.2 Hotplug PF

Hotplug PF is defined as virtio-net PFs which can be hotplugged or unplugged dynamically after the system comes up.

Hotplug PF does not support creating SR-IOV VFs.

The following is an example for enabling 16 hotplug PFs (`PCI_SWITCH_EMULATION_NUM_PORT`):

```
[dpu]# mlxconfig -d 03:00.0 s \
VIRTIO_NET_EMULATION_ENABLE=1 \
VIRTIO_NET_EMULATION_NUM_PF=0 \
VIRTIO_NET_EMULATION_NUM_VF=0 \
VIRTIO_NET_EMULATION_NUM_MSIX=64 \
PCI_SWITCH_EMULATION_ENABLE=1 \
PCI_SWITCH_EMULATION_NUM_PORT=16 \
PER_PF_NUM_SF=1 \
PF_TOTAL_SF=64 \
PF_BAR2_ENABLE=0 \
PF_SF_BAR_SIZE=8 \
SRIOV_EN=0
```

8.14.3.3.3 SR-IOV VF

SR-IOV VF is defined as virtio-net VFs created on top of PFs. Each VF gets an individual virtio-net PCIe devices.

> ⚠ VFs cannot be dynamically created or destroyed, they can only change from X to 0, or from 0 to X.

> ⚠ VFs will be destroyed when reboot host or unbind PF from virtio-net kernel driver.

The following is an example for enabling 126 VFs per static PF—504 (4 PF x 126) VFs in total:

```
[dpu]# mlxconfig -d 03:00.0 s \
VIRTIO_NET_EMULATION_ENABLE=1 \
VIRTIO_NET_EMULATION_NUM_PF=4 \
VIRTIO_NET_EMULATION_NUM_VF=126 \
VIRTIO_NET_EMULATION_NUM_MSIX=64 \
VIRTIO_NET_EMULATION_NUM_VF_MSIX=6 \
PCI_SWITCH_EMULATION_ENABLE=0 \
PCI_SWITCH_EMULATION_NUM_PORT=0 \
PER_PF_NUM_SF=1 \
PF_TOTAL_SF=512 \
PF_BAR2_ENABLE=0 \
PF_SF_BAR_SIZE=8 \
NUM_VF_MSIX=0 \
SRIOV_EN=1
```

8.14.3.3.4 PF/VF Combinations

Creating static/hotplug PFs and VFs at the same time is supported.

The total sum of PCIe functions to the external host must not exceed 1008. For example:

- If there are 2 PFs with no VFs (`NUM_OF_VFS=0`) and there is 1 RShim, then the remaining static functions is 1005 (1008-3).
- If 1 virtio-net PF is configured (`VIRTIO_NET_EMULATION_NUM_PF=1)` , then up to 1004 virtio-net VFs can be configured (`VIRTIO_NET_EMULATION_NUM_VF=1004`)
- If 2 virtio-net PF (`VIRTIO_NET_EMULATION_NUM_PF=2`), then up to 502 virtio-net VFs can be configured (`VIRTIO_NET_EMULATION_NUM_VF=502`)

The following is an example for enabling 15 hotplug PFs, 2 static PFs, and 200 VFs (2 PFs x 100):

```
[dpu]# mlxconfig -d 03:00.0 s \
VIRTIO_NET_EMULATION_ENABLE=1 \
VIRTIO_NET_EMULATION_NUM_PF=2 \
VIRTIO_NET_EMULATION_NUM_VF=100 \
VIRTIO_NET_EMULATION_NUM_MSIX=10 \
VIRTIO_NET_EMULATION_NUM_VF_MSIX=6 \
PCI_SWITCH_EMULATION_ENABLE=1 \
PCI_SWITCH_EMULATION_NUM_PORT=15 \
PER_PF_NUM_SF=1 \
PF_TOTAL_SF=256 \
```

```
PF_BAR2_ENABLE=0 \
PF_SF_BAR_SIZE=8 \
NUM_VF_MSIX=0 \
SRIOV_EN=1
```

In hotplug virtio-net PFs and virtio-net SR-IOV VFs setups, only up to 15 hotplug devices are supported.

8.14.3.4 System Configuration

8.14.3.4.1 Host System Configuration

For hotplug device configuration, it is recommended to modify the hypervisor OS kernel boot parameters and add the options below:

```
pci=realloc
```

For SR-IOV configuration, first enable SR-IOV from the host.

Refer to MLNX_OFED documentation under Features Overview and Configuration > Virtualization > Single Root IO Virtualization (SR-IOV) > Setting Up SR-IOV for instructions on how to do that.

Make sure to add the following options to Linux boot parameter.

```
intel_iommu=on iommu=pt
```

Add `pci=assign-busses` to the boot command line when creating more than 127 VFs. Without this option, the following errors may trigger from the host and the virtio driver would not probe those devices.

```
pci 0000:84:00.0: [1af4:1041] type 7f class 0xffffff
pci 0000:84:00.0: unknown header type 7f, ignoring device
```

Because the controller from the BlueField side provides hardware resources and acknowledges (ACKs) the request from the host's virtio-net driver, it is mandatory to reboot the host OS (or unload the virtio-net driver) first and the BlueField afterwards. This also applies to reconfiguring a controller from the BlueField platform (e.g., reconfiguring LAG). Unloading the virtio-net driver from host OS side is recommended.

8.14.3.4.2 BlueField System Configuration

Virtio-net full emulation is based on ASAP^2. For each virtio-net device created from host side, there is an SF representor created to represent the device from the BlueField side. It is necessary to have the SF representor in the same OVS bridge of the uplink representor.

The SF representor name is designed in a fixed pattern to map different type of devices.

	Static PF	Hotplug PF	SR-IOV VF
SF Range	1000-1999	2000-2999	3000 and above

For example, the first static PF gets the SF representor of `en3f0pf0sf1000` and the second hotplug PF gets the SF representor of `en3f0pf0sf2001`. It is recommended to verify the name of the SF representor from the `sf_rep_net_device` field in the output of `virtnet list`.

```
[dpu]# virtnet list
{
  ...
  "devices": [
    {
      "pf_id": 0,
      "function_type": "static PF",
      "transitional": 0,
      "vuid": "MT2151X03152VNETS0D0F2",
      "pci_bdf": "14:00.2",
      "pci_vhca_id": "0x2",
      "pci_max_vfs": "0",
      "enabled_vfs": "0",
      "msix_num_pool_size": 0,
      "min_msix_num": 0,
      "max_msix_num": 32,
      "min_num_of_qp": 0,
      "max_num_of_qp": 15,
      "qp_pool_size": 0,
      "num_msix": "64",
      "num_queues": "8",
      "enabled_queues": "7",
      "max_queue_size": "256",
      "msix_config_vector": "0x0",
      "mac": "D6:67:E7:09:47:D5",
      "link_status": "1",
      "max_queue_pairs": "3",
      "mtu": "1500",
      "speed": "25000",
      "rss_max_key_size": "0",
      "supported_hash_types": "0x0",
      "ctrl_mac": "D6:67:E7:09:47:D5",
      "ctrl_mq": "3",
      "sf_num": 1000,
      "sf_parent_device": "mlx5_0",
      "sf_parent_device_pci_addr": "0000:03:00.0",
      "sf_rep_net_device": "en3f0pf0sf1000",
      "sf_rep_net_ifindex": 15,
      "sf_rdma_device": "mlx5_4",
      "sf_cross_mkey": "0x18A42",
      "sf_vhca_id": "0x8C",
      "sf_rqt_num": "0x0",
      "aarfs": "disabled",
      "dim": "disabled"
    }
  ]
 }
```

Once SF representor name is located, add it to the same OVS bridge of the corresponding uplink representor and make sure the SF representor is up:

```
[dpu]# ovs-vsctl show
f2c431e5-f8df-4f37-95ce-aa0c7da738e0
    Bridge ovsbr1
        Port ovsbr1
            Interface ovsbr1
                type: internal
```

```
        Port en3f0pf0sf0
            Interface en3f0pf0sf0
        Port p0
            Interface p0
[dpu]# ovs-vsctl add-port ovsbr1 en3f0pf0sf1000
[dpu]# ovs-vsctl show
f2c431e5-f8df-4f37-95ce-aa0c7da738e0
    Bridge ovsbr1
        Port ovsbr1
            Interface ovsbr1
                type: internal
        Port en3f0pf0sf0
            Interface en3f0pf0sf0
        Port en3f0pf0sf1000
            Interface en3f0pf0sf1000
        Port p0
            Interface p0
[dpu]# ip link set dev en3f0pf0sf1000 up
```

8.14.3.5 Usage

After firmware/system configuration and after system power cycle, the virtio-net devices should be ready to deploy.

First, make sure that `mlxconfig` options take effect correctly by issuing the following command:

> The output has a list with 3 columns: `default` configuration, `current` configuration, and `next-boot` configuration. Verify that the values under the 2nd column match the expected configuration.

```
[dpu]# mlxconfig -d 03:00.0 -e q | grep -i \*
*        PER_PF_NUM_SF                           False(0)        True(1)         True(1)
*        NUM_OF_VFS                              16              0               0
*        PF_BAR2_ENABLE                          True(1)         False(0)        False(0)
*        PCI_SWITCH_EMULATION_NUM_PORT           0               8               8
*        PCI_SWITCH_EMULATION_ENABLE             False(0)        True(1)         True(1)
*        VIRTIO_NET_EMULATION_ENABLE             False(0)        True(1)         True(1)
*        VIRTIO_NET_EMULATION_NUM_VF             0               126             126
*        VIRTIO_NET_EMULATION_NUM_PF             0               1               1
*        VIRTIO_NET_EMULATION_NUM_MSIX           2               64              64
*        VIRTIO_NET_EMULATION_NUM_VF_MSIX        0               64              64
*        PF_TOTAL_SF                             0               508             508
*        PF_SF_BAR_SIZE                          0               8               8
```

If the system is configured correctly, virtio-net-controller service should be up and running. If the service does not appear as active, double check the firmware/system configurations above.

```
[dpu]# systemctl status virtio-net-controller.service
● virtio-net-controller.service - Nvidia VirtIO Net Controller Daemon
   Loaded: loaded (/etc/systemd/system/virtio-net-controller.service; enabled; vendor preset: disabled)
   Active: active (running)
     Docs: file:/opt/mellanox/mlnx_virtnet/README.md
 Main PID: 30715 (virtio_net_cont)
    Tasks: 55
   Memory: 11.7M
   CGroup: /system.slice/virtio-net-controller.service
           30715 /usr/sbin/virtio_net_controller
           30859 virtio_net_emu
           30860 virtio_net_ha
```

To reload or restart the service, run:

```
[dpu]# systemctl restart virtio-net-controller.service
```

When using "force kill" (i.e., `kill -9` or `kill -SIGKILL`) for the virtio-net-controller service, users should use `kill -9 -<pid of virtio_net_controller process, i.e. 30715 in previous example>` (note the dash "`-`" before the `pid`).

8.14.3.5.1 Hotplug PF Devices

8.14.3.5.1.1 Creating PF Devices

1. To create a hotplug virtio-net device, run:

```
[dpu]# virtnet hotplug -i mlx5_0 -f 0x0 -m 0C:C4:7A:FF:22:93 -t 1500 -n 3 -s 1024
```

> Refer to "Virtnet CLI Commands" for full usage.

This command creates one hotplug virtio-net device with MAC address `0C:C4:7A:FF:22:93`, MTU 1500, and 3 virtio queues with a depth of 1024 entries. The device is created on the physical port of `mlx5_0`. The device is uniquely identified by its index. This index is used to query and update device attributes. If the device is created successfully, an output similar to the following appears:

```
{
  "bdf": "15:00.0",
  "vuid": "MT2151X03152VNETS1D0F0",
  "id": 0,
  "transitional": 0,
  "sf_rep_net_device": "en3f0pf0sf2000",
  "mac": "0C:C4:7A:FF:22:93",
  "errno": 0,
  "errstr": "Success"
}
```

2. Add the representor port of the device to the OVS bridge and bring it up. Run:

```
[dpu]# ovs-vsctl add-port <bridge> en3f0pf0sf2000
[dpu]# ip link set dev en3f0pf0sf2000 up
```

Once steps 1-2 are completed, the virtio-net PCIe device should be available from hypervisor OS with the same PCIe BDF.

```
[host]# lspci | grep -i virtio
15:00.0 Ethernet controller: Red Hat, Inc. Virtio network device (rev 01)
```

3. Probe virtio-net driver (e.g., kernel driver):

```
[host]# modprobe -v virtio-pci && modprobe -v virtio-net
```

4. The virtio-net device should be created. There are two ways to locate the net device:
    - Check the dmesg from the host side for the corresponding PCIe BDF:

```
[host]# dmesg | tail -20 | grep 15:00.0 -A 10 | grep virtio_net
[3908051.494493] virtio_net virtio2 ens2f0: renamed from eth0
```

- Check all net devices and find the corresponding MAC address:

```
[host]# ip link show | grep -i "0c:c4:7a:ff:22:93" -B 1
31: ens2f0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP mode DEFAULT group
default qlen 1000
    link/ether 0c:c4:7a:ff:22:93 brd ff:ff:ff:ff:ff:ff
```

5. Check that the probed driver and its BDF match the output of the hotplug device:

```
[host]# ethtool -i ens2f0
driver: virtio_net
version: 1.0.0
firmware-version:
expansion-rom-version:
bus-info: 0000:15:00.0
supports-statistics: yes
supports-test: no
supports-eeprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

Now the hotplug virtio-net device is ready to use as a common network device.

8.14.3.5.1.2 Destroying PF Devices

To hot-unplug a virtio-net device, run:

```
[dpu]# virtnet unplug -p 0
{'id': '0x1'}
{
  "errno": 0,
  "errstr": "Success"
}
```

The hotplug device and its representor are destroyed.

8.14.3.5.1.3 Host-Aware Attention Button Mode (AB Mode)

The Host-Aware Attention Button (AB) mode provides a coordinated mechanism for device removal utilizing the PCIe Attention Button. This mode ensures the host operating system has the opportunity to gracefully shut down the device driver prior to physical or logical removal.

When utilizing AB mode (`-w 3`), the hotplug and unplug lifecycle operates as follows:

1. Hotplug initiation: The device is created with AB mode awareness, a state that persists for the lifetime of the device.
2. Unplug notification: Upon an unplug request, the controller sends an Attention Button notification to the host, signaling a pending device removal.
3. Host acknowledgment: The host OS receives the notification and gracefully shuts down the associated driver.
4. Clean removal: Once the host acknowledges the shutdown, the device is cleanly removed from the system.

Usage Commands

Creating a device with AB mode:

```
[dpu]# virtnet hotplug -i mlx5_0 -f 0x0 -m 0C:C4:7A:FF:22:93 -t 1500 -n 3 -s 1024 -w 3
```

Removing a device with AB mode:

```
[dpu]# virtnet unplug -p 0 -w 3
```

> **Mode Matching**
>
> Devices hotplugged using AB mode (`-w 3`) strictly require the same AB mode flag (`-w 3`) during the unplug operation. Attempting to unplug an AB-mode device without specifying `-w 3` will fail and return a mode mismatch error.

Verification and Querying

Checking AB Mode Support

Run the `virtnet list` command to verify if the underlying controller supports AB mode. Look for the `hp_host_aware_ab_supported` key in the JSON output.

```
{
    "controller": {
        "hp_host_awareness_supported": "1",
        "hp_host_aware_ab_supported": "1"
    }
}
```

Querying Device HP Mode

To verify which hotplug mode a specific device was created with, use the `virtnet query` command. An awareness mode of `3` indicates AB mode.

```
{
    "hp_host_awareness_mode": 3
}
```

Default AB Mode Configuration

To automate AB mode for all hotplug and unplug operations without manually specifying the `-w 3` flag on the CLI, configure the `virtnet.conf` file:

```
force_ab_hotplug_default=1
```

Behavior when enabled:

- Hotplug operations automatically default to AB mode (`-w 3`).
- Unplug operations automatically default to AB mode (`-w 3`).
- Explicit `-w` CLI options will always override this configuration.

- If the underlying Host Channel Adapter (HCA) does not support AB mode, the controller will safely fall back to mode `0`.

8.14.3.5.2 SR-IOV VF Devices

8.14.3.5.2.1 Creating SR-IOV VF Devices

After configuring the firmware and BlueField/host system with correct configuration, users can create SR-IOV VFs.

The following procedure provides an example of creating one VF on top of one static PF:

1. Locate the virtio-net PFs exposed to the host side:

```
[host]# lspci | grep -i virtio
14:00.2 Network controller: Red Hat, Inc. Virtio network device
```

2. Verify that the PCIe BDF matches the backend device from the BlueField side:

```
[dpu]# virtnet list
{
  ...
   "devices": [
    {
      "pf_id": 0,
      "function_type": "static PF",
      "transitional": 0,
      "vuid": "MT2151X03152VNETS0D0F2",
      "pci_bdf": "14:00.2",
      "pci_vhca_id": "0x2",
      "pci_max_vfs": "0",
      "enabled_vfs": "0",
      "msix_num_pool_size": 0,
      "min_msix_num": 0,
      "max_msix_num": 32,
      "min_num_of_qp": 0,
      "max_num_of_qp": 15,
      "qp_pool_size": 0,
      "num_msix": "64",
      "num_queues": "8",
      "enabled_queues": "7",
      "max_queue_size": "256",
      "msix_config_vector": "0x0",
      "mac": "D6:67:E7:09:47:D5",
      "link_status": "1",
      "max_queue_pairs": "3",
      "mtu": "1500",
      "speed": "25000",
      "rss_max_key_size": "0",
      "supported_hash_types": "0x0",
      "ctrl_mac": "D6:67:E7:09:47:D5",
      "ctrl_mq": "3",
      "sf_num": 1000,
      "sf_parent_device": "mlx5_0",
      "sf_parent_device_pci_addr": "0000:03:00.0",
      "sf_rep_net_device": "en3f0pf0sf1000",
      "sf_rep_net_ifindex": 15,
      "sf_rdma_device": "mlx5_4",
      "sf_cross_mkey": "0x18A42",
      "sf_vhca_id": "0x8C",
      "sf_rqt_num": "0x0",
      "aarfs": "disabled",
      "dim": "disabled"
    }
  ]
 }
```

3. Probe `virtio_pci` and `virtio_net` modules from the host:

```
[host]# modprobe -v virtio-pci && modprobe -v virtio-net
```

The PF net device should be created.

```
[host]# ip link show | grep -i "4A:82:E3:2E:96:AB" -B 1
21: ens2f2: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT group default qlen
1000
    link/ether 4a:82:e3:2e:96:ab brd ff:ff:ff:ff:ff:ff
```

The MAC address and PCIe BDF should match between the BlueField side (`virtnet list`) and host side (`ethtool`).

```
[host]# ethtool -i ens2f2
driver: virtio_net
version: 1.0.0
firmware-version:
expansion-rom-version:
bus-info: 0000:14:00.2
supports-statistics: yes
supports-test: no
supports-eeprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

4. To create SR-IOV VF devices on the host, run the following command with the PF PCIe BDF (`0000:14:00.2` in this example):

```
[host]# echo 1 > /sys/bus/pci/drivers/virtio-pci/0000\:14\:00.2/sriov_numvfs
```

1 extra virtio-net device is created from the host:

```
[host]# lspci | grep -i virtio
14:00.2 Ethernet controller: Red Hat, Inc. Virtio network device (rev 01)
14:00.4 Ethernet controller: Red Hat, Inc. Virtio network device (rev 01)
```

The BlueField side shows the VF information from `virtnet list` as well:

```
[dpu]# virtnet list
    ...
    {
      "vf_id": 0,
      "parent_pf_id": 0,
      "function_type": "VF",
      "transitional": 0,
      "vuid": "MT2151X03152VNETS0D0F2VF1",
      "pci_bdf": "14:00.4",
      "pci_vhca_id": "0xD",
      "pci_max_vfs": "0",
      "enabled_vfs": "0",
      "num_msix": "12",
      "num_queues": "8",
      "enabled_queues": "7",
      "max_queue_size": "256",
      "msix_config_vector": "0x0",
      "mac": "16:FF:A2:6E:6D:A9",
      "link_status": "1",
      "max_queue_pairs": "3",
      "mtu": "1500",
      "speed": "25000",
      "rss_max_key_size": "0",
      "supported_hash_types": "0x0",
      "ctrl_mac": "16:FF:A2:6E:6D:A9",
      "ctrl_mq": "3",
      "sf_num": 3000,
      "sf_parent_device": "mlx5_0",
      "sf_parent_device_pci_addr": "0000:03:00.0",
      "sf_rep_net_device": "en3f0pf0sf3000",
      "sf_rep_net_ifindex": 18,
      "sf_rdma_device": "mlx5_5",
      "sf_cross_mkey": "0x58A42",
      "sf_vhca_id": "0x8D",
      "sf_rqt_num": "0x0",
      "aarfs": "disabled",
      "dim": "disabled"
     }
```

5. Add the corresponding SF representor to the OVS bridge as the virtio-net PF and bring it up. Run:

```
[dpu]# ovs-vsctl add-port <bridge> en3f0pf0sf3000
[dpu]# ip link set dev en3f0pf0sf3000 up
```

Now the VF is functional.

SR-IOV enablement from the host side takes a few minutes. For example, it may take 5 minutes to create 504 VFs.

It is recommended to disable VF autoprobe before creating VFs.

```
[host]# echo 0 > /sys/bus/pci/drivers/virtio-pci/<virtio_pf_bdf>/sriov_drivers_autoprobe
[host]# echo <num_vfs> > /sys/bus/pci/drivers/virtio-pci/<virtio_pf_bdf>/sriov_numvfs
```

Users can pass through the VFs directly to the VM after finishing. If using the VFs inside the hypervisor OS is required, bind the VF PCIe BDF:

```
[host]# echo <virtio_vf_bdf> > /sys/bus/pci/drivers/virtio-pci/bind
```

Keep in mind to reenable the autoprobe for other use cases:

```
[host]# echo 1 > /sys/bus/pci/drivers/virtio-pci/<virtio_pf_bdf>/sriov_drivers_autoprobe
```

MAC addresses are randomly generated for the new virtual functions (VFs).

Creating VFs for the same PF on different threads may cause the hypervisor OS to hang.

8.14.3.5.2.2 Destroying SR-IOV VF Devices

To destroy SR-IOV VF devices on the host, run:

```
[host]# echo 0 > /sys/bus/pci/drivers/virtio-pci/<virtio_pf_bdf>/sriov_numvfs
```

When the echo command returns from the host OS, it does not necessarily mean the BlueField side has finished its operations. To verify that the BlueField is done, and it is safe to recreate the VFs, either:

- Check controller log from the BlueField and make sure you see a log entry similar to the following:

```
[dpu]# journalctl -u virtio-net-controller.service -n 3 -f
virtio-net-controller[5602]: [INFO] virtnet.c:675:virtnet_device_vfs_unload: static PF[0], Unload
(1) VFs finished
```

- Query the last VF from the BlueField side:

```
[dpu]# virtnet query -p 0 -v 0 -b
{'all': '0x0', 'vf': '0x0', 'pf': '0x0', 'dbg_stats': '0x0', 'brief': '0x1', 'latency_stats':
'0x0', 'stats_clear': '0x0'}
{
  "Error": "Device doesn't exist"
}
```

⚠ Once VFs are destroyed, SFs created for virtio-net from the BlueField side are not destroyed but are saved into the SF pool for reuse later.

⚠ Restarting virtio-net-controller service while performing device create/destroy for either hotplug or VF is unsupported.

8.14.3.6 Assigning Virtio-net Device to VM

All virtio-net devices (static/hotplug PF and VF) support PCIe passthrough to a VM. PCIe passthrough allows the device to get better performance in the VM.

Assigning a virtio-net device to a VM can be done via `virt-manager` or `virsh command`.

8.14.3.6.1 Locating Virtio-net Devices

All virtio-net devices can be scanned by the PCIe subsystem in hypervisor OS and displayed as a standard PCIe device. Run the following command to locate the virtio-net devices devices with its PCIe BDF.

```
[host]# lspci | grep 'Virtio network'
00:09.1 Ethernet controller: Red Hat, Inc. Virtio network device (rev 01)
```

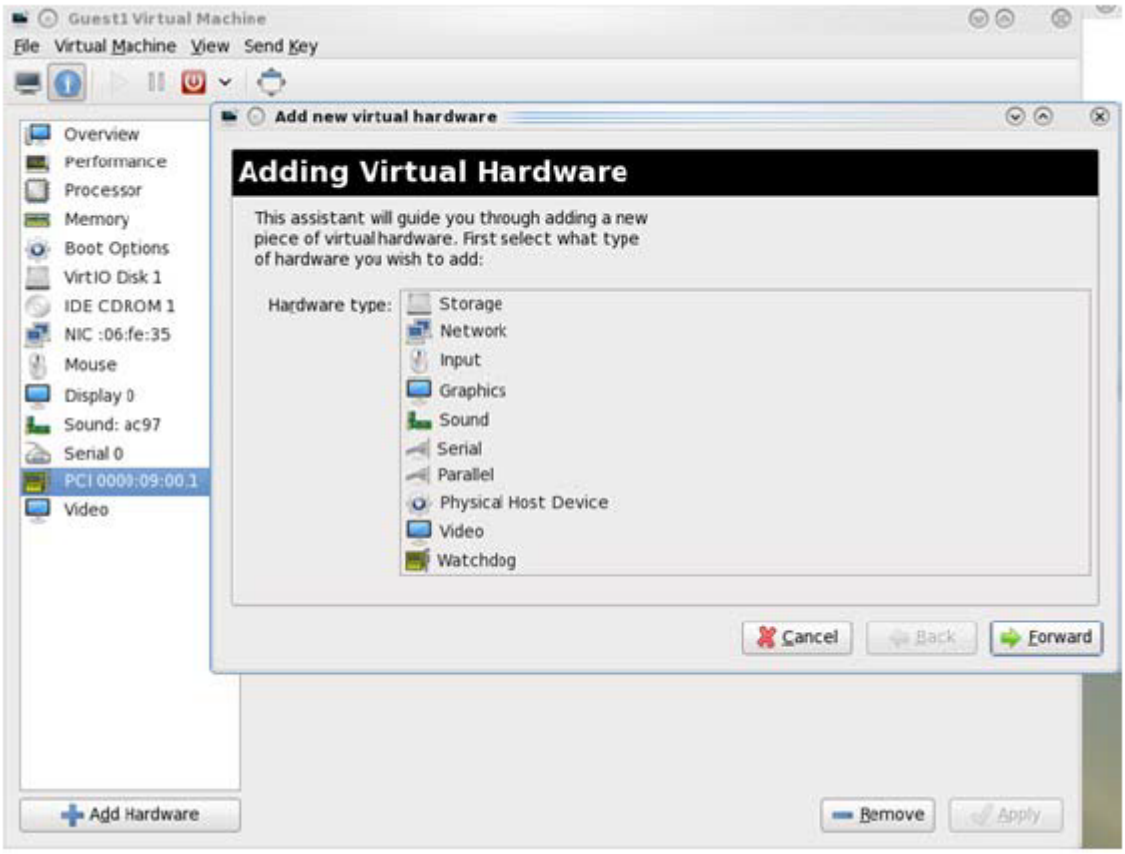
8.14.3.6.2 Using virt-manager

Start `virt-manager`, run the following command:

```
[host]# virt-manager
```

⚠ Make sure your system has xterm enabled to show the virt-manager GUI.

Double-click the virtual machine and open its Properties. Navigate to Details → Add hardware → PCIe host device.



Choose a virtio-net device virtual function according to its PCIe device (e.g., 00:09.1), reboot or start the VM.

8.14.3.6.3 Using virsh Command

1. Run the following command to get the VM list and select the target VM by `Name` field:

```
[host]# virsh list --all
 Id   Name                           State
----------------------------------------------
 1    host-101-CentOS-8.5            running
```

2. Edit the VMs XML file, run:

```
[host]# virsh edit <VM_NAME>
```

3. Assign the target virtio-net device PCIe BDF to the VM, using `vfio` as driver, replace `BUS/SLOT/FUNCTION/BUS_IN_VM/SLOT_IN_VM/FUNCTION_IN_VM` with corresponding settings.

```
<hostdev mode='subsystem' type='pci' managed='no'>
  <driver name='vfio'/>
    <source>
      <address domain='0x0000' bus='<#BUS>' slot='<#SLOT>' function='<#FUNCTION>'/>
    </source>
```

```
  <address type='pci' domain='0x0000' bus='<#BUS_IN_VM>' slot='<#SLOT_IN_VM>' function='<#FUNCTION_IN_VM>'/
>
</hostdev>
```

For example, assign target device `00.09.1` to the VM and its PCIe BDF within the VM is `01:00.0`:

```
<hostdev mode='subsystem' type='pci' managed='no'>
  <driver name='vfio'/>
    <source>
      <address domain='0x0000' bus='0x00' slot='0x09' function='0x1'/>
    </source>
  <address type='pci' domain='0x0000' bus='0x01' slot='0x00' function='0x0'/>
</hostdev>
```

4. Destroy the VM if it is already started:

```
[host]# virsh destory <VM_NAME>
```

5. Start the VM with new XML configuration:

```
[host]# virsh start <VM_NAME>
```

8.14.4 Configuration File

8.14.4.1 Configuration File Options

The controller service has an optional JSON format configuration file which allows users to customize several parameters. The configuration file should be defined on the DPU at `/opt/mellanox/mlnx_virtnet/virtnet.conf`. This file is read every time the controller starts.

⚠ Controller `systemd` service should be restarted when there is configuration file change. Dynamic change of `virtnet.conf` is not supported.

In DOCA 3.3.0, the `mrg_rxbuf` and `packed_vq` parameters will no longer be supported in the `virtnet.conf` configuration file. Configuration of the `mrg_rxbuf` and `packed_vq` features must now be performed using the CLI modify device option.

Parameter	Default Value	Type	Description
`ib_dev_p0`	`mlx5_0`	String	RDMA device (e.g., `mlx5_0`) used to create SF on port 0. This port is the EMU manager when `is_lag` is 0.

<table>
<tr><th>Parameter</th><th>Default Value</th><th>Type</th><th>Description</th></tr>
<tr><td><code>ib_dev_p1</code></td><td><code>mlx5_1</code></td><td>String</td><td>RDMA device (e.g., <code>mlx5_1</code>) used to create SF on port 1</td></tr>
<tr><td><code>ib_dev_for_static_pf</code></td><td><code>mlx5_0</code></td><td>String</td><td>The RDMA device (e.g., <code>mlx5_0</code>) which the static virtio PF is created on</td></tr>
<tr><td><code>ib_dev_lag</code></td><td><code>Null</code></td><td>String</td><td>RDMA LAG device (e.g., <code>mlx5_bond_0</code>) used to create SF on LAG. Default value is <code>mlx5_bond_0</code>. This port is EMU manager when <code>is_lag</code> is 1. <code>ib_dev_lag</code> and <code>ib_dev_p0</code> / <code>ib_dev_p1</code> cannot be configured simultaneously.</td></tr>
<tr><td><code>static_pf</code></td><td><code>N/A</code></td><td>List</td><td>The following sub-parameters can be used to configure the static PF:
<table>
<tr><th>Sub-parameter</th><th>Default Value</th><th>Type</th><th>Description</th></tr>
<tr><td><code>mac_base</code></td><td>Null</td><td>String</td><td>Base MAC address for static PFs. MACs are automatically assigned with the following pattern: <code>mac_base</code> → <code>pf_0</code>, <code>mac_base + 1</code> → <code>pf_1</code>, etc.
⚠ Controller does not validate the MAC address (other than its length). The user must ensure the MAC is valid and unique.
⚠ The virtio driver on the host OS must be unloaded when restarting the controller if the <code>mac_base</code> setting is enabled for the first time or is modified.</td></tr>
<tr><td><code>features</code></td><td>Auto</td><td>Number</td><td>Virtio spec-defined feature bits for static PFs.
⚠ If unsure, leave <code>features</code> out of the JSON file and a default value is automatically assigned. The default value is determined dynamically when controller starts. Refer to section "Feature Bits" for more information.</td></tr>
<tr><td><code>mtu</code></td><td>1500</td><td>Number</td><td>The maximum transmission unit for the PF, can be ≤ 9216</td></tr>
</table></td></tr>
<tr><td><code>is_lag</code></td><td><code>0</code></td><td>Number</td><td>Specifies whether LAG is used
⚠ If LAG is used, make sure to use the correct IB dev for static PF</td></tr>
</table>

Parameter	Default Value	Type	Description
`single_port`	`0`	Number	Specifies whether the DPU is a single port device. It is mutually exclusive with `is_lag`.
`recovery`	`1`	Number	Specifies whether recovery is enabled. If unspecified, recovery is enabled by default. To disable it, set `recovery` to 0. Refer to section "Recovery" for the items which are recovered and more information.
`sf_pool_percent`	`0`	Number	Determines the initial SF pool size as the percentage of `PF_TOTAL_SF` of `mlxconfig`. Valid range: [0, 100]. For instance, if the value is 5, an SF pool with 5% of `PF_TOTAL_SF` is created. 0 indicates that no SF pool is reserved beforehand (default). ⚠ `PF_TOTAL_SF` is shared by all applications. The user must ensure that the percent request is guaranteed, or else the controller would not be able to reserve the requested SFs resulting in failure.
`sf_pool_force_destroy`	`0`	Number	Specifies whether to destroy the SF pool. When set to 1, the controller destroys the SF pool when stopped/restarted (and the SF pool is recreated if `sf_pool_percent` is not 0 when starting). Otherwise, it does not. Default value is 0.
`dpa_core_start`	`0`	Number	Specifies the start DPA core for virtnet application. Valid only for NVIDIA® BlueField®-3 and up. Value must be greater than 0 and less than 11. Together with `dpa_core_end`, `dpa_core_start` defines how many DPA cores are used for the virtio-net data plane. ⚠ This is advanced options when there are multiple DPA applications running at the same time. Regular user should keep this option as default. ⚠ The number of cores/EUs impacts the maximum number of VQs that can be created.
`dpa_core_end`	`10`	Number	Specifies the end DPA core for virtnet application. Valid only for BlueField-3 and up. Value must be greater than `dpa_core_start` and less than 11.

<table>
<tr><th>Parameter</th><th>Default Value</th><th>Type</th><th>Description</th></tr>
<tr><td><code>vf</code></td><td><code>N/A</code></td><td>List</td><td>The following sub-parameters can be used to configure the VF:
<table>
<tr><th>Sub-parameter</th><th>Default Value</th><th>Type</th><th>Description</th></tr>
<tr><td><code>mac_base</code></td><td>Null</td><td>String</td><td>Base MAC address for VFs. MACs are automatically assigned with the following pattern: <code>mac_base</code> → <code>vf_0</code>, <code>mac_base + 1</code> → <code>vf_1</code>, etc.
⚠ Controller does not validate the MAC address (other than its length). The user must ensure the MAC is valid and unique.
⚠ The virtio driver on the guest OS must be unloaded when restarting the controller if the <code>mac_base</code> setting is enabled for the first time or is modified.</td></tr>
<tr><td><code>features</code></td><td>Auto</td><td>Number</td><td>Virtio spec-defined feature bits for VFs.
⚠ If unsure, leave <code>features</code> out of the JSON file and a default value is automatically assigned. The default value is determined dynamically when controller starts. Refer to section "Feature Bits" for more information.</td></tr>
<tr><td><code>vfs_per_pf</code></td><td><code>0</code></td><td>Number</td><td>The number of VFs to create on each PF. For example: if <code>vfs_per_pf</code> is 100, then <code>vf_0</code> on <code>pf_1</code> will use <code>mac_base + 100</code> as its MAC.
⚠ <code>vfs_per_pf</code> ≤ <code>VIRTIO_NET_EMULATION_NUM_VF</code> in mlxconfig.
⚠ User is responsible for ensuring, on each static PF, that the created VFs ≤ <code>vfs_per_pf.</code>
⚠ This parameter is mandatory if <code>mac_base</code> is specified.</td></tr>
<tr><td><code>max_queue_pairs</code></td><td>Auto</td><td>Number</td><td>Number of queue pairs to use. If not specified, default queue pair number is inherited from the parent PF.</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Parameter</th><th>Default Value</th><th>Type</th><th>Description</th></tr>
<tr><td></td><td></td><td></td><td>
<table>
<tr><th>Sub-parameter</th><th>Default Value</th><th>Type</th><th>Description</th></tr>
<tr><td><code>max_queue_size</code></td><td>Auto</td><td>Number</td><td>Virtqueue size (i.e., vq depth) to use. If not specified, default vq size is inherited from the parent PF.</td></tr>
<tr><td><code>mtu</code></td><td><code>1500</code></td><td>Number</td><td>Maximum transmission unit for the VF, can be ≤ 9216.</td></tr>
</table>
</td></tr>
<tr><td><code>virtio_spec_admin_legacy</code></td><td><code>0</code></td><td>Number</td><td>Enable <code>(1)</code> or disable <code>(0)</code> VirtIO Spec legacy interface commands.</td></tr>
<tr><td><code>virtio_spec_admin_lm</code></td><td><code>0</code></td><td>Number</td><td>Enable <code>(1)</code> or disable <code>(0)</code> VirtIO Spec live migration commands.</td></tr>
</table>

<table>
<tr><th>Parameter</th><th>Default Value</th><th>Type</th><th>Description</th></tr>
<tr><td><code>dpa_partition</code></td><td><code>N/A</code></td><td>String</td><td>DPA partition configuration file full path. Refer to section "DPA Configuration (SPRD)" for more information.
The DPA partition conf file is generated by the DOCA dpa-resource-mgmt tool. Refer to DOCA DPA Tools Configuration Requirements:
• App name is "virtio-net"
• The minimum EU's amount is 32
• EU groups are not supported

Example for config.yaml input to dpa-resource-mgmt
---
version: 25.04

DPA_APPS:
virtio-net:
- partition: ROOT
affinity_core:
- core: 1
num_EUs: 16
- core: 3
num_EUs: 16
- core: 5
num_EUs: 16

When the virtio-net controller is running on the DPU, the DPA app is running on the emulation manager device - which is an ECPF.
we can only use the default ROOT partition with ECPF, configure the ROOT partition with dpa-resource-mgmt tool on mlx5_0 or <code>ib_dev_p0</code> or <code>ib_dev_lag</code> (if specified).

If specified, <code>dpa_core_start</code> and <code>dpa_core_end</code> Parameters will be ignored.

The number of cores/EUs impacts the maximum number of VQs that can be created.</td></tr>
<tr><td><code>eth_vq_workers</code></td><td><code>0</code></td><td>Number</td><td>Number of worker threads for ETH Virtual Queue operations (VQ creation/destruction).
These operations are I/O-bound (firmware latency-driven), so more threads than CPU cores improve performance. Firmware supports 8-way parallelism, so 8-24 workers are optimal. If not specified, auto-calculated as (num_cpu * 4, min=8, max=24). Valid range: 1-24.</td></tr>
<tr><td><code>admin_cmd_workers</code></td><td><code>0</code></td><td>Number</td><td>Number of worker threads for admin command operations. Similar to ETH VQ operations, these are I/O-bound and benefit from more threads than CPU cores. If not specified, auto-calculated as (num_cpu * 2, min=4, max=16). Valid range: 1-16. This provides a conservative approach for admin command parallelism.</td></tr>
</table>

8.14.4.2 Configuration File Examples

> ⚠ Validate the JSON format of the configuration file before restarting the controller, especially the syntax and symbols. Otherwise, the controller may fail to start.

8.14.4.2.1 Configuring LAG on Dual Port BlueField

Refer to "Link Aggregation" documentation for information on configuring BlueField in LAG mode.

Refer to the "Link Aggregation" page for information on configuring virtio-net in LAG mode.

8.14.4.2.2 Configuring Static PF on Dual Port BlueField

The following configures all static PFs to use `mlx5_0` (port 0) as the data path device in a non-LAG configuration, and the default MAC and features for the PF:

```
{
  "ib_dev_p0": "mlx5_0",
  "ib_dev_p1": "mlx5_1",
  "ib_dev_for_static_pf": "mlx5_0",
  "is_lag": 0,
  "static_pf": {
    "mac_base": "08:11:22:33:44:55",
    "features": "0x230047082b"
  }
}
```

8.14.4.2.3 Configuring VF Specific Options

The following configures VFs with default parameters. With this configuration, each PF assigns the MAC based on `mac_base` up to 126 VFs. Each VF creates 4 queue pairs, with each queue having a depth of 256.

> ⚠ If `vfs_per_pf` is less than the `VIRTIO_NET_EMULATION_NUM_VF` in mlxconfig, and more VFs are created, duplicated MACs would be assigned to different VFs.

```
{
  "vf": {
    "mac_base": "06:11:22:33:44:55",
    "features": "0x230047082b",
    "vfs_per_pf": 126,
    "max_queue_pairs": 4,
    "max_queue_size": 256
  }
```

```
}
```

8.14.4.2.4 VirtIO Live Migration Settings

The following table provides an example of configurations for the new options introduced for VirtIO Live Migration:

virtio_spec_admin_legacy	virtio_spec_admin_lm	Expected Result
`1`	`1`	Enables both legacy interface and VFIO kernel Live Migration commands
`1`	`0`	Enables legacy interface commands only
`0`	`1`	Enables VFIO kernel Live Migration commands only
`0`	`0`	Disable both legacy interface and VFIO kernel live migration commands
`-`	`-`	Supports VDPA Live Migration solutions

8.14.4.2.5 DPA Configuration (SPRD)

The Single Point of Resource Distribution (SPRD) is a centralized orchestration system that manages Data Path Accelerator (DPA) Execution Unit (EU) allocation across applications and Virtual HCAs (VHCAs). By centralizing this process, SPRD prevents ad-hoc per-application sizing and eliminates resource over-commitment.

Administrators define EU assignments to partitions and applications within a single YAML configuration file. The SPRD system validates this configuration, programs the hardware partitions and EU groups accordingly, and generates per-partition configuration files for the applications to consume.

8.14.4.2.5.1 Control and Integration

- CLI utility: The system is managed using the `dpa-resource-mgmt` command-line tool.
- Virtio-net integration: The `virtio-net` controller consumes the SPRD-generated output file via the `dpa_partition` configuration option to inherit its managed EU affinity.

8.14.4.2.5.2 SPRD Configuration Workflow for Virtio-net

Inspect Available Resources

Query the DPU to verify the `ROOT` partition and determine the set of free EUs before assigning them to `virtio-net`.

```
dpa-resource-mgmt query -t resources -d mlx5_0
```

Create an Input SPRD YAML

Create an input file (e.g., `input_vnet.yaml`) that explicitly maps the `virtio-net` application to the `ROOT` partition and defines the required EUs per core.

Example for a virtio-net "solo app" deployment:

```
version: 26.01
DPA_APPS:
   "virtio-net":
       - partition: ROOT
         affinity_core:
             - core: 0
               num_EUs: 16
             - core: 1
               num_EUs: 16
             - core: 2
               num_EUs: 16
             - core: 3
               num_EUs: 16
             - core: 4
               num_EUs: 16
             - core: 5
               num_EUs: 16
             - core: 6
               num_EUs: 16
             - core: 7
               num_EUs: 16
             - core: 8
               num_EUs: 16
             - core: 9
               num_EUs: 16
```

Generate the SPRD Output YAML

Run the configuration command to generate the output file.

```
dpa-resource-mgmt config -d mlx5_0 -f input_vnet.yaml -v
```

> **Naming Conventions**
>
> When utilizing the `ROOT` partition on a DPU, the generated output file automatically inherits the partition name (e.g., `ROOT.yaml`). This is the exact file you must reference in the `virtio-net` controller using the `dpa_partition` configuration option.

8.14.4.2.5.3 Example SPRD Output & Validation

The generation command produces a parsed YAML file utilized by the application. The `affinity_EUs` list contains the absolute EU IDs reserved for `virtio-net`. During execution, SPRD converts these absolute IDs into partition-relative indices.

Example `ROOT.yaml` Output:

```
version: 26.01
DPA_APPS:
-   name: virtio-net
    number_of_affinity_EUs: 160
    affinity_EUs: [0, 1, 2, 4, 5, 6, 8, 9, 10, 11, 12, 13, 15, 16, 17, 19, 21, 22,
        23, 24, 26, 27, 28, 29, 30, 31, 33, 34, 36, 37, 39, 40, 41, 42, 43, 44, 45,
        48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 60, 61, 62, 63, 65, 66, 67, 69,
        70, 71, 72, 73, 74, 75, 76, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 89, 90,
        92, 93, 94, 95, 96, 97, 98, 99, 101, 102, 103, 104, 105, 106, 107, 108, 109,
```

```
        110, 111, 112, 113, 114, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125,
        126, 127, 129, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 143,
        144, 145, 147, 148, 149, 150, 151, 152, 154, 155, 156, 157, 158, 159, 160,
        161, 162, 163, 165, 166, 167, 168, 169, 172, 173, 174, 175, 177, 178, 179,
        181, 182, 183, 184, 185, 187, 188, 189]
```

Performance Validation (BlueField-3 DPU)

This specific SPRD configuration was validated in a "solo app" scenario (where `virtio-net` was the exclusive DPA application assigned EUs) to ensure all data-plane threads ran optimally across the 160 managed EUs.

Hardware and test profile:

- Devices: 32 full emulation virtio-net VFs (16 TX, 16 RX)
- Queue Configuration: Virtqueue (VQ) depth of 1024; 31 Queue Pairs (QPs) per device.
- CQE Moderation: Count = 32, Period = 32
- Traffic Profile: `testpmd` UDP, 16 streams, 64-byte message size.

Measured aggregate performance:

- RX-Only: 72.6 Mpps
- TX-Only: 81.05 Mpps
- Bidirectional (RX + TX): 100.36 Mpps total

8.14.5 Virtnet CLI Commands

8.14.5.1 User Front End CLI

To communicate with the virtio-net-controller backend service, a user frontend program, virtnet, is installed on the BlueField which is based on remote procedure call (RPC) protocol with JSON format output. Run the following command to check its usage:

```
usage: virtnet [-h] [-v]
{hotplug,unplug,list,query,modify,log,version,restart,validate,update,health,debug,stats} ...

Nvidia virtio-net-controller command line interface v24.10.20

positional arguments:
  {hotplug,unplug,list,query,modify,log,version,restart,validate,update,health,debug,stats}
                        ** Use -h for sub-command usage
    hotplug             hotplug virtnet device
    unplug              unplug virtnet device
    list                list all virtnet devices
    query               query all or individual virtnet device(s)
    modify              modify virtnet device
    log                 set log level
    version             show virtio net controller version info
    restart             Do fast restart of controller without killing the service
    validate            validate configurations
    update              update controller
    health              controller health utility
    debug               For debug purpose, cmds can be changed without notice
    stats               stats of virtnet device

options:
  -h, --help            show this help message and exit
  -v, --version         show program's version number and exit
```

Virtnet supports command line autocomplete by inputting one command with tab.

To check the currently running controller version:

```
# virtnet -v
```

8.14.5.2 Hotplug

This command hotplugs a virtio-net PCIe PF device exposed to the host side.

8.14.5.2.1 Syntax

```
virtnet hotplug -i IB_DEVICE -m MAC -t MTU -n MAX_QUEUES -s MAX_QUEUE_SIZE [-h] [-u SF_NUM] [-f FEATURES] [-l] [-w HP_HOST_AWARENESS]
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--ib_device`	`-i`	String	Yes	RDMA device (e.g., `mlx5_0`) of the physical port on top of which the hotplug device is created. Options: • `mlx5_0` – port 1 • `mlx5_1` – port 2 • `mlx5_bond_0` – LAG
`--features`	`-f`	Hex Number	No	Feature bits to be enabled in hex format. Refer to the "Virtio-net Feature Bits" page. ⚠ Note that some features are enabled by default. Query the device to show the supported bits.
`--mac`	`-m`	Number	Yes	MAC address of the virtio-net device. ⚠ Controller does not validate the MAC address (other than its length). The user must ensure MAC is valid and unique.
`--mtu`	`-t`	Number	Yes	Maximum transmission unit (MTU) size of the virtio-net device. It must be less than the uplink rep MTU size.
`--num_queues`	`-n`	Number	Yes	Mutually exclusive with `max_queue_pairs`. Max number of virt queues could be created for the virtio-net device. TX, RX, ctrl queues are counted separately (e.g., 3 has 1 TX VQ, 1 RX VQ, 1 Ctrl VQ). ⚠ This option will be depreciated in the future.

Option	Abbr	Argument Type	Required	Description
`--max_queue_pairs`	`-qp`	Number	Yes	Mutually exclusive with `num_queues`. Number of data VQ pairs. One VQ pair has one TX queue and one RX queue. It does not count control or admin VQ. From the host side, it appears as `Pre-set maximums->Combined` in `ethtool -l <virtio-dev>`.
`--max_queue_size`	`-s`	Number	Yes	Maximum number of buffers in the virt queue, between 0x4 and 0x8000. Must be power of 2.
`--sf_num`	`-u`	Number	No	SF number to be used for this hotplug device, must between 2000 and 2999.
`--legacy`	`-l`	N/A	No	Create legacy (transitional) hotplug device ⚠ Relevant for BlueField-2 only.

<table>
<tr><th>Option</th><th>Abbr</th><th>Argument Type</th><th>Required</th><th>Description</th></tr>
<tr><td><code>--hp_host_awareness</code></td><td><code>-w</code></td><td>Number</td><td>No</td><td>This setting determines how the device interacts with the host during hot plug operations. The following modes are available:
<table>
<tr><th>Value</th><th>Mode</th><th>Description</th></tr>
<tr><td><code>0</code></td><td>Device default (Default)</td><td>The device operates in its default mode. For virtio-net, the default is host-aware.</td></tr>
<tr><td><code>1</code></td><td>Host-aware</td><td>The device monitors the host's state and proceeds only after the host has completed initialization (e.g., after the PCIe bus has been fully scanned) and is ready for new PCIe connections</td></tr>
<tr><td><code>2</code></td><td>Host-unaware</td><td>The hot plug operation can proceed regardless of the host's state. This means the operation may complete even if the host has not finished initialization or cannot respond to events.
Using this mode may result in undefined behavior on systems with older BIOS or OS versions. It is not recommended for such environments.</td></tr>
<tr><td><code>3</code></td><td>Host-aware attention button</td><td>The device will be attached /de-attached in a graceful mode, using the PCIe attention button sequence.</td></tr>
</table>
For optimal stability and compatibility, it is recommended to use either the device default mode (<code>0</code>) or host-aware mode (<code>1</code>).
Always ensure that your system's BIOS and OS are up to date to avoid compatibility issues with hot plug features.
The <code>virtnet list</code> CLI command indicates whether the controller supports hot plug host awareness:
<pre>#virtnet list

{
        "controller":   {
                …
                "emulation_manager":   "mlx5_0",
                "max_hotplug_devices": "15",
                "hp_host_awareness_supported": "1",   // <===== new
indication
                "max_virt_net_devices": "15",
                "max_virt_queues":   "256",
                ...</pre></td></tr>
</table>

8.14.5.2.2 Output

Entry	Type	Description
`bdf`	String	The PCIe BDF (bus:device:function) number enumerated by host. The user should see this PCIe device from host side.
`vuid`	String	Unique device SN. It can be used as an index to query/modify/unplug this device.
`id`	Num	Unique device ID. It can be used as an index to query/modify/unplug this device.
`transitional`	Num	Is the current device a transitional hotplug device. • 0 – modern device • 1 – transitional device
`sf_rep_net_device`	String	The SF representor name represents the virtio-net device. It should be added into the OVS bridge.
`mac`	String	The hotplug virtio-net device MAC address
`errno`	Num	Error number if hotplug failed. • 0 – success • non-0 – failed
`errstr`	String	Explanation of the error number

8.14.5.2.3 Example

The following example of hot plugging one device with MAC address `0C:C4:7A:FF:22:93`, MTU 1500, and 1 pair of virtual queue (QP) pair with a depth of 1024 entries. The device is created on the physical port of `mlx5_0`.

```
# virtnet hotplug -i mlx5_0 -m 0C:C4:7A:FF:22:93 -t 1500 -qp 1 -s 1024
{
  "bdf": "15:00.0",
  "vuid": "MT2151X03152VNETS1D0F0",
  "id": 0,
  "transitional": 0,
  "sf_rep_net_device": "en3f0pf0sf2000",
  "mac": "0C:C4:7A:FF:22:93",
  "errno": 0,
  "errstr": "Success"
}
```

8.14.5.3 Unplug

This command unplugs a virtio-net PCIe PF device.

8.14.5.3.1 Syntax

```
virtnet unplug [-h] [-p PF | -u VUID] [-w HP_HOST_AWARENESS] [-T HOTPLUG_POWER_OFF_TIMEOUT]
```

Only one of `--pf` and `--vuid` is needed to unplug the device.

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--pf`	`-p`	Number	Yes	Unique device ID returned when doing hotplug. Can be retrieved by using `virtnet list`.
`--vuid`	`-u`	String	Yes	Unique device SN returned when doing hotplug. Can be retrieved by using `virtnet list`.

<table>
<tr><th>Option</th><th>Abbr</th><th>Argument Type</th><th>Required</th><th>Description</th></tr>
<tr><td><code>--hp_host_awareness</code></td><td><code>-w</code></td><td>Number</td><td>No</td><td>This setting determines how the device interacts with the host during hot unplug operations. The following modes are available:
<table>
<tr><th>Value</th><th>Mode</th><th>Description</th></tr>
<tr><td><code>0</code></td><td>Device default (Default)</td><td>The device operates in its default mode. For virtio-net, the default is host-aware.</td></tr>
<tr><td><code>1</code></td><td>Host-aware</td><td>The device monitors the host's state and proceeds only after the host has completed initialization (e.g., after the PCIe bus has been fully scanned) and is ready for new PCIe connections</td></tr>
<tr><td><code>2</code></td><td>Host-unaware</td><td>The hot unplug operation can proceed regardless of the host's state. This means the operation may complete even if the host has not finished initialization or cannot respond to events.
Using this mode may result in undefined behavior on systems with older BIOS or OS versions. It is not recommended for such environments.</td></tr>
</table>
For optimal stability and compatibility, it is recommended to use either the device default mode (<code>0</code>) or host-aware mode (<code>1</code>).
Always ensure that your system's BIOS and OS are up to date to avoid compatibility issues with hot unplug features.
The <code>virtnet list</code> CLI command indicates whether the controller supports hot unplug host awareness:
<pre>#virtnet list
{
        "controller":   {
                …
                "emulation_manager":   "mlx5_0",
                "max_hotplug_devices": "15",
                "hp_host_awareness_supported": "1",   // <=====
new indication
                "max_virt_net_devices": "15",
                "max_virt_queues":   "256",
                ...</pre></td></tr>
</table>

Option	Abbr	Argument Type	Required	Description
`--hotplug_poweroff_timeout`	`-T`	Number	No	Specifies the duration (in seconds) the controller waits for the host OS to power off during an unplug operation before executing a forced unplug. • Valid range: `1` to `900` seconds. • Default value: `10` seconds. • Important constraint: This timeout parameter is not applicable and will be ignored if the device is operating in Host-Aware Attention Button (AB) mode.

8.14.5.3.2 Output

Entry	Type	Description
`errno`	Num	Error number if operation failed • 0 – success • non-0 – failed
`errstr`	String	Explanation of the error number

8.14.5.3.3 Example

Unplug-hotplug device using the PF ID:

```
# virtnet unplug -p 0
{'id': '0x1'}
{
  "errno": 0,
  "errstr": "Success"
}
```

8.14.5.4 List

This command lists all existing virtio-net devices, with global information and individual information for each device.

8.14.5.4.1 Syntax

```
virtnet list [-h]
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit

8.14.5.4.2 Output

The output has two main sections. The first section wrapped by the `controller` are global configurations and capabilities.

Entry	Type	Description
`controller`	String	Entries under this section is global information for the controller
`emulation_manager`	String	The RDMA device manager used to manage internal resources. Should be default `mlx5_0`.
`max_hotplug_devices`	String	Maximum number of devices that can be hotpluged
`max_virt_net_devices`	String	Total number of emulated devices managed by the device emulation manager
`max_virt_queues`	String	Maximum number of virt queues supported per device
`max_tunnel_descriptors`	String	Maximum number of descriptors the device can send in a single tunnel request
`supported_features`	String	Total list of features supported by device
`supported_virt_queue_types`	String	Currently supported virt queue types: Packed and Split
`supported_event_modes`	String	Currently supported event modes: `no_msix_mode`, `qp_mode`, `msix_mode`
`hp_host_awareness_supported`	String	Indicates whether hot plug host awareness is supported

Each device has its own section under `devices`.

Entry	Type	Description
`devices`	String	Entries under this section is per device information
`pf_id`	Number	Physical function ID
`function_type`	String	Function type: Static PF, hotplug PF, VF
`transitional`	Number	The current device a transitional hotplug device: • 0 – modern device • 1 – transitional device

Entry	Type	Description
`vuid`	String	Unique device SN, it can be used as an index to query/modify/unplug a device
`pci_bdf`	String	Bus:device:function to describe the virtio-net PCIe device
`pci_vhca_id`	Number	Virtual HCA identifier for the general virtio-net device. For debug purposes only.
`pci_max_vfs`	Number	Maximum number of virtio-net VFs that can be created for this PF. Valid only for PFs.
`enabled_vfs`	Number	Currently enabled number of virtio-net VFs for this PF
`msix_num_pool_size`	Number	Number of free dynamic MSIX available for the VFs on this PF
`min_msix_num`	Number	The minimum number of dynamic MSI-Xs that can be set for an virtio-net VF
`max_msix_num`	Number	The maximum number of dynamic MSI-Xs that can be set for an virtio-net VF
`min_num_of_qp`	Number	The minimum number of dynamic data VQ pairs (i.e., each pair has one TX and 1 RX queue) that can be set for an virtio-net VF
`max_num_of_qp`	Number	The minimum number of dynamic data VQ pairs (i.e., each pair has one TX and 1 RX queue) that can be set for an virtio-net VF
`qp_pool_size`	Number	Number of free dynamic data VQ pairs (i.e., each pair has one TX and 1 RX queue) available for the VFs on this PF
`num_msix`	Number	Maximum number of MSI-X available for this device
`num_queues`	Number	Maximum virtual queues can be created for this device, driver can choose to create less
`enabled_queues`	Number	Currently enabled number of virtual queues by the driver
`max_queues_size`	Number	Maximum virtual queue depth in byte can be created for each VQ, driver can use less
`msix_config_vector`	String	MSIX vector number used by the driver for the virtio config space. 0xFFFF means that no vector is requested.
`mac`	String	The virtio-net device permanent MAC address, can be only changed from controller side via modify command

Entry	Type	Description
`link_status`	Number	Link status of the virtio-net device on the driver side • 0 – down • 1 – up
`max_queue_pairs`	Number	Number of data VQ pairs. One VQ pair has one TX queue and one RX queue. Control or admin VQ are not counted. From the host side, it appears as `Pre-set maximums->Combined` in `ethtool -l <virtio-dev>`.
`mtu`	Number	The virtio-net device MTU. Default is 1500.
`speed`	Number	The virtio-net device link speed in Mb/s
`rss_max_key_size`	Number	The maximum supported length of the RSS key. Only applicable when `VIRTIO_NET_F_RSS` or `VIRTIO_NET_F_HASH_REPORT` is enabled.
`supported_hash_types`	Number	Supported hash types for this device in hex. Only applicable when `VIRTIO_NET_F_HASH_REPORT` is enabled: • `VIRTIO_NET_HASH_TYPE_IPv4 (bit 0)` • `VIRTIO_NET_HASH_TYPE_TCPv4 (bit 1)` • `VIRTIO_NET_HASH_TYPE_UDPv4 (bit 2)` • `VIRTIO_NET_HASH_TYPE_IPv6 (bit 3)` • `VIRTIO_NET_HASH_TYPE_TCPv6 (bit 4)` • `VIRTIO_NET_HASH_TYPE_UDPv6 (bit 5)`
`ctrl_mac`	String	Admin MAC address configured by driver. Not persistent with driver reload or host reboot.
`ctrl_mq`	Number	Number of queue pairs/channels configured by the driver. From the host side, it appears as `Current hardware settings->Combined` in `ethtool -l <virtio-dev>`.
`sf_num`	Number	Scalable function number used for this virtio-net device
`sf_parent_device`	String	The RDMA device to use to create the SF
`sf_parent_device_pci_addr`	String	The PCIe device address (bus:device:function) to use to create the SF
`sf_rep_net_device`	String	Represents the virtio-net device
`sf_rep_net_ifindex`	Number	The SF representor network interface index
`sf_rdma_device`	String	The SF RDMA device interface name

Entry	Type	Description
`sf_cross_mkey`	Number	The cross-device MKEY created for the SF. For debug purposes only.
`sf_vhca_id`	Number	Virtual HCA identifier for the SF. For debug purposes only.
`rqt_num`	Number	The RQ table ID used for this virtio-net device. For debug purposes only.
`aarfs`	String	Whether Accelerated Receive Flow Steering configuration is enabled or disabled
`dim`	String	Whether dynamic interrupt moderation (DIM) is enabled or disabled

8.14.5.4.3 Example

The following is an example of a list with 1 static PF created:

```
# virtnet list
{
  "controller": {
    "emulation_manager": "mlx5_0",
    "max_hotplug_devices": "0",
    "max_virt_net_devices": "1",

}
```

8.14.5.5 Query

This command queries detailed information for a given device, including all VQ information if created.

8.14.5.5.1 Syntax

```
virtnet query [-h] {[-a] | [-p PF] [-v VF] | [-u VUID]} [--dbg_stats] [-b] [--latency_stats] [-q QUEUE_ID] [--stats_clear]
```

> The options `--pf`, `--vf`, `--vuid`, and `--all` are mutually exclusive (except `--pf` and `--vf` which can be used together), but one of them must be applied.

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--all`	`-a`	N/A	No	Query all the detailed information for all available devices. It can be time consuming if a large number of devices is available.
`--pf`	`-p`	Number	No	Unique device ID for the PF. Can be retrieved by using `virtnet list`.
`--vf`	`-v`	Number	No	Unique device ID for the VF. Can be retrieved by using `virtnet list`.
`--vuid`	`-u`	String	No	Unique device SN for the device (PF/VF). Can be retrieved by using `virtnet list`.

Option	Abbr	Argument Type	Required	Description
`--queue_id`	`-q`	Number	No	Queue index of the device VQs
`--brief`	`-b`	N/A	No	Query brief information of the device (does not print VQ information)
`--dbg_stats`	N/A	N/A	No	Print debug counters and information ⚠ This option will be depreciated in the future.
`--stats_clear`	N/A	N/A	No	Clear all the debug counter stats ⚠ This option will be depreciated in the future.

8.14.5.5.2 Output

Output has two main sections.

- The first section, wrapped by `devices`, are configuration and capabilities on the device level, the majority of which are the same as the `list` command. This section only covers the differences between the two.

Entry	Type	Description
`devices`	String	Entries under this section is per-device information
`pci_dev_id`	String	Virtio-net PCIe device ID. Default: 0x1041. ⚠ This option will be depreciated in the future.
`pci_vendor_id`	String	Virtio-net PCIe vendor ID. Default: 0x1af4. ⚠ This option will be depreciated in the future.
`pci_class_code`	String	Virtio-net PCIe device class code. Default: 0x20000. ⚠ This option will be depreciated in the future.
`pci_subsys_id`	String	Virtio-net PCIe vendor ID. Default: 0x1041. ⚠ This option will be depreciated in the future.
`pci_subsys_vendor_id`	String	Virtio-net PCIe subsystem vendor ID. Default: 0x1af4. ⚠ This option will be depreciated in the future.

Entry	Type	Description
`pci_revision_id`	String	Virtio-net PCIe revision ID. Default: 1. ⚠ This option will be depreciated in the future.
`device_features`	String	Enabled device feature bits according to the virtio spec. Refer to section "Feature Bits".
`driver_features`	String	Enabled driver feature bits according to the virtio spec. Valid only when the driver probes the device. Refer to "Feature Bits".
`status`	String	Device status field bit masks according to the virtio spec: • `ACKNOWLEDGE (bit 0)` • `DRIVER (bit 1)` • `DRIVER_OK (bit 2)` • `FEATURES_OK (bit 3)` • `DEVICE_NEEDS_RESET (bit 6)` • `FAILED (bit 7)`
`reset`	Number	Shows if the current virtio-net device undergoing reset: • 0 – not undergoing reset • 1 – undergoing reset
`enabled`	Number	Shows if the current virtio-net device is enabled: • 0 – disabled, likely FLR has occurred • 1 – enabled

- The second section, wrapped by `enabled-queues-info`, provides per-VQ information:

Entry	Type	Description
`index`	Number	VQ index starting from 0 to `enabled_queues`
`size`	Number	Driver VQ depth in bytes. It is bound by device `max_queues_size`.
`msix_vector`	Number	The MSI-X vector number used for this VQ
`enable`	Number	If current VQ is enabled or not • 0 – disabled • 1 – enabled
`notify_offset`	Number	Driver reads this to calculate the offset from start of notification structure at which this virtqueue is located

Entry	Type	Description
`descriptor_address`	Number	The physical address of the descriptor area
`driver_address`	Number	The physical address of the driver area
`device_address`	Number	The physical address of the device area
`received_desc`	Number	Total number of received descriptors by the device on this VQ ⚠ This option will be depreciated in the future.
`completed_desc`	Number	Total number of completed descriptors by the device on this VQ ⚠ This option will be depreciated in the future.
`bad_desc_errors`	Number	Total number of bad descriptors received on this VQ ⚠ This option will be depreciated in the future.
`error_cqes`	Number	Total number of error CQ entries on this VQ ⚠ This option will be depreciated in the future.
`exceed_max_chain`	Number	Total number of chained descriptors received that exceed the maximum allowed chain by device ⚠ This option will be depreciated in the future.
`invalid_buffer`	Number	Total number of times the device tried to read or write buffer that is not registered to the device ⚠ This option will be depreciated in the future.
`batch_number`	Number	The number of RX descriptors for the last received packet. Relevant for BlueField-3 only. ⚠ This option will be depreciated in the future.
`dma_q_used_number`	Number	The DMA q index used for this VQ. Relevant for BlueField-3 only. ⚠ This option will be depreciated in the future.

Entry	Type	Description
`handler_schd_number`	Number	Scheduler number for this VQ. Relevant for BlueField-3 only. ⚠ This option will be depreciated in the future.
`aux_handler_schd_number`	Number	Aux scheduler number for this VQ. Relevant for BlueField-3 only. ⚠ This option will be depreciated in the future.
`max_post_desc_number`	Number	Maximum number of posted descriptors on this VQ. Relevant for DPA. ⚠ This option will be depreciated in the future.
`total_bytes`	Number	Total number of bytes handled by this VQ. Relevant for BlueField-3 only ⚠ This option will be depreciated in the future.
`rq_cq_max_count`	Number	Event generation moderation counter of the queue. Relevant for RQ. ⚠ This option will be depreciated in the future.
`rq_cq_period`	Number	Event generation moderation timer for the queue in 1µsec granularity. Relevant for RQ. ⚠ This option will be depreciated in the future.
`rq_cq_period_mode`	Number	Current period mode for RQ • 0x0 – `default_mode` – use device best defaults • 0x1 – `upon_event` – `queue_period` timer restarts upon event generation • 0x2 – `upon_cqe` – `queue_period` timer restarts upon completion generation ⚠ This option will be depreciated in the future.

8.14.5.5.3 Example

The following is an example of querying the information of the first PF:

```
# virtnet query -p 0
{
  "devices": [
    {
      "pf_id": 0,
      "function_type": "static PF",
      "transitional": 0,

}
```

8.14.5.6 Stats

> This command is recommended for obtaining all packet counter information. The existing packet counter information available using the `virtnet list` and `virtnet query` commands, but will be deprecated in the future.

This command retrieves the packet counters for a specified device, including detailed information for all Rx and Tx virtqueues (VQs).

To enable/disable byte wise packet counters for each Rx queue, use the following command:

```
virtnet modify {[-p PF] [-v VF]} device -pkt_cnt {enable,disable}
```

- When enabled, byte-wise packet counters are initialized to zero.
- When disabled, the previous values are retained for debugging purposes. The command will still return these old, disabled counter values.

> Packet counters are attached to an RQ. Thus, RQ must be created first. This means that the virtio-net device should be probed by the driver on the host OS before running the commands above.

8.14.5.6.1 Syntax

```
virtnet stats [-h] {[-p PF] [-v VF] | [-u VUID]} [-q QUEUE_ID]
```

> The options `--pf`, `--vf`, and `--vuid` are mutually exclusive (except `--pf` and `--vf` which can be used together), but one of them must be applied.

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--pf`	`-p`	Number	No	Unique device ID for the PF. Can be retrieved by using `virtnet list`.
`--vf`	`-v`	Number	No	Unique device ID for the VF. Can be retrieved by using `virtnet list`.
`--vuid`	`-u`	String	No	Unique device SN for the device (PF/VF). Can be retrieved by using `virtnet list`.
`--queue_id`	`-q`	Number	No	Queue index of the device RQs or SQs

8.14.5.6.2 Output

The output has two sections.

- The first section wrapped by `device` are device details along with the packet counter statics enable state.

Entry	Type	Description
`device`	String	Entries under this section is per-device information
`pf_id`	String	Physical function ID
`packet_counters`	String	Indicates whether the packet counters feature is enabled or disabled

- The second section wrapped by queues-stats are information for each receive VQ.

Entry	Type	Description
`VQ Index`	Number	The VQ index starts at 0 (the first RQ) and continues up to the last SQ
`rx_64_or_less_octet_packets`	Number	The number of packets received with a size of 0 to 64 bytes. Relevant for BlueField-3 RQ.
`rx_65_to_127_octet_packets`	Number	The number of packets received with a size of 65 to 127 bytes. Relevant for BlueField-3 RQ.

Entry	Type	Description
`rx_128_to_255_octet_packets`	Number	The number of packets received with a size of 128 to 255 bytes. Relevant for BlueField-3 RQ.
`rx_256_to_511_octet_packets`	Number	The number of packets received with a size of 256 to 511 bytes. Relevant for BlueField-3 RQ.
`rx_512_to_1023_octet_packets`	Number	The number of packets received with a size of 512 to 1023 bytes. Relevant for BlueField-3 RQ.
`rx_1024_to_1522_octet_packets`	Number	The number of packets received with a size of 1024 to 1522 bytes. Relevant for BlueField-3 RQ.
`rx_1523_to_2047_octet_packets`	Number	The number of packets received with a size of 1523 to 2047 bytes. Relevant for BlueField-3 RQ.
`rx_2048_to_4095_octet_packets`	Number	The number of packets received with a size of 2048 to 4095 bytes. Relevant for BlueField-3 RQ.
`rx_4096_to_8191_octet_packets`	Number	The number of packets received with a size of 4096 to 8191 bytes. Relevant for BlueField-3 RQ.
`rx_8192_to_9022_octet_packets`	Number	The number of packets received with a size of 8192 to 9022 bytes. Relevant for BlueField-3 RQ.
`received_desc`	Number	Total number of received descriptors by the device on this VQ
`completed_desc`	Number	Total number of completed descriptors by the device on this VQ
`bad_desc_errors`	Number	Total number of bad descriptors received on this VQ
`error_cqes`	Number	Total number of error CQ entries on this VQ

Entry	Type	Description
`exceed_max_chain`	Number	Total number of chained descriptors received that exceed the max allowed chain by device
`invalid_buffer`	Number	Total number of times the device tried to read or write a buffer which is not registered to the device
`batch_number`	Number	The number of RX descriptors for the last received packet. Relevant for BlueField-3.
`dma_q_used_number`	Number	The DMA q index used for this VQ. Relevant for BlueField-3.
`handler_schd_number`	Number	Scheduler number for this VQ. Relevant for BlueField-3.
`aux_handler_schd_number`	Number	Aux scheduler number for this VQ. Relevant for BlueField-3.
`max_post_desc_number`	Number	Maximum number of posted descriptors on this VQ. Relevant for DPA.
`total_bytes`	Number	Total number of bytes handled by this VQ. Relevant for BlueField-3.
`rq_cq_max_count`	Number	Event generation moderation counter of the queue. Relevant for RQ.
`rq_cq_period`	Number	Event generation moderation timer for the queue in 1µsec granularity. Relevant for RQ.
`rq_cq_period_mode`	Number	Current period mode for RQ • 0x0 – `default_mode` – use device best defaults • 0x1 – `upon_event` – `queue_period` timer restarts upon event generation • 0x2 – `upon_cqe` – `queue_period` timer restarts upon completion generation

8.14.5.6.3 Example

The following is an example of querying the packet statistics information of PF 0 and VQ 0 (i.e., RQ):

```
# virtnet stats -p 0 -q 0
```

```
{'pf': '0x0', 'queue_id': '0x0'}
{
  "device": {
    "pf_id": 0,
    "packet_counters": "Enabled",
    "queues-stats": [
      {
        "VQ Index": 0,
        "rx_64_or_less_octet_packets": 0,
        "rx_65_to_127_octet_packets": 259,
        "rx_128_to_255_octet_packets": 0,
        "rx_256_to_511_octet_packets": 0,
        "rx_512_to_1023_octet_packets": 0,
        "rx_1024_to_1522_octet_packets": 0,
        "rx_1523_to_2047_octet_packets": 0,
        "rx_2048_to_4095_octet_packets": 199,
        "rx_4096_to_8191_octet_packets": 0,
        "rx_8192_to_9022_octet_packets": 0,
        "received_desc": "4096",
        "completed_desc": "0",
        "bad_desc_errors": "0",
        "error_cqes": "0",
        "exceed_max_chain": "0",
        "invalid_buffer": "0",
        "batch_number": "64",
        "dma_q_used_number": "0",
        "handler_schd_number": "44",
        "aux_handler_schd_number": "43",
        "max_post_desc_number": "0",
        "total_bytes": "0",
        "err_handler_schd_num": "0",
        "rq_cq_max_count": "0",
        "rq_cq_period": "0",
        "rq_cq_period_mode": "1"
      }
    ]
  }
}
```

8.14.5.7 Modify Device

This command modifies the attributes of a given device.

> When dynamic MSI-X mode is enabled, the user should provision the VF from the DPU side before attaching a VF to the VM.
>
> When dynamic MSI-X mode is disabled, the default number of MSI-X vectors is according to `VIRTIO_NET_EMULATION_NUM_VF_MSIX` value.

8.14.5.7.1 Syntax

```
virtnet modify [-h] [-p PF] [-v VF] [-u VUID] [-a] {device,queue} ...
```

> The options `--pf`, `--vf`, `--vuid`, and `--all` are mutually exclusive (except `--pf` and `--vf` which can be used together), but one of them must be applied.

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit

Option	Abbr	Argument Type	Required	Description
`--all`	`-a`	N/A	No	Modify all available device attributes depending on the selection of `device` or `queue`
`--pf`	`-p`	Number	No	Unique device ID for the PF. May be retrieved using `virtnet list`.
`--vf`	`-v`	Number	No	Unique device ID for the VF. May be retrieved using `virtnet list`.
`--vuid`	`-u`	String	No	Unique device SN for the device (PF/VF). May be retrieved by using `virtnet list`.
`device`	N/A	Number	No	Modify device specific options
`queue`	N/A	N/A	No	Modify queue specific options

8.14.5.7.1.1 Device Options

```
virtnet modify device [-h] [-m MAC] [-t MTU] [-e SPEED] [-l LINK]
                      [-s STATE] [-f FEATURES]
                      [-o SUPPORTED_HASH_TYPES] [-k RSS_MAX_KEY_SIZE]
                      [-r RX_MODE] [-n MSIX_NUM] [-q MAX_QUEUE_SIZE]
                      [-b RX_DMA_Q_NUM] [-dc {enable,disable}]
                      [-pkt_cnt {enable,disable}] [-aarfs {enable,disable}]
                      [-qp MAX_QUEUE_PAIRS] [-dim {enable,disable}]
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	String	No	Show the help message and exit
`--mac`	`-m`	Number	No	The virtio-net device MAC address
`--mtu`	`-t`	Number	No	The virtio-net device MTU
`--speed`	`-e`	Number	No	The virtio-net device link speed in Mb/s
`--link`	`-l`	Number	No	The virtio-net device link status • 0 – down • 1 – up
`--state`	`-s`	Number	No	The virtio-net device status field bit masks according to the virtio spec: • `ACKNOWLEDGE (bit 0)` • `DRIVER (bit 1)` • `DRIVER_OK (bit 2)` • `FEATURES_OK (bit 3)` • `DEVICE_NEEDS_RESET (bit 6)` • `FAILED (bit 7)`

Option	Abbr	Argument Type	Required	Description

`--features`	`-f`	Hex Number / Feature Name / Pattern	No	Configures the `virtio-net` device feature bits in accordance with the virtio specification. Administrators can explicitly set the base feature mask, or dynamically enable and disable specific features using hexadecimal bitmasks or predefined feature names.
				Supported syntax and patterns:
				• Enable features (`+`): Append a plus sign before a bitmask or feature name to enable it.
				  • Examples: `+0x8000` , `+VIRTIO_NET_F_MRG_RXBUF` , or `+MRG_RXBUF`
				• Disable features (`-`): Append a minus sign before a bitmask or feature name to disable it.
				  • Examples: `-0x400000000` , `-VIRTIO_NET_F_MRG_RXBUF` , or `-MRG_RXBUF`
				• Set exact features: Provide a raw bitmask to explicitly overwrite and set the feature bits.
				  • Example: `0x8100000300e7182f`
				• Combined operations: Set a base mask and sequentially append `+` or `-` operations to modify specific bits in a single, complex command.
				  • Format: `<bitmask>?([+-]<bitmask|name>)*`
				  • Example: `0x8100000300e7182f+0x400000000-MRG_RXBUF`

`--supported_hash_types`	`-o`	Hex Number	No	Supported hash types for this device in hex. Only applicable when `VIRTIO_NET_F_HASH_REPORT` is enabled. • `VIRTIO_NET_HASH_TYPE_IPv4 (bit 0)` • `VIRTIO_NET_HASH_TYPE_TCPv4 (bit 1)` • `VIRTIO_NET_HASH_TYPE_UDPv4 (bit 2)` • `VIRTIO_NET_HASH_TYPE_IPv6 (bit 3)` • `VIRTIO_NET_HASH_TYPE_TCPv6 (bit 4)` • `VIRTIO_NET_HASH_TYPE_UDPv6 (bit 5)`
`--rss_max_key_size`	`-k`	Number	No	The maximum supported length of RSS key. Only applicable when `VIRTIO_NET_F_RSS` or `VIRTIO_NET_F_HASH_REPORT` is enabled.
`--rx_mode`	`-r`	Hex Number	No	The RX mode exposed to the driver: • 0 – promisc • 1 – all-multi • 2 – all-uni • 3 – no-multi • 4 – no-uni • 5 – no-broadcast
`--msix_num`	`-n`	Number	No	Maximum number of VQs (both data and ctrl/admin VQ). It is bound by the cap of `max_virt_queues` at the controller level (`virtnet list`).

Option	Abbr	Argument Type	Required	Description
`--max_queue_size`	`-q`	Number	No	Maximum number of buffers in the VQ. The queue size value is always a power of 2. The maximum queue size value is 32768.
`--max_queue_pairs`	`-qp`	Number	No	Number of data VQ pairs. One VQ pair has one TX queue and one RX queue. Control or admin VQs are not counted. From the host side, it appears as `Pre-set maximums->Combined` in `ethtool -l <virtio-dev>`.
`--rx_dma_q_num`	`-b`	Number	No	Modify max RX DMA queue number
`--drop_counter`	`-dc`	String	No	Enable/disable virtio-net drop counter
`--packet_counter`	`-pkt_cnt`	String	No	Enable/disable virtio-net device packet counter stats
`--aarfs_config`	`-aarfs`	String	No	Enable/disable auto-AARFS. Only applicable for PF devices (static PF and hotplug PF).
`--dim_config`	`-dim`	String	No	Enable/disable dynamic interrupt moderation (DIM)

The following `modify` options require unbinding the virtio device from virtio-net driver in the guest OS:

- `mac`
- `mtu`
- `features`
- `msix_num`
- `max_queue_size`
- `max_queue_pairs`

For example:

1. On the guest OS:

```
[host]# echo "bdf of virtio-dev" > /sys/bus/pci/drivers/virtio-pci/unbind
```

2. On the DPU side:
    a. Modify the max queue size of device:

```
[dpu]# virtnet modify -p 0 -v 0 device -q 2048
```

    b. Modify the MSI-X number of VF device:

```
[dpu]# virtnet modify -p 0 -v 0 device -n 8
```

    c. Modify the MAC address of virtio physical device ID 0 (or with its "VUID string", which can be obtained through virtnet list/query):

```
[dpu]# virtnet modify -p 0 device -m 0C:C4:7A:FF:22:93
```

    d. Modify the maximum number of queue pairs of VF device:

```
[dpu]# virtnet modify -p 0 -v 0 device -qp 2
```

3. On the guest OS:

```
[host]# echo "bdf of virtio-dev" > /sys/bus/pci/drivers/virtio-pci/bind
```

8.14.5.7.1.2 Enabling and Disabling Virtio-net Features

Configuring virtio-net features involves verifying what the DPU supports, modifying the device configuration, and confirming that the host driver successfully negotiated the new features.

Verify Supported Features

Check the full list of features supported by the underlying controller using the `virtnet list` command.

```
virtnet list
```

Example JSON output:

```
"supported_features": {
    "value":         "0x8b00037700ef982f",
    "     0":         "VIRTIO_NET_F_CSUM",
    "     1":         "VIRTIO_NET_F_GUEST_CSUM",
    "     2":         "VIRTIO_NET_F_CTRL_GUEST_OFFLOADS",
    "     3":         "VIRTIO_NET_F_MTU",
    "     5":         "VIRTIO_NET_F_MAC",
    "    11":         "VIRTIO_NET_F_HOST_TSO4",
    "    12":         "VIRTIO_NET_F_HOST_TSO6",
    "    15":         "VIRTIO_NET_F_MRG_RXBUF",
    "    34":         "VIRTIO_F_RING_PACKED",
    "    63":         "VIRTIO_NET_F_SPEED_DUPLEX"
}
```

Important Constraints

- Feature names and bit numbers strictly follow the virtio-net specification.
- The specific list of supported features will vary depending on the device type, driver capabilities, and current application version.

Check Currently Enabled Device Features

Verify which features are currently enabled on your target device (e.g., Physical Function `0`) by inspecting the `device_feature` section of the query output.

```
virtnet query -p 0 -b
```

Example JSON output:

example, features enabled for PF 0

```
"pci_bdf": "0f:00.2",
"device_feature": {
    "value":         "0x8100032300ef982f",
    "    0":         "VIRTIO_NET_F_CSUM",
    "   32":         "VIRTIO_F_VERSION_1",
    "   33":         "VIRTIO_F_IOMMU_PLATFORM",
    "   63":         "VIRTIO_NET_F_SPEED_DUPLEX"
}
```

Modify Device Features

Driver Unbonding Required

You cannot modify device features while the device driver is actively bound. You must unbind the device driver before executing any `virtnet modify device` commands. Refer to the "Modify Device" section for exact unbinding steps.

Once unbound, use the `-f` flag to enable, disable, or explicitly set the feature bitmask.

- To enable a feature (`+`):

```
# Syntax: virtnet modify -p <pf> device -f +<feature_name>
virtnet modify -p 0 device -f +VIRTIO_F_RING_PACKED
```

- To disable a feature (`-`):

```
# Syntax: virtnet modify -p <pf> device -f -<feature_name>
virtnet modify -p 0 device -f -VIRTIO_F_RING_PACKED
```

- To set an explicit feature vector (bitmask) – You can overwrite the entire feature vector using a hex mask. For example, to add `VIRTIO_F_RING_PACKED` (bit 34) to a base vector of `0x8100032300EF182F`, you calculate the logical OR (`0x8100032300EF182F | 0x400000000 = 0x8100032700EF182F`) and apply it:

```
# Syntax: virtnet modify -p <pf> device -f <features_bitmask>
virtnet modify -p 0 device -f 0x8100032700EF182F
```

Verify Driver Negotiation

After modifying the features and rebonding the driver, you must verify that the host operating system successfully negotiated the new features.

A feature is only fully active if it appears in both the `device_feature` and `driver_feature` lists.

```
virtnet query -p 0 -b
```

Example output confirming `VIRTIO_F_RING_PACKED` (bit 34) was successfully negotiated:

```
"pci_bdf": "0f:00.2",

"device_feature": {
    "    34":         "VIRTIO_F_RING_PACKED"
},
"driver_feature": {
    "    34":         "VIRTIO_F_RING_PACKED"
}
```

8.14.5.7.1.3 Queue Options

```
virtnet modify queue [-h] -e {event,cqe} -n PERIOD -c MAX_COUNT
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	String	No	Show the help message and exit
`--period_mode`	`-e`	String	No	RQ period mode: `event` or `cqe`. Default is selected by device for the best result.
`--period`	`-n`	Number	No	The event generation moderation timer for the queue in 1µsec granularity
`--max_count`	`-c`	Number	No	The max event generation moderation counter of the queue

8.14.5.7.2 Output

Entry	Type	Description
`errno`	Number	Error number: • 0 – success • Non-0 – failed
`errstr`	String	Explanation of the error number

8.14.5.7.3 Example

To modify the link status of the first VF on the first PF to be down:

```
# virtnet modify -p 0 device -l 0
{'pf': '0x0', 'all': '0x0', 'subcmd': '0x0', 'link': '0x0'}
{
  "errno": 0,
  "errstr": "Success"
}
```

8.14.5.8 Log

This command manages the log level of virtio-net-controller.

8.14.5.8.1 Syntax

```
virtnet log [-h] -l {info,err,debug}
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--level`	`-l`	String	Yes	Change the log level of `virtio_net_controller` from the journal. Default is DEBUG.

8.14.5.8.2 Output

Entry	Type	Description
`Stdout`	String	Success or failed with message

8.14.5.8.3 Example

To change the log level to info:

```
# virtnet log -l info
{'level': 'info'}
"Success"
```

To monitor current log output of the controller service with the latest 100 lines printed out:

```
$ journalctl -u virtio-net-controller -f -n 100
```

8.14.5.9 Validate

This command validates configurations of virtio-net-controller.

8.14.5.9.1 Syntax

```
virtnet validate [-h] -f PATH_TO_FILE
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--file`	`-f`	String	No	Validate the JSON format of the `virtnet.conf` file of the `virtio_net_controller`

8.14.5.9.2 Output

Entry	Type	Description
`Stdout`	String	Success or failed with message

8.14.5.9.3 Example

To check if `virtnet.conf` is a valid JSON file:

```
# virtnet validate -f /opt/mellanox/mlnx_virtnet/virtnet.conf
/opt/mellanox/mlnx_virtnet/virtnet.conf is valid
```

8.14.5.10 Version

This command prints current and updated version of virtio-net-controller.

8.14.5.10.1 Syntax

```
virtnet version [-h]
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit

8.14.5.10.2 Output

Entry	Type	Description
`Original Controller`	String	The original controller version
`Destination Controller`	String	The to be updated controller version

8.14.5.10.3 Example

Check current and next available controller version:

```
# virtnet version
[
  {
    "Original Controller": "v24.10.17"
  },
  {
    "Destination Controller": "v24.10.19"
  }
]
```

8.14.5.11 Update

This command performs a live update to another version installed on the OS. Instead of a complete shutdown and recreating all existing devices, this procedure updates to the new version with minimal down time.

8.14.5.11.1 Syntax

```
virtnet update [-h] [-s | -t]
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--start`	`-s`	N/A	No	Start live update virtio-net-controller
`--status`	`-t`	N/A	No	Check live update status

8.14.5.11.2 Output

Entry	Type	Description
`stdout`	String	If the update started successfully

8.14.5.11.3 Example

To start the live update process, run:

```
# virtnet update -s
{'start': '0x1'}
"Update started, use 'virtnet update -t' or check logs for status"
```

To check the update status during the update process:

```
# virtnet update -t
{'status': '0x1'}
{
  "status": "inactive",
  "last live update status": "success",
  "time_used (s)": 0.604152
}
```

8.14.5.12 Restart

This command performs a fast restart of the virtio-net-controller service. Compared to regular restart (using `systemctl restart virtio-net-controller`) this command has shorter down time per device.

8.14.5.12.1 Syntax

```
virtnet restart [-h]
```

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit

8.14.5.12.2 Output

Entry	Type	Description
`stdout`	String	If the fast restart finishes successfully • SUCCESS • Failed to fast restart

8.14.5.12.3 Example

To start the live update process, run:

```
# virtnet restart
SUCCESS
```

8.14.5.13 Health

This command shows health information for given devices.

> ⚠ The virtio-net driver must be loaded for this command to show valid information.

8.14.5.13.1 Syntax

```
virtnet health [-h] {[-a] | [-p PF] [-v VF] | [-u VUID]} [show]
```

> ℹ The options `--pf`, `--vf`, `--vuid`, and `--all` are mutually exclusive (except `--pf` and `--vf` which can be used together), but one of them must be applied.

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--all`	`-a`	N/A	No	Query all the detailed information for all available devices. It can be time consuming if a large number of devices is available.
`--pf`	`-p`	Number	No	Unique device ID for the PF. Can be retrieved by using `virtnet list`.
`--vf`	`-v`	Number	No	Unique device ID for the VF. Can be retrieved by using `virtnet list`.
`--vuid`	`-u`	String	No	Unique device SN for the device (PF/VF). Can be retrieved by using `virtnet list`.

Sub-command	Required	Description
`show`	Yes	Show health information for given devices

8.14.5.13.2 Output

Entry	Type	Description
`pf_id`	Number	Physical function ID
`type`	String	Function type: Static PF, hotplug PF, VF
`vuid`	String	Unique device SN, it can be used as an index to query/modify/unplug a device

Entry	Type	Description
`dev_status`	String	Device status field bit masks according to the virtio spec: • `ACKNOWLEDGE (bit 0)` • `DRIVER (bit 1)` • `DRIVER_OK (bit 2)` • `FEATURES_OK (bit 3)` • `DEVICE_NEEDS_RESET (bit 6)` • `FAILED (bit 7)`
`health_status`	String	• Good • Fatal
`health_recover_counter`	Number	The number of recoveries has been performed
`dev_health_details`	Dictionary	Two types of health information are included: `control_plane_errors` and `data_plane_errors`, where `control_plane_errors` has following specific errors reported, with value either 0 or 1: • `sf_rqt_update_err` • `sf_drop_create_err` • `sf_tir_create_err` • `steer_rx_domain_err` • `steer_rx_table_err` • `sf_flows_apply_err` • `aarfs_flow_init_err` • `vlan_flow_init_err` • `drop_cnt_config_err` and `data_plane_errors` has following specific errors reported, with value either 0 or 1: • `sq_stall` • `dma_q_stall` • `spurious_db_invoke` • `aux_not_invoked` • `dma_q_errors` • `host_read_errors` Detailed descriptions of each error can be found in Health Statistics.

8.14.5.13.3 Example

The following is an example of showing the information of the first PF:

```
# virtnet health -p 0 show
{'pf': '0x0', 'all': '0x0', 'subcmd': '0x0'}
{
  "pf_id": 0,
  "type": "static PF",
  "vuid": "MT2306XZ00BPVNETS0D0F1",
  "dev_status": {
    "value": "0xf",
    "    0": "ACK",
    "    1": "DRIVER",
    "    2": "DRIVER_OK",
```

```
      "    3": "FEATURES_OK"
    },
    "health_status": "Good",
    "health_recover_counter": 0,
    "dev_health_details": {
      "control_plane_errors": {
        "sf_rqt_update_err": 0,
        "sf_drop_create_err": 0,
        "sf_tir_create_err": 0,
        "steer_rx_domain_err": 0,
        "steer_rx_table_err": 0,
        "sf_flows_apply_err": 0,
        "aarfs_flow_init_err": 0,
        "vlan_flow_init_err": 0,
        "drop_cnt_config_err": 0
      },
      "data_plane_errors": {
        "sq_stall": 0,
        "dma_q_stall": 0,
        "spurious_db_invoke": 0,
        "aux_not_invoked": 0,
        "dma_q_errors": 0,
        "host_read_errors": 0
      }
    }
  }
```

8.14.5.14 Error Code

CLI commands will return non-zero error code upon failure. All error numbers are negative. When an error occurs from the log, it could return an error number as well.

If the error number is greater than `-1000`, it is standard error. Please refer to Linux error code at errno

If the error number is less or equal `-1000`, please refer to the table below for the explanation.

Errno	Error Name	Error Description
-1000	VIRTNET_ERR_DEV_FEATURE_VALIDATE	Failed to validate device feature
-1001	VIRTNET_ERR_DEV_NOT_FOUND	Failed to find device
-1002	VIRTNET_ERR_DEV_NOT_PLUGGED	Failed - Device is not hotplugged
-1003	VIRTNET_ERR_DEV_NOT_STARTED	Failed - Device did not start
-1004	VIRTNET_ERR_DRIVER_PROBED	Failed - Virtio driver should not be loaded
-1005	VIRTNET_ERR_EPOLL_ADD	Failed to add epoll
-1006	VIRTNET_ERR_ID_OUT_OF_RANGE	Failed - ID input exceeds the max range
-1007	VIRTNET_ERR_VUID_INVALID	Failed - VUID is invalid
-1008	VIRTNET_ERR_MAC_INVALID	Failed - MAC is invalid
-1009	VIRTNET_ERR_MSIX_INVALID	Failed - MSIX is invalid
-1010	VIRTNET_ERR_MTU_INVALID	Failed - MTU is invalid
-1011	VIRTNET_ERR_PORT_CONTEXT_NOT_FOUND	Failed to find port context
-1012	VIRTNET_ERR_REC_CONFIG_LOAD	Failed to load config from recovery file
-1013	VIRTNET_ERR_REC_CONFIG_SAVE	Failed to save config into recovery file

Errno	Error Name	Error Description
-1014	VIRTNET_ERR_REC_FILE_CREATE	Failed to create recovery file
-1015	VIRTNET_ERR_REC_MAC_DEL	Failed to delete MAC in recovery file
-1016	VIRTNET_ERR_REC_MAC_LOAD	Failed to load MAC from recovery file
-1017	VIRTNET_ERR_REC_MAC_SAVE	Failed to save MAC into recovery file
-1018	VIRTNET_ERR_REC_MQ_SAVE	Failed to save MQ into recovery file
-1019	VIRTNET_ERR_REC_PFNUM_LOAD	Failed to load PF number from recovery file
-1020	VIRTNET_ERR_REC_RX_MODE_SAVE	Failed to save RX mode into recovery file
-1021	VIRTNET_ERR_REC_SF_SAVE	Failed to save PF and SF number into recovery file
-1022	VIRTNET_ERR_REC_SFNUM_LOAD	Failed to load SF number from recovery file
-1023	VIRTNET_ERR_SF_MAC_FLOW_APPLY	Failed to apply MAC flow by SF
-1024	VIRTNET_ERR_SF_MQ_UPDATE	Failed to update MQ by SF
-1025	VIRTNET_ERR_SF_RX_MODE_SET	Failed to set RX mode by SF
-1026	VIRTNET_ERR_SNAP_NET_CTRL_OPEN	Failed to open SNAP device control
-1027	VIRTNET_ERR_SNAP_CROSS_MKEY_CREATE	Failed to create SNAP cross mkey
-1028	VIRTNET_ERR_SNAP_DMA_Q_CREATE	Failed to create SNAP DMA Q
-1029	VIRTNET_ERR_SNAP_NET_DEV_QUERY	Failed to query SNAP device
-1030	VIRTNET_ERR_SNAP_NET_DEV_MODIFY	Failed to modify SNAP device
-1031	VIRTNET_ERR_SNAP_PF_HOTPLUG	Failed to hotplug SNAP PF
-1032	VIRTNET_ERR_VQ_PERIOD_UPDATE	Failed to update VQ period
-1033	VIRTNET_ERR_QUEUE_SIZE_INVALID	Failed - Queue size is invalid
-1034	VIRTNET_ERR_SF_PORT_ADD	Failed to add SF port
-1035	VIRTNET_ERR_WQ_WORKQUEUE_ALLOC	Failed to alloc workqueue
-1036	VIRTNET_ERR_ETH_VQS_OPERATION_ALLOC	Failed to alloc eth VQS operation
-1037	VIRTNET_ERR_ETH_VQS_OPERATION_COMP	Failed to complete eth VQS operation
-1038	VIRTNET_ERR_JSON_OBJ_NOT_EXIST	Failed - JSON obj does not exist
-1039	VIRTNET_ERR_DEV_LOAD_PREP	Failed to prepare device load
-1040	VIRTNET_ERR_DEV_SW_MIGRATION	Failed to sw migrate a device
-1041	VIRTNET_ERR_DEV_IS_SW_MIGRATING	Failed - Device is migrating
-1042	VIRTNET_ERR_MAX_QUEUE_SIZE	Error - queue size must be greater than 2 and is power of 2

Errno	Error Name	Error Description
-1043	VIRTNET_ERR_MSIX_LESS_EQUAL_THREE	Warning - this device won't function, don't try to probe with virtio driver
-1044	VIRTNET_ERR_SF_POOL_CREATING	SF pool is creating try again later
-1046	VIRTNET_ERR_INVALID_OPTION	Option is not supported
-1047	VIRTNET_ERR_SF_CREATE	Failed to create SF
-1048	VIRTNET_ERR_DEV_SF_NUM_OUT_OF_RANGE	SF number for hotplug device should be between 2000 and 2999
-1049	VIRTNET_ERR_DEV_SF_NUM_USED	SF number is already used
-1050	VIRTNET_ERR_QUEUE_NUMBER_INVALID	Queue index is invalid
-1051	VIRTNET_ERR_SPEED_INVALID	Invalid speed please check help menu for supported link speeds
-1052	VIRTNET_ERR_SUPPORTED_HASH_TYPES_INVALID	Invalid hash types please check help menu for supported hash types
-1053	VIRTNET_ERR_RSS_MAX_KEY_SIZE_INVALID	Invalid rss max key size supported key size is 40
-1054	VIRTNET_ERR_REC_OFFLOADS_SAVE	Failed to save OFFLOADS into recovery file
-1055	VIRTNET_ERR_SF_OFFLOADS_UPDATE	Failed to update OFFLOADS by SF
-1056	VIRTNET_ERR_READ_LINK	Failed to readlink
-1057	VIRTNET_ERR_PATH_FORMAT	Error - Path format is invalid
-1058	VIRTNET_ERR_Q_COUNTER_ALLOC	Failed to alloc q counter
-1059	VIRTNET_ERR_REC_DIRTY_LOG_SAVE	Failed to save dirty log
-1060	VIRTNET_ERR_REC_DIRTY_LOG_DEL	Failed to delete dirty log
-1061	VIRTNET_ERR_REC_LM_STATUS_SAVE	Failed to save LM status
-1062	VIRTNET_ERR_REC_LM_STATUS_REC	Failed to found LM status record
-1063	VIRTNET_ERR_REC_DEV_MODE_SAVE	Failed to save dev mode
-1064	VIRTNET_ERR_REC_DEV_MODE_REC	Failed to found dev mode record
-1065	VIRTNET_ERR_UNPLUG_NOT_READY	Error - Device is not ready to be unplugged please check host and retry
-1066	VIRTNET_ERR_REC_MAC_TABLE_DEL	Failed to delete MAC table in recovery file
-1067	VIRTNET_ERR_REC_MAC_TABLE_LOAD	Failed to load MAC table from recovery file
-1068	VIRTNET_ERR_REC_MAC_TABLE_SAVE	Failed to save MAC table into recovery file
-1069	VIRTNET_ERR_REC_HASH_CFG_DEL	Failed to delete hash cfg in recovery file
-1070	VIRTNET_ERR_REC_HASH_CFG_LOAD	Failed to load hash cfg from recovery file

Errno	Error Name	Error Description
-1071	VIRTNET_ERR_REC_HASH_CFG_SAVE	Failed to save hash cfg into recovery file
-1072	VIRTNET_ERR_DEV_VF_GET	Failed to get VF device
-1073	VIRTNET_ERR_MAX_QUEUES_INVALID	Failed - QUEUES is invalid
-1074	VIRTNET_ERR_DEBUGFS_SAVE	Failed to save into debugfs file
-1075	VIRTNET_ERR_DEBUGFS_DEL	Failed to delete from debugfs file

8.14.6 Feature Guidance

8.14.6.1 Counters

8.14.6.1.1 Packet Statistics

To query the packet counters, use `stats` command.

```
[dpu]# virtnet stats [-h] {[-p PF] [-v VF] | [-u VUID]} [-q QUEUE_ID]
```

> The options `--pf`, `--vf` and `--vuid` are mutually exclusive, but one of them must be applied.

Option	Abbr	Argument Type	Required	Description
`--help`	`-h`	N/A	No	Show the help message and exit
`--pf`	`-p`	Number	No	Unique device ID for the PF. Can be retrieved by using `virtnet list`.
`--vf`	`-v`	Number	No	Unique device ID for the VF. Can be retrieved by using `virtnet list`.
`--vuid`	`-u`	String	No	Unique device SN for the device (PF/VF). Can be retrieved by using `virtnet list`.
`--queue_id`	`-q`	Number	No	Queue index of the device RQs or SQs

⚠ This command is recommended for obtaining all packet counter information. The existing packet counter information available through the `virtnet list` and `virtnet query` commands will be deprecated in the future.

The following command queries PF 0 and VQ 0 (i.e., RQ):

```
[dpu]# virtnet stats -p 0 -q 0
```

Output:

```
# virtnet stats -p 0 -q 0
{'pf': '0x0', 'queue_id': '0x0'}
{
  "device": {
    "pf_id": 0,
    "packet_counters": "Enabled",
    "queues-stats": [
      {
        "VQ Index": 0,
        "rx_64_or_less_octet_packets": 0,
        "rx_65_to_127_octet_packets": 259,
        "rx_128_to_255_octet_packets": 0,
        "rx_256_to_511_octet_packets": 0,
        "rx_512_to_1023_octet_packets": 0,
        "rx_1024_to_1522_octet_packets": 0,
        "rx_1523_to_2047_octet_packets": 0,
        "rx_2048_to_4095_octet_packets": 199,
        "rx_4096_to_8191_octet_packets": 0,
        "rx_8192_to_9022_octet_packets": 0,
        "received_desc": "4096",
        "completed_desc": "0",
        "bad_desc_errors": "0",
        "error_cqes": "0",
        "exceed_max_chain": "0",
        "invalid_buffer": "0",
        "batch_number": "64",
        "dma_q_used_number": "0",
        "handler_schd_number": "44",
        "aux_handler_schd_number": "43",
        "max_post_desc_number": "0",
        "total_bytes": "0",
        "err_handler_schd_num": "0",
        "rq_cq_max_count": "0",
        "rq_cq_period": "0",
        "rq_cq_period_mode": "1"
      }
    ]
  }
}
```

The output has two sections.

- The first section, wrapped by `device`, are device details along with the packet counter statics enable state.

Entry	Type	Description
`device`	String	Entries under this section is per device information
`pf_id`	String	Physical function ID
`packet_counters`	String	packet counters feature: enabled/disabled

- The second section, wrapped by `queues-stats`, are information for each receive VQ.

Entry	Type	Description
`VQ Index`	Number	The VQ index starts at 0 (the first RQ) and continues up to the last SQ
`rx_64_or_less_octet_packets`	Number	The number of packets received with a size of 0 to 64 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_65_to_127_octet_packets`	Number	The number of packets received with a size of 65 to 127 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_128_to_255_octet_packets`	Number	The number of packets received with a size of 128 to 255 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_256_to_511_octet_packets`	Number	The number of packets received with a size of 256 to 511 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_512_to_1023_octet_packets`	Number	The number of packets received with a size of 512 to 1023 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_1024_to_1522_octet_packets`	Number	The number of packets received with a size of 1024 to 1522 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_1523_to_2047_octet_packets`	Number	The number of packets received with a size of 1523 to 2047 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_2048_to_4095_octet_packets`	Number	The number of packets received with a size of 2048 to 4095 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_4096_to_8191_octet_packets`	Number	The number of packets received with a size of 4096 to 8191 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`rx_8192_to_9022_octet_packets`	Number	The number of packets received with a size of 8192 to 9022 bytes. Relevant for BlueField-3 RQ when packet counter is enabled.
`received_desc`	Number	Total number of received descriptors by the device on this VQ
`completed_desc`	Number	Total number of completed descriptors by the device on this VQ
`bad_desc_errors`	Number	Total number of bad descriptors received on this VQ
`error_cqes`	Number	Total number of errors CQ entries on this VQ
`exceed_max_chain`	Number	Total number of chained descriptors received that exceed the max allowed chain by the device
`invalid_buffer`	Number	Total number of times device tried to read or write buffer that is not registered to the device
`batch_number`	Number	The number of RX descriptors for the last received packet. Relevant for BlueField-3.

Entry	Type	Description
`dma_q_used_number`	Number	The DMA q index used for this VQ. Relevant for BlueField-3.
`handler_schd_number`	Number	Scheduler number for this VQ. Relevant for BlueField-3.
`aux_handler_schd_number`	Number	Aux scheduler number for this VQ. Relevant for BlueField-3.
`max_post_desc_number`	Number	Maximum number of posted descriptors on this VQ. Relevant for DPA.
`total_bytes`	Number	Total number of bytes handled by this VQ. Relevant for BlueField-3.
`rq_cq_max_count`	Number	Event generation moderation counter of the queue. Relevant for RQ.
`rq_cq_period`	Number	Event generation moderation timer for the queue in 1µsec granularity. Relevant for RQ.
`rq_cq_period_mode`	Number	Current period mode for RQ • 0x0 – `default_mode` – use device best defaults • 0x1 – `upon_event` – `queue_period` timer restarts upon event generation • 0x2 – `upon_cqe` – `queue_period` timer restarts upon completion generation The second section wrapped by queues-stats IS information for each receive VQ.

8.14.6.1.1.1 VQ Statistics

To query Rx VQ statistics, use the corresponding VQ index. For example, If there are 3 queues configured then to query Rx, VQ uses queue 0, Tx VQ uses queue 1, and Ctrl VQ uses queue 2.

The following is the command to query PF 0, VF 0, and VQ 0 (i.e., Rx).

```
[dpu]# virtnet query -p 0 -v 0 -q 0
```

Output:

```
"enabled-queues-info": [
  {
    "index": "0",
    "size": "256",
    "msix_vector": "0x1",
    "enable": "1",
    "notify_offset": "0",
    "descriptor_address": "0xffffe000",
    "driver_address": "0xfffff000",
    "device_address": "0xffffff240",
    "received_desc": "256",
    "completed_desc": "19",
    "bad_desc_errors": "0",
    "error_cqes": "0",
    "exceed_max_chain": "0",
```

```
    "invalid_buffer": "0",
    "batch_number": "64",
    "dma_q_used_number": "0",
    "handler_schd_number": "4",
    "aux_handler_schd_number": "3",
    "max_post_desc_number": "0",
    "total_bytes": "6460",
    "rq_cq_max_count": "0",
    "rq_cq_period": "0",
    "rq_cq_period_mode": "1"
  }
```

The following are some of the important VQ counters:

Counter Name	Description
`total_bytes`	Number of bytes received
`received_desc`	Number of available descriptors received by device
`completed_desc`	Number of available descriptors completed by the device
`error_cqes`	Number of error CQEs received on the queue
`bad_desc_errors`	Number of bad descriptors received
`exceed_max_chain`	Number of chained descriptors received that exceed the max allowed chain by device
`invalid_buffer`	Number of times device tried to read or write buffer that is not registered to the device

8.14.6.1.2 RQ Drop Counter

When DPA is the data path provider, each RQ has its corresponding drop counter, which counts the number of packets dropped inside the DPA virtio RQs.

> The drop could also happen from the uplink or SF.

The drop counter only increments (initial value being 0), and its value gets reset to 0 when disabled.

RQ drop counter can be enabled and disabled as follows (using VF 0 on PF 0):

```
[dpu]# virtnet modify -p 0 -v 0 device -dc enable
[dpu]# virtnet modify -p 0 -v 0 device -dc disable
```

> Drop counter is attached to a RQ, thus RQ must be created first. This means that the virtio-net device should be probed by the driver on the host OS before running the commands above.

To query the drop counter value(s), run:

```
[dpu]# virtnet query -p 0 -v 0 | grep num_desc_drop_pkts
```

If there are more than one RQ for a device, the drop count is the sum of all RQ's value.

8.14.6.1.3 Packet Counter

> ⚠ Relevant for BlueField-3 only.

The packet counter feature helps the user query the byte-wise packet counters for each Rx queue.

By default, byte-wise packet counters are disabled as that negatively impacts performance. When the user is interested in the debug, enable the packet counter feature using the below command

Packet counter can be enabled and disabled as follows (using VF 0 on PF 0):

```
[dpu]# virtnet modify -p 0 -v 0 device -pkt_cnt enable
[dpu]# virtnet modify -p 0 -v 0 device -pkt_cnt disable
```

- When enabled, byte-wise packet counters are initialized to zero.
- When disabled, the previous values are retained for debugging purposes. The command will still return these old, disabled counter values.

> ⚠ Packet counters are attached to an RQ. Thus, RQ must be created first. This means that the virtio-net device should be probed by the driver on the host OS before running the commands above.

8.14.6.1.4 Health Statistics

> ⚠ Relevant for BlueField-3 only.

The health statistics are for displaying real-time health information of a specific device.

Output example (using VF 0 on PF 0):

```
[dpu]# virtnet health -p 0 -v 0 show
{
  "pf_id": 0,
  "vf_id": 0,
  "type": "VF",
  "vuid": "MT2306XZ00BPVNETS0D0F2",
  "dev_status": {
    "value": "0xf",
    "    0": "ACK",
    "    1": "DRIVER",
    "    2": "DRIVER_OK",
    "    3": "FEATURES_OK"
  },
  "health_status": "Good",
  "health_recover_counter": 0,
  "dev_health_details": {
    "control_plane_errors": {
      "sf_rqt_update_err": 0,
      "sf_drop_create_err": 0,
      "sf_tir_create_err": 0,
      "steer_rx_domain_err": 0,
      "steer_rx_table_err": 0,
      "sf_flows_apply_err": 0,
      "aarfs_flow_init_err": 0,
      "vlan_flow_init_err": 0,
      "drop_cnt_config_err": 0
```

```
    },
    "data_plane_errors": {
      "sq_stall": 0,
      "dma_q_stall": 0,
      "spurious_db_invoke": 0,
      "aux_not_invoked": 0,
      "dma_q_errors": 0,
      "host_read_errors": 0
    }
  }
```

Where:

- `health_status` represents the overall status of the device (`Good` or `Fatal`)
- `dev_health_details` has two sections, `control_plane_errors` and `data_plane_errors`, as explained in the following table:

Counter Name	Description
Control Plane Errors	
`sf_rqt_update_err`	Counter tallying receive queue table update failures
`sf_drop_create_err`	Counter tallying drop RQ creation failures
`sf_tir_create_err`	Counter tallying TIR create failures
`steer_rx_domain_err`	Counter tallying RX steering rule creation failures
`steer_rx_table_err`	Counter tallying RX table creation failures
`sf_flows_apply_err`	Counter tallying packet flow rule creation failures
`aarfs_flow_init_err`	Counter tallying packet flow initialization failures
`vlan_flow_init_err`	Counter tallying VLAN flow rule initialization failures
`drop_cnt_config_err`	Counter tallying drop counter configuration failures
Data Plane Errors	
`sq_stall`	One or more network send queues stalled without getting completions. This leads traffic stalling for packets flowing over this VQ.
`dma_q_stall`	QP which is paired to itself issues a read request from the DPA to the host to read either available index or descriptor table. This request does not result in a completion and hangs in a loop waiting for a response.
`spurious_db_invoke`	Doorbell handler is repeatedly invoked but DPA finds no new data to be read and posted. This could be due to a faulty driver or issue on the DPA side.

`aux_not_invoked`	To speed up descriptor processing, an auxiliary execution (EU) unit is used if available. The primary thread invokes this EU and waits for the expected thread to run on the auxiliary execution unit. If this EU is not invoked, the primary thread hangs.
`dma_q_errors`	QP which is paired to itself issues a read request from the DPA to the host to read either an available index or the descriptor table. This request results in an error and the QP becomes unavailable. An internal mechanism detects this error QP and recycles it for use at later stage.

8.14.6.2 Dynamic Interruption Moderation

Dynamic Interrupt Moderation (DIM) adjusts the interrupt moderation settings to optimize packet processing. For guest OS kernels older than version 6.8, DIM offloads this function to the DPU, reducing the interrupt rate from the guest OS.

By lowering the interrupt rate in high-bandwidth traffic scenarios, DIM enhances CPU utilization for both the hypervisor and guest VMs, while maintaining nearly the same bandwidth.

> ⚠ DIM is only supported on BlueField-3.

For example, the following table shows the benefit of using DIM:

	Tx Interrupt Rate (K irq/s)	Rx Interrupt Rate (K irq/s)	Tx Throughput (Gb/s)	Rx Throughput (Gb/s)
DIM Enabled	7.3	7.5	171	181
DIM Disabled	7.5	23.7	175	181

The following test parameters:

- Guest OS kernel version – 5.11.0
- Number of virtio-net device – 1
- Number of QPs – 31
- Queue depth – 1024
- MTU – 1500
- Benchmark – iPerf with 31 streams

8.14.6.2.1 Configuring DIM

DIM is a per-device configuration. To enable or disable it, use this command:

```
[dpu]# virtnet modify -p <pf> [-v <vf>] device -dim {enable | disable}
```

Configuration example:

1. Unload drivers from the guest-OS side:

   ```
   [host]# modprobe -rv virtio_net && modprobe -rv virtio_pci
   ```

2. Enable DIM:

   ```
   [dpu]# virtnet modify -p 0 device -dim enable
   {'pf': '0x0', 'all': '0x0', 'subcmd': '0x0', 'dim_config': 'enable'}
   {
     "errno": 0,
     "errstr": "Success"
   }
   ```

   > Using `disable` disables DIM.

3. Load the drivers:

   ```
   [host]# modprobe -v virtio_pci && modprobe -v virtio_net
   ```

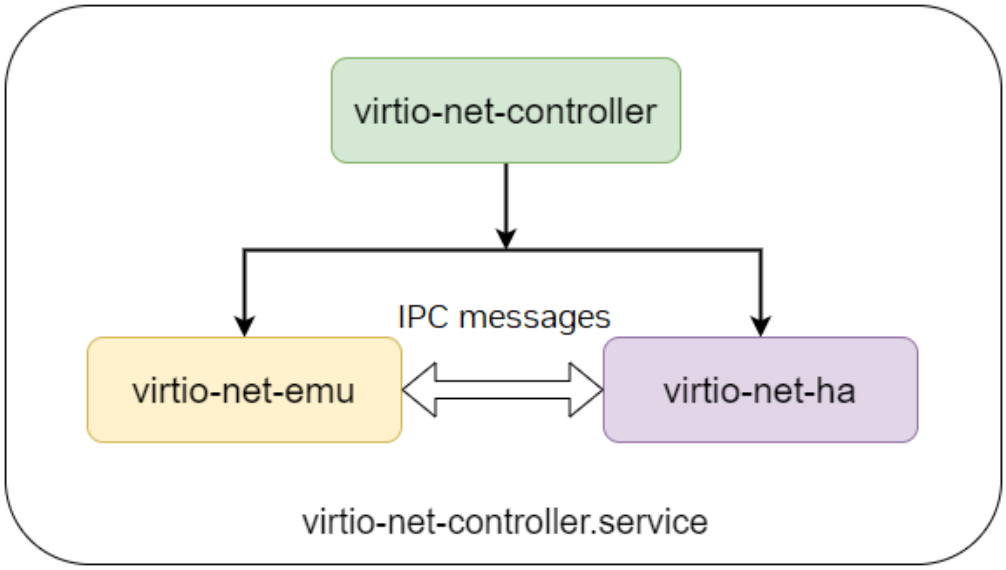
4. Query the device to verify `dim` is enabled:

   ```
   [dpu]# virtnet query -p 0 -b | grep -i dim
         "dim": "enabled"
   ```

8.14.6.3 High Availability

High availability (HA) is essential in network infrastructure to ensure continuous performance with minimal downtime, even during failures.

To support HA, the `virtio-net-controller` process creates the auxiliary processes `virtio-net-emu` and `virtio-net-ha`. The `virtio-net-emu` process handles primary controller functions, while `virtio-net-ha` manages HA. `virtio-net-ha` saves and oversees critical resources from `virtio-net-emu` and restores it to a working state if a failure occurs. The two processes communicate through IPC messages.



High availability is only supported on BlueField-3 and after.

The following table provides possible expected behaviors:

Scenarios	Behavior	Downtime Per Device (sec)	Fallback Action
Virtio-net-emu process crashes (e.g., Segfault)	The `virtio-net-ha` process tries to automatically recover all devices	< 1	The `virtnet restart` command if recovery failed
Device/VQ/SF create/ destroy failures	HA makes sure the existing device is not affected	N/A	Retry or restart service
DPA command timeout	No action from HA; DPA is likely stuck	N/A	The `virtnet restart` command

8.14.6.4 Jumbo MTU

Jumbo MTU is critical for increasing the efficiency of Ethernet and network processing by reducing the protocol overhead (ratio of headers and payload size).

To enable support for jumbo MTU, run the following virtnet command:

```
[dpu]# virtnet modify -p 0 -v 0 device -t 9216
```

The example sets the MTU to 9126 for VF 0 on PF 0.

Jumbo MTU is only supported starting from the following version:

	Release
Upstream	VM kernel: 4.18.0-193.el8.x86_64 (VM Linux version supports big MTU after 4.11)
Ubuntu	DOCA_2.5.0_BSP_4.5.0_Ubuntu_22.04
Virtnet controller	v1.7 or v1.6.26

To configure jumbo MTU (e.g., using VF 0 on PF 0):

1. Change the MTU of the uplink and SF representor from the BlueField:

   ```
   [dpu]# ifconfig p0 mtu 9216
   [dpu]# ifconfig en3f0pf0sf3000 mtu 9216
   ```

   If a bond is configured, change the MTU of the bond rather than `p0`:

   ```
   [dpu]# ifconfig bond0 mtu 9216
   [dpu]# ifconfig en3f0pf0sf3000 mtu 9216
   ```

2. Restart the virtio-net-controller from the BlueField:

   ```
   [dpu]# systemctl restart virtio-net-controller
   ```

3. Unload the virtio driver from the host OS:

   ```
   [host]# modprobe -rv virtio-net
   ```

4. Change the corresponding device MTU on the BlueField:

   ```
   [dpu]# virtnet modify -p 0 -v 0 device -t 9216
   ```

5. Reload virtio driver from the host OS:

   ```
   [host]# modprobe -v virtio-net
   ```

6. Check virtqueue MTU configuration is correct on the BlueField:

   ```
   [dpu]# virtnet query -p 0 -v 0 --dbg_stats | grep jumbo_mtu
       "jumbo_mtu": 1
       "jumbo_mtu": 1
   ```

7. Change the MTU of virtio-net interface from the host OS:

   ```
   [host]# ifconfig <vnet> mtu 9216
   ```

8.14.6.5 Link Aggregation

It is common to use link aggregation (LAG) or bond interfaces to increase reliability, availability, or bandwidth of networking devices. Virtio-net devices support this mode via DPU-side LAG configurations.

To configure the virtio-net-controller in LAG mode must follow a specific procedure due to the dependency on mlx5 RDMA device:

1. Stop the virtio-net-controller to avoid resource leakage (which would be caused by LAG destroying the existing mlx5 RDMA device and creating a new bond RDMA device).

```
[dpu]# systemctl stop virtio-net-controller.service
```

2. Configure the LAG interface for two uplink interfaces from the DPU side. Refer to the "Link Aggregation" page for detailed steps.

> The virtio-net-controller service starts by default. If DPU is rebooted during LAG configuration, it is necessary to stop the controller before creating a bond interfaces from the DPU side.

3. Update the controller configuration file to use bond interface.

```
[dpu]# cat /opt/mellanox/mlnx_virtnet/virtnet.conf
{
  "ib_dev_lag": "mlx5_bond_0",
  "ib_dev_for_static_pf": "mlx5_bond_0",
  "is_lag": 1,
}
```

> Refer to page "Configuration File" for details.

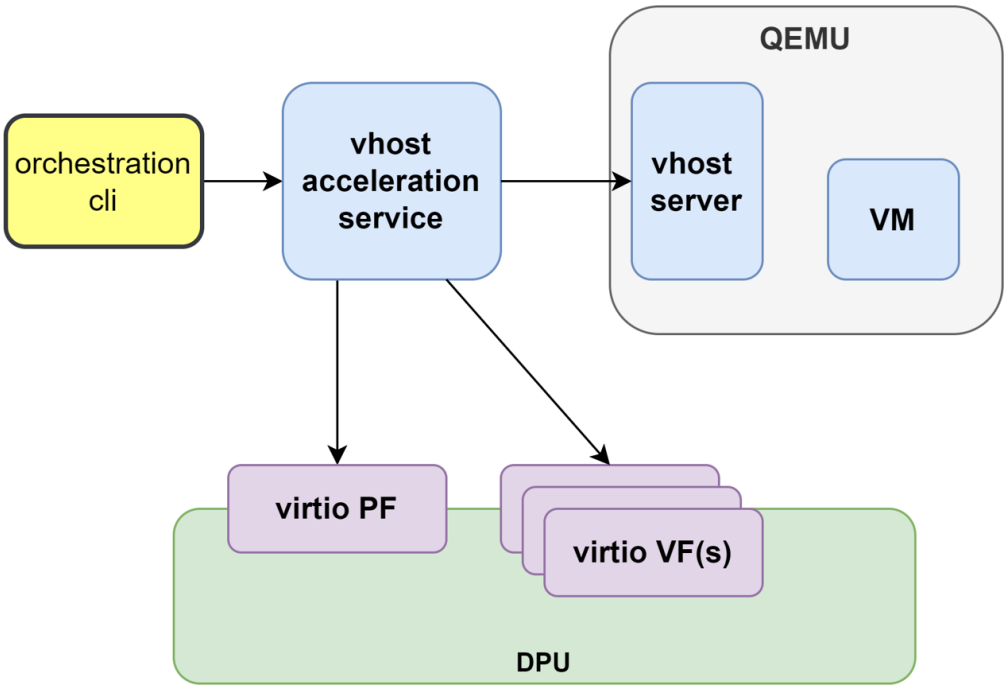
4. Start the controller for the new configuration to take effect.

```
[dpu]# systemctl start virtio-net-controller.service
```

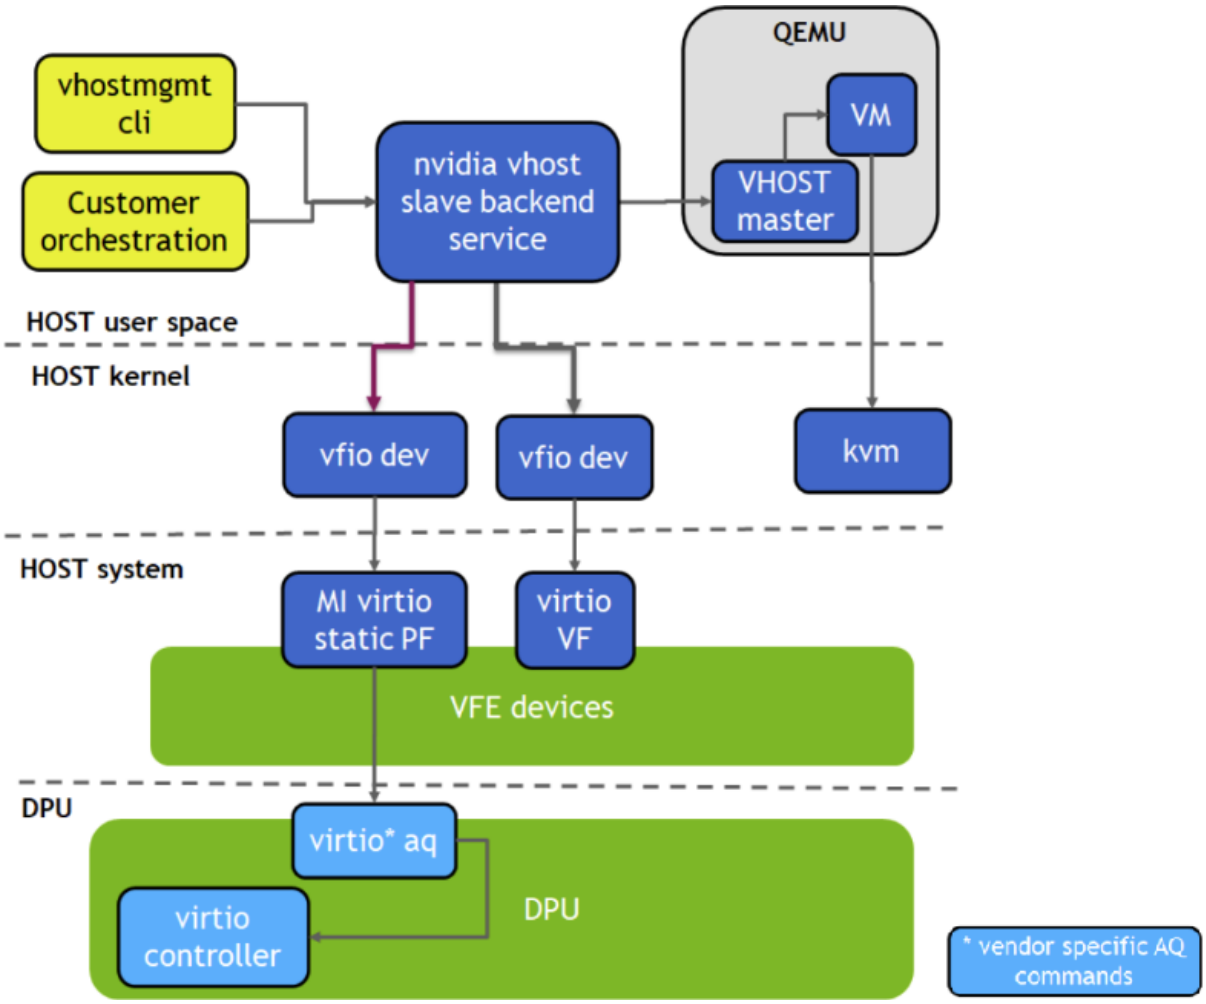
8.14.6.6 Live Migration

8.14.6.6.1 Live Migration Using vHost Acceleration Software Stack

Virtio VF PCIe devices can be attached to the guest VM using the vhost acceleration software stack. This enables performing live migration of guest VMs.



This section provides the steps to enable VM live migration using virtio VF PCIe devices along with vhost acceleration software.



8.14.6.6.1.1 Prerequisites

- Minimum hypervisor kernel version – Linux kernel 5.15 (for VFIO SR-IOV support)
- To use high-availability (the additional `vfe-vhostd-ha` service which can persist datapath when `vfe-vhostd` crashes), this kernel patch must be applied.

8.14.6.6.1.2 Install vHost Acceleration Software Stack

Vhost acceleration software stack is built using open-source BSD licensed DPDK.

- To install vhost acceleration software:

  a. Clone the software source code:

  ```
  [host]# git clone https://github.com/Mellanox/dpdk-vhost-vfe
  ```

  > The latest release tag is `vfe-24.10.0-rc2`.

  b. Build software:

```
[host]# apt-get install libev-dev -y
[host]# apt-get install libev-libevent-dev  -y
[host]# apt-get install uuid-dev  -y
[host]# apt-get install libnuma-dev -y
[host]# meson build --debug -Denable_drivers=vdpa/virtio,common/virtio,common/virtio_mi,common/
virtio_ha
[host]# ninja -C build install
```

- To install QEMU:

> Upstream QEMU later than 8.1 can be used or the following NVIDIA QEMU.

a. Clone NVIDIA QEMU sources.

```
[host]# git clone git@github.com:Mellanox/qemu.git -b stable-8.1-presetup
[host]# git checkout 24aaba9255
```

> Latest stable commit is `24aaba9255`.

b. Build NVIDIA QEMU.

```
[host]# mkdir bin
[host]# cd bin
[host]# ../configure --target-list=x86_64-softmmu --enable-kvm
[host]# make -j24
```

8.14.6.6.1.3 Configure vHost on Hypervisor

a. Configure 1G huge pages:

```
[host]# mkdir /dev/hugepages1G
[host]# mount -t hugetlbfs -o pagesize=1G none /dev/hugepages1G
[host]# echo 16 > /sys/devices/system/node/node0/hugepages/hugepages-1048576kB/nr_hugepages
[host]# echo 16 > /sys/devices/system/node/node1/hugepages/hugepages-1048576kB/nr_hugepages
```

b. Enable `qemu:commandline` in VM XML by adding the `xmlns:qemu` option:

```
<domain type='kvm' xmlns:qemu='http://libvirt.org/schemas/domain/qemu/1.0'>
```

c. Assign a memory amount and use 1GB page size for huge pages in VM XML:

```
 <memory unit='GiB'>4</memory>
 <currentMemory unit='GiB'>4</currentMemory>
 <memoryBacking>
    <hugepages>
      <page size='1' unit='GiB'/>
    </hugepages>
 </memoryBacking>
```

d. Set the memory access for the CPUs to be shared:

```
<cpu mode='custom' match='exact' check='partial'>
  <model fallback='allow'>Skylake-Server-IBRS</model>
  <numa>
    <cell id='0' cpus='0-1' memory='4' unit='GiB' memAccess='shared'/>
  </numa>
</cpu>
```

e. Add a virtio-net interface in VM XML:

```
<qemu:commandline>
  <qemu:arg value='-chardev'/>
  <qemu:arg value='socket,id=char0,path=/tmp/vhost-net0,server=on'/>
  <qemu:arg value='-netdev'/>
  <qemu:arg value='type=vhost-user,id=vhost1,chardev=char0,queues=4'/>
  <qemu:arg value='-device'/>
  <qemu:arg value='virtio-net-pci,netdev=vhost1,mac=00:00:00:00:33:00,vectors=10,page-per-
vq=on,rx_queue_size=1024,tx_queue_size=1024,mq=on,disable-legacy=on,disable-modern=off'/>
</qemu:commandline>
```

8.14.6.6.1.4 Run vHost Acceleration Service

1. Bind the virtio PF devices to the `vfio-pci` driver:

```
[host]# modprobe vfio vfio_pci
[host]# echo 1 > /sys/module/vfio_pci/parameters/enable_sriov
[host]# echo 0x1af4 0x1041 > /sys/bus/pci/drivers/vfio-pci/new_id
[host]# echo 0x1af4 0x1042 > /sys/bus/pci/drivers/vfio-pci/new_id
[host]# echo <pf_bdf> > /sys/bus/pci/drivers/virtio-pci/unbind
[host]# echo <vf_bdf> > /sys/bus/pci/drivers/virtio-pci/unbind
[host]# echo <pf_bdf> > /sys/bus/pci/drivers/vfio-pci/bind
[host]# echo <vf_bdf> > /sys/bus/pci/drivers/vfio-pci/bind
[host]# lspci -vvv -s <pf_bdf> | grep "Kernel driver"
Kernel driver in use: vfio-pci
[host]# lspci -vvv -s <vf_bdf> | grep "Kernel driver"
Kernel driver in use: vfio-pci
```

> Example of `<pf_bdf>` or `<vf_bdf>` format: `0000:af:00.3`

2. Run the vhost acceleration software service by starting the `vfe-vhostd` service:

```
[host]# systemctl start vfe-vhostd
```

> A log of the service can be viewed by running the following:
>
> ```
> [host]# journalctl -u vfe-vhostd
> ```

3. Provision the virtio-net PF:

```
[host]# /usr/local/bin/vfe-vhost-cli mgmtpf -a <pf_bdf>
```

Wait on the virtio-net-controller to finish handling PF FLR.

4. Enable SR-IOV and create a VF (or more):

```
[host]# echo 1 > /sys/bus/pci/devices/<pf_bdf>/sriov_numvfs
[host]# lspci | grep Virtio
0000:af:00.1 Ethernet controller: Red Hat, Inc. Virtio network device
0000:af:00.3 Ethernet controller: Red Hat, Inc. Virtio network device
```

5. Add a VF representor to the OVS bridge on the BlueField:

```
[dpu]# virtnet query -p 0 -v 0 | grep sf_rep_net_device
"sf_rep_net_device": "en3f0pf0sf3000",
[dpu]# ovs-vsctl add-port ovsbr1 en3f0pf0sf3000
```

6. Provision the virtio-net VF:
    a. On BlueField, change VF MAC address or other device options:

```
[dpu]# virtnet modify -p 0 -v 0 device -m 00:00:00:00:33:00
```

b. Add VF into vfe-dpdk

```
[host]# /usr/local/bin/vfe-vhost-cli vf -a <vf_bdf> -v /tmp/vhost-net0
```

> ⚠ If the SR-IOV is disabled and reenabled, the user must re-provision the VFs. `00:00:00:00:33:00` is a virtual MAC address used in VM XML.

8.14.6.6.1.5 Start the VM

```
[host]# virsh start <vm_name>
```

8.14.6.6.1.6 HA Service

Running the `vfe-vhostd-ha` service allows the datapath to persist should `vfe-vhostd` crash:

```
[host]# systemctl start vfe-vhostd-ha
```

8.14.6.6.1.7 Simple Live Migration

1. Prepare two identical hosts and perform the provisioning of the virtio device to DPDK on both.
2. Boot the VM on one server:

```
[host]# virsh migrate --verbose --live --persistent <vm_name> qemu+ssh://<dest_node_ip_addr>/system --
unsafe
```

8.14.6.6.1.8 Remove Device

When finished with the virtio devices, use following commands to remove them from DPDK:

```
[host]# /usr/local/bin/vfe-vhost-cli vf -r <vf_bdf>
[host]# /usr/local/bin/vfe-vhost-cli mgmtpf -r <pf_bdf>
```

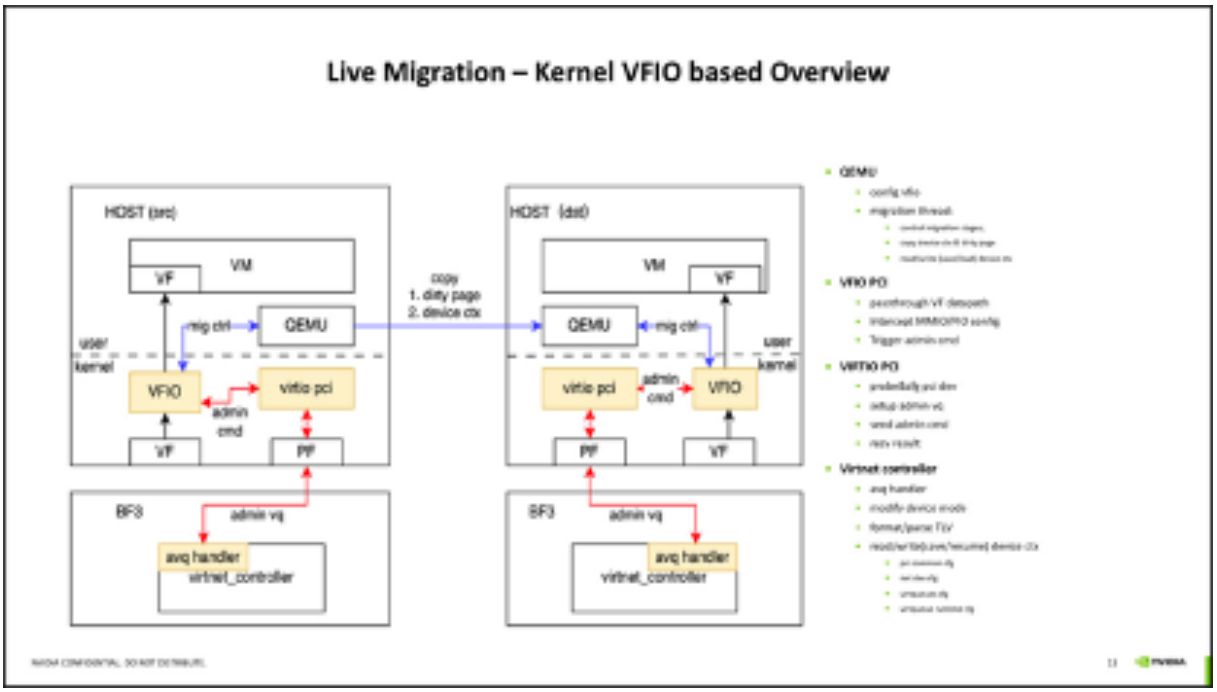
> ⚠ During live migration, the device state may change temporarily. As a result, Linux NetworkManager may reset the associated network interface properties (e.g., IP address).
>
> To prevent NetworkManager from managing a specific interface, run:

```
nmcli device set {device-interface} managed no
```

8.14.6.6.2 Live Migration Using VFIO With Full Emulation

Virtio VF PCIe devices can be attached to the guest VM using the `virtio-vfio-pci` driver. This enables performing live migration of guest VMs.

This section demonstrates how to perform basic live migration of a QEMU VM with a virtio VF assigned to it. It does not explain how to create VMs using libvirt or directly via QEMU.



8.14.6.6.2.1 Prerequisites

1. Minimum Hypervisor kernel version - Linux kernel 6.13-rc2 with `virtio_vfio_pci` and IOMMU dirty page tracking
2. Minimum qemu version - 9.1
3. Minimum libvirt version - 9.2

8.14.6.6.2.2 DPU Configuration

1. Install new `virtio-net-controller` (version `25.04` or newer) on source and destination systems.
2. Add the following flags on the source and destination systems.

```
[dpu]# vim /opt/mellanox/mlnx_virtnet/virtnet.conf
{
  ...
  "virtio_spec_admin_legacy": 1,
  "virtio_spec_admin_lm": 1
```

```
}
```

3. Restart the controller
4. Provision device attributes. [After loading `virtio-pci-vfio` driver and before starting the VM]
5. Get the MAC of the source device

```
[dpu]# virtnet query -p $pf_id -v $vf_id | grep "\"mac"
```

6. Set the MAC of the destination device

```
[dpu]# virtnet modify -p $dst_pf_id -v $dst_vf_id device -m $mac
```

8.14.6.6.2.3 Kernel Configuration

Needs to be compiled with the driver `virtio_vfio_pci` enabled. (i.e. CONFIG_VIRTIO_VFIO_PCI).

To load the driver, run:

```
[host]# modprobe virtio_vfio_pci
```

8.14.6.6.2.4 QEMU Configuration

1. Needs to be compiled with VFIO_PCI enabled (this is enabled by default).
2. Add the following to qemu.conf:

```
user = "root"
group = "root"
cgroup_device_acl = [
    "/dev/null", "/dev/full", "/dev/zero",
    "/dev/random", "/dev/urandom",
    "/dev/ptmx", "/dev/kvm",
    "/dev/iommu", "/dev/vfio/devices/vfio0",
    "/dev/vfio/devices/vfio1"
]
```

3. Restart libvirt

8.14.6.6.2.5 Host Preparation

As stated earlier, creating the VMs is beyond the scope of this guide, and we assume that they have already been created. However, the VM configuration should be a migratable configuration, similarly to how it is done without virtio VFs.

> ⚠ The steps below should be done before running the VMs.

1. Create the VFs that will be assigned to the VMs.

```
[host]# echo "<NUM_OF_VFS>" > /sys/bus/pci/devices/<PF_BDF>/sriov_numvfs
```

2. Unbind the VFs from `virtio-pci`, run:

```
[host]# echo '<VF_BDF>' > /sys/bus/pci/drivers/virtio-pci/unbind
```

3. Assign the VFs to the VMs
    a. Edit the VMs XML file, run:

```
[host]# virsh edit <VM_NAME>
```

    b. Enable `qemu:commandline` in VM XML by adding the `xmlns:qemu` option:

```
<domain type='kvm' xmlns:qemu='http://libvirt.org/schemas/domain/qemu/1.0'>
```

    c. Assign the VFs to the VM by adding the following under the `device` tag:

```
<hostdev mode='subsystem' type='pci' managed='no'>
    <driver name='vfio'/>
    <source>
    <address domain='0x0000' bus='0xb1' slot='0x00' function='0x4'/>
    </source>
    <alias name='hostdev0'/>
    <address type='pci' domain='0x0000' bus='0x01' slot='0x01' function='0x0'/>
</hostdev>
```

> ⚠ The domain, bus, slot, and function values above are dummy values; replace them with your VFs values.

4. Set the source VM
    a. Edit the source VM XML file, run:

```
[host]# virsh edit <VM_NAME>
```

    b. Set up the source VM by adding the following under `domain` tag:

```
<qemu:commandline>
    <qemu:arg value='-object'/>
    <qemu:arg value='iommufd,id=iommufd0'/>
    <qemu:arg value='-snapshot'/>
</qemu:commandline>
<qemu:override>
    <qemu:device alias='hostdev0'>
        <qemu:frontend>
            <qemu:property name='enable-migration' type='string' value='on'/>
            <qemu:property name='iommufd' type='string' value='iommufd0'/>
        </qemu:frontend>
    </qemu:device>
</qemu:override>
```

> ⚠ To save the file, the above "xmlns:qemu" attribute of the "domain" tag must also be added.

5. Set the destination VM in incoming mode
    a. Edit the destination VM XML file, run:

```
[host]# virsh edit <VM_NAME>
```

    b. Set the destination VM in migration incoming mode by adding the following under the `domain` tag:

```
<domain type='kvm' xmlns:qemu='http://libvirt.org/schemas/domain/qemu/1.0'>
[...]
    <qemu:commandline>
        <qemu:arg value='--incoming'/>
        <qemu:arg value='tcp:<DEST_IP>:<DEST_PORT>'/>
        <qemu:arg value='-object'/>
        <qemu:arg value='iommufd,id=iommufd0'/>
    </qemu:commandline>
    <qemu:override>
        <qemu:device alias='hostdev0'>
        <qemu:frontend>
            <qemu:property name='enable-migration' type='string' value='on'/>
            <qemu:property name='iommufd' type='string' value='iommufd0'/>
        </qemu:frontend>
        </qemu:device>
    </qemu:override>
</domain>
```

> ⚠ To save the file, the above "xmlns:qemu" attribute of the "domain" tag must also be added.

6. Bind the VFs to `virtio_vfio_pci` driver
    a. Detach the VFs from `libvirt` management, run:

```
[host]# virsh nodedev-detach pci_<VF_BDF>
```

    b. Unbind the VFs from `vfio-pci` driver (the VFs are automatically bound to it after running "`virsh nodedev-detach`"), run:

```
[host]# echo '<VF_BDF>' > /sys/bus/pci/drivers/vfio-pci/unbind
```

    c. Set driver override, run:

```
[host]# echo 'virtio_vfio_pci' > /sys/bus/pci/devices/<VF_BDF>/driver_override
```

    d. Bind the VFs to `virtio_vfio_pci` driver, run:

```
[host]# echo '<VF_BDF>' > /sys/bus/pci/drivers/virtio_vfio_pci/bind
```

8.14.6.6.2.6 Running the Migration

1. Start the VMs in source and in destination, run:

```
[host]# virsh start <VM_NAME>
```

2. Enable `switchover-ack` QEMU migration capability. Run the following commands both in the source and the destination:

```
[host]# virsh qemu-monitor-command <VM_NAME> --hmp "migrate_set_capability return-path on"
[host]# virsh qemu-monitor-command <VM_NAME> --hmp "migrate_set_capability switchover-ack on"
```

3. [Optional] Configure the migration bandwidth and downtime limit on the source side:

```
[host]# virsh qemu-monitor-command <VM_NAME> --hmp "migrate_set_parameter max-bandwidth <VALUE>"
[host]# virsh qemu-monitor-command <VM_NAME> --hmp "migrate_set_parameter downtime-limit <VALUE>"
```

4. Start migration by running the migration command on the source side:

```
[host]# virsh qemu-monitor-command <VM_NAME> --hmp "migrate -d tcp:<DEST_IP>:<DEST_PORT>"
```

5. Check the migration status by running the info command on the source side:

```
[host]# virsh qemu-monitor-command <VM_NAME> --hmp "info migrate"
```

When the migration status is `completed` it means the migration has finished successfully.

During live migration, the device state may change temporarily. As a result, Linux NetworkManager may reset the associated network interface properties (e.g., IP address).

To prevent NetworkManager from managing a specific interface, run:

```
nmcli device set {device-interface} managed no
```

8.14.6.7 Live Update

Live update minimizes network interface downtime by performing online upgrade of the virtio-net controller without necessitating a full restart.

8.14.6.7.1 Requirements

To perform a live update, the user must install a newer version of the controller either using the `rpm` or `deb` package (depending on the OS distro used). Run:

For Ubuntu/Debian	`[dpu]# dpkg --force-all -i virtio-net-controller-x.y.z-1.mlnx.aarch64.deb`
For CentOS/RedHat	`[dpu]# rpm -Uvh virtio-net-controller-x.y.z-1.mlnx.aarch64.rpm --force`

8.14.6.7.2 Check Versions

Before staring live update, the following command can be used to check the version of the original and destination controllers:

```
[dpu]# virtnet version
  {
```

```
    "Original Controller": "v24.10.13"
  },
  {
    "Destination Controller": "v24.10.16"
  }
```

8.14.6.7.3 Start Updating

If no errors occur, issue the following command to start the live update process:

```
[dpu]# virtnet update -s
```

> ⚠ If an error indicates that the `update` command is unsupported, this means the controller version you are attempting to install is outdated. Reinstalling the correct version resolves the issue.

8.14.6.7.4 Check Status

During the update process, the following command may be used to check the update status:

```
[dpu]# virtnet update -t
```

Example output:

```
{
  "status": "inactive",                       # updating status, whether live update is finished or ongoing
  "last live update status": "success",       # last live update status
  "time_used (s)": 1.655439                   # time cost for last live update
}
```

> ⚠ During the update, it is recommended to not issue any virtnet CLI command.

When the update process completes successfully, the command `virtnet update status` reflects the status accordingly

> ⚠ If a device is actively migrating, the existing `virtnet` commands appear as "migrating" for that specific device so that the user can retry later.

> ⚠ **Limitation**
>
> When live update is in progress, hotplug/unplug and VF creation/deletion are not supported.

8.14.6.8 Mergeable Rx Buffer

The Mergeable Rx Buffer is a receive-side-only performance enhancement. When successfully negotiated with the driver, this feature allows the device to utilize multiple descriptors to accommodate a single jumbo-sized packet received from the network. It significantly improves memory utilization and throughput in environments configured for large Maximum Transmission Units (MTUs), such as 9K jumbo frames.

8.14.6.8.1 Configuration

Administrators control this feature using the `VIRTIO_NET_F_MRG_RXBUF` (bit 15) feature flag.

- Default State: Disabled.
- Scope: Can be enabled on a per-device basis.

Refer to the "Enabling and Disabling Virtio-net Features" section for the exact `virtnet modify` command syntax.

8.14.6.8.2 Limitations

Before enabling the Mergeable Rx Buffer, carefully review the following environmental constraints:

Limitation	Description
Strict MTU ceiling	The absolute maximum supported MTU when utilizing this feature is 9000. The feature will fail to operate if the MTU is set to 9216.
Performance degradation (standard MTU)	Because the number of descriptors per Work Queue Entry (WQE) depends on the MTU size, enabling this feature with a default MTU (1500) is not recommended and will negatively impact performance.
Performance degradation (small packets)	The system will experience a performance drop when processing high rates of small-sized packets (e.g., 64 bytes) from the wire. Reserve this feature exclusively for heavy jumbo-frame traffic.
Feature Incompatibility	The Mergeable Rx Buffer feature is strictly incompatible with the Packed Virtqueue feature (`VIRTIO_F_RING_PACKED`). You cannot enable both simultaneously on the same device.

8.14.6.9 Performance Tuning

8.14.6.9.1 Number of Queues and MSIX

8.14.6.9.1.1 Driver Configuration

The virtio-net driver can configure the number of combined channels via ethtool. This determines how many virtqueues (VQs) can be used for the netdev. Normally, more VQs result in better overall throughput when multi-threaded (e.g., iPerf with multiple streams).

```
[host]# ethtool -l eth0
Channel parameters for eth0:
Pre-set maximums:
RX:             n/a
TX:             n/a
Other:          n/a
Combined:       31
Current hardware settings:
RX:             n/a
TX:             n/a
Other:          n/a
Combined:       15
```

Therefore, it is common to pick a larger number (less than pre-set maximums) of channels using the following command.

Normally, configuring the combined number of channels to be the same as number of CPUs available on the guest OS will yield good performance.

```
[host]# ethtool -L eth0 combined 31
[host]# ethtool -l eth0
Channel parameters for eth0:
Pre-set maximums:
RX:             n/a
TX:             n/a
Other:          n/a
Combined:       31
Current hardware settings:
RX:             n/a
TX:             n/a
Other:          n/a
Combined:       31
```

8.14.6.9.1.2 Device Configuration

To reach the best performance, it is required to make sure each tx/rx queue has an assigned MSIX. Check the information of a particular device and make sure `num_queues` is less than `num_msix`.

```
[dpu]# virtnet query -p 0 -b | grep -i num_
      "num_msix": "64",
      "num_queues": "8",
```

If `num_queues` is greater than `num_msix`, it is necessary to change mlxconfig to reserve more MSIX than queues. It is determined by the

`VIRTIO_NET_EMULATION_NUM_VF_MSIX` and `VIRTIO_NET_EMULATION_NUM_MSIX`. Please refer to the "Virtio-net Deployment" page for more information.

8.14.6.9.2 Queue Depth

By default, queue depth is set to 256. It is common to use a larger queue depth (e.g., 1024). This cannot be requested from the driver side but must be done from the device side.

Refer to the "Virtnet CLI Commands" page to learn how to modify device `max_queue_size`.

8.14.6.9.3 MTU

To improve performance, the user can use jumbo MTU. Refer to "Jumbo MTU" page for information regarding MTU configuration.

8.14.6.10 Device State Recovery

The recovery process is critical for restoring both control plane and data plane statuses during disruptive events, such as a controller restart, a live update, or a live migration.

The system relies on persistent JSON files stored in the `/opt/mellanox/mlnx_virtnet/recovery` directory. Each physical function (PF) or virtual function (VF) device maintains a corresponding recovery file, uniquely named after the device's VUID.

8.14.6.10.1 Recovery File Structure

The controller saves the following configuration states to the recovery file and automatically restores them when necessary:

Entry Name	Type	Description
`port_ib_dev`	String	The RDMA device name on which the `virtio-net` device is created.
`pf_id`	Number	The ID of the Physical Function (PF).
`vf_id`	Number	The ID of the Virtual Function (VF). *(Valid for VFs only).*
`function_type`	String	Identifies the function as either a `pf` or `vf`.
`bdf_raw`	Number	The `virtio-net` device Bus:Device:Function (BDF) represented as a `uint16` type.

Entry Name	Type	Description
`device_type`	String	Specifies if the device is `static` or `hotplug`. *(Valid for PFs only).*
`mac`	String	The MAC address of the device.
`pf_num`	Number	The PCIe function number.
`sf_num`	Number	The Sub-Function (SF) number utilized for this `virtio-net` device.
`mq`	Number	The number of multi-queues created for this `virtio-net` device.
`rx_mode`	Number	A 32-bit value representing reception modes. Bits 0–5 correspond to: • 0: Promiscuous • 1: All multicast • 2: All unicast • 3: No multicast • 4: No unicast • 5: No broadcast
`vlan_tags`	Array	An array storing VLAN IDs (0–4095) configured for VLAN filtering.
`mac_table`	Array	Contains MAC addresses for filtering, alongside metadata (e.g., entry count, first multicast index, and overflow flags).
`offloads`	Number	Stores the active state of hardware offload features (e.g., `VIRTIO_NET_F_GUEST_CSUM`).
`sf_parent_device`	String	The Sub-Function (SF) parent device identifier.
`rx_mode_cmd`	Number	The RX mode command state.
`mac_cmd`	Number	The MAC command state.
`vlan_table_cmd`	Number	The VLAN table command state.
`announce_cmd`	Number	The Announce command state.
`announce`	Number	The Announce flag status.
`lm_status`	Number	The current Live Migration status.
`dev_mode`	Number	The operational device mode.
`dirty_log`	String	Dirty log tracking information (vital for live migration).
`transitional`	Number	Transitional mode flags.
`sys_path`	String	The system path required for SF restoration.
`sys_name`	String	The system name required for SF restoration.
`hash_cfg`	Object	The active Hash configuration.

Entry Name	Type	Description
`pkt_cnt`	Number	Packet count mode flags.
`net_dim`	Number	Net-DIM (Dynamic Interrupt Moderation) mode flags.
`aarfs`	Number	aRFS (Accelerated Receive Flow Steering) mode flags.
`hp_host_awareness_mode`	Number	Hotplug host awareness mode configuration (e.g., AB mode status).

8.14.6.10.2 Example Recovery File

The following JSON payload illustrates a standard recovery file for a hotplugged PF device:

```
{
  "port_ib_dev": "mlx5_0",
  "pf_id": 0,
  "function_type": "pf",
  "bdf_raw": 57611,
  "device_type": "hotplug",
  "mac": "0c:c4:7a:ff:22:93",
  "pf_num": 0,
  "sf_num": 2000,
  "mq": 3
}
```

8.14.6.10.3 Use Cases

Depending on the actions of the BlueField or host, recovery may or may not be performed. Please refer to the following table for individual scenarios:

	DPU Actions			Host Actions				
	Restart Controller	Live Update	Hot Unplug	Destroy VFs	Unload Driver	Power Cycle Host & DPU	Warm Reboot	Live Migration
`Static PF`	Recover	Recover	N/A	N/A	Recover	No recover	Recover	Recover
`Hotplug PF`	Recover	Recover	No recover	N/A	Recover	No recover	Recover	Recover
`VF`	Recover	Recover	N/A	Recovery file deleted	No Recover	No recover	No recover	Recover

These recovery files are internal to the controller and should not be modified.

Controller recovery is enabled by default and does not need user configuration or intervention. When the `mlxconfig` settings used by the controller take effect, the newly started controller service automatically deletes all recovery files.

Recovery File Validation and Corruption Handling

During startup, the controller strictly validates the integrity of all stored JSON recovery files before applying any state restorations. If the controller detects corrupted, malformed, or invalid data in any single recovery file during the startup sequence, it will automatically purge all recovery files in the directory and perform a fresh restart.

8.14.6.11 Transitional Device

A transitional device is a virtio device which supports drivers conforming to virtio specification `1.x` and legacy drivers operating under virtio specification `0.95` (i.e., legacy mode) so servers with old Linux kernels can still utilize virtio-based technology.

Currently, only transitional VF devices are supported.

Host kernel version must be newer than v6.9.

When using this feature, vfe-vdpa-dpdk solutions cannot be used anymore, including vfe-vdpa-dpdk live migration.

Libvirt does not support the `virtio_vfio_pci` kernel driver. Use the QEMU command line to start the VM instead.

8.14.6.11.1 Transitional Virtio-net VF Device

1. Configure virtio-net SR-IOV. Refer to "Virtio-net Deployment" for details.
2. Modify the configuration file to add the `"virtio_spec_admin_legacy": 1` option.

```
[dpu]# cat /opt/mellanox/mlnx_virtnet/virtnet.conf
{
...
"virtio_spec_admin_legacy": 1,
...
```

```
}
```

3. Restart the virtio-net controller for the configuration to take effect:

```
[dpu]# systemctl restart virtio-net-controller.service
```

4. Create virtio-net VF devices on the host:

```
[host]# modprobe -r virtio_net
[host]# modprobe -r virtio_pci
[host]# modprobe virtio_net
[host]# modprobe virtio_pci
[host]# echo <vf_num> > /sys/bus/pci/devices/<pf_bdf>/sriov_numvfs
```

5. Bind the VF devices with the `virtio_vfio_pci` kernel driver:

```
[host]# echo <vf_bdf> > /sys/bus/pci/devices/<vf_bdf>/driver/unbind
[host]# echo 0x1af4 0x1041 > /sys/bus/pci/drivers/virtio_vfio_pci/new_id
[host]# modprobe -v virtio_vfio_pci
[host]# lspci -s <vf_bdf> -vvv | grep -i virtio_vfio_pci
Kernel driver in use: virtio_vfio_pci
```

6. Add the following option into the QEMU command line to passthrough the VF device into the VM:

```
-device vfio-pci,host=<vf_bdf>,id=hostdev0,bus=pci.<#BUS_IN_VM>,addr=<#FUNC_IN_VM>
```

7. Load virtio-net driver as legacy mode inside the VM:

```
[vm]# modprobe -r virtio_net
[vm]# modprobe -r virtio_pci
[vm]# modprobe virtio_pci force_legacy=1
[vm]# modprobe virtio_net
[vm]# lspci -s <vf_bdf_in_vm> -n
00:0a.0 0200: 1af4:1000
```

8. Verify that the VF is a transitional device:

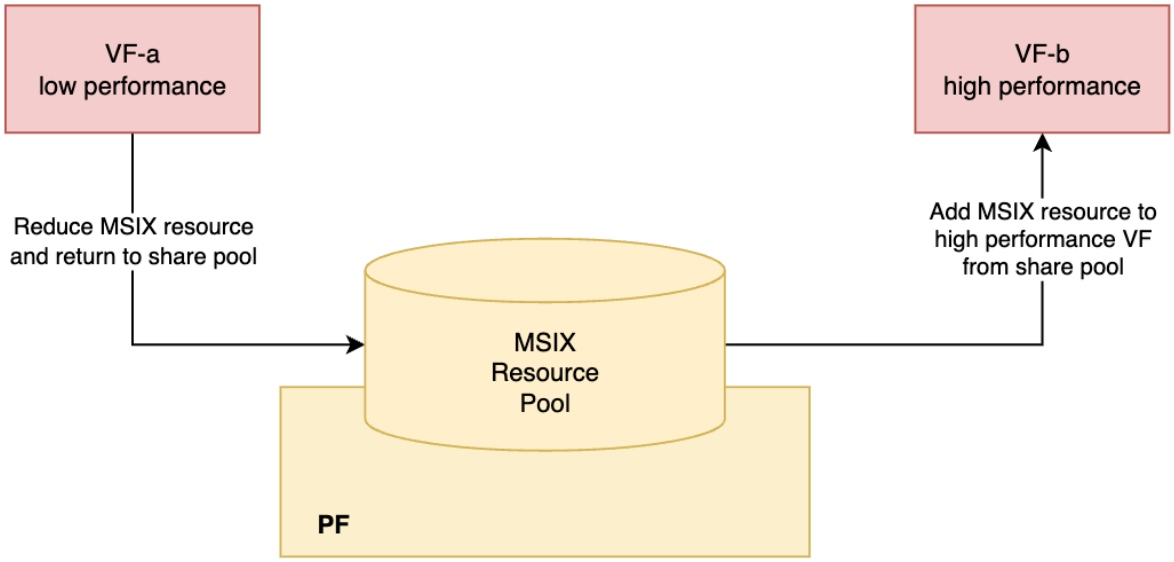
```
[dpu]# virtnet query -p <pf_id> -v <vf_id> | grep transitional
      "transitional": 1,
```

8.14.6.12 VF Dynamic MSIX

In virtio-net controller, each VF gets the same number of MSIX and virtqueues (VQs) so that each data VQ has a MSIX assigned. This means that changing the number of MSIX updates the number of VQs.

By default, each VF is assigned with the same number of MSIX, the default number is determined by the minimum of `NUM_VF_MSIX` and `VIRTIO_NET_EMULATION_NUM_MSIX`.

Using dynamic VF MSIX, a VF can be assigned with more MSIX/queues than its default. MSIX hardware resources of all VF devices are managed by PF via a shared MSIX pool. The user can reduce the MSIX of one VF, thus releasing its MSIX resources to the shared pool. On the other hand, another VF can be assigned with more MSIX than its default to gain more performance.



8.14.6.12.1 Firmware Configuration

The emulation VF device uses `VIRTIO_NET_EMULATION_NUM_VF_MSIX` to set the MSIX number.

`VIRTIO_NET_EMULATION_NUM_VF_MSIX` is available to set the MSIX number of the emulation VF device. For the emulation VF device, uses the new configuration VIRTIO_NET_EMULATION_NUM_VF_MSIX instead of the old configuration NUM_VF_MSIX.

- If `VIRTIO_NET_EMULATION_NUM_VF_MSIX` !=0, `VIRTIO_NET_EMULATION_NUM_ MSIX` is used for the PF only, and VF uses `VIRTIO_NET_EMULATION_NUM_VF_MSIX`.
  For example, to configure the default MSIX number for a VF to 32:

  ```
  [dpu]# mlxconfig -y -d 03:00.0 s VIRTIO_NET_EMULATION_NUM_ MSIX=32 VIRTIO_NET_EMULATION_NUM_VF_MSIX=32
  ```

- If `VIRTIO_NET_EMULATION_NUM_VF_MSIX` ==0, `VIRTIO_NET_EMULATION_NUM_ MSIX` is used for the PF and VF.

The default number of MSIX for each VF is determined by `minimum(NUM_VF_MSIX, VIRTIO_NET_EMULATION_NUM_MSIX)`. For example, to configure the default MSIX number for a VF to 32:

```
[dpu]# mlxconfig -y -d 03:00.0 s VIRTIO_NET_EMULATION_NUM_MSIX=32 NUM_VF_MSIX=32
```

Power cycle the BlueField and host to have the `mlxconfig` taking effect.

8.14.6.12.2 MSIX

8.14.6.12.2.1 MSIX Capability

The MSIX pool for VFs is managed by their PF. To check the share pool size, run the following command (using PF 0 as example):

```
[dpu]# virtnet list | grep -i '"pf_id": 0' -A 8 | grep -i msix_num_pool_size
```

By default, the share pool size is empty (0), since all MSIX resources have already been allocated to VFs evenly. Upon reducing the MSIX of one or more VFs, the reduced MSIX is released back to the pool.

However, the number of MSIX can be assigned to a given VF is also bound by capability. To check those caps, run the following command:

```
[dpu]# virtnet list | grep -i '"pf_id": 0' -A 10 | grep -i max_msix_num
[dpu]# virtnet list | grep -i '"pf_id": 0' -A 10 | grep -i min_msix_num
```

To check the currently assigned number of MSIX, run the following command:

```
[dpu]# virtnet query -p 0 -v 0 | grep num_msix
```

If `num_msix` is less than `max_msix_num` cap, more MSIX can be assigned to the VF.

8.14.6.12.2.2 Reallocating VF MSIX

To allocate more MSIX to one VF, there should be MSIX available from the pool. This is done by reducing the MSIX from another VF(s).

The following example shows the steps to reallocate MSIX from VF1 to VF0, assuming that each VF has `32` MSIX available as default:

1. Unbind both VF devices from host driver.

   ```
   [host]# echo <vf0_bdf> > /sys/bus/pci/drivers/virtio-pci/unbind
   [host]# echo <vf1_bdf> > /sys/bus/pci/drivers/virtio-pci/unbind
   ```

2. Reduce the MSIX of VF1.

   ```
   [dpu]# virtnet modify -p 0 -v 1 device -n 4
   ```

3. Check pool size of PF0.

   ```
   [dpu]# virtnet list | grep -i '"pf_id": 0' -A 8 | grep -i msix_num_pool_size
   ```

   Confirm the reduced MSIX are added to the share pool.

4. Increase the MSIX of VF0.

```
[dpu]# virtnet modify -p 0 -v 0 device -n 48
```

5. Check the MSIX of VF0.

```
[dpu]# virtnet query -p 0 -v 0 | grep -i num_msix
```

6. Bind both VF devices to host driver.

```
[host]# echo <vf0_bdf> > /sys/bus/pci/drivers/virtio-pci/bind
[host]# echo <vf1_bdf> > /sys/bus/pci/drivers/virtio-pci/bind
```

> ⚠ The number of MSIX must be an even number greater than 4.

8.14.6.12.2.3 MSIX Limitations

- MSIX and QP configuration is mutually exclusive (i.e., only one of them can be configured at a time). For example, the following `modify` command should result in failure:

```
[dpu]# virtnet modify -p 0 -v 1 device -qp 2 -n 6
```

- To use a VF, make sure to assign a valid MSIX number:

```
[dpu]# virtnet modify -p 0 -v 1 device -n 10
```

  The minimum number of MSIX resources required for the VF to load the host driver is 4 if `VIRTIO_NET_F_CTRL_VQ` is negotiated, or 2 if it is not.
- The MSIX resources of a VF can be reduced to 0, but doing so prevents the VF from functioning.

```
[dpu]# virtnet modify -p 0 -v 1 device -n 0
```

8.14.6.12.3 Queue Pairs

Queue pairs (QPs) are the number of data virtio queue (VQ) pairs. Each VQ pair has one transmit (TX) queue and one receive (RX) queue. These pairs are dedicated to handling data traffic and do not include control or admin VQs.

8.14.6.12.3.1 QP Capability

The QP pool for VFs is managed by their PF.

To check the shared pool size, run the following command (using PF 0 as example):

```
[dpu]# virtnet list | grep -i '"pf_id": 0' -A 13 | grep -i qp_pool_size
```

By default, the shared pool size is empty (0), since all QP resources have already been allocated to VFs evenly. Upon reducing the QP of one or more VFs, the reduced QP is released back into the pool.

However, the number of QPs assignable to a VF depends on its supported capabilities. To verify these capabilities, run the following command:

```
[dpu]# virtnet list | grep -i '"pf_id": 0' -A 12 | grep -i max_num_of_qp
[dpu]# virtnet list | grep -i '"pf_id": 0' -A 12 | grep -i min_num_of_qp
```

To check the currently assigned number of QPs, run the following command:

```
[dpu]# virtnet query -p 0 -v 0 | grep max_queue_pairs
```

If `max_queue_pairs` is less than `max_num_of_qp` cap, then more QPs can be assigned to the VF.

8.14.6.12.3.2 Reallocating VF QPs

To allocate more QPs to one VF, there should be QPs available from the pool as explained in the previous section.

The following example illustrates the process of reallocating a QP from VF1 to VF0, assuming that each VF initially has 32 QPs available by default:

1. Unbind both VF devices from the host driver:

   ```
   [host]# echo <vf0_bdf> > /sys/bus/pci/drivers/virtio-pci/unbind
   [host]# echo <vf1_bdf> > /sys/bus/pci/drivers/virtio-pci/unbind
   ```

2. Reduce the number of QPs VF1 has:

   ```
   [dpu]# virtnet modify -p 0 -v 1 device -qp 1
   ```

3. Check the pool size of PF0 and confirm that the reduced number of QPs are added to the shared pool:

   ```
   [dpu]# virtnet list | grep -i '"pf_id": 0' -A 13 | grep -i qp_pool_size
   ```

4. Increase the number of QPs VF0 has:

   ```
   [dpu]# virtnet modify -p 0 -v 0 device -qp 23
   ```

5. Check the number of QPs VF0 has:

   ```
   [dpu]# virtnet query -p 0 -v 0 | grep -i max_queue_pairs
   ```

6. Bind both VF devices to the host driver:

   ```
   [host]# echo <vf0_bdf> > /sys/bus/pci/drivers/virtio-pci/bind
   [host]# echo <vf1_bdf> > /sys/bus/pci/drivers/virtio-pci/bind
   ```

> ⚠ The number of QPs must be greater than 0.

8.14.6.12.3.3 QP Limitations

- QP and MSIX configuration is mutually exclusive (i.e., only one of them can be configured at a time). For example, the following `modify` command should result in failure:

```
[dpu]# virtnet modify -p 0 -v 1 device -qp 2 -n 6
```

- To use a VF, assign it with a valid QP number:

```
[dpu]# virtnet modify -p 0 -v 1 device -n 4
```

  The minimum number of QP resources which allows the VF to load the host driver is 1.
- The QP resources of a VF can be reduced to 0. However, the VF would not be functional in this case.

```
[dpu]# virtnet modify -p 0 -v 1 device -qp 0
```

8.14.6.13 Virt Queue Types

Virt queues (VQs) are the mechanism for bulk data transport on virtio devices. Each device can have zero or more VQs.

VQs can be in one of the following modes:

- Split
- Packed

> ⛔ When changing the supported VQ types, make sure to unload the guest driver first so the device can modify the supported feature bits.

8.14.6.13.1 Split VQ

Currently the default VQ type. Split VQ format is the only format supported by version 1.0 of the virtio spec.

In split VQ mode, each VQ is separated into three parts:

- Descriptor table – occupies the descriptor area
- Available ring – occupies the driver area

- Used ring – occupies the device area

Each of these parts is physically-contiguous in guest memory. Split VQ has a very simple design, but its sparse memory usage puts pressure on CPU cache utilization and requires several PCIe transactions for each descriptor.

8.14.6.13.1.1 Configuration

The following shows how the output of the `virtnet list` command appears only when split VQ mode is enabled:

```
"supported_virt_queue_types": {
     "value": "0x1",
     "    0": "SPLIT"
   },
```

8.14.6.13.2 Packed VQ

Packed Virtqueue addresses the inherent limitations of the legacy Split VQ design by merging the three separate descriptor rings into a single, contiguous location within the virtual environment's guest memory.

This streamlined memory layout significantly reduces the number of PCIe transactions required and improves CPU cache utilization per descriptor access, leading to better overall network performance.

8.14.6.13.2.1 Prerequisites

Packed VQ is supported from kernel 5.0 onwards, specifically requiring the virtio-support-packed-ring commit within the guest operating system.

8.14.6.13.2.2 Configuration

Administrators control this feature using the `VIRTIO_F_RING_PACKED` (bit 34) feature flag.

- Default State: Disabled.
- Scope: Can be enabled on a per-device basis.

Refer to the "Enabling and Disabling Virtio-net Features" section for the exact `virtnet modify` command syntax.

8.14.6.13.2.3 Limitations

The following features are not currently supported when packed VQ is enabled:

- Mergeable Rx buffer
- Jumbo MTU
- UDP segmentation offload (USO)

- RSS hash report

8.14.6.14 Virtio-net Feature Bits

Per virtio spec, virtio the device negotiates with the virtio driver on the supported features when the driver probes the device. The final negotiated features are a subset of the features supported by the device.

From the controller's perspective, all feature bits can be supported by a device are populated by `virtnet list`. Each individual virtio-net device is able to choose the feature bits supported by itself.

The following is a list of the feature bits currently supported by controller:

- `VIRTIO_NET_F_CSUM`
- `VIRTIO_NET_F_GUEST_CSUM`
- `VIRTIO_NET_F_CTRL_GUEST_OFFLOADS`
- `VIRTIO_NET_F_MTU`
- `VIRTIO_NET_F_MAC`
- `VIRTIO_NET_F_HOST_TSO4`
- `VIRTIO_NET_F_HOST_TSO6`
- `VIRTIO_NET_F_MRG_RXBUF`
- `VIRTIO_NET_F_STATUS`
- `VIRTIO_NET_F_CTRL_VQ`
- `VIRTIO_NET_F_CTRL_RX`
- `VIRTIO_NET_F_CTRL_VLAN`
- `VIRTIO_NET_F_GUEST_ANNOUNCE`
- `VIRTIO_NET_F_MQ`
- `VIRTIO_NET_F_CTRL_MAC_ADDR`
- `VIRTIO_F_VERSION_1`
- `VIRTIO_F_IOMMU_PLATFORM`
- `VIRTIO_F_RING_PACKED`
- `VIRTIO_F_ORDER_PLATFORM`
- `VIRTIO_F_SR_IOV`
- `VIRTIO_F_NOTIFICATION_DATA`
- `VIRTIO_F_RING_RESET`
- `VIRTIO_F_ADMIN_VQ`
- `VIRTIO_NET_F_HOST_USO`
- `VIRTIO_NET_F_HASH_REPORT`
- `VIRTIO_NET_F_GUEST_HDRLEN`

- `VIRTIO_NET_F_SPEED_DUPLEX`

> For more information on these bits, refer to the VIRTIO Version 1.2 Specifications.

8.14.7 Virtio-net Service Guide Release Notes

The following subsections provide information on virtio-net service new features, interoperability, known issues, and bug fixes.

8.14.7.1 Changes and New Features in This Release

- Configuration of `mrg_rxbuf` and `packed_vq` features can now only be performed using the CLI `modify`; no longer from `virtnet.conf` file
- Added support for Host-Aware Attention Button (AB) mode (`-w 3`) for virtio-net hotplug and hot-unplug operations, enabling coordinated device removal by notifying the host OS before removing the device for graceful driver shutdown

8.14.7.2 Bug Fixes

Ref #	Issue Details
4720234	Description: Virtio-net-controller app crash occurs due to live update when an unplug operation is still in progress.
	Keyword: Update; hotplug
	Detected in version: 25.10
4735205	Description: The `virtio-net-controller` may fail to restart or terminate gracefully, logging an `ipc_server.c:112:ipc_server_handler: Failed to epoll ctl del for fd 7` error.
	Keyword: Virtio-net controller; `dpa_partition`
	Detected in version: 25.10
4745706	Description: The `virtnet query` command incorrectly accepts and executes queries for non-existent or invalid queue IDs (e.g., `-q 999`) without returning an error.
	Keyword: Virtio-net controller; input validation
	Detected in version: 25.10
4779252	Description: A crash (program terminates with signal `SIGABRT` and `Aborted`) occurs when trying to enable packet count to device with no eth queues.
	Keyword: Packet_count; counters; CLI

Ref #	Issue Details
	Detected in version: 25.10
4780761	Description: The virtio-net-controller incorrectly inherits VF MTU settings from the PF section of the `virtnet.conf` configuration file.
	Keyword: VF; MTU
	Detected in version: 25.10
4785728	Description: A hot-unplug operation for a virtio-net PF can block the controller for up to 10 minutes.
	Keyword: Unplug; RPC; CLI
	Detected in version: 25.10
4819572	Description: Device modify commands during driver unbind cause "device's health compromised" errors in dmesg due to firmware commands order violation.
	Keyword: CLI; logging
	Detected in version: 25.10
4794617	Description: Crash occurs during application load due to invalid number of EU's in SPRD config file.
	Keyword: Execution units; SPRD
	Detected in version: 25.10
4834032	Description: Virtio-net service may fail to terminate gracefully if a system reboot or shutdown is initiated during the service's early initialization phase, causing the system to hang for up to 30 minutes.
	Keyword: Reboot hang; SIGTERM
	Detected in version: 25.10
4407495	Description: The AARFS feature on BlueField-3 virtio-net devices is not persistent across controller restarts.
	Keyword: Recovery; Accelerated Adaptive Receive Flow Steering
	Detected in version: 25.10
4407517	Description: The DIM and AARFS features are not persistent across virtio-net controller restarts, potentially impacting network performance and CPU utilization.
	Keyword: Recovery; Dynamic Interrupt Moderation; Accelerated Adaptive Receive Flow Steering
	Detected in version: 25.10
4408123	Description: The `pkt_cnt` (packet counter) feature on virtio-net devices is not persistent across controller restarts, causing all hardware-level packet statistics to return to zero if the virtio-net-controller service is restarted.
	Keyword: Recovery; `pkt_cnt`
	Detected in version: 25.10
4731868	Description: Invalid recovery data may cause repeated startup failures.
	Keyword: Recovery
	Detected in version: 25.10
4739902	Description: Controller crash occurs during host shutdown when VF SF creation fails due to resource exhaustion.

8.14.7.3 Known Issues

The following are known limitations of this NVIDIA® BlueField® virtio-net software version.

Ref #	Issue Details
4797496	Description: Virtio-net does not support Packed Virtqueues (`"packed_vq": 1`) in the following scenarios: • It is not supported on any VF configured for live migration. • It is not supported on any PF that has the Admin Queue (AQ) enabled.
	Workaround: Explicitly disable Packed VQs by setting `"packed_vq": 0` in the `virtnet.conf` configuration file for any PFs using AQs or VFs intended for live migration. Use the default Split VQ (`split_vq`) mode instead.
	Keyword: VQ; live migration
	Reported in version: 25.10
4498529	Description: Windows VM may take a lot of time to load when VLAN tagging is enabled.
	Workaround: Disable VLAN tagging.
	Keyword: Windows; VLAN
	Reported in version: 25.10
4534273	Description: After installing a new version, `virtnet -v` or `--version` displays the version of the updated CLI, not the source or target upgrade versions.
	Workaround: Run `virtnet version` to view both the original and destination versions.
	Keyword: CLI; version; update
	Reported in version: 25.07
3879093	Description: When creating a large number of virtio-net VFs, the representor name of the SF may not be renamed.
	Workaround: Use the `ip` command to rename the representor manually.
	Keyword: Representor
	Reported in version: 24.10
3943905	Description: Host OS kernel <3.19 does not support 31 hotplug devices.
	Workaround: Avoid hotplugging more than 20 devices if host OS kernel is <3.19, or upgrade the kernel to ≥3.19.
	Keyword: Host OS; kernel; hotplug
	Reported in version: 24.07
4022160	Description: Feature bit `VIRTIO_NET_F_CTRL_VLAN` is not supported. Enabling it from the hotplug device may results in anomalous behavior.
	Workaround: Disable `VIRTIO_NET_F_CTRL_VLAN` .
	Keyword: Feature bit
	Reported in version: 24.07
4001261	Description: The `virtnet.conf` file does not check invalid values such as negative numbers or 0.
	Workaround: N/A
	Keyword: Virtnet; config; invalid value
	Reported in version: 24.07

Ref #	Issue Details
3965598	Description: Admin-VQ-based transitional VF show a `vf_get` error when the controller is restarted. However, VF functionality is not affected.
	Workaround: N/A
	Keyword: Admin VQ; transitional device
	Reported in version: 24.07
3961951	Description: Out-of-memory call trace occurs when creating many (>300) VFs on a BlueField running OpenEuler or CentOS 7.6.
	Workaround: Update the kernel to support shared RQ.
	Keyword: OOM; OpenEuler; CentOS 7.6; virtual function
	Reported in version: 24.07
3862683	Description: Creating VFs and hotplug PFs in parallel can lead to controller crash.
	Workaround: Create VFs followed by hotplug PF or vice versa.
	Keyword: Virtio-net emulation
	Reported in version: 1.9.0
3665070	Description: Virtio-net controller fails to load if `DPA_AUTHENTICATION` is enabled.
	Workaround: N/A

3232444	Description: After live migration of virtio-net devices using the VFE driver, the `max_queues_size` output from the `virtnet list` may be wrong. This does not affect the actual value.
	Workaround: N/A
	Keywords: Virtio-net; live migration
	Reported in version: DOCA 1.4.0
2801780	Description: When running virtio-net-controller with host kernel older than 3.10.0-1160.el7, host virtio driver may get error (`Unexpected TXQ (13) queue failure: -28`) from dmesg in traffic stress test.
	Workaround: N/A
	Keywords: Virtio-net; error
	Reported in version: DOCA 1.2.0
2870213	Description: Servers do not recover after configuring `PCI_SWITCH_EMULATION_NUM_PORT` to 32 followed by power cycle.
	Workaround: Clear NVRAM and reset mlxconfig to default
	Keywords: Virtio-net; power cycle
	Reported in version: DOCA 1.2.0
2685191	Description: Once virtio-net is enabled, the mlx5 Windows VF becomes unavailable.
	Workaround: N/A
	Keywords: Virtio-net; virtual function; WinOF-2
	Reported in version: DOCA 1.2.0
2702395	Description: When a device is hot-plugged from the virtio-net controller, the host OS may hang when warm reboot is performed on the host and Arm at the same time.
	Workaround: Reboot the host OS first and only then reboot DPU.
	Keywords: Virtio-net controller; hot-plug; reboot
	Reported in version: DOCA 1.2.0

8.15 OpenvSwitch Acceleration - OVS in DOCA

This page provides an overview of Open vSwitch (OVS) acceleration on NVIDIA® BlueField® DPUs, explaining how OVS tasks are offloaded to hardware (using OVS-Kernel, OVS-DPDK, or OVS-DOCA) to improve performance and network efficiency.

Note on naming conventions:

- OVS – Refers to the Open vSwitch distribution within DOCA framework
- OVS-DOCA – Describes the datapath offloading layer (DPIF) that utilizes the DOCA Flow library for offloading tasks. This layer is a component of OVS, along with additional DPIF implementations that facilitate offloading via DPDK or Kernel, known respectively as OVS-DPDK and OVS-Kernel.

NVIDIA advises utilizing the OVS-DOCA DPIF to maximize efficiency, performance, scalability, and feature support.

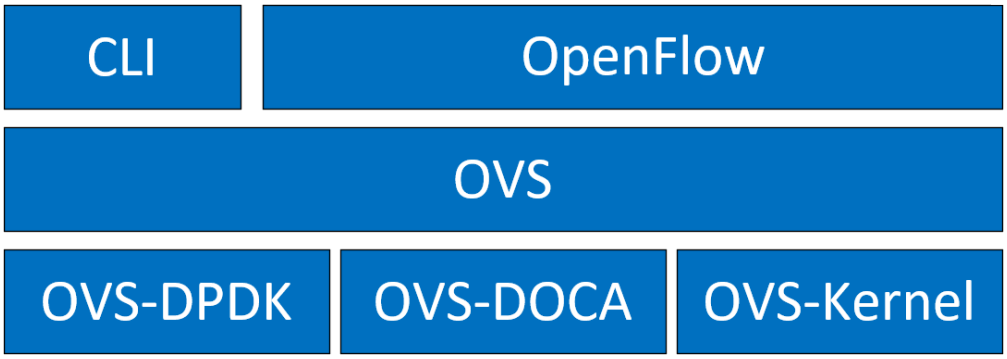
The DPDK and Kernel DPIFs are maintained in their current form primarily for backward compatibility and are not planned to be updated with new features.

8.15.1 Introduction

Open vSwitch (OVS) is a software-based network technology that enhances virtual machine (VM) communication within internal and external networks. Typically deployed in the hypervisor, OVS employs a software-based approach for packet switching, which can strain CPU resources, impacting system performance and network bandwidth utilization. Addressing this, NVIDIA's Accelerated Switching and Packet Processing (ASAP^2) technology offloads OVS data-plane tasks to specialized hardware, like the embedded switch (eSwitch) within the NIC subsystem, while maintaining an unmodified OVS control-plane. This results in notably improved OVS performance without burdening the CPU.

NVIDIA's DOCA-OVS extends the traditional OVS-DPDK and OVS-Kernel data-path offload interfaces (DPIF), introducing OVS-DOCA as an additional DPIF implementation. DOCA-OVS, built upon NVIDIA's networking API, preserves the same interfaces as OVS-DPDK and OVS-Kernel while utilizing the DOCA Flow library with the additional OVS-DOCA DPIF. Unlike the use of the other DPIFs (DPDK, Kernel), OVS-DOCA DPIF exploits unique hardware offload mechanisms and application techniques, maximizing performance and features for NVIDA NICs and DPUs. This mode is especially efficient

due to its architecture and DOCA library integration, enhancing e-switch configuration and accelerating hardware offloads beyond what the other modes can achieve.



NVIDIA OVS installation contains all three OVS flavors. The following subsections describe the three flavors (default is OVS-Kernel) and how to configure each of them.

8.15.2 OVS and Virtualized Devices

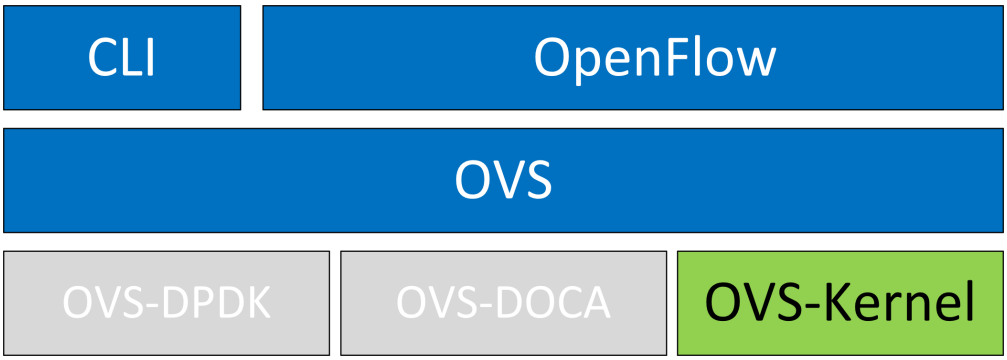
When OVS is combined with NICs and DPUs (such as NVIDIA® ConnectX®-6 Lx/Dx and NVIDIA® BlueField®-2 and later), it utilizes the hardware data plane of ASAP^2. This data plane can establish connections to VMs using either SR-IOV virtual functions (VFs) or virtual host data path acceleration (vDPA) with virtio.

In both scenarios, an accelerator engine within the NIC accelerates forwarding and offloads the OVS rules. This integrated solution accelerates both the infrastructure (via VFs through SR-IOV or virtio) and the data plane. For DPUs (which include a NIC subsystem), an alternate virtualization technology implements full virtio emulation within the DPU, enabling the host server to communicate with the DPU as a software virtio device.

- When using ASAP^2 data plane over SR-IOV virtual functions (VFs), the VF is directly passed through to the VM, with the NVIDIA driver running within the VM.
- When using vDPA, the vDPA driver allows VMs to establish their connections through VirtIO. As a result, the data plane is established between the SR-IOV VF and the standard virtio driver within the VM, while the control plane is managed on the host by the vDPA application.

8.15.3 OVS-Kernel Hardware Acceleration

OVS-Kernel is enabled by default on your NVIDIA device.



8.15.3.1 Switchdev Configuration

1. Make sure no VFs exists:

```
# echo 0 > /sys/class/net/enp4s0f0/device/sriov_numvfs
```

> ⚠ VMs with attached VFs must be powered off to unbind the VFs.

2. Ensure that all VFs are unbound. Then change the eSwitch mode from `legacy` to `switchdev` on the PF device:

```
# devlink dev eswitch set pci/0000:3b:00.0 mode switchdev
```

This also creates the VF representor netdevices in the host OS.

> ℹ To return to SR-IOV legacy mode, run:
>
> ```
> # devlink dev eswitch set pci/0000:3b:00.0 mode legacy
> ```
>
> This also removes the VF representor netdevices.

For operating systems or kernels that do not support devlink, you can move to switchdev mode using sysfs:

```
# echo switchdev > /sys/class/net/enp4s0f0/compat/devlink/mode
```

3. Turn on SR-IOV on the PF device:

```
# echo 2 > /sys/class/net/enp4s0f0/device/sriov_numvfs
```

4. At this stage, VFs and VF representors have been created. To map a representor to its VF, obtain the representor's `switchid` and `portname`:

```
# ip -d link show eth4
41: enp0s8f0_1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT group default
 qlen 1000
```

```
    link/ether ba:e6:21:37:bc:d4 brd ff:ff:ff:ff:ff:ff promiscuity 0 addrgenmode eui64 numtxqueues 10
numrxqueues 10 gso_max_size 65536 gso_max_segs 65535 portname pf0vf1 switchid f4ab580003a1420c
```

Where:

- `switchid` is used to map a representor to a device. Both device PFs have the same `switchid.`
- `portname` is used to map a representor to PF and VF. The returned value is `pf<X>vf<Y>`, where `X` is the PF number and `Y` is the VF number.

8.15.3.2 Switchdev Performance Tuning

Switchdev tuning improves its performance.

8.15.3.2.1 Steering Mode

OVS-kernel supports two steering modes for rule insertion into hardware:

- SMFS (software-managed flow steering) is the default mode; rules are inserted directly to the hardware by the software (driver). This mode is optimized for rule insertion.
- DMFS (device-managed flow steering) rule are inserted using firmware commands. This mode is optimized for throughput with a small number of rules in the system.

The steering mode can be configured via `sysfs` or `devlink` API in kernels that support it:

- For `sysfs`:

```
echo <smfs|dmfs> > /sys/class/net/<pf-netdev>/compat/devlink/steering_mode
```

- For `devlink`:

```
devlink dev param set pci/0000:00:08.0 name flow_steering_mode value "<smfs|dmfs>" cmode runtime
```

Notes:

- The mode should be set prior to moving to `switchdev`, by echoing to the `sysfs` or invoking the `devlink` command.
- Only when moving to `switchdev` will the driver use the mode configured.
- The mode cannot be changed after moving to `switchdev`.
- The steering mode is applicable for `switchdev` mode only (it does not affect legacy SR-IOV or other configurations).

8.15.3.2.2 Troubleshooting SMFS

`mlx5 debugfs` displays software steering resources. `dr_domain` including its tables, matchers, and rules. The interface is read-only.

> ⚠ New steering rules cannot be inserted or deleted while the dump is being created,

The steering information is dumped in CSV form in the following format: `<object_type>,<object_ID>, <object_info>,...,<object_info>`.

This data can be read at the following path: `/sys/kernel/debug/mlx5/<BDF>/steering/fdb/<domain_handle>`.

Example:

```
# cat /sys/kernel/debug/mlx5/0000:82:00.0/steering/fdb/dmn_000018644
3100,0x55caa4621c50,0xee802,4,65533
3101,0x55caa4621c50,0xe0100008
```

You can then use the steering dump parser to make the output human-readable. The parser can be found in this GitHub repository.

8.15.3.2.3 vPort Match Mode

OVS-kernel supports two modes that define how the rules match on vPort.

Mode	Description
Metadata	Rules match on metadata instead of vPort number (default mode). This mode is required to support SR-IOV live migration and dual-port RoCE. ⚠ Metadata matching might impact performance.
Legacy	Rules match on vPort number. Legacy matching does not affect performance to the extent that metadata matching does. It can be used only if SR-IOV live migration or dual port RoCE are enabled/used.

vPort match mode can be controlled via `sysfs`:

- Set legacy:

```
echo legacy > /sys/class/net/<PF netdev>/compat/devlink/vport_match_mode
```

- Set metadata:

```
echo metadata > /sys/class/net/<PF netdev>/compat/devlink/vport_match_mode
```

⚠ This mode must be set prior to moving to `switchdev`.

8.15.3.2.4 Flow Table Large Group Number

Offloaded flows, including connection tracking (CT), are added to the virtual switch forwarding data base (FDB) flow tables. FDB tables have a set of flow groups, where each flow group saves the same traffic pattern flows. For example, for CT offloaded flow, TCP and UDP are different traffic patterns which end up in two different flow groups.

A flow group is limited in size to save flow entries. By default, the driver has 15 big FDB flow groups. Each of these big flow groups can save 4M/(15+1)=256k different 5-tuple flow entries at most. For scenarios with more than 15 traffic patterns, the driver provides a module parameter (`num_of_groups`) to allow customization and performance tuning.

The mode can be controlled via module param or devlink API for kernels that support it:

- Module param:

```
echo <num_of_groups> > /sys/module/mlx5_core/parameters/num_of_groups
```

- Devlink:

```
devlink dev param set pci/0000:82:00.0 name fdb_large_groups cmode driverinit value 20
```

⚠ The change takes effect immediately if the FDB table is empty (no traffic and all offloaded flows have aged out). You can switch this dynamically without reloading the driver. However, if there are still offloaded flows when you change this parameter, the change will take effect only after all flows have aged out.

8.15.3.3 Open vSwitch Configuration

OVS configuration is a simple OVS bridge configuration with `switchdev`.

1. Run the OVS service:

```
systemctl start openvswitch
```

2. Create an OVS bridge (named `ovs-sriov` here):

```
ovs-vsctl add-br ovs-sriov
```

3. Enable hardware offload (disabled by default):

```
ovs-vsctl set Open_vSwitch . other_config:hw-offload=true
```

4. Restart the OVS service:

```
systemctl restart openvswitch
```

This step is required for hardware offload changes to take effect.

5. Add the PF and the VF representor netdevices as OVS ports:

```
ovs-vsctl add-port ovs-sriov enp4s0f0
ovs-vsctl add-port ovs-sriov enp4s0f0_0
ovs-vsctl add-port ovs-sriov enp4s0f0_1
```

Make sure to bring up the PF and representor netdevices:

```
ip link set dev enp4s0f0 up
ip link set dev enp4s0f0_0 up
ip link set dev enp4s0f0_1 up
```

The PF represents the uplink (wire):

```
# ovs-dpctl show
system@ovs-system:
        lookups: hit:0 missed:192 lost:1
        flows: 2
        masks: hit:384 total:2 hit/pkt:2.00
        port 0: ovs-system (internal)
        port 1: ovs-sriov (internal)
        port 2: enp4s0f0
        port 3: enp4s0f0_0
        port 4: enp4s0f0_1
```

6. Run traffic from the VFs and observe the rules added to the OVS data-path:

```
# ovs-dpctl dump-flows

recirc_id(0),in_port(3),eth(src=e4:11:22:33:44:50,dst=e4:1d:2d:a5:f3:9d),
eth_type(0x0800),ipv4(frag=no), packets:33, bytes:3234, used:1.196s, actions:2

recirc_id(0),in_port(2),eth(src=e4:1d:2d:a5:f3:9d,dst=e4:11:22:33:44:50),
eth_type(0x0800),ipv4(frag=no), packets:34, bytes:3332, used:1.196s, actions:3
```

In this example, the ping is initiated from VF0 (OVS port 3) to the outer node (OVS port 2), where the VF MAC is `e4:11:22:33:44:50` and the outer node MAC is `e4:1d:2d:a5:f3:9d`. As previously shown, two OVS rules are added, one in each direction.

Users can also verify offloaded packets by adding `type=offloaded` to the command. For example:

```
ovs-appctl dpctl/dump-flows type=offloaded
```

8.15.3.4 OVS Performance Tuning

8.15.3.4.1 Flow Aging

The aging timeout of OVS is displayed in milliseconds and can be controlled by running:

```
ovs-vsctl set Open_vSwitch . other_config:max-idle=30000
```

8.15.3.4.2 TC Policy

TC policy specifies the policy used with hardware offloading:

- `none` – adds a TC rule to both the software and the hardware (default)
- `skip_sw` – adds a TC rule only to the hardware
- `skip_hw` – adds a TC rule only to the software

Example:

```
ovs-vsctl set Open_vSwitch . other_config:tc-policy=skip_sw
```

TC policy should only be used for debugging purposes.

8.15.3.4.3 max-revalidator

Specifies the maximum time (in milliseconds) for the revalidator threads to wait for kernel statistics before executing flow revalidation.

```
ovs-vsctl set Open_vSwitch . other_config:max-revalidator=10000
```

8.15.3.4.4 n-handler-threads

Specifies the number of threads for software datapaths to use to handle new flows.

```
ovs-vsctl set Open_vSwitch . other_config:n-handler-threads=4
```

The default value is the number of online CPU cores minus the number of revalidators.

8.15.3.4.5 n-revalidator-threads

Specifies the number of threads for software datapaths to use to revalidate flows in the datapath.

```
ovs-vsctl set Open_vSwitch . other_config:n-revalidator-threads=4
```

8.15.3.4.5.1 vlan-limit

Limits the number of VLAN headers that can be matched to the specified number.

```
ovs-vsctl set Open_vSwitch . other_config:vlan-limit=2
```

8.15.3.5 Basic TC Rules Configuration

Offloading rules can also be added directly---not only through OVS---using the `tc` utility.

To create an offloading rule using TC:

1. Create an ingress `qdisc` (queueing discipline) for each interface that you wish to add rules into:

   ```
   tc qdisc add dev enp4s0f0 ingress
   tc qdisc add dev enp4s0f0_0 ingress
   tc qdisc add dev enp4s0f0_1 ingress
   ```

2. Add TC rules using flower classifier in the following format:

   ```
   tc filter add dev NETDEVICE ingress protocol PROTOCOL prio PRIORITY [chain CHAIN] flower [MATCH_LIST]
   [action ACTION_SPEC]
   ```

   > ⚠ A list of supported matches (specifications) and actions can be found in Classification Fields (Matches).

3. Dump the existing `tc` rules using flower classifier in the following format:

   ```
   tc [-s] filter show dev NETDEVICE ingress
   ```

8.15.3.6 SR-IOV VF LAG

SR-IOV VF LAG allows the NIC's physical functions (PFs) to receive the rules that the OVS attempts to offload to the bond net-device, and then offloads them to the hardware e-switch.

The supported bond modes are as follows:

- Active-backup
- XOR
- LACP

SR-IOV VF LAG enables complete offload of the LAG functionality to the hardware. The bonding creates a single bonded PF port. Packets from the up-link can arrive from any of the physical ports and are forwarded to the bond device.

When hardware offload is used, packets from both ports can be forwarded to any of the VFs. Traffic from the VF can be forwarded to both ports according to the bonding state. This means that when in active-backup mode, only one PF is up, and traffic from any VF goes through this PF. When in XOR or LACP mode, if both PFs are up, traffic from any VF is split between these two PFs.

8.15.3.6.1 SR-IOV VF LAG Configuration on ASAP^2

To enable SR-IOV VF LAG, both physical functions of the NIC must first be configured to SR-IOV `switchdev` mode, and only afterwards bond the up-link representors.

The following example shows the creation of a bond interface over two PFs:

1. Switch the eSwitch mode from Legacy to SwitchDev on the PF devices.:

```
# devlink dev eswitch set pci/0000:3b:00.0 mode switchdev
# devlink dev eswitch set pci/0000:3b:00.1 mode switchdev
```

2. Load the bonding device and attach the uplink representor (currently the PF) network devices as as members of the bond.

```
# modprobe bonding mode=802.3ad
# Ifup bond0 (make sure ifcfg file is present with desired bond configuration)
# ip link set enp4s0f0 master bond0
# ip link set enp4s0f1 master bond0
```

3. Create the VFs:

```
# echo 2 > /sys/class/net/enp4s0f0/device/sriov_numvfs
```

4. Add the representor network devices as OVS ports. If tunneling is not used, include the bond device as well:

```
# ovs-vsctl add-port ovs-sriov bond0
# ovs-vsctl add-port ovs-sriov enp4s0f0_0
# ovs-vsctl add-port ovs-sriov enp4s0f1_0
```

5. Ensure that both the PF and the representor network devices are brought up:

```
# ip link set dev bond0 up
# ip link set dev enp4s0f0_0 up
# ip link set dev enp4s0f1_0 up
```

8.15.3.6.2 Scalable/Sub-Function (SF) LAG Configuration on ASAP^2

1. Switch the eSwitch mode from Legacy to SwitchDev on the PF devices.:

```
# devlink dev eswitch set pci/0000:3b:00.0 mode switchdev
# devlink dev eswitch set pci/0000:3b:00.1 mode switchdev
```

2. Load the bonding device and attach the uplink representor (currently the PF) network devices as as members of the bond.

```
# modprobe bonding mode=802.3ad
# Ifup bond0 (make sure ifcfg file is present with desired bond configuration)
# ip link set enp4s0f0 master bond0
# ip link set enp4s0f1 master bond0
```

3. Create the VFs:

```
# mlxdevm port add pci/0000:3b:00.0 flavour pcisf pfnum 0 sfnum 1000
# mlxdevm port function set pci/0000:3b:00.0/32768 state active
```

4. Add the representor network devices as OVS ports. If tunneling is not used, include the bond device as well:

```
# ovs-vsctl add-port ovs-sriov bond0
# ovs-vsctl add-port ovs-sriov en8f0pf0sf1000
```

5. Ensure that both the PF and the representor network devices are brought up:

```
# ip link set dev bond0 up
# ip link set dev en8f0pf0sf1000 up
```

For more information about SFs, refer to the BlueField Scalable Function User Guide or the scalable functions GitHub wiki.

8.15.3.6.3 Using TC with VF LAG

Both rules can be added either with or without shared block:

- With shared block (supported from kernel 4.16 and RHEL/CentOS 7.7 and above):

```
tc qdisc add dev bond0 ingress_block 22 ingress
tc qdisc add dev ens4p0 ingress_block 22 ingress
tc qdisc add dev ens4p1 ingress_block 22 ingress
```

a. Add drop rule:

```
# tc filter add block 22 protocol arp parent ffff: prio 3 \
    flower \
        dst_mac e4:11:22:11:4a:51 \
        action drop
```

b. Add redirect rule from bond to representor:

```
# tc filter add block 22 protocol arp parent ffff: prio 3 \
        flower \
        dst_mac e4:11:22:11:4a:50 \
```

```
        action mirred egress redirect dev ens4f0_0
```

c. Add redirect rule from representor to bond:

```
# tc filter add dev ens4f0_0 protocol arp parent ffff: prio 3 \
    flower \
        dst_mac ec:0d:9a:8a:28:42 \
        action mirred egress redirect dev bond0
```

- Without shared block (supported from kernel 4.15 and below):

a. Add redirect rule from bond to representor:

```
# tc filter add dev bond0 protocol arp parent ffff: prio 1 \
        flower \
        dst_mac e4:11:22:11:4a:50 \
        action mirred egress redirect dev ens4f0_0
```

b. Add redirect rule from representor to bond:

```
# tc filter add dev ens4f0_0 protocol arp parent ffff: prio 3 \
        flower \
        dst_mac ec:0d:9a:8a:28:42 \
        action mirred egress redirect dev bond0
```

8.15.3.7 Classification Fields (Matches)

OVS-Kernel supports multiple classification fields which packets can fully or partially match.

8.15.3.7.1 Ethernet Layer 2

- Destination MAC
- Source MAC
- Ethertype

Supported on all kernels.

In OVS dump flows:

```
skb_priority(0/0),skb_mark(0/0),in_port(eth6),eth(src=00:02:10:40:10:0d,dst=68:54:ed:00:af:de),eth_type(0x8100),
packets:1981, bytes:206024, used:0.440s, dp:tc, actions:eth7
```

Using TC rules:

```
tc filter add dev $rep parent ffff: protocol arp pref 1 \
flower \
dst_mac e4:1d:2d:5d:25:35 \
src_mac e4:1d:2d:5d:25:34 \
action mirred egress redirect dev $NIC
```

8.15.3.7.2 IPv4/IPv6

- Source address
- Destination address
- Protocol
    - TCP/UDP/ICMP/ICMPv6
- TOS
- TTL (HLIMIT)

Supported on all kernels.

In OVS dump flows:

```
Ipv4:
ipv4(src=0.0.0.0/0.0.0.0,dst=0.0.0.0/0.0.0.0,proto=17,tos=0/0,ttl=0/0,frag=no)
Ipv6:
ipv6(src=::/::,dst=1:1:1::3:1040:1008,label=0/0,proto=58,tclass=0/0x3,hlimit=64),
```

Using TC rules:

```
IPv4:
tc filter add dev $rep parent ffff: protocol ip pref 1 \
flower \
dst_ip 1.1.1.1 \
src_ip 1.1.1.2 \
ip_proto TCP \
ip_tos 0x3 \
ip_ttl 63 \
action mirred egress redirect dev $NIC

IPv6:
tc filter add dev $rep parent ffff: protocol ipv6 pref 1 \
flower \
dst_ip 1:1:1::3:1040:1009 \
src_ip 1:1:1::3:1040:1008 \
ip_proto TCP \
ip_tos 0x3 \
ip_ttl 63\
action mirred egress redirect dev $NIC
```

8.15.3.7.3 TCP/UDP Source and Destination Ports and TCP Flags

- TCP/UDP source and destinations ports
- TCP flags

Supported on kernel >4.13 and RHEL >7.5.

In OVS dump flows:

```
TCP: tcp(src=0/0,dst=32768/0x8000),
UDP: udp(src=0/0,dst=32768/0x8000),
TCP flags: tcp_flags(0/0)
```

Using TC rules:

```
tc filter add dev $rep parent ffff: protocol ip pref 1 \
flower \
ip_proto TCP \
dst_port 100 \
src_port 500 \
tcp_flags 0x4/0x7 \
```

```
action mirred egress redirect dev $NIC
```

8.15.3.7.4 VLAN

- ID
- Priority
- Inner vlan ID and Priority

Supported kernels: All (QinQ: kernel 4.19 and higher, and RHEL 7.7 and higher).

In OVS dump flows:

```
eth_type(0x8100),vlan(vid=2347,pcp=0),
```

Using TC rules:

```
tc filter add dev $rep parent ffff: protocol 802.1Q pref 1 \
                    flower \
                    vlan_ethtype 0x800 \
                    vlan_id 100 \
                    vlan_prio 0 \
                    action mirred egress redirect dev $NIC
QinQ:
tc filter add dev $rep parent ffff: protocol 802.1Q pref 1 \
                    flower \
                    vlan_ethtype 0x8100  \
                    vlan_id 100 \
                    vlan_prio 0 \
                    cvlan_id 20 \
                    cvlan_prio 0 \
                    cvlan_ethtype 0x800 \
                    action mirred egress redirect dev $NIC
```

8.15.3.7.5 Tunnel

- ID (Key)
- Source IP address
- Destination IP address
- Destination port
- TOS (supported from kernel 4.19 and above & RHEL 7.7 and above)
- TTL (support from kernel 4.19 and above & RHEL 7.7 and above)
- Tunnel options (Geneve)

Supported kernels:

- VXLAN: All
- GRE: Kernel >5.0, RHEL 7.7 and above
- Geneve: Kernel >5.0, RHEL 7.7 and above

In OVS dump flows:

```
tunnel(tun_id=0x5,src=121.9.1.1,dst=131.10.1.1,ttl=0/0,tp_dst=4789,flags(+key))
```

Using TC rules:

```
# tc filter add dev $rep protocol 802.1Q parent ffff: pref 1
flower \
vlan_ethtype 0x800 \
vlan_id 100 \
vlan_prio 0 \
action mirred egress redirect dev $NIC
QinQ:
# tc filter add dev vxlan100 protocol ip parent ffff: \
                flower \
                        skip_sw \
                        dst_mac e4:11:22:11:4a:51 \
                        src_mac e4+:11:22:11:4a:50 \
                        enc_src_ip 20.1.11.1 \
                        enc_dst_ip 20.1.12.1 \
                        enc_key_id 100 \
                        enc_dst_port 4789 \
                        action tunnel_key unset \
                        action mirred egress redirect dev ens4f0_0
```

8.15.3.8 Supported Actions

8.15.3.8.1 Forward

Forward action allows for packet redirection:

- From VF to wire
- Wire to VF
- VF to VF

Supported on all kernels.

In OVS dump flows:

```
skb_priority(0/0),skb_mark(0/0),in_port(eth6),eth(src=00:02:10:40:10:0d,dst=68:54:ed:00:af:de),eth_type(0x8100),
packets:1981, bytes:206024, used:0.440s, dp:tc, actions:eth7
```

Using TC rules:

```
tc filter add dev $rep parent ffff: protocol arp pref 1 \
                        flower \
                        dst_mac e4:1d:2d:5d:25:35 \
                        src_mac e4:1d:2d:5d:25:34 \
                        action mirred egress redirect dev $NIC
```

8.15.3.8.2 Drop

Drop action allows to drop incoming packets.

Supported on all kernels.

In OVS dump flows:

```
skb_priority(0/0),skb_mark(0/0),in_port(eth6),eth(src=00:02:10:40:10:0d,dst=68:54:ed:00:af:de),eth_type(0x8100),
packets:1981, bytes:206024, used:0.440s, dp:tc, actions:drop
```

Using TC rules:

```
tc filter add dev $rep parent ffff: protocol arp pref 1 \
                            flower \
                            dst_mac e4:1d:2d:5d:25:35 \
                            src_mac e4:1d:2d:5d:25:34 \
                            action drop
```

8.15.3.8.3 Statistics

By default, each flow collects the following statistics:

- Packets – number of packets which hit the flow
- Bytes – total number of bytes which hit the flow
- Last used – the amount of time passed since last packet hit the flow

Supported on all kernels.

In OVS dump flows:

```
skb_priority(0/0),skb_mark(0/0),in_port(eth6),eth(src=00:02:10:40:10:0d,dst=68:54:ed:00:af:de),eth_type(0x8100),
packets:1981, bytes:206024, used:0.440s, dp:tc, actions:drop
```

Using TC rules:

```
#tc -s filter show dev $rep ingress

filter protocol ip pref 2 flower chain 0
filter protocol ip pref 2 flower chain 0 handle 0x2
eth_type ipv4
ip_proto tcp
src_ip 192.168.140.100
src_port 80
skip_sw
in_hw
    action order 1: mirred (Egress Redirect to device p0v11_r) stolen
    index 34 ref 1 bind 1 installed 144 sec used 0 sec
    Action statistics:
    Sent 388344 bytes 2942 pkt (dropped 0, overlimits 0 requeues 0)
    backlog 0b 0p requeues 0
```

8.15.3.8.4 Tunnels: Encapsulation/Decapsulation

OVS-kernel supports offload of tunnels using encapsulation and decapsulation actions.

- Encapsulation – pushing of tunnel header is supported on Tx
- Decapsulation – popping of tunnel header is supported on Rx

Supported Tunnels:

- VXLAN (IPv4/IPv6) – supported on all Kernels
- GRE (IPv4/IPv6) – supported on kernel 5.0 and above & RHEL 7.6 and above
- Geneve (IPv4/IPv6) – supported on kernel 5.0 and above & RHEL 7.6 and above

OVS configuration:

In case of offloading tunnel, the PF/bond should not be added as a port in the OVS datapath. It should rather be assigned with the IP address to be used for encapsulation.

The following example shows two hosts (PFs) with IPs 1.1.1.177 and 1.1.1.75, where the PF device on both hosts is enp4s0f0, and the VXLAN tunnel is set with VNID 98:

- On the first host:

```
# ip addr add 1.1.1.177/24 dev enp4s0f1
# ovs-vsctl add-port ovs-sriov vxlan0 -- set interface vxlan0 type=vxlan options:local_ip=1.1.1.177
 options:remote_ip=1.1.1.75 options:key=98
```

- On the second host:

```
# ip addr add 1.1.1.75/24 dev enp4s0f1
# ovs-vsctl add-port ovs-sriov vxlan0 -- set interface vxlan0 type=vxlan options:local_ip=1.1.1.75
 options:remote_ip=1.1.1.177 options:key=98
```

For a GRE IPv4 tunnel, use `type=gre`. For a GRE IPv6 tunnel, use `type=ip6gre`. For a Geneve tunnel, use `type=geneve`.

When encapsulating guest traffic, the VF's device MTU must be reduced to allow the host/hardware to add the encap headers without fragmenting the resulted packet. As such, the VF's MTU must be lowered by 50 bytes from the uplink MTU for IPv4 and 70 bytes for IPv6.

Tunnel offload using TC rules:

```
Encapsulation:
# tc filter add dev ens4f0_0 protocol 0x806 parent ffff: \
                flower \
                        skip_sw \
                        dst_mac e4:11:22:11:4a:51 \
                        src_mac e4:11:22:11:4a:50 \
                action tunnel_key set \
                src_ip 20.1.12.1 \
                dst_ip 20.1.11.1 \
                id 100 \
                action mirred egress redirect dev vxlan100

Decapsulation:
# tc filter add dev vxlan100 protocol 0x806 parent ffff: \
                flower \
                         skip_sw \
                         dst_mac e4:11:22:11:4a:51 \
                         src_mac e4:11:22:11:4a:50 \
                         enc_src_ip 20.1.11.1 \
                         enc_dst_ip 20.1.12.1 \
                         enc_key_id 100 \
                         enc_dst_port 4789 \
                action tunnel_key unset \
                action mirred egress redirect dev ens4f0_0
```

8.15.3.8.5 VLAN Push/Pop

OVS-kernel supports offload of VLAN header push/pop actions:

- Push – pushing of VLAN header is supported on Tx
- Pop – popping of tunnel header is supported on Rx

8.15.3.8.5.1 OVS Configuration

Add a tag=$TAG section for the OVS command line that adds the representor ports. For example, VLAN ID 52 is being used here.

```
# ovs-vsctl add-port ovs-sriov enp4s0f0
# ovs-vsctl add-port ovs-sriov enp4s0f0_0 tag=52
# ovs-vsctl add-port ovs-sriov enp4s0f0_1 tag=52
```

The PF port should not have a VLAN attached. This will cause OVS to add VLAN push/pop actions when managing traffic for these VFs.

Dump Flow Example

```
recirc_id(0),in_port(3),eth(src=e4:11:22:33:44:50,dst=00:02:c9:e9:bb:b2),eth_type(0x0800),ipv4(frag=no), \
packets:0, bytes:0, used:never, actions:push_vlan(vid=52,pcp=0),2

recirc_id(0),in_port(2),eth(src=00:02:c9:e9:bb:b2,dst=e4:11:22:33:44:50),eth_type(0x8100), \
vlan(vid=52,pcp=0),encap(eth_type(0x0800),ipv4(frag=no)), packets:0, bytes:0, used:never, actions:pop_vlan,3
```

VLAN Offload Using TC Rules Example

```
# tc filter add dev ens4f0_0 protocol ip parent ffff: \
                flower \
                        skip_sw \
                        dst_mac e4:11:22:11:4a:51 \
                        src_mac e4:11:22:11:4a:50 \
                action vlan push id 100 \
                action mirred egress redirect dev ens4f0

# tc filter add dev ens4f0 protocol 802.1Q parent ffff: \
                flower \
                        skip_sw \
                        dst_mac e4:11:22:11:4a:51 \
                        src_mac e4:11:22:11:4a:50 \
                        vlan_ethtype 0x800 \
                        vlan_id 100 \
                        vlan_prio 0 \
                action vlan pop \
                action mirred egress redirect dev ens4f0_0
```

8.15.3.8.5.2 TC Configuration

Example of VLAN Offloading with popping header on Tx and pushing on Rx using TC rules:

```
# tc filter add dev ens4f0_0 ingress protocol 802.1Q parent ffff: \
        flower \
                vlan_id 100 \
        action vlan pop \
        action tunnel_key set \
                src_ip 4.4.4.1 \
                dst_ip 4.4.4.2 \
                dst_port 4789 \
                id 42 \
        action mirred egress redirect dev vxlan0

# tc filter add dev vxlan0 ingress protocol all parent ffff: \
        flower \
                enc_dst_ip 4.4.4.1 \
                enc_src_ip 4.4.4.2 \
                enc_dst_port 4789 \
                enc_key_id 42 \
        action tunnel_key unset \
        action vlan push id 100 \
        action mirred egress redirect dev ens4f0_0
```

8.15.3.8.6 Header Rewrite

This action allows for modifying packet fields.

8.15.3.8.7 Ethernet Layer 2

- Destination MAC
- Source MAC

Supported kernels:

- Kernel 4.14 and above
- RHEL 7.5 and above

In OVS dump flows:

```
skb_priority(0/0),skb_mark(0/0),in_port(eth6),eth(src=00:02:10:40:10:0d,dst=68:54:ed:00:af:de),eth_type(0x8100),
packets:1981, bytes:206024, used:0.440s, dp:tc, actions: set(eth(src=68:54:ed:00:f4:ab,dst=fa:16:3e:dd:69:c4)),eth7
```

Using TC rules:

```
tc filter add dev $rep parent ffff: protocol arp pref 1 \
                            flower \
                            dst_mac e4:1d:2d:5d:25:35 \
                            src_mac e4:1d:2d:5d:25:34 \
                    action pedit ex \
                    munge eth dst set 20:22:33:44:55:66 \
                    munge eth src set aa:ba:cc:dd:ee:fe \
                    action mirred egress redirect dev $NIC
```

8.15.3.8.8 IPv4/IPv6

- Source address
- Destination address
- Protocol
- TOS
- TTL (HLIMIT)

Supported kernels:

- Kernel 4.14 and above
- RHEL 7.5 and above

In OVS dump flows:

```
Ipv4:
    set(eth(src=de:e8:ef:27:5e:45,dst=00:00:01:01:01:01)),
    set(ipv4(src=10.10.0.111,dst=10.20.0.122,ttl=63))
Ipv6:
    set(ipv6(dst=2001:1:6::92eb:fcbe:f1c8,hlimit=63)),
```

Using TC rules:

```
IPv4:
tc filter add dev $rep parent ffff: protocol ip pref 1 \
                            flower \
                            dst_ip 1.1.1.1 \
                            src_ip 1.1.1.2 \
                            ip_proto TCP \
                            ip_tos 0x3 \
                            ip_ttl 63 \
                    pedit ex \
                    munge ip src set 2.2.2.1 \
                    munge ip dst set 2.2.2.2 \
                    munge ip tos set 0 \
                    munge ip ttl dec \
                    action mirred egress redirect dev $NIC

IPv6:
tc filter add dev $rep parent ffff: protocol ipv6 pref 1 \
                            flower \
                            dst_ip 1:1:1::3:1040:1009 \
                            src_ip 1:1:1::3:1040:1008 \
                            ip_proto tcp \
                            ip_tos 0x3 \
                            ip_ttl 63\
                    pedit ex \
                    munge ipv6 src set 2:2:2::3:1040:1009 \
                    munge ipv6 dst set 2:2:2::3:1040:1008 \
                    munge ipv6 hlimit dec \
                    action mirred egress redirect dev $NIC
```

IPv4 and IPv6 header rewrite is only supported with match on UDP/TCP/ICMP protocols.

8.15.3.8.8.1 TCP/UDP Source and Destination Ports

- TCP/UDP source and destinations ports

Supported kernels:

- Kernel 4.16 and above
- RHEL 7.6 and above

In OVS dump flows:

```
TCP:

        set(tcp(src= 32768/0xffff,dst=32768/0xffff)),
UDP:

        set(udp(src= 32768/0xffff,dst=32768/0xffff)),
```

Using TC rules:

```
TCP:

        tc filter add dev $rep parent ffff: protocol ip pref 1 \
                            flower \
                            dst_ip 1.1.1.1 \
                            src_ip 1.1.1.2 \
                            ip_proto tcp \
                            ip_tos 0x3 \
                            ip_ttl 63 \
                    pedit ex \
                    pedit ex munge ip tcp sport set 200
                    pedit ex munge ip tcp dport set 200
                    action mirred egress redirect dev $NIC

UDP:
        tc filter add dev $rep parent ffff: protocol ip pref 1 \
                            flower \
                            dst_ip 1.1.1.1 \
                            src_ip 1.1.1.2 \
                            ip_proto udp \
                            ip_tos 0x3 \
                            ip_ttl 63 \
```

```
                    pedit ex \
                    pedit ex munge ip udp sport set 200
                    pedit ex munge ip udp dport set 200
                    action mirred egress redirect dev $NIC
```

8.15.3.8.8.2 VLAN

- ID

Supported on all kernels.

In OVS dump flows:

```
Set(vlan(vid=2347,pcp=0/0)),
```

Using TC rules:

```
tc filter add dev $rep parent ffff: protocol 802.1Q pref 1 \
                    flower \
                    vlan_ethtype 0x800 \
                    vlan_id 100 \
                    vlan_prio 0 \
              action vlan modify id 11 pipe
              action mirred egress redirect dev $NIC
```

8.15.3.8.9 Connection Tracking

The TC connection tracking (CT) action performs CT lookup by sending the packet to netfilter conntrack module. Newly added connections may be associated, via the `ct commit` action, with a 32 bit mark, 128 bit label, and source/destination NAT values.

The following example allows ingress TCP traffic from the uplink representor to `vf1_rep`, while assuring that egress traffic from `vf1_rep` is only allowed on established connections. In addition, mark and source IP NAT is applied.

In OVS dump flows:

```
ct(zone=2,nat)
ct_state(+est+trk)
actions:ct(commit,zone=2,mark=0x4/0xffffffff,nat(src=5.5.5.5))
```

Using TC rules:

```
# tc filter add dev $uplink_rep ingress chain 0 prio 1 proto ip \
                    flower \
                    ip_proto tcp   \
                    ct_state -trk \
               action ct zone 2 nat pipe
               action goto chain 2
# tc filter add dev $uplink_rep ingress chain 2 prio 1 proto ip \
                     flower \
                     ct_state +trk+new \
               action ct zone 2 commit mark 0xbb nat src addr 5.5.5.7 pipe \
               action mirred egress redirect dev $vf1_rep
# tc filter add dev $uplink_rep ingress chain 2 prio 1 proto ip \
                    flower \
                    ct_zone 2 \
                    ct_mark 0xbb \
                    ct_state +trk+est \
                action mirred egress redirect dev $vf1_rep

// Setup filters on $vf1_rep, allowing only established connections of zone 2 through, and reverse nat (dst nat in
this case)

# tc filter add dev $vf1_rep ingress chain 0 prio 1 proto ip \
                     flower \
```

```
                    ip_proto tcp \
                    ct_state -trk \
                action ct zone 2 nat pipe \
                action goto chain 1
# tc filter add dev $vf1_rep ingress chain 1 prio 1 proto ip \
                    flower \
                    ct_zone 2 \
                    ct_mark 0xbb \
                    ct_state +trk+est \
                action mirred egress redirect dev eth0
```

8.15.3.8.9.1 CT Performance Tuning

- Max offloaded connections – specifies the limit on the number of offloaded connections. Example:

```
devlink dev param set pci/${pci_dev} name ct_max_offloaded_conns value $max cmode runtime
```

- Allow mixed NAT/non-NAT CT – allows offloading of the following scenario:

```
•   cookie=0x0, duration=21.843s, table=0, n_packets=4838718, n_bytes=241958846, ct_state=-
trk,ip,in_port=enp8s0f0 actions=ct(table=1,zone=2)
•   cookie=0x0, duration=21.823s, table=1, n_packets=15363, n_bytes=773526,
ct_state=+new+trk,ip,in_port=enp8s0f0 actions=ct(commit,zone=2,nat(dst=11.11.11.11)),output:"enp8s0f0_1" •
cookie=0x0, duration=21.806s, table=1, n_packets=4767594, n_bytes=238401190,
ct_state=+est+trk,ip,in_port=enp8s0f0 actions=ct(zone=2,nat),output:"enp8s0f0_1"
```

Example:

```
echo enable > /sys/class/net/<device>/compat/devlink/ct_action_on_nat_conns
```

8.15.3.8.10 Forward to Chain (TC Only)

TC interface supports adding flows on different chains. Only chain 0 is accessed by default. Access to the other chains requires the `goto` action.

In this example, a flow is created on chain 1 without any match and redirect to wire. The second flow is created on chain 0 and match on source MAC and action `goto` chain 1.

This example simulates simple MAC spoofing:

```
#tc filter add dev $rep parent ffff: protocol all chain 1 pref 1 \
                    flower \
                action mirred egress redirect dev $NIC

#tc filter add dev $rep parent ffff: protocol all chain 1 pref 1 \
                    flower \
                    src_mac aa:bb:cc:aa:bb:cc \
                action goto chain 1
```

8.15.3.9 Port Mirroring: Flow-based VF Traffic Mirroring for ASAP²

Unlike para-virtual configurations, when the VM traffic is offloaded to hardware via SR-IOV VF, the host-side admin cannot snoop the traffic (e.g., for monitoring).

ASAP² uses the existing mirroring support in OVS and TC along with the enhancement to the offloading logic in the driver to allow mirroring the VF traffic to another VF.

The mirrored VF can be used to run traffic analyzer (e.g., tcpdump, wireshark, etc.) and observe the traffic of the VF being mirrored.

The following example shows the creation of port mirror on the following configuration:

```
# ovs-vsctl show
  09d8a574-9c39-465c-9f16-47d81c12f88a
      Bridge br-vxlan
                  Port "enp4s0f0_1"
                     Interface "enp4s0f0_1"
                  Port "vxlan0"
                      Interface "vxlan0"
                                type: vxlan
                                options: {key="100", remote_ip="192.168.1.14"}
                  Port "enp4s0f0_0"
                      Interface "enp4s0f0_0"
                  Port "enp4s0f0_2"
                      Interface "enp4s0f0_2"
                  Port br-vxlan
                      Interface br-vxlan
                                type: internal
      ovs_version: "2.14.1"
```

- To set `enp4s0f0_0` as the mirror port and mirror all the traffic:

  ```
  # ovs-vsctl -- --id=@p get port enp4s0f0_0 \
              -- --id=@m create mirror name=m0 select-all=true output-port=@p \
              -- set bridge br-vxlan mirrors=@m
  ```

- To set `enp4s0f0_0` as the mirror port, only mirror the traffic, and set `enp4s0f0_1` as the destination port:

  ```
  # ovs-vsctl -- --id=@p1 get port enp4s0f0_0 \
              -- --id=@p2 get port enp4s0f0_1 \
              -- --id=@m create mirror name=m0 select-dst-port=@p2 output-port=@p1 \
              -- set bridge br-vxlan mirrors=@m
  ```

- To set `enp4s0f0_0` as the mirror port, only mirror the traffic, and set `enp4s0f0_1` as the source port:

  ```
  # ovs-vsctl -- --id=@p1 get port enp4s0f0_0 \
              -- --id=@p2 get port enp4s0f0_1 \
              -- --id=@m create mirror name=m0 select-src-port=@p2 output-port=@p1 \
              -- set bridge br-vxlan mirrors=@m
  ```

- To set `enp4s0f0_0` as the mirror port and mirror all the traffic on `enp4s0f0_1`:

  ```
  # ovs-vsctl -- --id=@p1 get port enp4s0f0_0 \
              -- --id=@p2 get port enp4s0f0_1 \
              -- --id=@m create mirror name=m0 select-dst-port=@p2 select-src-port=@p2 output-port=@p1 \
              -- set bridge br-vxlan mirrors=@m
  ```

To clear the mirror port:

```
ovs-vsctl clear bridge br-vxlan mirrors
```

Mirroring using TC:

- Mirror to VF:

```
tc filter add dev $rep parent ffff: protocol arp pref 1 \
                        flower \
                        dst_mac e4:1d:2d:5d:25:35 \
                        src_mac e4:1d:2d:5d:25:34 \
                        action mirred egress mirror dev $mirror_rep pipe \
                        action mirred egress redirect dev $NIC
```

- Mirror to tunnel:

```
tc filter add dev $rep parent ffff: protocol arp pref 1 \
                        flower \
                        dst_mac e4:1d:2d:5d:25:35 \
                        src_mac e4:1d:2d:5d:25:34 \
                action tunnel_key set \
                src_ip 1.1.1.1 \
                dst_ip 1.1.1.2 \
                dst_port 4789 \
                id 768 \
                pipe \
                action mirred egress mirror dev vxlan100 pipe \
                action mirred egress redirect dev $NIC
```

8.15.3.10 Forward to Multiple Destinations

Forwarding to up 32 destinations (representors and tunnels) is supported using TC:

- Example 1: forwarding to 32 VFs:

```
tc filter add dev $NIC parent ffff: protocol arp pref 1 \
                        flower \
                        dst_mac e4:1d:2d:5d:25:35 \
                        src_mac e4:1d:2d:5d:25:34 \
                        action mirred egress mirror dev $rep0 pipe \
                        action mirred egress mirror dev $rep1 pipe \
...
                        action mirred egress mirror dev $rep30 pipe \
                        action mirred egress redirect dev $rep31
```

- Example 2: forwarding to 16 tunnels:

```
tc filter add dev $rep parent ffff: protocol arp pref 1 \
                        flower \
                        dst_mac e4:1d:2d:5d:25:35 \
                        src_mac e4:1d:2d:5d:25:34 \
                        action tunnel_key set src_ip $ip_src dst_ip $ip_dst \
                        dst_port 4789 id 0 nocsum \
                        pipe action mirred egress mirror dev vxlan0 pipe \
                        action tunnel_key set src_ip $ip_src dst_ip $ip_dst \
                        dst_port 4789 id 1 nocsum \
                        pipe action mirred egress mirror dev vxlan0 pipe \
                        ...
                        action tunnel_key set src_ip $ip_src dst_ip $ip_dst \
                        dst_port 4789 id 15 nocsum \
                        pipe action mirred egress redirect dev vxlan0
```

⚠ TC supports up to 32 actions.

⚠ If header rewrite is used, then all destinations should have the same header rewrite.

⚠ If VLAN push/pop is used, then all destinations should have the same VLAN ID and actions.

8.15.3.11 sFlow

sFlow allows for monitoring traffic sent between two VMs on the same host using an sFlow collector.

The following example assumes the environment is configured as described later.

```
# ovs-vsctl show
  09d8a574-9c39-465c-9f16-47d81c12f88a
      Bridge br-vxlan
                Port "enp4s0f0_1"
                  Interface "enp4s0f0_1"
                Port "vxlan0"
                  Interface "vxlan0"
                            type: vxlan
                            options: {key="100", remote_ip="192.168.1.14"}
                Port "enp4s0f0_0"
                  Interface "enp4s0f0_0"
                Port "enp4s0f0_2"
                  Interface "enp4s0f0_2"
                Port br-vxlan
                  Interface br-vxlan
                            type: internal
      ovs_version: "2.14.1"
```

To sample all traffic over the OVS bridge:

```
# ovs-vsctl -- --id=@sflow create sflow agent=\"$SFLOW_AGENT\" \
                                      target=\"$SFLOW_TARGET:$SFLOW_PORT\" \
                                      header=$SFLOW_HEADER \
                                      sampling=$SFLOW_SAMPLING polling=10 \
              -- set bridge br-vxlan sflow=@sflow
```

Parameter	Description
`SFLOW_AGENT`	Indicates that the sFlow agent should send traffic from `SFLOW_AGENT` 's IP address
`SFLOW_TARGET`	Remote IP address of the sFlow collector
`SFLOW_HEADER`	Size of packet header to sample (in bytes)
`SFLOW_SAMPLING`	Sample rate

To clear the sFlow configuration:

```
# ovs-vsctl clear bridge br-vxlan sflow
```

To list the sFlow configuration:

```
# ovs-vsctl list sflow
```

sFlow using TC:

```
Sample to VF
tc filter add dev $rep parent ffff: protocol arp pref 1 \
                        flower \
                        dst_mac e4:1d:2d:5d:25:35 \
                        src_mac e4:1d:2d:5d:25:34 \
                        action sample rate 10 group 5 trunc 96 \
                        action mirred egress redirect dev $NIC
```

⚠ A userspace application is needed to process the sampled packet from the kernel. An example is available on Github.

8.15.3.12 Rate Limit

OVS-kernel supports offload of VF rate limit using OVS configuration and TC.

The following example sets the rate limit to the VF related to representor `eth0` to 10Mb/s:

- OVS:

```
ovs-vsctl set interface eth0 ingress_policing_rate=10000
```

- TC:

```
tc_filter add dev eth0 root prio 1 protocol ip matchall skip_sw action police rate 10mbit burst 20k
```

8.15.3.13 Kernel Requirements

This kernel config should be enabled to support `switchdev` offload.

- `CONFIG_NET_ACT_CSUM` – needed for action csum
- `CONFIG_NET_ACT_PEDIT` – needed for header rewrite
- `CONFIG_NET_ACT_MIRRED` – needed for basic forward
- `CONFIG_NET_ACT_CT` – needed for CT (supported from kernel 5.6)
- `CONFIG_NET_ACT_VLAN` – needed for action vlan push/pop
- `CONFIG_NET_ACT_GACT`
- `CONFIG_NET_CLS_FLOWER`
- `CONFIG_NET_CLS_ACT`
- `CONFIG_NET_SWITCHDEV`
- `CONFIG_NET_TC_SKB_EXT` – needed for CT (supported from kernel 5.6)
- `CONFIG_NET_ACT_CT` – needed for CT (supported from kernel 5.6)
- `CONFIG_NFT_FLOW_OFFLOAD`
- `CONFIG_NET_ACT_TUNNEL_KEY`
- `CONFIG_NF_FLOW_TABLE` – needed for CT (supported from kernel 5.6)
- `CONFIG_SKB_EXTENSIONS` – needed for CT (supported from kernel 5.6)
- `CONFIG_NET_CLS_MATCHALL`
- `CONFIG_NET_ACT_POLICE`

- `CONFIG_MLX5_ESWITCH`

8.15.3.14 VF Metering

OVS-kernel supports offloading of VF metering (TX and RX) using `sysfs`. Metering for packets per second (PPS) and bytes per second (BPS) is supported.

The following example sets the Rx meter on VF 0 with value 10Mbps:

```
echo 10000000 > /sys/class/net/enp4s0f0/device/sriov/0/meters/rx/bps/rate
echo 65536 > /sys/class/net/enp4s0f0/device/sriov/0/meters/rx/bps/burst
```

The following example sets Tx meter on VF 0 with value 1000 PPS:

```
echo 1000 > /sys/class/net/enp4s0f0/device/sriov/0/meters/tx/pps/rate
echo 100 > /sys/class/net/enp4s0f0/device/sriov/0/meters/tx/pps/burst
```

Both `rate` and `burst` must be non-zero and `burst` may need to be adjusted according to requirements.

The following counters can be used to query the number dropped packet or bytes:

```
cat /sys/class/net/enp8s0f0/device/sriov/0/meters/rx/pps/packets_dropped
cat /sys/class/net/enp8s0f0/device/sriov/0/meters/rx/pps/bytes_dropped
cat /sys/class/net/enp8s0f0/device/sriov/0/meters/rx/bps/packets_dropped
cat /sys/class/net/enp8s0f0/device/sriov/0/meters/rx/bps/bytes_dropped
cat /sys/class/net/enp8s0f0/device/sriov/0/meters/tx/pps/packets_dropped
cat /sys/class/net/enp8s0f0/device/sriov/0/meters/tx/pps/bytes_dropped
cat /sys/class/net/enp8s0f0/device/sriov/0/meters/tx/bps/packets_dropped
cat /sys/class/net/enp8s0f0/device/sriov/0/meters/tx/bps/bytes_dropped
```

8.15.3.15 Representor Metering

Metering for uplink and VF representors traffic is supported.

Traffic going to a representor device can be a result of a miss in the embedded switch (eSwitch) FDB tables. This means that a packet which arrives from that representor into the eSwitch has not matched against the existing rules in the hardware FDB tables and must be forwarded to software to be handled there and is, therefore, forwarded to the originating representor device driver.

The meter allows to configure the max rate [packets per second] and max burst [packets] for traffic going to the representor driver. Any traffic exceeding values provided by the user are dropped in hardware. There are statistics that show the number of dropped packets.

The configuration of representor metering is done via `miss_rl_cfg`.

- Full path of the `miss_rl_cfg` parameter: `/sys/class/net//rep_config/miss_rl_cfg`
- Usage: `echo "<rate> <burst>" > /sys/class/net//rep_config/miss_rl_cfg`.
  - `rate` is the max rate of packets allowed for this representor (in packets/sec units)
  - `burst` is the max burst size allowed for this representor (in packets units)
  - Both values must be specified. Both of their default values is 0, signifying unlimited rate and burst.

To view the amount of packets and bytes dropped due to traffic exceeding the user-provided rate and burst, two read-only `sysfs` for statistics are available:

- `/sys/class/net//rep_config/miss_rl_dropped_bytes` – counts how many FDB-miss bytes are dropped due to reaching the miss limits
- `/sys/class/net//rep_config/miss_rl_dropped_packets` – counts how many FDB-miss packets are dropped due to reaching the miss limits

8.15.3.16 OVS Metering

There are two types of meters, kpps (kilobits per second) and pktps (packets per second). OVS-Kernel supports offloading both of them.

The following example is to offload a kpps meter.

1. Create OVS meter with a target rate:

```
ovs-ofctl -O OpenFlow13 add-meter ovs-sriov meter=1,kbps,band=type=drop,rate=204800
```

2. Delete the default rule:

```
ovs-ofctl del-flows ovs-sriov
```

3. Configure OpenFlow rules:

```
ovs-ofctl -O OpenFlow13 add-flow ovs-sriov 'ip,dl_dst=e4:11:22:33:44:50,actions= meter:1,output:enp4s0f0_0'
ovs-ofctl -O OpenFlow13 add-flow ovs-sriov 'ip,dl_src=e4:11:22:33:44:50,actions= output:enp4s0f0'
ovs-ofctl -O OpenFlow13 add-flow ovs-sriov 'arp,actions=normal'
```

   Here, the VF bandwidth on the receiving side is limited by the rate configured in step 1.

4. Run iperf server and be ready to receive UDP traffic. On the outer node, run iperf client to send UDP traffic to this VF. After traffic starts, check the offloaded meter rule:

```
ovs-appctl dpctl/dump-flows --names type=offloaded

recirc_id(0),in_port(enp4s0f0),eth(dst=e4:11:22:33:44:50),eth_type(0x0800),ipv4(frag=no), packets:11626587,
bytes:17625889188, used:0.470s, actions:meter(0),enp4s0f0_0
```

To verify metering, the iperf client should set the target bandwidth to a number which is larger than the configured meter rate. Then it should apparent that packets are received with the limited rate on the server side and the extra packets are dropped by hardware.

8.15.3.17 Multiport eSwitch Mode

The multiport eSwitch mode allows adding rules on a VF representor with an action forwarding the packet to the physical port of the physical function. This can be used to implement failover or forward packets based on external information such as the cost of the route.

1. To configure multiport eSwitch mode, set the nvconfig parameter, `LAG_RESOURCE_ALLOCATION`.
2. After the driver loads, configure multiport eSwitch for each PF where `enp8s0f0` and `enp8s0f1` represent the netdevices for the PFs:

   ```
   echo multiport_esw > /sys/class/net/enp8s0f0/compat/devlink/lag_port_select_mode
   echo multiport_esw > /sys/class/net/enp8s0f1/compat/devlink/lag_port_select_mode
   ```

   The mode becomes operational after entering `switchdev` mode on both PFs.

Rule example:

```
tc filter add dev enp8s0f0_0 prot ip root flower dst_ip 7.7.7.7 action mirred egress redirect dev enp8s0f1
```

8.15.4 OVS-DPDK Hardware Acceleration

> OVS-DPDK builds and hardware acceleration have been officially discontinued and are no longer supported by the Open vSwitch (OVS) version bundled with the DOCA platform.

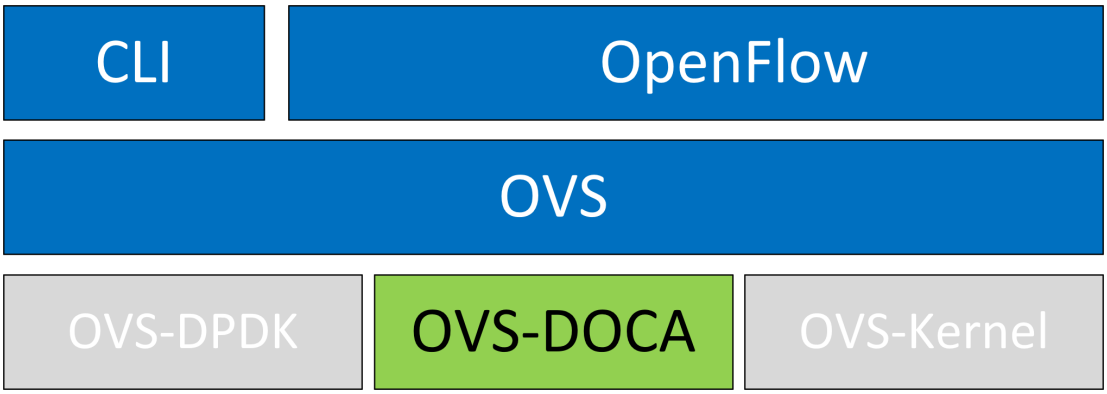
It is recommended to transition to OVS-DOCA Hardware Acceleration, that now fully replaces OVS-DPDK and provides significantly enhanced feature set along with improved performance.

OVS-DOCA is designed as a complete, modern replacement for OVS-DPDK, providing:

- A significantly enhanced feature set tailored for BlueField DPUs.
- Substantially improved hardware-accelerated network performance.
- Native integration with the DOCA platform.

8.15.5 OVS-DOCA Hardware Acceleration

OVS-DOCA is designed on top of NVIDIA's networking API to preserve the same OpenFlow, CLI, and data interfaces (e.g., vdpa, VF passthrough), as well as OVS-Kernel. While all OVS flavors make use of flow offloads for hardware acceleration, due to its architecture and use of DOCA libraries, the OVS-DOCA mode provides the most efficient performance and feature set among them, making the most out of NVIDA NICs and DPUs.



The following subsections provide the necessary steps to launch/deploy OVS DOCA.

8.15.5.1 Configuring OVS-DOCA

To configure OVS DOCA HW offloads:

1. Unbind the VFs:

```
echo 0000:04:00.2 > /sys/bus/pci/drivers/mlx5_core/unbind
echo 0000:04:00.3 > /sys/bus/pci/drivers/mlx5_core/unbind
```

> ⚠ VMs with attached VFs must be powered off to be able to unbind the VFs.

2. Change the e-switch mode from `legacy` to `switchdev` on the PF device (make sure all VFs are unbound):

```
echo switchdev > /sys/class/net/enp4s0f0/compat/devlink/mode
```

> ⚠ This command also creates the VF representor netdevices in the host OS.

   To revert to SR-IOV `legacy` mode:

```
echo legacy > /sys/class/net/enp4s0f0/compat/devlink/mode
```

3. Bind the VFs:

```
echo 0000:04:00.2 > /sys/bus/pci/drivers/mlx5_core/bind
echo 0000:04:00.3 > /sys/bus/pci/drivers/mlx5_core/bind
```

4. Configure huge pages:

```
mkdir -p /hugepages
mount -t hugetlbfs hugetlbfs /hugepages
echo 4096 > /sys/devices/system/node/node0/hugepages/hugepages-2048kB/nr_hugepages
```

5. Run the Open vSwitch service:

```
systemctl start openvswitch
```

6. Enable DOCA mode and hardware offload (disabled by default):

```
ovs-vsctl --no-wait set Open_vSwitch . other_config:doca-init=true
ovs-vsctl set Open_vSwitch . other_config:hw-offload=true
```

7. For hardware offload changes to take effect, restart the Open vSwitch service:
   - For Debian-based systems:

     ```
     systemctl restart openvswitch-switch
     ```

   - For RPM-based systems:

     ```
     systemctl restart openvswitch
     ```

8. Create OVS-DOCA bridge:

```
ovs-vsctl --no-wait add-br br0-ovs -- set bridge br0-ovs datapath_type=doca
```

9. Add PF to OVS:

```
ovs-vsctl add-port br0-ovs enp4s0f0 -- set Interface enp4s0f0 type=doca
```

10. Add representor to OVS:

```
ovs-vsctl add-port br0-ovs enp4s0f0_0 -- set Interface enp4s0f0_0 type=doca
```

11. Optional configuration:
    a. To set port MTU, run:

    ```
    ovs-vsctl set interface enp4s0f0 mtu_request=9000
    ```

    ⚠ Representors inherit their configuration from the ESW manager.

    b. To set VF/SF MAC, run:

    ```
    ovs-vsctl add-port br0-ovs enp4s0f0 -- set Interface enp4s0f0 type=doca options:dpdk-vf-
    mac=00:11:22:33:44:55
    ```

> ⚠ Unbinding and rebinding the VFs/SFs is required for the change to take effect.

8.15.5.1.1 Setting Default Datapath

OVS commands can be simplified by configuring a default datapath type, which minimizes repetitive configurations and streamlines the OVS setup process for hardware-accelerated deployments.

To set a default datapath type, use the following command:

```
ovs-vsctl set Open_vSwitch . other_config:default-datapath-type=<type>
```

For example, to set the default datapath type to doca:

```
ovs-vsctl set Open_vSwitch . other_config:default-datapath-type=doca
```

This configuration allows bridges and interfaces to be created without specifying the datapath type explicitly for each command. For example:

```
ovs-vsctl --no-wait add-br br0-ovs
ovs-vsctl add-port br0-ovs enp4s0f0
```

This is equivalent to the following commands where the datapath type is explicitly set:

```
ovs-vsctl --no-wait add-br br0-ovs -- set bridge br0-ovs datapath_type=doca
ovs-vsctl add-port br0-ovs enp4s0f0 -- set Interface enp4s0f0 type=doca
```

> ⚠ If a non-supported datapath type is specified, OVS will automatically fall back to the default "system" type.

8.15.5.2 OVS-DOCA Design Considerations

OVS-DOCA is engineered to maximize the benefits of the DOCA offload architecture. To achieve this, specific behaviors of the userland datapath and ports have been modified from legacy OVS designs.

8.15.5.2.1 Eswitch Dependency

When configured in `switchdev` mode, the physical port and all supported functions share a single general domain (i.e., the eswitch) to execute offloaded flows.

Because all ports on the same eswitch are intrinsically linked to its main Physical Function (PF), their operational states are coupled. If the main PF is deactivated (e.g., administratively removed from OVS or its link state goes down), all dependent ports on that eswitch are automatically disabled as well.

8.15.5.2.2 Pre-allocated Offload Tables

To guarantee maximum flow insertion speeds, DOCA offloads utilize pre-allocated offload structures (entries and containers).

When the vSwitch daemon starts, these offloads are initialized with sensible, performance-optimized defaults. If your specific environment requires a different scale or number of offloads, you must adjust the OVS-DOCA specific configuration entries.

These configuration parameters are detailed in the next section.

8.15.5.2.3 Unsupported CT-CT-NAT

The specialized `ct-ct-nat` (Connection Tracking to Connection Tracking with Network Address Translation) mode, which is configurable in the standard OVS-kernel datapath, is not supported by OVS-DOCA.

8.15.5.3 OVS-DOCA Specific vSwitch Configuration

The following configuration is particularly useful or specific to OVS-DOCA mode.

> The full list of OVS vSwitch configuration is documented in `man ovs-vswitchd.conf.db`.

8.15.5.3.1 other_config

The following table provides `other_config` configurations which are global to the vSwitch (non-exhaustive list, check manpage for more):

Configuration	Description
`other_config:doca-init`	• Optional string, either true or false • Set this value to true to enable DOCA Flow HW offload • The default value is false. Changing this value requires restarting the daemon. • This is only relevant for userspace datapath

Configuration	Description
`other_config:hw-offload-ct-size`	• Optional string, containing an integer, at least 0 • Only for the DOCA offload provider on doca datapath • Configure the usable amount of connection tracking (CT) offload entries • The default value is 250000. Changing this value requires restarting the daemon. • Setting a value of 0 disables CT offload • Changing this configuration affects the OVS memory usage as CT tables are allocated on OVS start • Maximum number of supported connections is 2M Setting this parameter to more than 2M might result in failures. Do not exceed CT size of 1M for best performance.
`other_config:hw-offload-ct-ipv6-enabled`	• Optional string, either true or false • Only for the DOCA offload provider on doca datapath • Set this value to true to enable IPv6 CT offload • The default value is false. Changing this value requires restarting the daemon. • Changing this configuration affects the OVS memory usage as CT tables are allocated on OVS start
`other_config:doca-congestion-threshold`	• Optional string, containing an integer, in range 30 to 90 • The occupancy rate of DOCA offload structures that triggers a resize, as a percentage • Default to 80, but only relevant if `other_config:doca-init` is true. Changing this value requires restarting the daemon.
`other_config:ctl-pipe-size`	• Optional string, containing an integer • The initial size of DOCA control pipes • Default to 0, which is DOCA's internal default value
`other_config:ctl-pipe-infra-size`	• Optional string, containing an integer • The initial size of infrastructure DOCA control pipes: root, post-hash, post-ct, post-meter, split, miss. • Default to 0, which fallbacks to `other_config:ctl-pipe-size`
`other_config:pmd-quiet-idle`	• Optional string, either true or false • Allow the PMD threads to go into quiescent mode when idling. If no packets are received or waiting to be processed and sent, enter a continuous quiescent period. End this period as soon as a packet is received. • This option is disabled by default
`other_config:pmd-sleep-max`	• Optional string, containing an integer, in range 0 to 10,000 • Specifies the maximum sleep time in microseconds per iteration for a PMD thread which has received zero or a small amount of packets from the Rx queues it is polling. • The actual sleep time requested is based on the load of the Rx queues that the PMD polls and may be less than the maximum value • The default value is 0 microseconds, which means that the PMD does not sleep regardless of the load from the Rx queues that it polls • To avoid requesting very small sleeps (e.g., less than 10 µs) the value is rounded up to the nearest 10 µs • The maximum value is 10000 microseconds. • `other_config:pmd-maxsleep` is deprecated but still functional
`other_config:dpdk-max-memzones`	• Optional string, containing an integer • Specifies the maximum number of memzones that can be created in DPDK • The default is empty, keeping DPDK's default. Changing this value requires restarting the daemon.

Configuration	Description
`other_config:pmd-cpu-mask`	With PMD multi-threading support, OVS creates one PMD thread for each NUMA node by default if there is at least one DPDK interface added to OVS from that NUMA node. However, in cases where there are multiple ports/rxqs producing traffic, performance can be improved by creating multiple PMD threads running on separate cores. These PMD threads can share the workload by each being responsible for different ports/rxqs. Assignment of ports/rxqs to PMD threads is done automatically. A set bit in the mask means a PMD thread is created and pinned to the corresponding CPU core. For example, to run PMD threads on cores 1 and 2, run: `$ ovs-vsctl set Open_vSwitch . other_config:pmd-cpu-mask=0x6`
`other_config:hw-offload-ct-unidir-udp-enabled`	• Optional string, either `true` or `false` (default). Changing this value requires restarting the daemon. • Set this value to true to enable unidirectional UDP CT offload • Only for the DOCA offload provider on doca datapath

8.15.5.4 Offloading VXLAN Encapsulation/Decapsulation Actions

vSwitch in userspace rather than kernel-based Open vSwitch requires an additional bridge. The purpose of this bridge is to allow use of the kernel network stack for routing and ARP resolution.

The datapath must look up the routing table and ARP table to prepare the tunnel header and transmit data to the output port.

VXLAN encapsulation/decapsulation offload configuration is done with:

- PF on `0000:03:00.0` PCIe
- Local IP `56.56.67.1` – the `br-phy` interface is configured to this IP
- Remote IP `56.56.68.1`

To configure OVS DOCA VXLAN:

1. Create a `br-phy` bridge:

```
ovs-vsctl add-br br-phy -- set Bridge br-phy datapath_type=doca -- br-set-external-id br-phy bridge-id br-phy -- set bridge br-phy fail-mode=standalone
```

2. Attach PF interface to `br-phy` bridge:

```
ovs-vsctl add-port br-phy enp4s0f0 -- set Interface enp4s0f0 type=doca
```

3. Configure IP to the bridge:

```
ip addr add 56.56.67.1/24 dev br-phy
```

4. Create a `br-ovs` bridge:

```
ovs-vsctl add-br br-ovs -- set Bridge br-ovs datapath_type=doca -- br-set-external-id br-ovs bridge-id br-
ovs -- set bridge br-ovs fail-mode=standalone
```

5. Attach representor to `br-ovs`:

```
ovs-vsctl add-port br-ovs enp4s0f0_0 -- set Interface enp4s0f0_0 type=doca
```

6. Add a port for the VXLAN tunnel:

```
ovs-vsctl add-port br-ovs vxlan0 -- set interface vxlan0 type=vxlan options:local_ip=56.56.67.1
options:remote_ip=56.56.68.1 options:key=45 options:dst_port=4789
```

8.15.5.4.1 VXLAN GBP Extension

The VXLAN group-based policy (GBP) model outlines an application-focused policy framework that specifies connectivity requirements for applications, independent of the network's physical layout.

Setting GBP extension for a VXLAN port allows for matching on and setting a GBP ID per flow. To enable GBP extension when the port `vxlan0` is first added:

```
ovs-vsctl add-port br-int vxlan0 -- set interface vxlan0 type=vxlan options:key=30 options:remote_ip=10.0.30.1
options:exts=gbp
```

It is also possible to enable GBP extension for an existing VXLAN port:

```
ovs-vsctl set interface vxlan1 options:exts=gbp
```

This approach has a limitation that it does not take effect until after the OVS `vswitchd` service is restarted. In cases where there are multiple VXLAN ports, they must all share the same GBP extension configuration in their port options. A mixed configuration with some VXLAN ports having the GBP extension enabled and others disabled is not supported.

When GBP extension is enabled, the following OpenFlow rules which match on a GBP ID 32 or set a GBP ID 64 in the actions, can be offloaded:

```
ovs-ofctl add-flow br-int table=0,priority=100,in_port=vxlan0,tun_gbp_id=32 actions=output:pf0vf0
ovs-ofctl add-flow br-int table=0,priority=100,in_port=pf0vf0 actions=load:64->NXM_NX_TUN_GBP_ID[],output:vxlan0
```

8.15.5.4.2 VF-Tunnel Configuration

To offload underlay traffic effectively, configuring the underlay IP directly on the bridge port is insufficient. Instead, a dedicated VF or SF should be allocated, and its representor added to the `br-phy` bridge. This setup allows for proper offloading of underlay traffic.

To add the representor to the bridge, use the following command:

```
ovs-vsctl add-port br-phy <REP> -- set interface <REP> type=doca
```

Configure the underlay IP address directly on the VF or SF device.

Restrictions:

- `<REP>` refers to the Linux interface name of the representor
- The VF or SF must be bound to its driver before attaching the representor to OVS
- The VF or SF must reside in the same namespace as OVS
- The underlay IP address should be configured after the representor is attached to OVS. It is acceptable to restart OVS while the underlay IP is configured.

8.15.5.5 Offloading Connection Tracking

Connection tracking enables stateful packet processing by keeping a record of currently open connections.

OVS flows utilizing connection tracking can be accelerated using advanced NICs by offloading established connections.

To view offload statistics, run:

```
ovs-appctl dpctl/offload-stats-show
```

8.15.5.6 SR-IOV VF LAG

To configure OVS-DOCA SR-IOV VF LAG:

1. Enable SR-IOV on the NICs:

   ```
   // It is recommended to query the parameters first to determine if a change is needed, to save potentially
   unnecessary reboot.
   mst start
   mlxconfig -d <mst device> -y set PF_NUM_OF_VF_VALID=0   SRIOV_EN=1 NUM_OF_VFS=8
   ```

   > ⚠ If configuration did change, perform a BlueField system reboot for the `mlxconfig` settings to take effect.

2. To be able to move to VF LAG mode while VFs/SFs exist, set the nvconig parameter `LAG_RESOURCE_ALLOCATION=1` in the BlueField Arm OS or on the host for ConnectX:

   ```
   mst start
   mlxconfig -d /dev/mst/mt*conf0 -y s LAG_RESOURCE_ALLOCATION=1
   ```

3. Allocate the desired number of VFs per port:

```
echo $n > /sys/class/net/<net name>/device/sriov_numvfs
```

4. Unbind all VFs:

```
echo <VF PCI> >/sys/bus/pci/drivers/mlx5_core/unbind
```

5. Change both NICs' mode to SwitchDev:

```
devlink dev eswitch set pci/<PCI> mode switchdev
```

6. Create Linux bonding using kernel modules:

```
modprobe bonding mode=<desired mode>
```

> ⚠ Other bonding parameters can be added here. The supported bond modes are Active-Backup, XOR, and LACP.

7. Bring all PFs and VFs down:

```
ip link set <PF/VF> down
```

8. Attach both PFs to the bond:

```
ip link set <PF> master bond0
```

9. Bring PFs and bond link up:

```
ip link set <PF0> up
ip link set <PF1> up
ip link set bond0 up
```

10. Add the bond interface to the bridge as `type=doca`:

```
ovs-vsctl add-port br-phy bond0 -- set Interface bond0 type=doca options:dpdk-lsc-interrupt=true
```

11. Add the VF representors of PF0 or PF1 to a bridge:

```
ovs-vsctl add-port br-phy enp4s0f0_0 -- set Interface enp4s0f0_0 type=doca
```

Or:

```
ovs-vsctl add-port br-phy enp4s0f1_0 -- set Interface enp4s0f1_0 type=doca
```

8.15.5.7 Multiport eSwitch Mode

In multiport eswitch mode, all uplinks and VFs/SFs representors of all physical ports are managed by the same hardware switch. This allows forwarding from the physical port entity to the physical port two entity.

1. To configure multiport eswitch mode, the nvconig parameter `LAG_RESOURCE_ALLOCATION=1` must be set in the BlueField Arm OS, according to the following instructions:

```
mst start
mlxconfig -d /dev/mst/mt*conf0 -y s  LAG_RESOURCE_ALLOCATION=1
```

2. Perform a BlueField system reboot for the `mlxconfig` settings to take effect.
3. After the driver loads, and after moving to switchdev mode, configure multiport eswitch for each PF where p0 and p1 represent the netdevices for the PFs:

```
devlink dev param set pci/0000:03:00.0 name esw_multiport value 1 cmode runtime
devlink dev param set pci/0000:03:00.1 name esw_multiport value 1 cmode runtime
```

> The mode becomes operational after entering switchdev mode on both PFs.

4. This mode can be activated by default in BlueField by adding the following line into `/etc/mellanox/mlnx-bf.conf`:

```
ENABLE_ESWITCH_MULTIPORT="yes"
```

While in this mode, the second port is not an eswitch manager, and should be add to OVS using this command:

```
ovs-vsctl add-port br-phy enp4s0f1 -- set interface enp4s0f1 type=doca
```

VFs for the second port can be added using this command:

```
ovs-vsctl add-port br-phy enp4s0f1_0 -- set interface enp4s0f1_0 type=doca
```

8.15.5.8 Offloading Geneve Encapsulation/Decapsulation

Geneve tunneling offload support includes matching on extension header.

> OVS-DOCA Geneve option limitations:
> - Only 1 Geneve option is supported
> - Max option len is 7

- To change the Geneve option currently being matched and encapsulated, users must remove all ports or restart OVS and configure the new option
- Matching on Geneve options can work with `FLEX_PARSER` profile 0 (the default profile). Working with `FLEX_PARSER` profile 8 is also supported as well. To configure it, run:

```
mst start
mlxconfig -d <mst device> s FLEX_PARSER_PROFILE_ENABLE=8
```

> ⚠ Perform a BlueField system reboot for the `mlxconfig` settings to take effect.

To configure OVS-DOCA Geneve encapsulation/decapsulation:

1. Create a `br-phy` bridge:

```
ovs-vsctl --may-exist add-br br-phy -- set Bridge br-phy datapath_type=doca -- br-set-external-id br-phy
bridge-id br-phy -- set bridge br-phy fail-mode=standalone
```

2. Attach a PF interface to `br-phy` bridge:

```
ovs-vsctl add-port br-phy enp4s0f0 -- set Interface enp4s0f0 type=doca
```

3. Configure an IP to the bridge:

```
ifconfig br-phy <$local_ip_1> up
```

4. Create a `br-int` bridge:

```
ovs-vsctl --may-exist add-br br-int -- set Bridge br-int datapath_type=doca -- br-set-external-id br-int
bridge-id br-int -- set bridge br-int fail-mode=standalone
```

5. Attach a representor to `br-int` :

```
ovs-vsctl add-port br-int rep$x -- set Interface rep$x type=doca
```

6. Add a port for the Geneve tunnel:

```
ovs-vsctl add-port br-int geneve0 -- set interface geneve0 type=geneve options:key=<VNI>
options:remote_ip=<$remote_ip_1> options:local_ip=<$local_ip_1>
```

8.15.5.9 GRE Tunnel Offloads

To configure OVS-DOCA GRE encapsulation/decapsulation:

1. Create a `br-phy` bridge:

```
ovs-vsctl --may-exist add-br br-phy -- set Bridge br-phy datapath_type=doca -- br-set-external-id br-phy
bridge-id br-phy -- set bridge br-phy fail-mode=standalone
```

2. Attach a PF interface to `br-phy` bridge:

```
ovs-vsctl add-port br-phy enp4s0f0 -- set Interface enp4s0f0 type=doca
```

3. Configure an IP to the bridge:

```
ifconfig br-phy <$local_ip_1> up
```

4. Create a `br-int` bridge:

```
ovs-vsctl --may-exist add-br br-int -- set Bridge br-int datapath_type=doca -- br-set-external-id br-int
bridge-id br-int -- set bridge br-int fail-mode=standalone
```

5. Attach a representor to `br-int`:

```
ovs-vsctl add-port br-int enp4s0f0_0 -- set Interface enp4s0f0_0 type=doca
```

6. Add a port for the GRE tunnel:

```
ovs-vsctl add-port br-int gre0 -- set interface gre0 type=gre options:key=<VNI>
options:remote_ip=<$remote_ip_1> options:local_ip=<$local_ip_1>
```

8.15.5.10 Slow Path Rate Limiting/SW-Meter

Slow path rate limiting allows controlling the rate of traffic that bypasses hardware offload rules and is subsequently processed by software.

To configure slow path rate limiting:

1. Create a `br-phy` bridge:

```
ovs-vsctl --may-exist add-br br-phy -- set Bridge br-phy datapath_type=doca -- br-set-external-id br-phy
bridge-id br-phy -- set bridge br-phy fail-mode=standalone
```

2. Attach a PF interface to `br-phy` bridge:

```
ovs-vsctl add-port br-phy enp4s0f0 -- set Interface enp4s0f0 type=doca
```

3. Rate limit `enp4s0f0` to 10Kpps with 6K burst size:

```
ovs-vsctl set interface enp4s0f0 options:sw-meter=pps:10k:6k
```

A dry-run option is also supported to allow testing different software meter configurations in a production environment. This allows gathering statistics without impacting the actual traffic flow. These statistics can then be analyzed to determine appropriate rate limiting thresholds. When the dry-run option is enabled, traffic is not dropped or rate-limited, allowing normal operations to continue without disruption.

However, the system simulates the rate limiting process and increment counters as though packets are being dropped.

To enable slow path rate limiting dry-run:

1. Create a `br-phy` bridge:

```
ovs-vsctl --may-exist add-br br-phy -- set Bridge br-phy datapath_type=doca -- br-set-external-id br-phy
bridge-id br-phy -- set bridge br-phy fail-mode=standalone
```

2. Attach a PF interface to `br-phy` bridge:

```
ovs-vsctl add-port br-phy enp4s0f0 -- set Interface enp4s0f0 type=doca
```

3. Rate limit `enp4s0f0` to 10Kpps with 6K burst size:

```
ovs-vsctl set interface enp4s0f0 options:sw-meter=pps:10k:6k
```

4. Set the `sw-meter-dry-run` option:

```
ovs-vsctl set interface enp4s0f0 options:sw-meter-dry-run=true
```

8.15.5.11 Hairpin

Hairpin allows forwarding packets from wire to wire.

To configure hairpin :

1. Create a `br-phy` bridge:

```
ovs-vsctl --may-exist add-br br-phy -- set Bridge br-phy datapath_type=doca -- br-set-external-id br-phy
bridge-id br-phy -- set bridge br-phy fail-mode=standalone
```

2. Attach a PF interface to `br-phy` bridge:

```
ovs-vsctl add-port br-phy enp4s0f0 -- set Interface enp4s0f0 type=doca
```

3. Add hairpin OpenFlow rule:

```
ovs-ofctl add-flow br-phy"in_port=enp4s0f0,ip,actions=in_port"
```

8.15.5.12 OpenFlow Meters

OVS-DOCA supports OpenFlow meter action as covered in this document in section "OpenFlow Meters". In addition, OVS-DOCA supports chaining multiple meter actions together in a single datapth rule.

The following is an example configuration of such OpenFlow rules:

```
ovs-ofctl add-flow br-phy -O OpenFlow13 "table=0,priority=1,in_port=enp4s0f0_0,ip actions=meter=1,resubmit(,1)"
ovs-ofctl add-flow br-phy -O OpenFlow13 "table=1,priority=1,in_port=enp4s0f0_0,ip actions=meter=2,normal"
```

Meter actions are applied sequentially, first using meter ID 1 and then using meter ID 2.

Use case examples for such a configuration:

- Rate limiting the same logical flow with different meter types—bytes per second and packets per second
- Metering a group of flows. As meter IDs can be used by multiple flows, it is possible to re-use meter ID 2 from this example with other logical flows; thus, making sure that their cumulative bandwidth is limited by the meter.

8.15.5.13 DP-HASH Offloads

OVS supports group configuration. The "select" type executes one bucket in the group, balancing across the buckets according to their weights. To select a bucket, for each live bucket, OVS hashes flow data with the bucket ID and multiplies that by the bucket weight to obtain a "score". The bucket with the highest score is selected.

For more details, refer to the ovs-ofctl man.

For example:

- `ovs-ofctl add-group br-int 'group_id=1,type=select,bucket=<port1>'`
- `ovs-ofctl add-flow br-int in_port=<port0>,actions=group=1`

Limitations:

- Offloads are supported on IP traffic only (IPv4 or IPv6)

8.15.5.14 sFlow

The sFlow standard outlines a method for capturing traffic data in switched or routed networks. It employs sampling technology to gather statistics from the device, making it suitable for high-speed networks.

With a predetermined sampling rate, one out of every N packets is captured. While this sampling method does not yield completely accurate results, it does offer acceptable accuracy.

To activate sampling for 0.2% of all traffic traversing an OVS bridge named `br-int`, run:

```
ovs-vsctl -- --id=@sflow create sflow agent=lo target=127.0.0.1:6343 header=96 sampling=512 -- set bridge br-int
sflow=@sflow
```

With this sFlow configuration on the bridge, captured packets are mirrored to an sFlow collector application that listens on the default sFlow port, 6343, on localhost.

> sFlow collector applications fall outside the scope of this guide.

It is possible to set the sampling rate to 1 while configuring sFlow on a bridge, which effectively mirrors all traffic to the sFlow collector.

8.15.5.15 Mirroring

Mirroring can be used to duplicate packets from one port to another besides the original packet destination. This can be done using either an OpenFlow output action or an `ovs-vsctl create mirror` command.

For example, to configure mirror all traffic from port `enp4s0f0_0` to port `enp4s0f0_1` on OVS bridge `br-int`, run:

```
ovs-vsctl -- --id=@p1 get port enp4s0f0_0 -- --id=@p2 get port enp4s0f0_1 -- --id=@m create mirror name=m1
select_dst_port=@p1 select_src_port=@p1 output-port=@p2 -- set bridge br-int mirrors=@m
```

This produces datapath rules with multiple output ports. Each output port permutation requires a different mirror configuration. By default, only 128 different such configurations can be supported. To change this number, use the `doca-mirror-max` `other_config`. For example, set `other_config:doca-mirror-max` to 2048 by running the following:

```
ovs-vsctl set Open_vSwitch . other_config:doca-mirror-max=2048
```

8.15.5.16 Guaranteed Packet Rate

Guaranteed Packet Rate (GPR) is a traffic control feature designed to mitigate noisy neighbor scenarios, in which one port transmits at a significantly higher rate than others—potentially causing starvation for other ports sharing the same queue.

GPR helps ensure fair access to resources by exposing per-core and per-port metering. These meters allow administrators to configure limits on:

- The number of packets per second (PPS) each port can transmit
- The total number of packets reaching the software layer

Benefits of GPR:

- Prevents traffic starvation caused by aggressive ports
- Enables fair scheduling across representors and PFs
- Can be dynamically configured—no service restart required

Enabling and configuring GPR:

- To set the desired GPR mode:

```
ovs-vsctl set o . other_config:gpr-mode=<mode>
```

Where `<mode>` can be one of the following:

Mode	Description
`disabled`	Default. GPR is turned off
`rep-only`	GPR applies only to representor ports
`all-ports`	GPR applies to all ports, including PFs

- To set metering rates:

```
ovs-vsctl set o . other_config:per-core-meter-rate=<rate-in-pps>
ovs-vsctl set o . other_config:per-port-meter-rate=<rate-in-pps>
```

  - `per-core-meter-rate` – Sets the maximum PPS allowed per core
  - `per-port-meter-rate` – Sets the maximum PPS allowed per port

    If `per-port-meter-rate` is not explicitly set, it is calculated automatically using the formula:

    ```
    per-port-meter-rate = (per-core-meter-rate * number_of_cores) / number_of_attached_ports
    ```

8.15.5.17 Configuring OVS-DOCA Pre-Miss Rules (Kernel Punting)

The OVS-DOCA pre-miss feature allows administrators to match specific Ethernet types (EtherTypes) and route them directly to the OS kernel. By punting these specific protocols to the kernel, they bypass the Software OVS datapath entirely, saving processing overhead for control-plane or specific L2 traffic.

8.15.5.17.1 Constraints and Default Behavior

- Port Restriction: This configuration applies strictly to Physical Function (PF) ports.
- Rule Limit: You can configure a maximum of 16 distinct EtherTypes to be sent to the kernel.
- Default Rules: If no `doca-pre-miss-rules` are explicitly configured, OVS-DOCA defaults to sending LACP, LLDP, and 802.1X packets to the kernel.

8.15.5.17.2 Configuration Commands

1. Set custom pre-miss rules: To punt specific EtherTypes to the kernel, provide a comma-separated list of hexadecimal EtherType values.

```
# Syntax
ovs-vsctl set interface <pf_port> options:doca-pre-miss-rules="<comma-separated-list-of-ethertypes>"

# Example: Punt IPv4 (0x800) and custom EtherType (0x8899) on port p0
ovs-vsctl set interface p0 options:doca-pre-miss-rules="0x800,0x8899"
```

> ⚠ Packets matching these EtherTypes will be sent to the kernel and will not be processed by OVS.

2. Clear all pre-miss rules (drop defaults): To clear the default rules and prevent *any* pre-miss punting to the kernel, you must set the list to an empty value containing at least one whitespace character.

```
# Clear default rules by passing a whitespace string
ovs-vsctl set interface <pf_port> options:doca-pre-miss-rules=" "
```

3. Restore default pre-miss rules: To restore the default behavior (punting LACP, LLDP, and 802.1X to the kernel), completely remove the `doca-pre-miss-rules` option from the interface configuration.

```
# Remove the configuration key to restore defaults
ovs-vsctl remove interface <pf_port> options doca-pre-miss-rules
```

8.15.5.18 OVS-DOCA Known Limitations

- When using two PFs with 127 VFs each and adding their representors to OVS bridge, the user must configure `dpdk-memzones`:

```
ovs-vsctl set o . other_config:dpdk-max-memzones=6500
restart ovs
```

- In an OVS topology that includes both physical and internal bridges, sFlow offloads are only supported on the internal bridge when employing a VXLAN tunnel. Utilizing sFlow on the physical bridge leads to only partial offload of flows in this scenario.

8.15.5.19 OVS-DOCA Debugging

Additional debugging information can be enabled in the vSwitch log file using the `dbg` log level:

```
(
    topics='netdev|ofproto|ofp|odp|doca'
    IFS=$'\n'; for topic in $(ovs-appctl vlog/list | grep -E "$topics" | cut -d' ' -f1)
    do
        printf "$topic:file:dbg "
    done
) | xargs ovs-appctl vlog/set
```

The listed topics are relevant to DOCA offload operations.

Coverage counters specific to the DOCA offload provider have been added. The following command should be used to check them:

```
ovs-appctl coverage/show # Print the current non-zero coverage counters
```

The following table provides the meaning behind these DOCA-specific counters:

Counter	Description
`doca_async_queue_full`	The asynchronous offload insertion queue was full while the daemon attempted to insert a new offload. The queue will have been flushed and insertion attempted again. This is not a fatal error but is the sign of a slowed down hardware.
`doca_async_queue_blocked`	The asynchronous offload insertion queue has remained full even after several attempts to flush its currently enqueued requests. While not a fatal error, it should never happen during normal offload operations and should be considered a bug.
`doca_async_add_failed`	An asynchronous insertion failed specifically due to its asynchronous nature. This is not expected to happen and should be considered a bug.
`doca_pipe_resize`	The number of time a DOCA pipe has been resized. This is normal and expected as DOCA pipes receives more entries.
`doca_pipe_resize_over_10_ms`	A DOCA pipe resize took longer than 10ms to complete. It can happen infrequently. If a sudden drop in insertion rate is measured, this counter could help identify the root cause.

8.15.5.20 Scaling Megaflows

Megaflows aggregate multiple microflows into a single flow entry, reduce the load on the flow table, and improve packet processing efficiency. Scaling megaflows in OVS is crucial for optimizing network performance and ensuring efficient handling of high traffic volumes. By default, OVS-DOCA can handle up to 200k megaflows.

To effectively manage and scale megaflows, several key configurations in the `other_config` section of OVS can be adjusted:

- The `flow-limit` parameter sets the maximum number of flows that can be stored in the flow table, helping to control memory usage and prevent overflow.
- The `max-revalidator` parameter defines the longest duration (in milliseconds) that re-validator threads will wait before initiating flow revalidation. It is crucial to understand that this represents the upper limit, and the actual timeout employed by OVS is the lesser of the `max-idle` and `max-revalidator` values. Modifying

this parameter is generally not recommended without a thorough understanding of its effects. For systems with less powerful CPUs, setting a higher `max-revalidator` value is suggested to compensate for reduced computational capacity and ensure revalidation completes.

Fine-tuning these settings can improve the scalability and performance of an OVS deployment, allowing it to manage a greater number of megaflows efficiently.

- To set `flow-limit` (default is 200k):

```
$ ovs-vsctl set o . other_config:flow-limit=<desired_value>
```

- To set `max-revalidator` (default is 250ms).

```
$ ovs-vsctl set o . other_config:max-revalidator=<desired_value>
```

8.15.5.21 Software Datapath Packet Capture (ovs-doca-tcpdump)

⚠ This tool is supported at beta level.

`ovs-doca-tcpdump` provides a tcpdump-compatible interface for capturing and analyzing packets processed by the OVS software datapath. It supports per-interface or global capture, configurable capture points, and real-time packet inspection for debugging, flow verification, and network troubleshooting.

Capability	Description
Configurable capture hooks	• `rx` (default): captures after initial processing • `tx` : captures before packets exit the datapath • `rx_pre_restore` : captures before hardware metadata is stripped
Target scope	Capture traffic on specific interfaces or globally
Filter support	Fully compatible with standard `tcpdump` flags and filters
Control	Managed via UnixCtl commands: • `dpif-doca/tcpdump-set` – enable packet capture • `dpif-doca/tcpdump-unset` – disable capture and clear configs • `dpif-doca/tcpdump-show` – display active configuration

Example usage:

```
# Capture all software datapath traffic
ovs-doca-tcpdump -vv

# Capture from specific interface with TX hook
ovs-doca-tcpdump -i pf0vf0:tx

# Capture from multiple interfaces with different hooks
```

```
ovs-doca-tcpdump -i pf0vf0:rx_pre_restore,rx,tx+pf0vf1:tx

# Save capture to a file for offline analysis
ovs-doca-tcpdump -w capture.pcap -i any
```

Enabling packet capture may affect datapath throughput (performance impact).

This tool is intended for troubleshooting and is not recommended for use in production setups.

8.15.5.22 Multi-PMD Configuration

Poll Mode Driver (PMD) threads are responsible for performing datapath processing of packets that traverse the software datapath (e.g., slow path) and for handling connection tracking (CT) offloads.

Scaling PMD threads can improve those on systems with multiple cores. The following configuration steps enable you to control how PMD threads are scheduled and how ports are assigned to RX queues.

8.15.5.22.1 Configuring PMD CPU Mask

Set the `pmd-cpu-mask` in `other_config` to specify which CPU cores are used by PMD threads. By default, Open vSwitch (OVS) assigns one core per NUMA node.

Changing the PMD CPU mask requires restarting the OVS daemon for the changes to take effect.

8.15.5.22.2 Configuring Multiple RX Queues

For ESW manager ports, configure multiple RX queues to allow parallel packet processing.

The following is an example command to configure `N` RX queues for port `P`:

```
ovs-vsctl set interface <P> options:n_rxq=<N>
```

This change does not require an OVS restart. However, the port and its representors will be restarted, which flushes related flows and offloads. Representors inherit their configuration from the ESW manager.

8.15.5.22.3 Scheduling Queues on PMD Threads

OVS automatically schedules port-queue tuples across available PMD threads, using only cores from the card's NUMA node by default.

You can customize this scheduling by setting the `pmd-rxq-affinity` on the interface, using `<QUEUE>:<CORE>` tuples:

```
ovs-vsctl set interface <P> other_config:pmd-rxq-affinity="0:4,1:17"
```

In this example:

- Queue 0 is scheduled on core 4
- Queue 1 is scheduled on core 17

8.15.5.22.4 Verifying PMD Thread Scheduling

To view the current PMD thread-to-queue scheduling, run:

```
ovs-appctl dpif-doca/pmd-rxq-show
```

8.15.5.22.5 Limitations

CT offload size is configured by hw-offload-ct-size (500,000 by default). This size is distributed among the number of PMDs, configured by `pmd-cpu-mask`) (default is by the number of NUMAs in the system).

Each port accesses to CT according to number of RX queue it use (n_rxq).

For example if n_rxq is set to 2 but pmd-cpu-mask has 3 PMDs, only 2/3 of the doca-ct size can be utilized.

To overcome it, either align n_rxq to the number of PMDs if applicable (single NUMA systems) or increase hw-offload-ct-size by this factor (3/2 in this case).

For more information, refer to the Open vSwitch DPDK Installation Guide.

8.15.6 OVS Metrics

Open vSwitch (OVS) with DOCA provides Prometheus-compatible metrics to monitor health and performance.

8.15.6.1 Introduction

NVIDIA DOCA-accelerated Open vSwitch (OVS) offers comprehensive observability through real-time performance and health metrics. These metrics provide deep visibility into packet processing paths (both software and hardware) and are critical for monitoring, debugging, and optimizing virtual network functions (VNFs) and cloud-native workloads.

Metrics are exported in Prometheus format, making them easy to integrate with popular observability stacks such as Prometheus and Grafana. DOCA Telemetry Services (DTS) can also aggregate and forward these metrics as part of a broader telemetry pipeline.

This page outlines the available tools for accessing OVS metrics, how to configure them, and how to integrate them with Prometheus and DTS for automated monitoring and alerting.

> **Python Dependencies**
>
> You must have Python 3.8 or later installed. Operating systems utilizing older versions of Python are strictly not supported.

8.15.6.2 Prometheus Metrics

8.15.6.2.1 Running ovs-exporter

The OVS metrics exporter (`ovs-exporter`) is included with the OVS-DOCA package. It runs an HTTP server that can be scraped by a Prometheus instance.

Use `systemd` to manage the exporter:

Managing the ovs-exporter

```
# Start and enable the service
systemctl start ovs-exporter
systemctl enable ovs-exporter

# Check service status
systemctl status ovs-exporter

# Stop or disable the service
systemctl stop ovs-exporter
systemctl disable ovs-exporter
```

The default configuration exposes metrics on TCP port `6103` .

To modify the configuration, edit `/etc/openvswitch/ovs-exporter.conf` :

Default ovs-exporter configuration

```
[exporter]
port = 6103
extended = no
debug = no
```

OVS metrics are divided into three pages:

- `basic` – always enabled; suitable for most users
- `extended` – includes additional software counters
- `debug` – includes experimental or low-level counters

Additional metric pages can be enabled by setting their respective options to `yes` in the configuration file.

- `Debug` metrics are experimental and may change without notice.
- `Basic` and `extended` metrics are stable across LTS releases.
- Metrics scheduled for removal are marked as `deprecated` in their Prometheus `HELP` description.

To retrieve metrics from the HTTP endpoint:

HTTP Metrics query

```
curl -s 0.0.0.0:6103
```

8.15.6.2.2 Integration with DOCA Telemetry Services

To integrate OVS metrics with DTS, configure the `prometheus_aggr` DTS provider to scrape the `ovs-exporter` endpoint.

For configuration details, refer to the Prometheus Aggregator section in the *DOCA Telemetry Service Guide* for more information.

8.15.6.3 OVS CLI Metrics

OVS also exposes metrics directly through its control socket, without needing the `ovs-exporter` service. Run:

```
ovs-appctl metrics/show [-x] [-d]
```

- Use `-x` to include extended metrics
- Use `-d` to include debug metrics

The output format is Prometheus-compatible and printed to the terminal.

8.15.6.4 OVS-metrics Dashboard

The `ovs-metrics` tool provides a real-time view of hardware and software counters:

```
ovs-metrics
```

Dependency

This tool requires the `python3-doca-openvswitch` package. To install it:

- On Ubuntu:

```
sudo apt install python3-doca-openvswitch
```

- On RHEL:

```
sudo yum install python3-doca-openvswitch
```

The tool reports the following metrics every second:

- `sw-pkts` – number of packets passed in software (total)
- `sw-pps` – last second packet per second in software
- `sw-conns` – number of CT connections in software
- `sw-cps` – last second new connections per second in software
- `hw-pkts` – number of packets passed in hardware (total)
- `hw-pps` – last second packet per second in hardware
- `hw-conns` – number of CT connections in hardware
- `hw-cps` – last second new connections per second in hardware
- `enqueued` – number of rules pending hardware offload
- `hw-rules` – number of offloaded rules in hardware (including infrastructure rules)
- `hw-rps` – last second new hardware rules offloaded per second

8.15.6.5 OVS-Per Flow Counters

OVS allows users to register human-readable names for flow cookies. This capability exposes per-flow counters via `ovs-metrics`, which can then be accessed and monitored through DTS.

8.15.6.5.1 Management Commands

The following `ovs-appctl` commands are used to manage flow metric registrations.

8.15.6.5.1.1 Register or Update Metric

Associates a name with a flow cookie. If the cookie is already registered, this command updates the associated name (renames it).

```
ovs-appctl ofproto/flow-metric-add <bridge> <cookie> <name>
```

8.15.6.5.1.2 Remove Metric

Deletes the mapping for a specific cookie.

```
ovs-appctl ofproto/flow-metric-del <bridge> <cookie>
```

8.15.6.5.1.3 List Metrics

Displays all currently registered flow metrics.

```
ovs-appctl ofproto/flow-metric-list
```

8.15.6.5.2 Parameters

Parameter	Description	Format / Constraints
`bridge`	The name of the existing OVS bridge.	Example: `br0`
`cookie`	The flow identifier.	Hexadecimal value prefixed with `0x` (e.g., `0x1234`).
`name`	The human-readable identifier for the flow.	Must match the pattern `[A-Za-z][_A-Za-z0-9]*` (e.g., `failover_counter`).

8.15.6.5.3 Operational Behavior

- Metric registration is local to the specified bridge. A name is associated with a cookie only within that bridge's context.
- Counters are aggregated (summed) across all OpenFlow rules in the bridge that share the same registered cookie.
- A metric entry is automatically removed from the system only when the last OpenFlow entry utilizing that specific cookie is removed from the bridge.

8.15.7 OVS Inside BlueField

8.15.7.1 Verifying Host Connection on Linux

When the DPU is connected to another DPU on another machine, manually assign IP addresses with the same subnet to both ends of the connection.

1. Assuming the link is connected to `p3p1` on the other host, run:

```
$ ifconfig p3p1 192.168.200.1/24 up
```

2. On the host which the DPU is connected to, run:

```
$ ifconfig p4p2 192.168.200.2/24 up
```

3. Have one ping the other. This is an example of the DPU pinging the host:

```
$ ping 192.168.200.1
```

8.15.7.2 Verifying Connection from Host to BlueField

There are two SFs configured on the BlueField device, `enp3s0f0s0` and `enp3s0f1s0`, and their representors are part of the built-in bridge. These interfaces will get IP addresses from the DHCP server if it is present. Otherwise it is possible to configure IP address from the host. It is possible to access BlueField via the SF netdev interfaces.

For example:

1. Verify the default OVS configuration. Run:

```
# ovs-vsctl show
5668f9a6-6b93-49cf-a72a-14fd64b4c82b
    Bridge ovsbr1
        Port pf0hpf
            Interface pf0hpf
        Port ovsbr1
            Interface ovsbr1
                type: internal
        Port p0
            Interface p0
        Port en3f0pf0sf0
            Interface en3f0pf0sf0
    Bridge ovsbr2
        Port en3f1pf1sf0
            Interface en3f1pf1sf0
        Port ovsbr2
            Interface ovsbr2
                type: internal
        Port pf1hpf
            Interface pf1hpf
        Port p1
            Interface p1
    ovs_version: "2.14.1"
```

2. Verify whether the SF netdev received an IP address from the DHCP server. If not, assign a static IP. Run:

```
# ifconfig enp3s0f0s0
enp3s0f0s0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
        inet 192.168.200.125  netmask 255.255.255.0  broadcast 192.168.200.255
        inet6 fe80::8e:bcff:fe36:19bc  prefixlen 64  scopeid 0x20<link>
        ether 02:8e:bc:36:19:bc  txqueuelen 1000  (Ethernet)
        RX packets 3730  bytes 1217558 (1.1 MiB)
        RX errors 0  dropped 0  overruns 0  frame 0
        TX packets 22  bytes 2220 (2.1 KiB)
        TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

3. Verify the connection of the configured IP address. Run:

```
# ping 192.168.200.25 -c 5
PING 192.168.200.25 (192.168.200.25) 56(84) bytes of data.
64 bytes from 192.168.200.25: icmp_seq=1 ttl=64 time=0.228 ms

8.15.7.3 Verifying Host Connection on Windows

Set IP address on the Windows side for the RShim or Physical network adapter, please run the following command in Command Prompt:

```
PS C:\Users\Administrator> New-NetIPAddress -InterfaceAlias "Ethernet 16" -IPAddress "192.168.100.1" -PrefixLength
22
```

To get the interface name, please run the following command in Command Prompt:

```
PS C:\Users\Administrator> Get-NetAdapter
```

Output should give us the interface name that matches the description (e.g. NVIDIA BlueField Management Network Adapter).

```
Ethernet 2          NVIDIA ConnectX-4 Lx Ethernet Adapter        6 Not Present  24-8A-07-0D-E8-1D
Ethernet 6          NVIDIA ConnectX-4 Lx Ethernet Ad...#2       23 Not Present  24-8A-07-0D-E8-1C
Ethernet 16         NVIDIA BlueField Management Netw...#2       15 Up           CA-FE-01-CA-FE-02
```

Once IP address is set, Have one ping the other.

```
C:\Windows\system32>ping 192.168.100.2

Reply from 192.168.100.2: bytes=32 time=152ms TTL=64
Reply from 192.168.100.2: bytes=32 time=158ms TTL=64
Reply from 192.168.100.2: bytes=32 time=158ms TTL=64
```

8.15.8 Virtual Switch on BlueField

For general information on OVS offload using ASAP² direct, please refer to the MLNX_OFED documentation under OVS Offload Using ASAP² Direct.

ASAP^2 is only supported in Embedded (DPU) mode.

NVIDIA® BlueField® networking platforms (DPUs or SuperNICs) support ASAP^2 technology. It utilizes the representors mentioned in the previous section. The BlueField software package includes OVS installation which already supports ASAP^2. The virtual switch running on the Arm cores allows us to pass all the traffic to and from the host functions through the Arm cores while performing all the operations supported by OVS. ASAP^2 allows us to offload the datapath by programming the NIC embedded switch and avoiding the need to pass every packet through the Arm cores. The control plane remains the same as working with standard OVS.

OVS bridges are created by default upon first boot of the BlueField after BFB installation.

If manual configuration of the default settings for the OVS bridge is desired, run:

```
systemctl start openvswitch-switch.service
ovs-vsctl add-port ovsbr1 p0
ovs-vsctl add-port ovsbr1 pf0hpf
ovs-vsctl add-port ovsbr2 p1
ovs-vsctl add-port ovsbr2 pf1hpf
```

To verify successful bridging:

```
$ ovs-vsctl show
9f635bd1-a9fd-4f30-9bdc-b3fa21f8940a
    Bridge ovsbr2
        Port ovsbr2
            Interface ovsbr2
                type: internal
        Port p1
            Interface p1
        Port pf1sf0
            Interface en3f1pf1sf0
        Port pf1hpf
            Interface pf1hpf
    Bridge ovsbr1
        Port pf0hpf
            Interface pf0hpf
        Port p0
            Interface p0
        Port ovsbr1
            Interface ovsbr1
                type: internal
        Port pf0sf0
            Interface en3f0pf0sf0
    ovs_version: "2.14.1"
```

The host is now connected to the network.

TC-offload is not supported for IPv6 fragment packets. To make IPv6 fragment packets pass through OVS, the MTU of a specific port must be set to equal to or larger than the fragmented packet size. IPv4 fragment packets can be TC-offloaded as their packet size is not checked by OVS.

8.15.8.1 Verifying Host Connection on Linux

When BlueField is connected to another BlueField on another machine, manually assign IP addresses with the same subnet to both ends of the connection.

1. Assuming the link is connected to p3p1 on the other host, run:

```
$ ifconfig p3p1 192.168.200.1/24 up
```

2. On the host to which BlueField is connected, run:

```
$ ifconfig p4p2 192.168.200.2/24 up
```

3. Have one ping the other. This is an example of the BlueField pinging the host:

```
$ ping 192.168.200.1
```

8.15.8.2 Verifying Connection from Host to BlueField

There are two SFs configured on the BlueFIeld-2 device, `enp3s0f0s0` and `enp3s0f1s0`, and their representors are part of the built-in bridge. These interfaces will get IP addresses from the DHCP server if it is present. Otherwise it is possible to configure IP address from the host. It is possible to access BlueField via the SF netdev interfaces.

For example:

1. Verify the default OVS configuration. Run:

```
# ovs-vsctl show
5668f9a6-6b93-49cf-a72a-14fd64b4c82b
    Bridge ovsbr1
        Port pf0hpf
            Interface pf0hpf
        Port ovsbr1
            Interface ovsbr1
                type: internal
        Port p0
            Interface p0
        Port en3f0pf0sf0
            Interface en3f0pf0sf0
    Bridge ovsbr2
        Port en3f1pf1sf0
            Interface en3f1pf1sf0
        Port ovsbr2
            Interface ovsbr2
                type: internal
        Port pf1hpf
            Interface pf1hpf
        Port p1
            Interface p1
    ovs_version: "2.14.1"
```

2. Verify whether the SF netdev received an IP address from the DHCP server. If not, assign a static IP. Run:

```
# ifconfig enp3s0f0s0
enp3s0f0s0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
        inet 192.168.200.125  netmask 255.255.255.0  broadcast 192.168.200.255
        inet6 fe80::8e:bcff:fe36:19bc  prefixlen 64  scopeid 0x20<link>
        ether 02:8e:bc:36:19:bc  txqueuelen 1000  (Ethernet)
        RX packets 3730  bytes 1217558 (1.1 MiB)
        RX errors 0  dropped 0  overruns 0  frame 0
        TX packets 22  bytes 2220 (2.1 KiB)
```

```
        TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

3. Verify the connection of the configured IP address. Run:

```
# ping 192.168.200.25 -c 5
PING 192.168.200.25 (192.168.200.25) 56(84) bytes of data.
64 bytes from 192.168.200.25: icmp_seq=1 ttl=64 time=0.228 ms

64 bytes from 192.168.200.25: icmp_seq=3 ttl=64 time=0.232 ms
64 bytes from 192.168.200.25: icmp_seq=4 ttl=64 time=0.174 ms
64 bytes from 192.168.200.25: icmp_seq=5 ttl=64 time=0.168 ms

--- 192.168.200.25 ping statistics ---
5 packets transmitted, 5 received, 0% packet loss, time 91ms
rtt min/avg/max/mdev = 0.168/0.195/0.232/0.031 ms
```

8.15.8.3 Verifying Host Connection on Windows

Set IP address on the Windows side for the RShim or Physical network adapter, please run the following command in Command Prompt:

```
PS C:\Users\Administrator> New-NetIPAddress -InterfaceAlias "Ethernet 16" -IPAddress "192.168.100.1" -PrefixLength
22
```

To get the interface name, please run the following command in Command Prompt:

```
PS C:\Users\Administrator> Get-NetAdapter
```

Output should give us the interface name that matches the description (e.g. NVIDIA BlueField Management Network Adapter).

```
Ethernet 2          NVIDIA ConnectX-4 Lx Ethernet Adapter        6 Not Present  24-8A-07-0D-E8-1D
Ethernet 6          NVIDIA ConnectX-4 Lx Ethernet Ad...#2       23 Not Present  24-8A-07-0D-E8-1C
Ethernet 16         NVIDIA BlueField Management Netw...#2       15 Up           CA-FE-01-CA-FE-02
```

Once IP address is set, Have one ping the other.

```
C:\Windows\system32>ping 192.168.100.2

Pinging 192.168.100.2 with 32 bytes of data:
Reply from 192.168.100.2: bytes=32 time=148ms TTL=64
Reply from 192.168.100.2: bytes=32 time=152ms TTL=64
Reply from 192.168.100.2: bytes=32 time=158ms TTL=64
Reply from 192.168.100.2: bytes=32 time=158ms TTL=64
```

8.15.8.4 Enabling OVS HW Offloading

OVS HW offloading is set by default by the `/sbin/mlnx_bf_configure` script upon first boot after installation.

1. Enable TC offload on the relevant interfaces. Run:

```
$ ethtool -K <PF> hw-tc-offload on
```

2. Enable the HW offload: run the following commands (after enabling the HW offload):

```
$ ovs-vsctl set Open_vSwitch . Other_config:hw-offload=true
```

3. Restarting OVS is required for the configuration to apply:
   - For Ubuntu:

```
$ systemctl restart openvswitch-switch
```

   - For CentOS/RHEL:

```
$ systemctl restart openvswitch
```

To show OVS configuration:

```
$ ovs-dpctl show
system@ovs-system:
  lookups: hit:0 missed:0 lost:0
  flows: 0
  masks: hit:0 total:0 hit/pkt:0.00
  port 0: ovs-system (internal)
  port 1: armbr1 (internal)
  port 2: p0
  port 3: pf0hpf
  port 4: pf0vf0
  port 5: pf0vf1
  port 6: pf0vf2
```

At this point OVS would automatically try to offload all the rules.

To see all the rules that are added to the OVS datapath:

```
$ ovs-appctl dpctl/dump-flows
```

To see the rules that are offloaded to the HW:

```
$ ovs-appctl dpctl/dump-flows type=offloaded
```

8.15.8.5 Enabling OVS-DPDK Hardware Offload

1. Remove previously configured OVS bridges. Run:

```
ovs-vsctl del-br <bridge-name>
```

   Issue the command `ovs-vsctl show` to see already configured OVS bridges.
2. Enable the Open vSwitch service. Run:

```
systemctl start openvswitch
```

3. Configure huge pages:

```
echo 1024 > /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
```

4. Configure DPDK socket memory and limit. Run:

```
# ovs-vsctl set Open_vSwitch . other_config:dpdk-socket-limit=2048
# ovs-vsctl set Open_vSwitch . other_config:dpdk-socket-mem=2048
```

5. Enable hardware offload (disabled by default). Run:

```
ovs-vsctl --no-wait set Open_vSwitch . other_config:dpdk-init=true
ovs-vsctl --no-wait set Open_vSwitch . other_config:hw-offload=true
```

6. Configure the DPDK whitelist. Run:

```
ovs-vsctl set Open_vSwitch . other_config:dpdk-extra="-a
0000:03:00.0,representor=[0,65535],dv_flow_en=1,dv_xmeta_en=1,sys_mem_en=1"
```

7. Create OVS-DPDK bridge. Run:

```
ovs-vsctl add-br br0-ovs -- set Bridge br0-ovs datapath_type=netdev -- br-set-external-id br0-ovs bridge-id
br0-ovs -- set bridge br0-ovs fail-mode=standalone
```

8. Add PF to OVS. Run:

```
ovs-vsctl add-port br0-ovs p0 -- set Interface p0  type=dpdk options:dpdk-devargs=0000:03:00.0
```

9. Add representor to OVS. Run:

```
ovs-vsctl add-port br0-ovs pf0vf0 -- set Interface pf0vf0 type=dpdk options:dpdk-
devargs=0000:03:00.0,representor=[0]
ovs-vsctl add-port br0-ovs pf0hpf -- set Interface pf0hpf type=dpdk options:dpdk-
devargs=0000:03:00.0,representor=[65535]
```

10. Restart the Open vSwitch service. This step is required for HW offload changes to take effect.
    - For CentOS, run:

      ```
      systemctl restart openvswitch
      ```

    - For Debian/Ubuntu, run:

      ```
      systemctl restart openvswitch-switch
      ```

8.15.8.6 Configuring DPDK and Running TestPMD

1. Configure hugepages. Run:

```
echo 1024 > /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
```

2. Run testpmd.
    - For Ubuntu/Debian:

```
env LD_LIBRARY_PATH=/opt/mellanox/dpdk/lib/aarch64-linux-gnu /opt/mellanox/dpdk/bin/dpdk-testpmd -a
03:00.0,representor=[0,65535] --socket-mem=1024 -- --total-num-mbufs=131000 -i
```

- For CentOS:

```
env LD_LIBRARY_PATH=/opt/mellanox/dpdk/lib64/ /opt/mellanox/dpdk/bin/dpdk-testpmd -a
03:00.0,representor=[0,65535] --socket-mem=1024 -- --total-num-mbufs=131000 -i
```

For a detailed procedure with port display, refer to the article "Configuring DPDK and Running testpmd on BlueField-2".

8.15.8.7 Flow Statistics and Aging

The aging timeout of OVS is given in milliseconds and can be configured by running the following command:

```
$ ovs-vsctl set Open_vSwitch . other_config:max-idle=30000
```

8.15.8.8 Connection Tracking Offload

This feature enables tracking connections and storing information about the state of these connections. When used with OVS, BlueField can offload connection tracking, so that traffic of established connections bypasses the kernel and goes directly to hardware.

Both source NAT (SNAT) and destination NAT (DNAT) are supported with connection tracking offload.

8.15.8.8.1 Configuring Connection Tracking Offload

This section provides an example of configuring OVS to offload all IP connections of host PF0.

1. Enable OVS HW offloading.
2. Create OVS connection tracking bridge. Run:

   ```
   $ ovs-vsctl add-br ctBr
   ```

3. Add p0 and pf0hpf to the bridge. Run:

   ```
   $ ovs-vsctl add-port ctBr p0
   $ ovs-vsctl add-port ctBr pf0hpf
   ```

4. Configure ARP packets to behave normally. Packets which do not comply are routed to table1. Run:

   ```
   $ ovs-ofctl add-flow ctBr "table=0,arp,action=normal"
   ```

```
$ ovs-ofctl add-flow ctBr "table=0,ip,ct_state=-trk,action=ct(table=1)"
```

5. Configure RoCEv2 packets to behave normally. RoCEv2 packets follow UDP port 4791 and a different source port in each direction of the connection. RoCE traffic is not supported by CT. In order to run RoCE from the host add the following line before `ovs-ofctl add-flow ctBr "table=0,ip,ct_state=-trk,action=ct(table=1)"`:

```
$ ovs-ofctl add-flow ctBr table=0,udp,tp_dst=4791,action=normal
```

   This rule allows RoCEv2 UDP packets to skip connection tracking rules.
6. Configure the new established flows to be admitted to the connection tracking bridge and to then behave normally. Run:

```
$ ovs-ofctl add-flow ctBr "table=1,priority=1,ip,ct_state=+trk+new,action=ct(commit),normal"
```

7. Set already established flows to behave normally. Run:

```
$ ovs-ofctl add-flow ctBr "table=1,priority=1,ip,ct_state=+trk+est,action=normal"
```

8.15.8.8.2 Connection Tracking With NAT

This section provides an example of configuring OVS to offload all IP connections of host PF0, and performing source network address translation (SNAT). The server host sends traffic via source IP from 2.2.2.1 to 1.1.1.2 on another host. Arm performs SNAT and changes the source IP to 1.1.1.16. Note that static ARP or route table must be configured to find that route.

1. Configure untracked IP packets to do nat. Run:

```
ovs-ofctl add-flow ctBr "table=0,ip,ct_state=-trk,action=ct(table=1,nat)"
```

2. Configure new established flows to do SNAT, and change source IP to 1.1.1.16. Run:

```
ovs-ofctl add-flow ctBr "table=1,in_port=pf0hpf,ip,ct_state=+trk+new,action=ct(commit,nat(src=1.1.1.16)),
p0"
```

3. Configure already established flows act normal. Run:

```
ovs-ofctl add-flow ctBr "table=1,ip,ct_state=+trk+est,action=normal"
```

   Conntrack shows the connection with SNAT applied. Run `conntrack -L` for Ubuntu 22.04 kernel or `cat /proc/net/nf_conntrack` for older kernel versions. Example output:

```
ipv4     2 tcp      6 src=2.2.2.1 dst=1.1.1.2 sport=34541 dport=5001 src=1.1.1.2 dst=1.1.1.16 sport=5001
dport=34541 [OFFLOAD] mark=0 zone=1 use=3
```

8.15.8.8.3 Querying Connection Tracking Offload Status

Start traffic on PF0 from the server host (e.g., iperf) with an external network. Note that only established connections can be offloaded. TCP should have already finished the handshake, UDP should have gotten the reply.

> ⚠ ICMP is not currently supported.

To check if specific connections are offloaded from Arm, run `conntrack -L` for Ubuntu 22.04 kernel or `cat /proc/net/nf_conntrack` for older kernel versions.

The following is example output of offloaded TCP connection:

```
ipv4     2 tcp      6 src=1.1.1.2 dst=1.1.1.3 sport=51888 dport=5001 src=1.1.1.3 dst=1.1.1.2 sport=5001 dport=51888
[HW_OFFLOAD] mark=0 zone=0 use=3
```

8.15.8.8.4 Performance Tune Based on Traffic Pattern

Offloaded flows (including connection tracking) are added to virtual switch FDB flow tables. FDB tables have a set of flow groups. Each flow group saves the same traffic pattern flows. For example, for connection tracking offloaded flow, TCP and UDP are different traffic patterns which end up in two different flow groups.

A flow group has a limited size to save flow entries. By default, the driver has 4 big FDB flow groups. Each of these big flow groups can save at most 4000000/(4+1)=800k different 5-tuple flow entries. For scenarios with more than 4 traffic patterns, the driver provides a module parameter (`num_of_groups`) to allow customization and performance tune.

> ⚠ The size of each big flow groups can be calculated according to formula: size = 4000000/(num_of_groups+1)

To change the number of big FDB flow groups, run:

```
$ echo <num_of_groups> > /sys/module/mlx5_core/parameters/num_of_groups
```

The change takes effect immediately if there is no flow inside the FDB table (no traffic running and all offloaded flows are aged out), and it can be dynamically changed without reloading the driver.

If there are residual offloaded flows when changing this parameter, then the new configuration only takes effect after all flows age out.

8.15.8.8.5 Connection Tracking Aging

Aside from the aging of OVS, connection tracking offload has its own aging mechanism with a default aging time of 30 seconds.

8.15.8.8.6 Maximum Tracked Connections

> ⚠ The maximum number for tracked offloaded connections is limited to 1M by default.

The OS has a default setting of maximum tracked connections which may be configured by running:

```
$ /sbin/sysctl -w net.netfilter.nf_conntrack_max=1000000
```

This changes the maximum tracked connections (both offloaded and non-offloaded) setting to 1 million.

The following option specifies the limit on the number of offloaded connections. For example:

```
# devlink dev param set pci/${pci_dev} name ct_max_offloaded_conns value $max cmode runtime
```

This value is set to 1 million by default from BlueFiled. Users may choose a different number by using the `devlink` command.

> ⚠ Make sure `net.netfilter.nf_conntrack_tcp_be_liberal=1` when using connection tracking.

8.15.8.9 Offloading VLANs

OVS enables VF traffic to be tagged by the virtual switch.

For BlueField, the OVS can add VLAN tag (VLAN push) to all the packets sent by a network interface running on the host (either PF or VF) and strip the VLAN tag (VLAN pop) from the traffic going from the wire to that interface. Here we operate in Virtual Switch Tagging (VST) mode. This means that the host/VM interface is unaware of the VLAN tagging. Those rules can also be offloaded to the HW embedded switch.

To configure OVS to push/pop VLAN you need to add the tag=$TAG section for the OVS command line that adds the representor ports. So if you want to tag all the traffic of VF0 with VLAN ID 52, you should use the following command when adding its representor to the bridge:

```
$ ovs-vsctl add-port armbr1 pf0vf0 tag=52
```

If the virtual port is already connected to the bridge prior to configuring VLAN, you would need to remove it first:

```
$ ovs-vsctl del-port pf0vf0
```

In this scenario all the traffic being sent by VF 0 will have the same VLAN tag. We could set a VLAN tag by flow when using the TC interface, this is explained in section "Using TC Interface to Configure Offload Rules".

8.15.8.10 VXLAN Tunneling Offload

VXLAN tunnels are created on the Arm side and attached to the OVS. VXLAN decapsulation/encapsulation behavior is similar to normal VXLAN behavior, including over `hw_offload=true`.

To allow VXLAN encapsulation, the uplink representor (`p0`) should have an MTU value at least 50 bytes greater than that of the host PF/VF. Please refer to "Configuring Uplink MTU" for more information.

8.15.8.10.1 Configuring VXLAN Tunnel

1. Consider `p0` to be the local VXLAN tunnel interface (or VTEP).

   To be consistent with the examples below, it is assumed that `p0` is configured with a 1.1.1.1 IPv4 address.

2. Remove `p0` from any OVS bridge.
3. Build a VXLAN tunnel over OVS arm-ovs. Run:

   ```
   ovs-vsctl add-br arm-ovs -- add-port arm-ovs vxlan11 -- set interface vxlan11 type=vxlan
   options:local_ip=1.1.1.1 options:remote_ip=1.1.1.2 options:key=100
   options:dst_port=4789
   ```

4. Connect any host representor (e.g., `pf0hpf`) for which VXLAN is desired to the same arm-ovs bridge.
5. Configure the MTU of the VTEP (`p0`) used by VXLAN to at least 50 bytes larger than the host representor's MTU.

At this point, the host is unaware of any VXLAN operations done by the BlueField's OVS. If the remote end of the VXLAN tunnel is properly set, any network traffic traversing arm-ovs undergoes VXLAN encap/decap.

8.15.8.10.2 Querying OVS VXLAN hw_offload Rules

Run the following:

```
ovs-appctl dpctl/dump-flows type=offloaded
in_port(2),eth(src=ae:fd:f3:31:7e:7b,dst=a2:fb:09:85:84:48),eth_type(0x0800), packets:1, bytes:98, used:0.900s,
actions:set(tunnel(tun_id=0x64,src=1.1.1.1,dst=1.1.1.2,tp_dst=4789,flags(key))),3
tunnel(tun_id=0x64,src=1.1.1.2,dst=1.1.1.1,tp_dst=4789,flags(+key)),in_port(3),eth(src=a2:fb:09:85:84:48,dst=ae:fd:
f3:31:7e:7b),eth_type(0x0800), packets:75, bytes:7350, used:0.900s, actions:2
```

⚠ For the host PF, in order for VXLAN to work properly with the default 1500 MTU, follow these steps.

1. Disable host PF as the port owner from Arm (see section "Zero-trust Mode"). Run:

   ```
   $ mlxprivhost -d /dev/mst/mt41682_pciconf0 --disable_port_owner r
   ```

2. The MTU of the end points (`pf0hpf` in the example above) of the VXLAN tunnel must be smaller than the MTU of the tunnel interfaces (`p0`) to account for the size of the VXLAN headers. For example, you can set the MTU of P0 to 2000.

8.15.8.11 GRE Tunneling Offload

GRE tunnels are created on the Arm side and attached to the OVS. GRE decapsulation/ encapsulation behavior is similar to normal GRE behavior, including over `hw_offload=true` .

To allow GRE encapsulation, the uplink representor (`p0`) should have an MTU value at least 50 bytes greater than that of the host PF/VF.

Please refer to "Configuring Uplink MTU" for more information.

8.15.8.11.1 Configuring GRE Tunnel

1. Consider `p0` to be the local GRE tunnel interface. `p0` should not be attached to any OVS bridge.

   ⚠ To be consistent with the examples below, it is assumed that `p0` is configured with a 1.1.1.1 IPv4 address and that the remote end of the tunnel is 1.1.1.2.

2. Create an OVS bridge, `br0` , with a GRE tunnel interface, `gre0` . Run:

```
ovs-vsctl add-port br0 gre0 -- set interface gre0 type=gre options:local_ip=1.1.1.1
options:remote_ip=1.1.1.2 options:key=100
```

3. Add `pf0hpf` to `br0`.

```
ovs-vsctl add-port br0 pf0hpf
```

4. At this point, any network traffic sent or received by the host's PF0 undergoes GRE processing inside the BlueField OS.

8.15.8.11.2 Querying OVS GRE hw_offload Rules

Run the following:

```
ovs-appctl dpctl/dump-flows type=offloaded
recirc_id(0),in_port(3),eth(src=50:6b:4b:2f:0b:74,dst=de:d0:a3:63:0b:30),eth_type(0x0800),ipv4(frag=no),
packets:878, bytes:122802, used:0.440s,
actions:set(tunnel(tun_id=0x64,src=1.1.1.1,dst=1.1.1.2,ttl=64,flags(key))),2
tunnel(tun_id=0x64,src=1.1.1.1,dst=1.1.1.2,flags(+key)),recirc_id(0),in_port(2),eth(src=de:d0:a3:63:0b:30,dst=50:6b
:4b:2f:0b:74),eth_type(0x0800),ipv4(frag=no), packets:995, bytes:97510, used:0.440s, actions:3
```

⚠ For the host PF, in order for GRE to work properly with the default 1500 MTU, follow these steps.

1. Disable host PF as the port owner from Arm (see section "Zero-trust Mode"). Run:

```
$ mlxprivhost -d /dev/mst/mt41682_pciconf0 --disable_port_owner r
```

2. The MTU of the end points (`pf0hpf` in the example above) of the GRE tunnel must be smaller than the MTU of the tunnel interfaces (`p0`) to account for the size of the GRE headers. For example, you can set the MTU of P0 to 2000.

8.15.8.12 GENEVE Tunneling Offload

GENEVE tunnels are created on the Arm side and attached to the OVS. GENEVE decapsulation/encapsulation behavior is similar to normal GENEVE behavior, including over `hw_offload=true`.

To allow GENEVE encapsulation, the uplink representor (`p0`) must have an MTU value at least 50 bytes greater than that of the host PF/VF.

Please refer to "Configuring Uplink MTU" for more information.

8.15.8.12.1 Configuring GENEVE Tunnel

1. Consider `p0` to be the local GENEVE tunnel interface. `p0` should not be attached to any OVS bridge.
2. Create an OVS bridge, `br0`, with a GENEVE tunnel interface, `gnv0`. Run:

```
ovs-vsctl add-port br0 gnv0 -- set interface gnv0 type=geneve options:local_ip=1.1.1.1
options:remote_ip=1.1.1.2 options:key=100
```

3. Add `pf0hpf` to `br0`.

```
ovs-vsctl add-port br0 pf0hpf
```

4. At this point, any network traffic sent or received by the host's PF0 undergoes GENEVE processing inside the BlueField OS.

Options are supported for GENEVE. For example, you may add option `0xea55` to tunnel metadata, run:

```
ovs-ofctl add-tlv-map geneve_br "{class=0xffff,type=0x0,len=4}->tun_metadata0"
ovs-ofctl add-flow geneve_br ip,actions="set_field:0xea55->tun_metadata0",normal
```

For the host PF, in order for GENEVE to work properly with the default 1500 MTU, follow these steps.

1. Disable host PF as the port owner from Arm (see section "Zero-trust Mode"). Run:

```
$ mlxprivhost -d /dev/mst/mt41682_pciconf0 --disable_port_owner r
```

2. The MTU of the end points (`pf0hpf` in the example above) of the GENEVE tunnel must be smaller than the MTU of the tunnel interfaces (`p0`) to account for the size of the GENEVE headers. For example, you can set the MTU of P0 to 2000.

8.15.8.13 Using TC Interface to Configure Offload Rules

Offloading rules can also be added directly, and not just through OVS, using the tc utility. To enable TC ingress on all the representors (i.e., uplink, PF, and VF).

```
$ tc qdisc add dev p0 ingress
$ tc qdisc add dev pf0hpf ingress
$ tc qdisc add dev pf0vf0 ingress
```

8.15.8.13.1 L2 Rules Example

The rule below drops all packets matching the given source and destination MAC addresses.

```
$ tc filter add dev pf0hpf protocol ip parent ffff: \
                               flower \
                                           skip_sw \
                                           dst_mac e4:11:22:11:4a:51 \
                                           src_mac e4:11:22:11:4a:50 \
                                action drop
```

8.15.8.13.2 VLAN Rules Example

The following rules push VLAN ID 100 to packets sent from VF0 to the wire (and forward it through the uplink representor) and strip the VLAN when sending the packet to the VF.

```
$ tc filter add dev pf0vf0 protocol 802.1Q parent ffff: \
                                    flower \
                                              skip_sw \
                                              dst_mac e4:11:22:11:4a:51 \
                                              src_mac e4:11:22:11:4a:50 \
                                    action vlan push id 100 \
                                    action mirred egress redirect dev p0

$ tc filter add dev p0 protocol 802.1Q parent ffff: \
                                    flower \
                                             skip_sw \
                                             dst_mac e4:11:22:11:4a:51 \
                                             src_mac e4:11:22:11:4a:50 \
                                             vlan_ethtype 0x800 \
                                             vlan_id 100 \
                                             vlan_prio 0 \
                                  action vlan pop \
                                  action mirred egress redirect dev pf0vf0
```

8.15.8.13.3 VXLAN Encap/Decap Example

```
$ tc filter add dev pf0vf0 protocol 0x806 parent ffff: \
                                    flower \
                                              skip_sw \
                                              dst_mac e4:11:22:11:4a:51 \
                                              src_mac e4:11:22:11:4a:50 \
                                    action tunnel_key set \
                                    src_ip 20.1.12.1 \
                                    dst_ip 20.1.11.1 \
                                    id 100 \
                                    action mirred egress redirect dev vxlan100

$ tc filter add dev vxlan100 protocol 0x806 parent ffff: \
                                    flower \
                                             skip_sw \
                                             dst_mac e4:11:22:11:4a:51 \
                                             src_mac e4:11:22:11:4a:50 \
                                             enc_src_ip 20.1.11.1 \
                                             enc_dst_ip 20.1.12.1 \
                                             enc_key_id 100 \
                                             enc_dst_port 4789 \
                                  action tunnel_key unset \
                                  action mirred egress redirect dev pf0vf0
```

8.15.8.14 Virtio Acceleration Through Hardware vDPA

For configuration procedure, please refer to the MLNX_OFED documentation under OVS Offload Using ASAP² Direct > Virtio Acceleration through Hardware vDPA.

8.15.9 OVS Live Upgrade

This document describes the procedure for performing a live upgrade of Open vSwitch (OVS) with NVIDIA DOCA datapath support, enabling seamless transitions with minimal or no network traffic disruption.

8.15.9.1 Introduction

Non-disruptive upgrade (NDU), also known as a live or hot upgrade, replaces the OVS user-space process without disrupting active network traffic. It achieves this by synchronizing runtime state between the running process and a newly launched one, enabling a seamless handoff. NDU supports high-availability requirements and can also be used to restart OVS after configuration changes, ensuring continuous operation without downtime or packet loss.

8.15.9.2 NDU Operational Model

The NDU procedure involves two cooperating OVS processes:

- Server – the currently running OVS process
- Client – the new OVS process launched for the upgrade

The upgrade sequence consists of the following steps:

1. Client initialization – The new OVS process is launched in client mode.
2. State Synchronization – The client connects to the server and synchronizes essential runtime state, including:
    - Datapath and OpenFlow ports
    - Tunnel neighbor entries
    - OpenFlow tables, rules, meters, groups, and TLV mappings
    - Connection tracking (CT) state
    - MAC learning tables (FDB)
    - Routing entries

    > ⚠ Datapath rules (e.g., megaflows) are not transferred; the new process relearns them upon takeover.

3. Control plane handover – Upon successful synchronization, the client assumes control, and the server process is gracefully terminated.

Throughout the process, packet forwarding continues with negligible disruption.

8.15.9.3 Prerequisites

To support live upgrade:

- Both the existing and new OVS processes must support NDU.
- The datapath type must be set to `doca`.

8.15.9.4 Upgrade Procedure

8.15.9.4.1 Initiating the Upgrade

No manual intervention is required during the upgrade process. To initiate an NDU, reload the OVS systemd service:

initiate live upgrade

```
systemctl reload ovs-vswitchd.service
```

This command launches the client process, triggers synchronization, and transitions control to the new instance. The old process exits cleanly after handover.

Progress and any anomalies are logged to the OVS log files.

8.15.9.4.2 Post-Upgrade Validation

After the upgrade, confirm that:

- The new OVS process is active and managing the datapath
- All ports, flow rules, and dynamic state have been retained
- No traffic interruption occurred during the upgrade

Use standard OVS utilities to verify status:

```
ovs-vsctl show
ovs-ofctl dump-flows <bridge>
ovs-appctl dpctl/offload-stats-show
ovs-appctl dpctl/dump-flows
```

8.15.9.4.3 Error Handling and Rollback

If an error occurs during the synchronization or switchover phase, OVS will automatically revert to the original process to maintain service continuity. All rollback operations and failures are recorded in the log.

> ⚠ On Debian-based distributions (including Ubuntu), the `dpkg` package manager currently restarts OVS during `.deb` package upgrades. This behavior conflicts with the NDU mechanism. Once the installer behavior is updated, this limitation will be removed.

9 API References

For DOCA SDK API documentation, please refer to the API References for DOCA 3.2.0.

10 DOCA Troubleshooting

DOCA troubleshooting topics are available in the DOCA page of the *NVIDIA BlueField Platform Software Troubleshooting Guide*.

- fTPM over OP-TEE

11.1 DOCA Glossary

The table below provides an extensive glossary of terms, abbreviations, and acronyms used throughout the DOCA SDK documentation.

Term/ Acronym	Description/Definition
b	Lower-case b is used to indicate size in bits or multiples of bits (e.g., 1Kb = 1024 bits)
B	Upper-case B is used to indicate size in bytes or multiples of bytes (e.g., 1KB = 1024 bytes)
ACS	Access control services
ASAP 2	Accelerated Switching and Packet Processing
ASN	Autonomous system number
ATF	Arm-trusted firmware
BAR	Base address register
BDF address	Bus, device, function address. The device's PCIe bus address.
BFB	BlueField bootstream
BGP	Border gateway protocol
BMC	Board management controller
BSP	BlueField support package
BUF	Buffer
CBS	Committed burst size

Term/ Acronym	Description/Definition
CIR	Committed information rate
CMDQ	Command queue
CPDS	Control pipe dynamic size
CQE	Completion queue events
CTX	Context
DEK	Data encryption key
DMA	Direct memory access
DN	Data network
DOCA	DPU SDK (Data Processing Unit Software Development Kit)
DPA	Data path accelerator; an auxiliary processor designed to accelerate data-path operations.
DPCP	Direct packet control plane
DPDK	Data plane development kit
DPI	Deep packet inspection
DPU	Data processing unit, the third pillar of the data center with CPU and GPU.
DW	Dword
EBS	Excess burst size
ECE	Enhanced connection establishment
ECMP	Equal-cost multi-path
ECPF	Embedded CPU physical function
EIR	Excess information rate
EM	Exact match
eMMC	Embedded multi-media card
ESP	Encapsulating security payload (or EFI system partition)
EU	Execution unit. HW thread; a logical DPA processing unit.
FAR	Forwarding action rule
FIFO	First-in-first-out
FIPS	Federal Information Processing Standards
FLR	Function level reset
FPGA	Field-programmable gate arrays
FW	Firmware
GDAKIN	GPUDirect async kernel-initiated network
GDB	GNU debugger
gNB	Next Generation NodeB
HCA	Host-channel adapter – an InfiniBand (IB) device that terminates an IB link.
Host	When used alone, refers to the server host. Arm host refers to the AARCH64 Linux OS running on the BlueField Arm cores.

Term/ Acronym	Description/Definition
HW	Hardware
hwmon	Hardware monitoring
IB	InfiniBand
ICM	Interface configuration memory
ICV	Integrity check value
IDE	Integrated development environment
IKE	Internet key exchange
In-band	Administration activities traversing the IB connectivity only.
IPoIB	IP over InfiniBand
IR	Intermediate representation
IRQ	Interrupt request
iSER	iSCSI RDMA protocol
KPI	Key performance indicator
LFT	Unicast linear forwarding tables
LRO	Large receive offload
LSB	Least significant byte (or least significant bit as *lsb*)
LSO	Large send offload
LTO	Link-time optimization
MFT	Mellanox firmware tools
MLNX_OFED	Mellanox OpenFabrics Enterprise Distribution
MPI	Message passing interface
MSB	Most significant byte (or most significant bit as *msb*)
MSS	Maximum segment size (or Memory subsystem)
MST	Mellanox software tools
MTU	Maximum transmission unit
NAT	Network address translation
NIC	Network interface card
NIST	National Institute of Standards and Technology
NP	Notification point
NS	Namespace
NUMA	Non-uniform memory access
OOB	Out-of-band
OS	Operating system
OVS	Open vSwitch
PAT	Port address translation
PBA	Pending bit array

Term/ Acronym	Description/Definition
PBS	Peak burst size
PCIe	PCI Express
PDR	Packet detection rule
PE	Progress engine
PF	Physical function
PFC	Priority flow control
PHC	Physical hardware clock
PIR	Peak information rate
PK	Platform key
PKA	Public key accelerator
POC	Proof of concept
PR	Path record
PUD	Process under debug
QER	QoS enforcement rule
QoS	Quality of service
RAN	Radio access network
RAP	Reference application
RD	Route distinguisher
RDMA	Remote direct memory access
RDMA CM	RDMA connection manager
RegEx	Regular expression
RN	Request node (e.g., RN-F: Fully coherent, RN-D: IO coherent)
RNG	Random number generator/generation
RoCE	RDMA over converged Ethernet
RP	Reaction point
RQ	Receive queue
RShim	Random shim
RSP	Remote serial protocol
RT	Route target
RTOS	Real-time operating system
RTT	Round-trip time
RX	Receive
RXP	Regular expression processor
SA	Security association (or Subnet administrator)
SBSA	Server base system architecture
SDK	Software development kit

Term/ Acronym	Description/Definition
SF	Sub-function or Scalable function
SFC	Service function chaining (in HBN)
SG	Scatter-gather
SHA	Secure hash algorithm
SL	Service level
SM	Subnet Manager
SMF	Session management function
SNAP	Storage-defined network-accelerated processing
SNAT	Source NAT
SPDK	Storage performance development kit
SPI	Security parameters index
SQ	Send queue
SR-IOV	Single-root IO virtualization
SRP	SCSI RDMA protocol
SuperNIC	A configuration of a DPU specific for E-W (East-West) networking.
SVI	Switch virtual interface
SW	Software
Sync event	Synchronization event
TAI	International Atomic Time
TIR	Transport interface receive
TIS	Transport interface send
TLS	Transport layer security
TSO	TCP segmentation offload
TX	Transmit
uDAPL	User direct access programming library
UDS	Unix domain socket
UE	User equipment
UEFI	Unified extensible firmware interface
ULP	Upper layer protocol
UPF	User-plane function
URR	Usage reporting rule
UTC	Coordinated Universal Time
vDPA	Virtual data path acceleration
VF	Virtual function
VFE	Virtio full emulation
vHBA	Virtual SCSI host bus adapter

Term/ Acronym	Description/Definition
VM	Virtual machine
VMA	NVIDIA® Messaging Accelerator
VNI	Virtual network identifier (or VXLAN network identifier)
VPI	Virtual protocol interconnect
VRF	Virtual routing and forwarding
VTEP	VXLAN tunnel endpoint
WAN	Wide area network
WorkQ / workq	Work queue
WQE	Work queue elements
WR	Write
XLIO	NVIDIA® Accelerated IO

11.2 DOCA Crypto Acceleration

NVIDIA® BlueField® DPU incorporates several Public Key Acceleration (PKA) engines to offload the processor of the Arm host, providing high-performance computation of PK algorithms. BlueField's PKA is useful for a wide range of security applications. It can assist with SSL acceleration, or a secure high-performance PK signature generator/ checker and certificate related operations.

BlueField's PKA software libraries implement a simple, complete framework for crypto public key infrastructure (PKI) acceleration. It provides direct access to hardware resources from the user space, and makes available a number of arithmetic operations—some basic (e.g., addition and multiplication), and some complex (e.g., modular exponentiation and modular inversion)—and high-level operations such as RSA, Diffie-Hallman, Elliptic Curve Cryptography, and the Federal Digital Signature Algorithm (DSA as documented in FIPS-186) public-private key systems.

Some of the use cases for the BlueField PKA involve integrating OpenSSL software applications with BlueField's PKA hardware. The BlueField PKA dynamic engine for OpenSSL allows applications integrated with OpenSSL (e.g., StrongSwan) to accomplish a variety of security-related goals and to accelerate the cryptographic processing with the BlueField PKA hardware. OpenSSL versions ≥1.0.0, ≤1.1.1, and 3.0.2 are supported.

> ⚠ With CentOS 7.6, only OpenSSL 1.1 (not 1.0) works with PKA engine and keygen. Use `openssl11` with PKA engine and keygen.

The engine supports the following operations:

- RSA

- DH
- DSA
- ECDSA
- ECDH
- Random number generation that is cryptographically secure.

Up to 4096-bit keys for RSA, DH, and DSA operations are supported. Elliptic Curve Cryptography support of (nist) prime curves for 160, 192, 224, 256, 384 and 521 bits.

For example:

To sign a file using BlueField's PKA engine:

```
$ openssl dgst -engine pka -sha256 -sign <privatekey> -out <signature> <filename>
```

To verify the signature, execute:

```
$ openssl dgst -engine pka -sha256 -verify <publickey> -signature <signature> <filename>
```

For further details on BlueField PKA, please refer to "PKA Driver Design and Implementation Architecture Document" and/or "PKA Programming Guide". Directions and instructions on how to integrate the BlueField PKA software libraries are provided in the README files on our PKA GitHub.

11.3 DOCA Services Fluent Logger

This guide provides instructions on how to use the logging infrastructure for DOCA services on top of NVIDIA® BlueField® DPU.

11.3.1 Introduction

Fluent Bit is a fast log collector that collects information from multiple sources and then forwards the data onward using Fluent.

On NVIDIA DPUs, the Fluent Bit logger can be easily configured to collect system data and the logs from the different DOCA services.

11.3.2 Deployment

The deployment is based on a recommended configuration template for the existing Fluent Bit container.

For information about the deployment of DOCA containers on top of the BlueField DPU, refer to NVIDIA DOCA Container Deployment Guide.

The following is an example YAML file for deploying the Fluent Bit pod:

```
apiVersion: v1
kind: Pod
metadata:
  name: fluent-bit
spec:
  hostNetwork: true
  containers:
  - name: fluent-bit
    image: fluent/fluent-bit:latest
    imagePullPolicy: Always
    # Example resource definitions
    resources:
      requests:
        memory: "100Mi"
        cpu: "200m"
      limits:
        memory: "200Mi"
        cpu: "300m"
    volumeMounts:
    - name: varlog
      mountPath: /var/log
    - name: config-file
      mountPath: /fluent-bit/etc/fluent-bit.conf
  volumes:
  - name: varlog
    hostPath:
      path: /var/log
  - name: config-file
    hostPath:
      path: /opt/mellanox/doca/services/fluent-bit.conf
      type: File
```

As explained in the "Configuration" section, Fluent Bit uses a configuration file. As such, to ensure that the example YAML file is shared from the DPU to the deployed Fluent Bit container, use the following:

```
path: /opt/mellanox/doca/services/fluent-bit.conf
```

> ⚠ The path below is just an example for where the user can place the `fluent-bit.conf` file. The file could be placed in a different directory on the DPU as long as the YAML file points to the updated location.

11.3.3 Configuration

The Fluent Bit configuration file should have the following sections:

- `[SERVICE]` – to define the service specifications
- `[INPU]` – to define folders to collect logs from (there could be multiple inputs)
- `[OUTPUT]` – IP and port to stream the data to

Example configuration file:

```
[SERVICE]
    Flush         2
    Log_Level     info
    Daemon        off
    Parsers_File  parsers.conf
    HTTP_Server   On
    HTTP_Listen   0.0.0.0
    HTTP_Port     2020
```

```
[INPUT]
    Name              tail
    Tag               kube.*
    Path              /var/log/containers/*.log
    Parser            docker
    Mem_Buf_Limit     5MB
    Skip_Long_Lines   On
    Refresh_Interval  10

[INPUT]
    Name              tail
    Tag               sys.*
    Path              /var/log/doca/*/*.log
    Mem_Buf_Limit     5MB
    Skip_Long_Lines   On
    Refresh_Interval  10

[OUTPUT]
    Name  es
    Match *
    Host 10.20.30.40
    Port 9201
    Index fluent_bit
    Type cpu_metrics
```

The most important field to pay attention to is `Path` for the `INPUT` section. DOCA services report their logs to a unique directory under `/var/log/doca/<service_name>/*.log` per the respective DOCA service. As such, the configuration above defines the `/var/log/doca/*/*.log` input definition.

More information about the full specifications can be found in the official Fluent Bit manual.

11.3.4 Troubleshooting

For container-related troubleshooting, refer to the "Troubleshooting" section in the NVIDIA DOCA Container Deployment Guide.

For general troubleshooting, refer to the DOCA Troubleshooting.

When copying the above YAML file, it is possible that the container infrastructure logs give an error related to RFC 1123". These errors are usually a result of a spacing error in the file, which sometimes occur when copying the file as is from this page. To fix this issue, make sure that only the space character (' ') is used as a spacer in the file and not other whitespace characters that might have been added during the copy operation.

11.4 DOCA DPU CLI

This guide provides quick access to a useful set of CLI commands and utilities on the NVIDIA® BlueField® DPU environment.

11.4.1 Introduction

This guide provides a concise guide on useful commands for DOCA deployment and configuration.

The tables in this guide provide two categories of commands:

- General commands for Linux/networking environment
- DOCA/DPU-specific commands

> ⚠ For more information about these commands, such as usage instructions, flag options, arguments and so on, use the `-h` option after the command or use the manual (e.g., `man lspci`).

11.4.2 General Commands

Command	Description
`ifconfig`	Used to configure kernel-resident network interfaces. It is used at boot time to set up interfaces as necessary. After that, it is usually only needed when debugging or when system tuning is needed. If no arguments are given, `ifconfig` displays the status of the currently active interfaces. If a single interface argument is given, it displays the status of the given interface only. If a single `-a` argument is given, it displays the status of all interfaces, even those that are down. Otherwise, it configures an interface.
`ethtool <devname>`	Used to query and control network device driver and hardware settings, particularly for wired Ethernet devices. `<devname>` is the name of the network device on which `ethtool` should operate. ⚠ This command shows the speed of the network card of the DPU.
`lspci`	Displays information about PCIe buses in the system and devices connected to them. By default, it shows a brief list of devices.
`tcpdump`	Dump traffic on a network. Usage: `tcpdump -i <interface>` where `<interface>` is any port interface (physical/SF rep/VF port rep).
`ovs-vsctl`	Utility for querying and configuring `ovs-vswitchd`. The `ovs-vsctl` program supports the model of a bridge implemented by Open vSwitch in which a single bridge supports ports on multiple VLANs.
`mount 10.0.0.10:/vol/myshare/myshare/`	Used for mounting a work directory on the DPU. ⚠ Must be used after creating a new directory named `myshare` under root (i.e., `mkdir /myshare`)

Command	Description
`scp`	Secure copy (remote file copy program). Useful for copying files from BlueField to the host and vice versa.
`iperf`	Used for server-client connection. Useful to check if the network connection achieves the speed of the network card on the DPU (line rate).

11.4.3 DPU/DOCA Commands

Command	Description
`ibdev2netdev`	Displays available `mlnx` interfaces
`mst`	Used to start MST service, to stop it, and for other operations with NVIDIA devices like reset and enabling remote access
`cat /etc/mlnx-release`	Displays the full BlueField image (bfb) version
`cat /etc/os-release`	Displays the details of the underlying OS installed on BlueField
`ibv_devinfo`	Displays the current InfiniBand connected devices and relevant information. Useful for checking current firmware version.
`ipmitool power cycle`	Power cycle ⚠ Prior to performing a power cycle, make sure to perform a graceful shutdown.

`echo '1024' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages`
`sudo mkdir /mnt/huge`
`sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge`
	DPDK setup. Allocates hugepages for DPDK environment abstraction layer (EAL).

`mlxdevm tool`	`mlxdevm tool` is found under `/opt/mellanox/iproute2/sbin/`. With this tool it is possible to create an SF and set its state to active, configure a HW address and set it to trusted, deploy the created SF and print info about it.
`/opt/mellanox/iproute2/sbin/mlxdevm port add pci/<pci_address> flavour pcisf pfnum <correspondig_physical_function_number> sfnum <unique_sf_number>`	Creates an SF in the flavor of the given PF with the given unique SF number. Example: `/opt/mellanox/iproute2/sbin/mlxdevm port add pci/0000:03`:00.0 flavour pcisf pfnum 0 sfnum 4`
`/opt/mellanox/iproute2/sbin/mlxdevm port show`	Displays information about the available SFs

Command	Description
`/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/<sf_index> hw_addr <HW_address> trust on state active`	Configures SF capabilities such as setting the HW address, making it "trusted", and setting its state to active. `<sf_index>` the SF. To obtain this index, you may run `mlxdevm port show`. Example: `/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/229377 hw_addr 02:25:f2:8d:a2:4c trust on state active`
`$ echo mlx5_core.sf.<next_serial> > /sys/bus/auxiliary/drivers/mlx5_core.sf_cfg/unbind` `$ echo mlx5_core.sf.<next_serial> > /sys/bus/auxiliary/drivers/mlx5_core.sf/bind`	These two commands deploy the created SF. The first command unbinds the SF from the default driver, while the second command binds the SF to the actual driver. The deployment phase should be done after the capabilities of the SF are configured. The SF is identified by `<next_serial>` which can be obtained by running the command below.
`ls /sys/bus/auxiliary/devices/mlx5_core.sf.*`	Displays additional information about the created SFs and their "next serial numbers". For example, if `mlx5_core.sf.2` exists in the output of the command, then running `cat /sys/bus/auxiliary/devices/mlx5_core.sf.2/sfnum` would output the sfnum related to `mlx5_core.sf.2`.
`/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/<pci_address>/<sf_index> state inactive` `/opt/mellanox/iproute2/sbin/mlxdevm port del pci/<pci_address>/<sf_index>`	These two commands must be executed to delete a given SF. First, users must set the state of the SF to inactive, and only then should it be deleted.
`/opt/mellanox/iproute2/sbin/mlxdevm port help`	Displays additional information about operations that can be used on created SF ports
`crictl pods`	Displays currently active K8S pods, and their IDs (it might take up to 20-30 seconds for the pod to start)
`crictl ps`	Displays currently active containers and their IDs
`crictl ps -a`	Displays all containers, including containers that recently finished their execution
`crictl logs <container-id>`	Examines the logs of a given container
`crictl exec -it <container-id> /bin/bash`	Attaches a shell to a running container
`journalctl -u kubelet`	Examines the Kubelet logs. Useful when a pod/container fails to spawn.
`crictl stopp <pod-id>`	Stops a running K8S pod
`crictl stop <container-id>`	Stops a running container

Command	Description
`crictl rmi <image-id>`	Removes a container image from the local K8S registry

11.5 DOCA Switching

NVIDIA® BlueField® and NVIDIA® ConnectX® platforms provide robust support for diverse applications through hardware-based offloads, offering unparalleled scalability, performance, and efficiency.

This section lists the extensive switching capabilities enabled by DOCA libraries and services on these platforms. It includes detailed configurations of Open Virtual Switch (OVS) such as the setup of representors, virtualization options, and optional bridge configurations. The subsections guide users through the steps to effectively implement these software components.

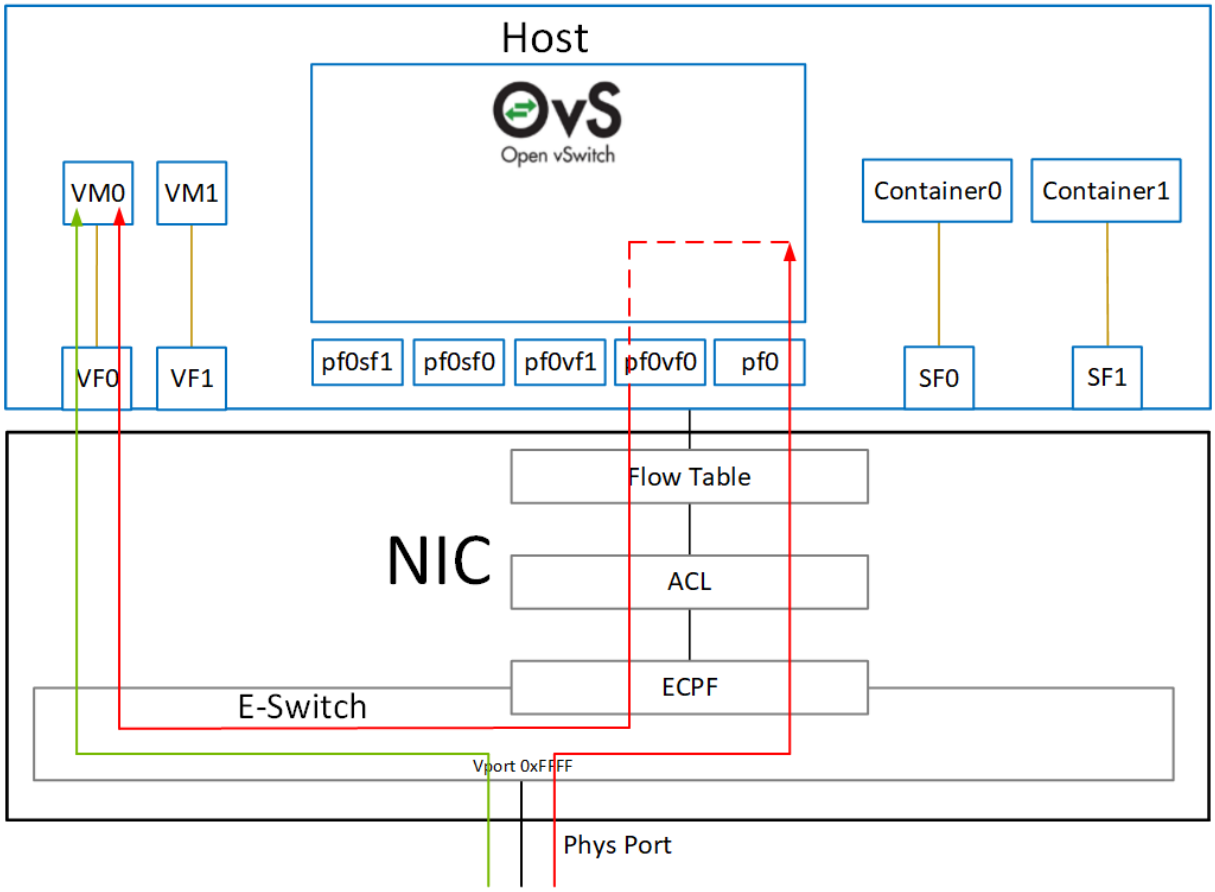
11.5.1 Switch Device Mode

Switchdev mode allows the physical function (PF) to operate as a virtual switch, granting software a means to control associated virtual function (VF) and scalable function (SF) traffic. In this mode, software can intercept incoming/outgoing VF/SF traffic and configure steering rules that offload traffic.

Once this mode is configured, the PF is considered an E-Switch, and additional ports are allocated for each associated VF and SF. The additional ports are referred to as port representors.

11.5.1.1 ConnectX and BlueField NIC Mode

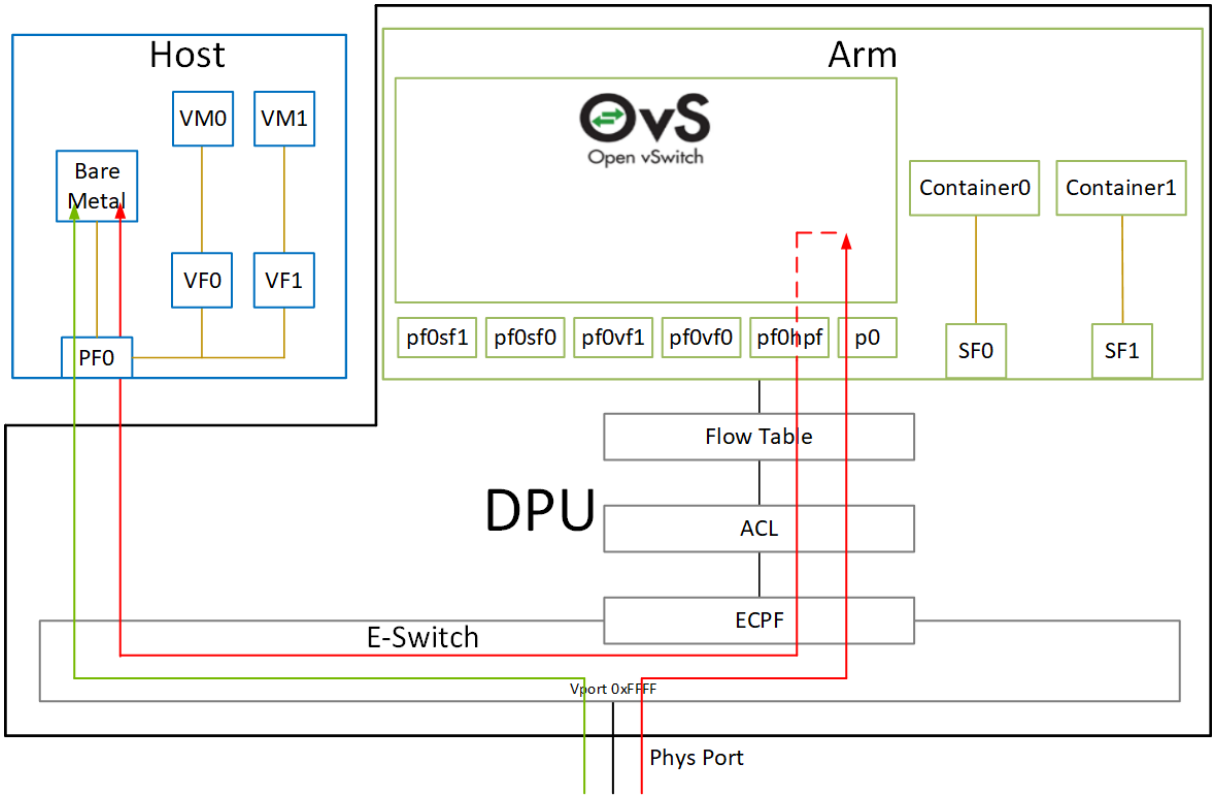
Switchdev mode may be configured for each PF as described in the "Configuring Switchdev Mode" section.



11.5.1.2 BlueField DPU Mode

When BlueField operates in DPU mode, switchdev mode is configured by default for all PFs on the Arm. That configuration must not be changed. In this mode, the host cannot configure PFs to operate in switchdev mode. Instead, host PFs operate in legacy mode only.

The following diagram shows the mapping of between the PCIe functions exposed on the host side and the representors. For the sake of simplicity, the diagram shows a single port model (duplicated for the second port).



The red arrow demonstrates packet flow through the representors, while the green arrow demonstrates the packet flow when steering rules are offloaded to the embedded switch.

11.5.2 E-Switch Port

Once switchdev mode is configured, the PF acts as an e-switch and manages all switch ports. The e-switch can be used to control VF and SF traffic. Software can then use the e-switch through the netdev and RDMA core interfaces.

11.5.2.1 Netdev Interface

The e-switch has a netdev interface (e.g., `pf0`), allowing it to be used with common Linux networking tools (e.g., `ifconfig`) and OVS. While the interface looks like a regular network port, in reality it is considered the upstream representor and it cannot host an IP server. That is, configuring an IP address to this interface is not useful (e.g., it cannot be pinged).

The netdev interface can be used mainly by OVS and the Linux bridge.

To overcome this limitation, it is possible to create SFs. For more details, see BlueField Scalable Function User Guide.

11.5.2.2 RDMA Core Interface

The e-switch has an RDMA device instance (e.g., `mlx5_0`) which grants software access to the e-switch capabilities for offloading steering rules and accessing various RDMA capabilities.

The instance behaves like an RDMA core device with the following limitations:

- It cannot host an RDMA connection and cannot be used to connect to the remote RDMA target (e.g., cannot do RDMA send)
- It cannot have an RDMA GID

The RDMA device can mainly be used to configure the e-switch.

To overcome this limitation, it is possible to create SFs. For more details, see BlueField Scalable Function User Guide.

11.5.3 Representor Port

For each network function (i.e., VF/SF) a corresponding representor port is created. The representor port represents the actual port. The network function can then be used to access the network by a VM/container, while the representor can be used to manage switching by virtual switch software (e.g., bare metal host).

11.5.3.1 Netdev Interface

Each representor port would have a netdev interface (e.g., `pf0vf0`), allowing it to be used with common Linux networking tools (e.g., `ifconfig`) as well as OVS.

While the interface looks like a regular network port, in reality it is a VF/SF representor and it cannot host an IP server. That is, configuring an IP address to this interface is not useful (e.g., it cannot be pinged).

The representor netdev can be used to refer to a specific network function when configuring steering rules using OVS or Linux bridge.

11.5.3.2 RDMA Core Interface

The representor does not have a corresponding RDMA core instance (e.g., `mlx5_0`). Instead, it is managed by the RDMA core instance of the e-switch manager. Each representor is an RDMA port of the e-switch RDMA device.

11.5.4 Configuring Switchdev Mode

> For BlueField in DPU mode, there is no need to follow these steps as the PFs are already configured to switchdev mode by default.

1. Unbind all VFs:

```
# echo 0000:3d:00.2 > /sys/bus/pci/drivers/mlx5_core/unbind
# echo 0000:3d:00.3 > /sys/bus/pci/drivers/mlx5_core/unbind
```

> VMs with attached VFs must be powered off to be able to unbind the VFs.

2. Change the e-switch mode from legacy to switchdev on the PF device:

```
# devlink dev eswitch set pci/0000:3d:00.0 mode switchdev
```

This creates the VF/SF representor ports in the host OS.

> Before changing the mode, make sure that all VFs are unbound.

> To return to legacy mode, run:
>
> ```
> # devlink dev eswitch set pci/0000:3d:00.0 mode legacy
> ```
>
> This removes the VF/SF representor ports.

On OSes or kernels that do not support devlink, moving to switchdev mode can be done using sysfs:

```
# echo switchdev > /sys/class/net/pf0/compat/devlink/mode
```

3. At this stage, VF representors have been created. To map a representor to its VF, make sure to obtain the representor's `switchid` and `portname` by running:

```
# ip -d link show eth0
41: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT group default qlen 1000
    link/ether ba:e6:21:37:bc:d4 brd ff:ff:ff:ff:ff:ff promiscuity 0 addrgenmode eui64 numtxqueues 10
 numrxqueues 10 gso_max_size 65536 gso_max_segs 65535 portname pf0vf0 switchid f4ab580003a1420c
```

Where:

- `switchid` – used to map representor to device, both device PFs have the same `switchid`
- `portname` – used to map representor to PF and VF. Value returned is `pf<X>vf<Y>`, where `X` is the PF number and `Y` is the number of VF.

4. Bind the VFs:

```
echo 0000:3d:00.2 > /sys/bus/pci/drivers/mlx5_core/bind
echo 0000:3d:00.3 > /sys/bus/pci/drivers/mlx5_core/bind
```

11.5.5 DPU Kernel Representors Model

> ⚠ This model is only applicable when the NVIDIA® BlueField® networking platform (DPUs or SuperNIC) is operating in DPU mode.

BlueField uses netdev representors to map each one of the host side physical and virtual functions.

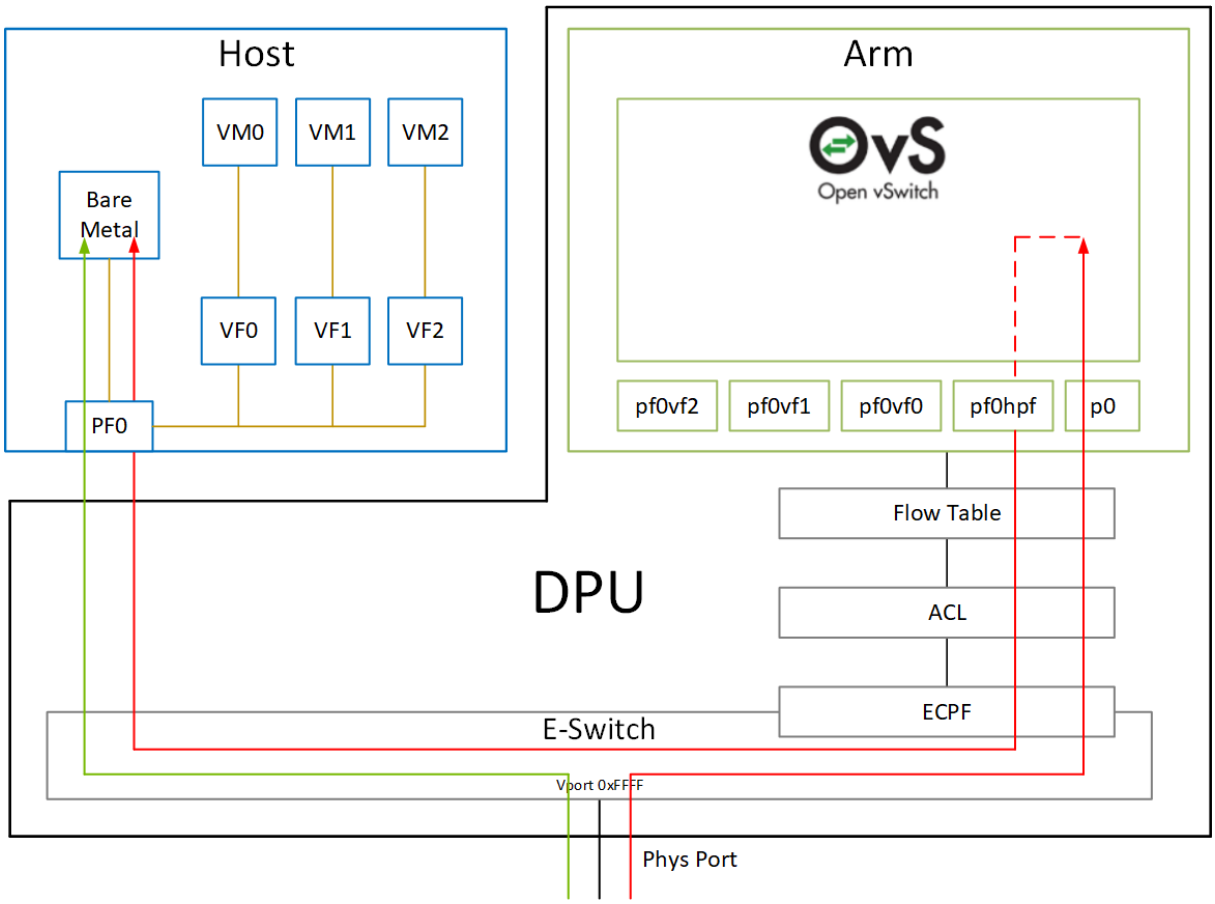
1. Serve as the tunnel to pass traffic for the virtual switch or application running on the Arm cores to the relevant PF or VF on the host side.
2. Serve as the channel to configure the embedded switch with rules to the corresponding represented function.

Those representors are used as the virtual ports being connected to OVS or any other virtual switch running on the Arm cores.

When operating in DPU mode, we see 2 representors for each one of the BlueField's network ports: one for the uplink, and another one for the host side PF (the PF representor created even if the PF is not probed on the host side). For each one of the VFs created on the host side a corresponding representor would be created on the Arm side. The naming convention for the representors is as follows:

- Uplink representors: `p<port_number>`
- PF representors: `pf<port_number>hpf`
- VF representors: `pf<port_number>vf<function_number>`

The following diagram shows the mapping of between the PCIe functions exposed on the host side and the representors. For the sake of simplicity, a single port model (duplicated for the second port) is shown.



The red arrow demonstrates a packet flow through the representors, while the green arrow demonstrates the packet flow when steering rules are offloaded to the embedded switch. More details on that are available in the switch offload section.

> ⚠ The MTU of host functions (PF/VF) must be smaller than the MTUs of both the uplink and corresponding PF/VF representor. For example, if the host PF MTU is set to 9000, both uplink and PF representor must be set to above 9000.

11.5.6 Virtio Acceleration through Hardware vDPA

11.5.6.1 Hardware vDPA Installation

Hardware vDPA requires QEMU v2.12 (or with upstream 6.1.0) and DPDK v20.11 as minimal versions.

To install QEMU:

1. Clone the sources:

```
git clone https://git.qemu.org/git/qemu.git
```

```
cd qemu
git checkout v2.12
```

2. Build QEMU:

```
mkdir bin
cd bin
../configure --target-list=x86_64-softmmu --enable-kvm
make -j24
```

To install DPDK:

1. Clone the sources:

```
git clone git://dpdk.org/dpdk
cd dpdk
git checkout v20.11
```

2. Install dependencies (if needed):

```
yum install cmake gcc libnl3-devel libudev-devel make pkgconfig valgrind-devel pandoc libibverbs libmlx5
libmnl-devel -y
```

3. Configure DPDK:

```
export RTE_SDK=$PWD
make config T=x86_64-native-linuxapp-gcc
cd build
sed -i 's/\(CONFIG_RTE_LIBRTE_MLX5_PMD=\)n/\1y/g' .config
sed -i 's/\(CONFIG_RTE_LIBRTE_MLX5_VDPA_PMD=\)n/\1y/g' .config
```

4. Build DPDK:

```
make -j
```

5. Build the vDPA application:

```
cd $RTE_SDK/examples/vdpa/
make -j
```

11.5.6.2 Hardware vDPA Configuration

To configure huge pages:

```
mkdir -p /hugepages
mount -t hugetlbfs hugetlbfs /hugepages
echo <more> > /sys/devices/system/node/node0/hugepages/hugepages-1048576kB/nr_hugepages
echo <more> > /sys/devices/system/node/node1/hugepages/hugepages-1048576kB/nr_hugepages
```

To configure a vDPA VirtIO interface in an existing VM's xml file (using `libvirt`):

1. Open the VM's configuration XML for editing:

```
virsh edit <domain name>
```

2. Perform the following:
    a. Change the top line to:

```
<domain type='kvm' xmlns:qemu='http://libvirt.org/schemas/domain/qemu/1.0'>
```

b. Assign a memory amount and use 1GB page size for huge pages (size must be the same as that used for the vDPA application), so that the memory configuration looks as follows.

```
<memory unit='KiB'>4194304</memory>
<currentMemory unit='KiB'>4194304</currentMemory>
<memoryBacking>
  <hugepages>
    <page size='1048576' unit='KiB'/>
  </hugepages>
</memoryBacking>
```

c. Assign an amount of CPUs for the VM CPU configuration, so that the `vcpu` and `cputune` configuration looks as follows:

```
<vcpu placement='static'>5</vcpu>
<cputune>
  <vcpupin vcpu='0' cpuset='14'/>
  <vcpupin vcpu='1' cpuset='16'/>
  <vcpupin vcpu='2' cpuset='18'/>
  <vcpupin vcpu='3' cpuset='20'/>
  <vcpupin vcpu='4' cpuset='22'/>
</cputune>
```

d. Set the memory access for the CPUs to be shared, so that the `cpu` configuration looks as follows:

```
<cpu mode='custom' match='exact' check='partial'>
  <model fallback='allow'>Skylake-Server-IBRS</model>
  <numa>
    <cell id='0' cpus='0-4' memory='8388608' unit='KiB' memAccess='shared'/>
  </numa>
</cpu>
```

e. Set the emulator in use to be the one built in step 2, so that the emulator configuration looks as follows:

```
<emulator><path to qemu executable></emulator>
```

f. Add a virtio interface using QEMU command line argument entries, so that the new interface snippet looks as follows:

```
<qemu:commandline>
  <qemu:arg value='-chardev'/>
  <qemu:arg value='socket,id=charnet1,path=/tmp/sock-virtio0'/>
  <qemu:arg value='-netdev'/>
  <qemu:arg value='vhost-user,chardev=charnet1,queues=16,id=hostnet1'/>
  <qemu:arg value='-device'/>
  <qemu:arg value='virtio-net-
pci,mq=on,vectors=6,netdev=hostnet1,id=net1,mac=e4:11:c6:d3:45:f2,bus=pci.0,addr=0x6,
    page-per-vq=on,rx_queue_size=1024,tx_queue_size=1024'/>
</qemu:commandline>
```

In this snippet, the vhostuser socket file path, the amount of queues, the MAC and the PCIe slot of the virtio device can be configured.

11.5.6.3 Running Hardware vDPA

⚠ Hardware vDPA supports switchdev mode only.

1. Create the ASAP^2 environment:
   a. Create the VFs.
   b. Enter switchdev mode.
   c. Set up OVS.
2. Run the vDPA application:

```
cd $RTE_SDK/examples/vdpa/build
./vdpa -w <VF PCI BDF>,class=vdpa --log-level=pmd,info -- -i
```

3. Create a vDPA port via the vDPA application CLI:

```
create /tmp/sock-virtio0 <PCI DEVICE BDF>
```

⚠ The vhostuser socket file path must be the one used when configuring the VM.

4. Start the VM:

```
virsh start <domain name>
```

For further information on the vDPA application, visit the Vdpa Sample Application DPDK documentation.

11.5.7 Bridge Offload

⚠ Bridge offload is supported switchdev mode only.

⚠ Bridge offload is supported from kernel version 5.15 onward.

A Linux bridge is an in-kernel software network switch (based on and implementing a subset of IEEE 802.1D standard) used to connect Ethernet segments together in a protocol-independent manner. Packets are forwarded based on L2 Ethernet header addresses.

mlx5 provides the ability to offload bridge dataplane unicast packet forwarding and VLAN management to hardware.

11.5.7.1 Basic Configuration

1. Initialize the ASAP^2 environment:
    a. Create the VFs.
    b. Enter switchdev mode.
2. Create a bridge and add mlx5 representors to bridge:

```
ip link add name bridge0 type bridge
ip link set enp8s0f0_0 master bridge0
```

11.5.7.2 Configuring VLAN

1. Enable VLAN filtering on the bridge:

```
ip link set bridge0 type bridge vlan_filtering 1
```

2. Configure port VLAN matching (trunk mode). In this configuration, only packets with specified VID are allowed.

```
bridge vlan add dev enp8s0f0_0 vid 2
```

3. Configure port VLAN tagging (access mode). In this configuration, VLAN header is pushed/popped upon reception/transmission on port.

```
bridge vlan add dev enp8s0f0_0 vid 2 pvid untagged
```

11.5.7.3 VF LAG Support

Bridge supports offloading on bond net device that is fully initialized with mlx5 uplink representors and is in single (shared) FDB LAG mode. Details about initialization of LAG are provided in section "SR-IOV VF LAG".

To add a bonding net device to bridge:

```
ip link set bond0 master bridge0
```

For further information on interacting with Linux bridge via iproute2 bridge tool, refer to man 8 bridge.

11.5.8 Link Aggregation

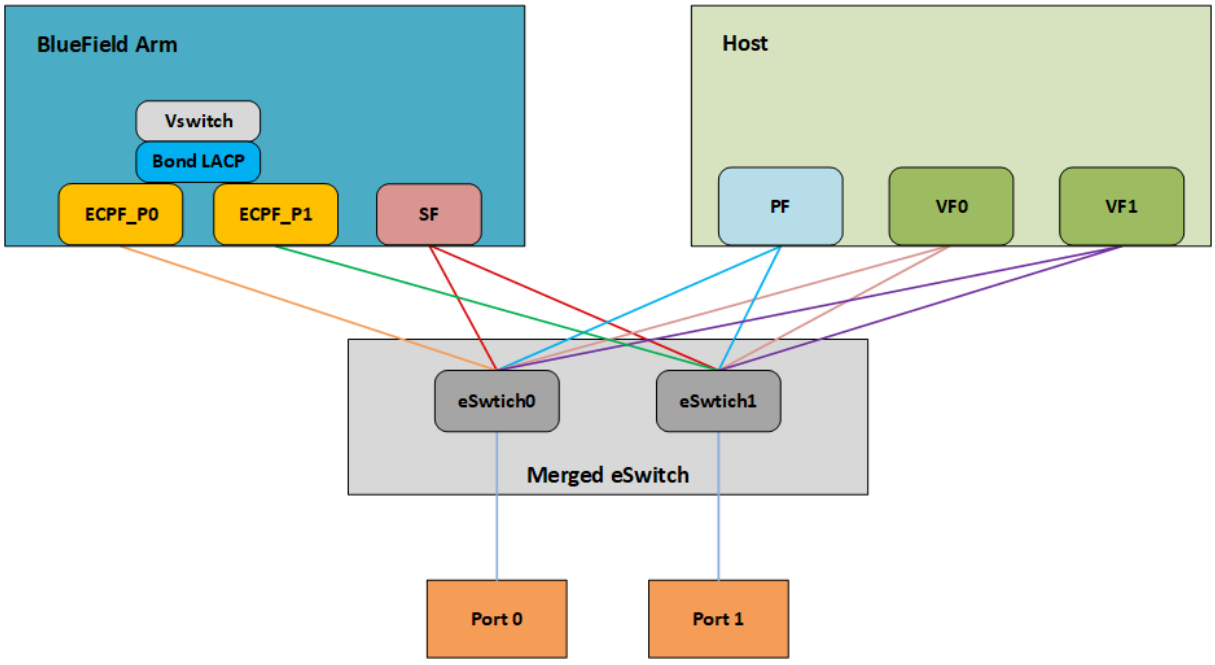
Network bonding enables combining two or more network interfaces into a single interface. It increases the network throughput, bandwidth and provides redundancy if one of the interfaces fails.

NVIDIA® BlueField® networking platforms (DPUs or SuperNICs) have an option to configure network bonding on the Arm side in a manner transparent to the host. Under such configuration, the host would only see a single PF.

> ⚠ This functionality is supported when BlueField is set in embedded function ownership mode for both ports.

> ⚠ While LAG is being configured (starting with step 2 under section "LAG Configuration"), traffic cannot pass through the physical ports.

The following diagram describes this configuration:



11.5.8.1 LAG Modes

Two LAG modes are supported on BlueField:

- Queue Affinity mode
- Hash mode

11.5.8.1.1 Queue Affinity Mode

In this mode, packets are distributed according to the QPs.

1. To enable this mode, run:

   ```
   $ mlxconfig -d /dev/mst/<device-name> s LAG_RESOURCE_ALLOCATION=0
   ```

   Example device name: `mt41686_pciconf0`.
2. Add/edit the following field from `/etc/mellanox/mlnx-bf.conf` as follows:

   ```
   LAG_HASH_MODE="no"
   ```
3. Perform BlueField system reboot for the `mlxconfig` settings to take effect.

11.5.8.1.2 Hash Mode

In this mode, packets are distributed to ports according to the hash on packet headers.

> ⚠ For this mode, prerequisite steps 3 and 4 are not required.

1. To enable this mode, run:

   ```
   $ mlxconfig -d /dev/mst/<device-name> s LAG_RESOURCE_ALLOCATION=1
   ```

   Example device name: `mt41686_pciconf0`.
2. Add/edit the following field from `/etc/mellanox/mlnx-bf.conf` as follows:

   ```
   LAG_HASH_MODE="yes"
   ```
3. Perform BlueField system reboot for the `mlxconfig` settings to take effect.

11.5.8.2 Prerequisites

1. Set the LAG mode to work with.
2. (Optional) Hide the second PF on the host. Run:

   ```
   $ mlxconfig -d /dev/mst/<device-name> s HIDE_PORT2_PF=True NUM_OF_PF=1
   ```

   Example device name: `mt41686_pciconf0`.

   > ⚠ Perform BlueField system reboot for the `mlxconfig` settings to take effect.

3. Delete any installed Scalable Functions (SFs) on the Arm side.
4. Stop the driver on the host side. Run:

```
$ systemctl stop openibd
```

5. The uplink interfaces (`p0` and `p1`) on the Arm side must be disconnected from any OVS bridge.

11.5.8.3 LAG Configuration

1. Create the bond interface. Run:

```
$ ip link add bond0 type bond
$ ip link set bond0 down
$ ip link set bond0 type bond miimon 100 mode 4 xmit_hash_policy layer3+4
```

> ⚠ While LAG is being configured (starting with the next step), traffic cannot pass through the physical ports.

2. Subordinate both the uplink representors to the bond interface. Run:

```
$ ip link set p0 down
$ ip link set p1 down
$ ip link set p0 master bond0
$ ip link set p1 master bond0
```

3. Bring the interfaces up. Run:

```
$ ip link set p0 up
$ ip link set p1 up
$ ip link set bond0 up
```

The following is an example of LAG configuration in Ubuntu:

```
# cat  /etc/netplan/70-bf-lag.yaml

network:
  renderer: networkd
  bonds:
    bond0:
      optional: true
      dhcp4: no
      interfaces: [p0, p1]
      parameters:
        mode: 802.3ad
        mii-monitor-interval: 100
  ethernets:
    p0:
      dhcp4: no
      optional: true
    p1:
      dhcp4: no
      optional: true
  version: 2
```

As a result, only the first PF of the BlueFields would be available to the host side for networking and SR-IOV.

When in shared RQ mode (enabled by default), the uplink interfaces (`p0` and `p1`) must always stay enabled. Disabling them will break LAG support and VF-to-VF communication on same host.

For OVS configuration, the bond interface is the one that needs to be added to the OVS bridge (interfaces `p0` and `p1` should not be added). The PF representor for the first port (`pf0hpf`) of the LAG must be added to the OVS bridge. The PF representor for the second port (`pf1hpf`) would still be visible, but it should not be added to OVS bridge. Consider the following examples:

```
ovs-vsctl add-br bf-lag
ovs-vsctl add-port bf-lag bond0
ovs-vsctl add-port bf-lag pf0hpf
```

Trying to change bonding configuration in Queue Affinity mode (including bringing the subordinated interface up/down) while the host driver is loaded would cause FW syndrome and failure of the operation. Make sure to unload the host driver before altering BlueField bonding configuration to avoid this.

When performing driver reload (`openibd restart`) or reboot, it is required to remove bond configuration and to reapply the configurations after the driver is fully up. Refer to steps 1-4 of "Removing LAG Configuration".

11.5.8.4 Removing LAG Configuration

1. If Queue Affinity mode LAG is configured (i.e., `LAG_RESOURCE_ALLOCATION=0`):
   a. Delete any installed Scalable Functions (SFs) on the Arm side.
   b. Stop driver (openibd) on the host side. Run:

   ```
   systemctl stop openibd
   ```
2. Delete the LAG OVS bridge on the Arm side. Run:

   ```
   ovs-vsctl del-br bf-lag
   ```

   This allows for later restoration of OVS configuration for non-LAG networking.
3. Stop OVS service. Run:

   ```
   systemctl stop openvswitch-switch.service
   ```
4. Run:

```
ip link set bond0 down
modprobe -rv bonding
```

As a result, both of the BlueField's network interfaces would be available to the host side for networking and SR-IOV.

5. For the host to be able to use BlueField's ports, make sure to attach the ECPF and host representor in an OVS bridge on the Arm side. Refer to "Virtual Switch on BlueField" for instructions on how to perform this.
6. Revert from `HIDE_PORT2_PF`, on the Arm side. Run:

```
mlxconfig -d /dev/mst/<device-name> s HIDE_PORT2_PF=False NUM_OF_PF=2
```

7. Restore default LAG settings in BlueField's firmware. Run:

```
mlxconfig -d /dev/mst/<device-name> s LAG_RESOURCE_ALLOCATION=DEVICE_DEFAULT
```

8. Delete the following line from `/etc/mellanox/mlnx-bf.conf` on the Arm side:

```
LAG_HASH_MODE=...
```

9. Perform BlueField system reboot for the `mlxconfig` settings to take effect.

11.5.8.5 LAG on Multi-host

Only LAG hash mode is supported with BlueField multi-host.

11.5.8.5.1 LAG Multi-host Prerequisites

1. Enable LAG hash mode.
2. Hide the second PF on the host. Run:

```
$ mlxconfig -d /dev/mst/<device-name> s HIDE_PORT2_PF=True NUM_OF_PF=1
```

3. Make sure NVME emulation is disabled:

```
$ mlxconfig -d /dev/mst/<device-name> s NVME_EMULATION_ENABLE=0
```

Example device name: `mt41686_pciconf0`.

4. The uplink interfaces (`p0` and `p4`) on the Arm side, representing port0 and port1, must be disconnected from any OVS bridge. As a result, only the first PF of BlueField would be available to the host side for networking and SR-IOV.

11.5.8.5.2 LAG Configuration on Multi-host

1. Create the bond interface. Run:

```
$ ip link add bond0 type bond
$ ip link set bond0 down
$ ip link set bond0 type bond miimon 100 mode 4 xmit_hash_policy layer3+4
```

2. Subordinate both the uplink representors to the bond interface. Run:

```
$ ip link set p0 down
$ ip link set p4 down
$ ip link set p0 master bond0
$ ip link set p4 master bond0
```

3. Bring the interfaces up. Run:

```
$ ip link set p0 up
$ ip link set p4 up
$ ip link set bond0 up
```

4. For OVS configuration, the bond interface is the one that must be added to the OVS bridge (interfaces p0 and p4 should not be added). The PF representor, `pf0hpf`, must be added to the OVS bridge with the bond interface. The rest of the uplink representors must be added to another OVS bridge along with their PF representors. Consider the following examples:

```
ovs-vsctl add-br br-lag
ovs-vsctl add-port br-lag bond0
ovs-vsctl add-port br-lag pf0hpf
ovs-vsctl add-br br1
ovs-vsctl add-port br1 p1
ovs-vsctl add-port br1 pf1hpf
ovs-vsctl add-br br2
ovs-vsctl add-port br2 p2
ovs-vsctl add-port br2 pf2hpf
ovs-vsctl add-br br3
ovs-vsctl add-port br3 p3
ovs-vsctl add-port br3 pf3hpf
```

> ⚠ When performing driver reload (`openibd restart`) or reboot, you must remove bond configuration from NetworkManager, and to reapply the configurations after the driver is fully up.

11.5.8.5.3 Removing LAG Configuration on Multi-host

Refer to section "Removing LAG Configuration".

11.5.9 Controlling Host PF and VF Parameters

NVIDIA® BlueField® networking platforms (DPUs or SuperNICs) allow control over some of the networking parameters of the PFs and VFs running on the host side.

11.5.9.1 Setting Host PF and VF Default MAC Address

From the Arm, users may configure the MAC address of the physical function in the host. After sending the command, users must reload the NVIDIA driver in the host to see the newly configured MAC address. The MAC address goes back to the default value in the firmware after system reboot.

Example:

```
$ echo "c4:8a:07:a5:29:59" > /sys/class/net/p0/smart_nic/pf/mac
$ echo "c4:8a:07:a5:29:61" > /sys/class/net/p0/smart_nic/vf0/mac
```

11.5.9.2 Setting Host PF and VF Link State

vPort state can be configured to Up, Down, or Follow. For example:

```
$ echo "Follow" > /sys/class/net/p0/smart_nic/pf/vport_state
```

11.5.9.3 Querying Configuration

To query the current configuration, run:

```
$ cat /sys/class/net/p0/smart_nic/pf/config
MAC        : e4:8b:01:a5:79:5e
MaxTxRate  : 0
State      : Follow
```

Zero signifies that the rate limit is unlimited.

11.5.9.4 Disabling Host Networking PFs

It is possible to not expose networking functions to the host for users interested in using storage or virtio functions only. When this feature is enabled, the host PF representors (i.e. `pf0hpf` and `pf1hpf`) will not be seen on the Arm.

- Without a PF on the host, it is not possible to enable SR-IOV, so VF representors will not be seen on the Arm either
- Without PFs on the host, there can be no SFs on it

To disable host networking PFs, run:

```
mlxconfig -d /dev/mst/mt41686_pciconf0 s NUM_OF_PF=0
```

To reactivate host networking PFs:

- For single-port BlueFields, run:

```
mlxconfig -d /dev/mst/mt41686_pciconf0 s NUM_OF_PF=1
```

- For dual-port BlueFields, run:

```
mlxconfig -d /dev/mst/mt41686_pciconf0 s NUM_OF_PF=2
```

⚠ When there are no networking functions exposed on the host, the reactivation command must be run from the Arm.

⚠ Perform BlueField system reboot for the `mlxconfig` settings to take effect.

11.5.9.5 Configuring Uplink MTU

To configure the port MTU while operating in DPU mode, users must restrict the external host port ownership by issuing the following command on the BlueField:

```
mlxprivhost -d /dev/mst/<pciconf0 device> r --disable_port_owner
```

Server cold reboot is required for this restriction to take effect.

Once the host is restricted, the port MTU is configured by changing the MTU of the uplink representor (`p0` or `p1`).

11.5.10 DPDK on BlueField

Please refer to "NVIDIA BlueField Board Support Package" in the DPDK documentation.

11.6 DOCA with OpenSSL

This guide provides instructions on using DOCA SHA for OpenSSL implementations.

11.6.1 Introduction

The `doca_sha_offload_engine` is an OpenSSL dynamic engine with the ability of offloading SHA calculation. It can offload the OpenSSL one-shot SHA-1, SHA-256, and SHA-512. It supports synchronous mode and asynchronous mode by leveraging the

OpenSSL `async_jobs` library. For more information on the `async_jobs` library, please refer to official OpenSSL documentation.

This engine is based on the `doca_sha` library and the OpenSSL dynamic engine interface API. For more information on the OpenSSL dynamic engine, please refer to official OpenSSL documentation.

This engine can be called by an OpenSSL application through the OpenSSL high-level algorithm call interface, `EVP_Digest`. For more information on the `EVP_Digest`, please refer to official OpenSSL documentation.

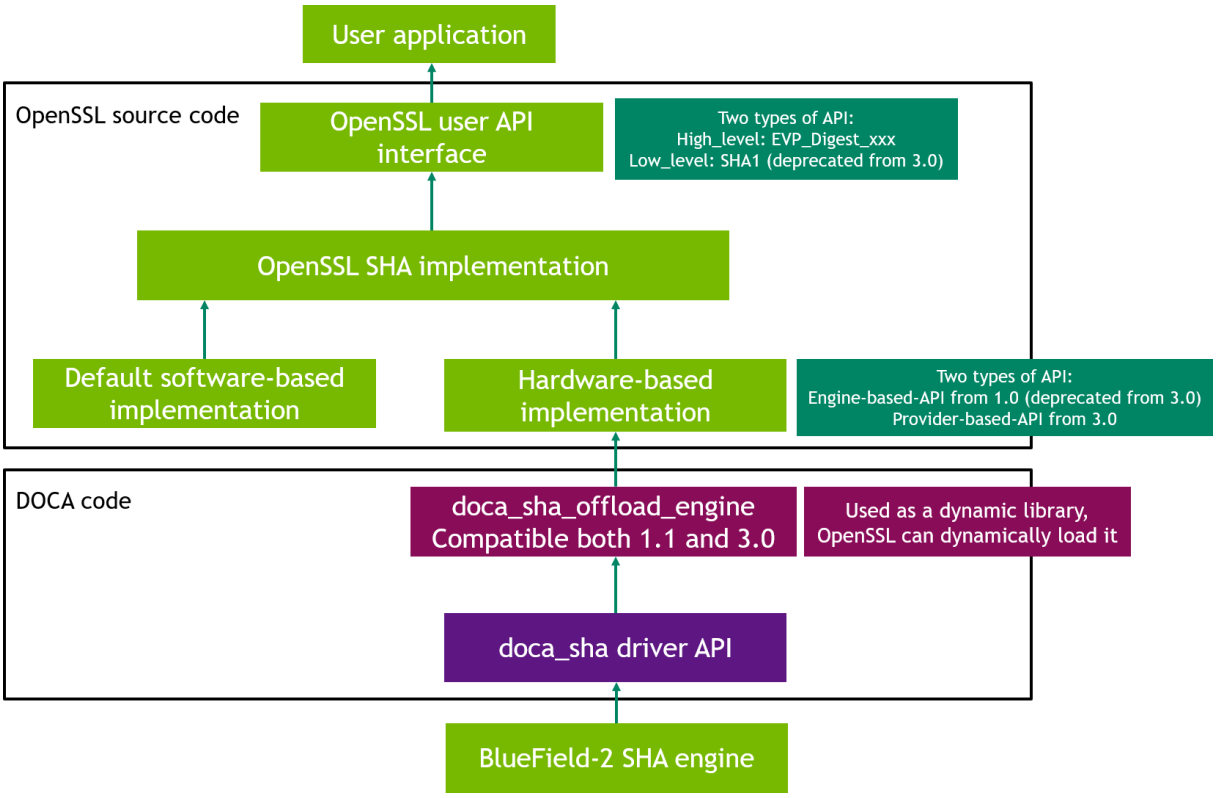
11.6.2 Prerequisites

- Hardware-based `doca_sha` engine which can be verified by calling `doca_sha_get_hardware_supported()`
- Installed OpenSSL version ≥ 1.1.1

11.6.3 Architecture

The following diagram shows the software hierarchy of `doca_sha_offload_engine` and its location in the whole DOCA repository.

From the perspective of OpenSSL, this engine is an instantiation of the OpenSSL dynamic engine interface API by leveraging the `doca_sha` library.



11.6.4 Capabilities and Limitations

- Only one-shot OpenSSL SHA is supported
- The maximum message length ≤ 2GB, the same as `doca_sha` library

11.6.5 OpenSSL Command Line Verification

Verify that the engine can be loaded:

```
$ openssl engine dynamic -pre NO_VCHECK:1 -pre SO_PATH:${DOCA_DIR}/infrastructure/doca_sha_offload_engine/
libdoca_sha_offload_engine.so -pre LOAD -vvv -t -c
(dynamic) Dynamic engine loading support
[Success]: SO_PATH:${DOCA_DIR}/infrastructure/doca_sha_offload_engine/libdoca_sha_offload_engine.so
[Success]: LOAD
Loaded: (doca_sha_offload_engine) Openssl SHA offloading engine based on doca_sha
 [SHA1, SHA256, SHA512]
     [ available ]
     set_pci_addr: set the pci address of the doca_sha_engine
          (input flags): STRING
```

- For SHA-1:

```
$ echo "hello world" | openssl dgst -sha1 -engine {DOCA_DIR}/infrastructure/doca_sha_offload_engine/
libdoca_sha_offload_engine.so -engine_impl
```

- For SHA-256:

```
$ echo "hello world" | openssl dgst -sha256 -engine {DOCA_DIR}/infrastructure/doca_sha_offload_engine/
libdoca_sha_offload_engine.so -engine_impl
```

- For SHA-512:

```
$ echo "hello world" | openssl dgst -sha512 -engine {DOCA_DIR}/infrastructure/doca_sha_offload_engine/
libdoca_sha_offload_engine.so -engine_impl
```

11.6.6 OpenSSL Throughput Test

`openssl-speed` is the OpenSSL throughput benchmark tool. For more information, consult official OpenSSL documentation. `doca_sha_offload_engine` throughput can also be measured using `openssl-speed`.

- SHA-1, each job 10000 bytes, using engine:

```
$ openssl speed -evp sha1 -bytes 10000 -elapsed --engine {DOCA_DIR}/infrastructure/doca_sha_offload_engine/
libdoca_sha_offload_engine.so
```

- SHA-256, each job 10000 bytes, using engine, `async_jobs=256`:

```
$ openssl speed -evp sha256 -bytes 10000 -elapsed --engine {DOCA_DIR}/infrastructure/
doca_sha_offload_engine/libdoca_sha_offload_engine.so -async_jobs 256
```

- SHA-512, each job 10000 bytes, using engine, `async_jobs=256`, `threads=8`:

```
$ openssl speed -evp sha512 -bytes 10000 -elapsed --engine {DOCA_DIR}/infrastructure/
doca_sha_offload_engine/libdoca_sha_offload_engine.so -async_jobs 256 -multi 8
```

11.6.7 Using DOCA SHA Offload Engine in OpenSSL Application

More information on the dynamic engine usage can be found in the official OpenSSL documentation.

1. To load the `doca_sha_offload_engine` (optionally, set engine PCIe address):

```
ENGINE *e;
const char *doca_engine_path = "${DOCA_DIR}/infrastructure/doca_sha_offload_engine/
libdoca_sha_offload_engine.so";
const char *default_doca_pci_addr = "03:00.0";
ENGINE_load_dynamic();
e = ENGINE_by_id(doca_engine_path);
ENGINE_ctrl_cmd_string(e, "set_pci_addr", doca_engine_pci_addr, 0);
ENGINE_init(e);
ENGINE_set_default_digests(e);
```

2. To perform SHA calculation by calling the OpenSSL high-level function EVP_XXX:

```
const EVP_MD *evp_md = EVP_sha1();
EVP_MD_CTX *mdctx = EVP_MD_CTX_create();
EVP_DigestInit_ex(mdctx, evp_md, e);
EVP_DigestUpdate(mdctx, msg, msg_len);
```

```
EVP_DigestFinal_ex(mdctx, digest, digest_len);
EVP_MD_CTX_destroy(mdctx);
```

3. To unload the engine:

```
ENGINE_unregister_digests(e);
ENGINE_finish(e);
ENGINE_free(e);
```

11.7 BlueField Scalable Function User Guide

This document provides an overview and configuration of scalable functions (sub-functions, or SFs) for NVIDIA® BlueField® DPU.

11.7.1 Introduction

Scalable functions (SFs), or sub-functions, are very similar to virtual functions (VFs) which are part of a Single Root I/O Virtualization (SR-IOV) solution. I/O virtualization is one of the key features used in data centers today. It improves the performance of enterprise servers by giving virtual machines direct access to hardware I/O devices. The SR-IOV specification allows one PCI Express (PCIe) device to present itself to the host as multiple distinct "virtual" devices. This is done with a new PCIe capability structure added to a traditional PCIe function (i.e., a physical function or PF).

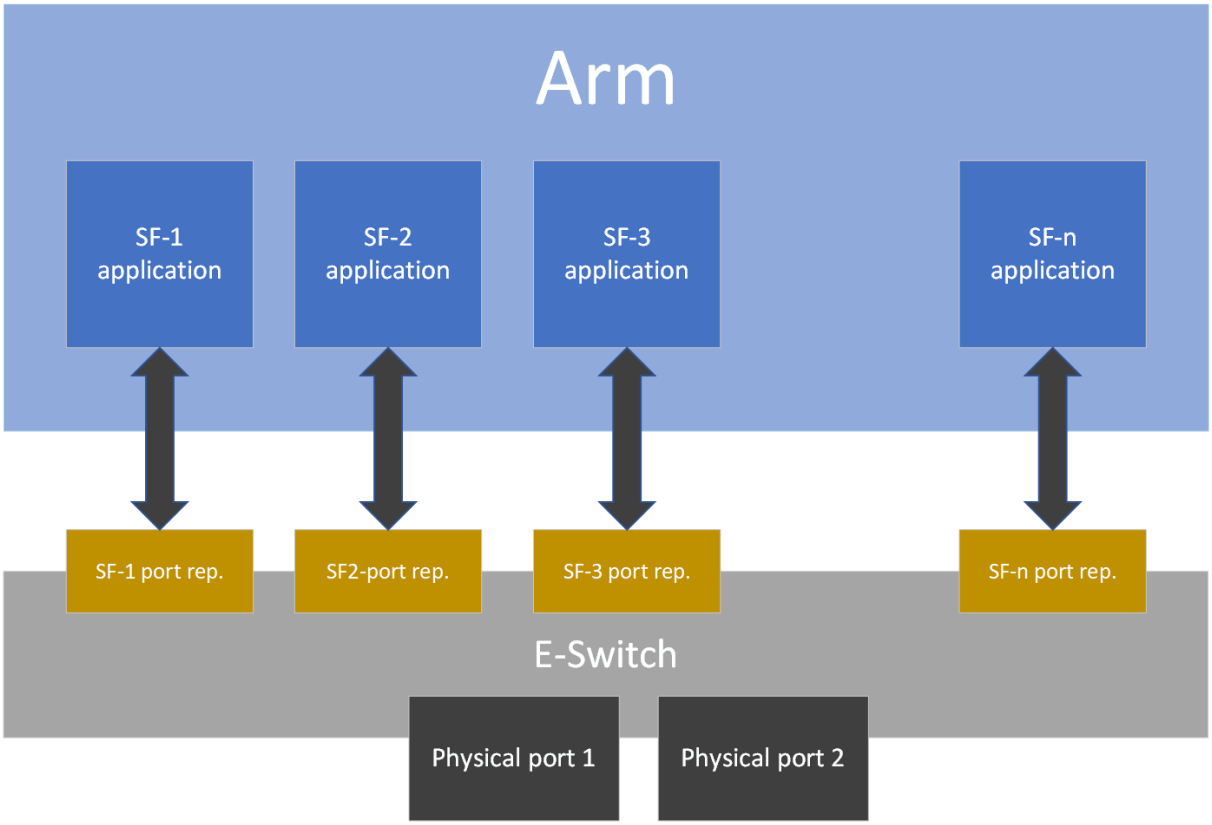
The PF provides control over the creation and allocation of new VFs. VFs share the device's underlying hardware and PCIe. A key feature of the SR-IOV specification is that VFs are very lightweight so that many of them can be implemented in a single device.

To utilize the capabilities of VF in the BlueField, SFs are used. SFs allow support for a larger number of functions than VFs, and more importantly, they allow running multiple services concurrently on the DPU.

An SF is a lightweight function which has a parent PCIe function on which it is deployed. The SF, therefore, has access to the capabilities and resources of its parent PCIe function and has its own function capabilities and its own resources. This means that an SF would also have its own dedicated queues (i.e., txq, rxq).

SFs co-exist with PCIe SR-IOV virtual functions (on the host) but also do not require enabling PCIe SR-IOV.

SFs support E-Switch representation offload like existing PF and VF representors. An SF shares PCIe-level resources with other SFs and/or with its parent PCIe function.



11.7.2 Prerequisites

Refer to the DOCA Installation Guide for Linux for details on how to install BlueField related software.

- Make sure your firmware version is 20.30.1004 or higher
- Enable support for Linux kernel mlx5 SFs by setting the following Kconfig flags:
  - `MLX5_ESWITCH`
  - `MLX5_SF`
- To enable SF support on the device, change the PCIe address for each port:

```
$ mlxconfig -d 0000:03:00.0 s PF_BAR2_ENABLE=0 PER_PF_NUM_SF=1 PF_TOTAL_SF=236
 PF_SF_BAR_SIZE=10

PF_BAR2_ENABLE: if this config is set, then all PFs and ECPFs have the same number of SFs. This should be
off (deprecated).
If set. PF_TOTAL_SF and PF_SF_BAR_SIZE won't work.
PER_PF_NUM_SF: If this config is set, each PF and ECPF configure/control its own number of SFs.
THE ABOVE TWO CONFIGS AFFECS BOTH BF AND HOST, TREAT WITH CARE!
Also, only one of them can be set. It is INVALID to set them both

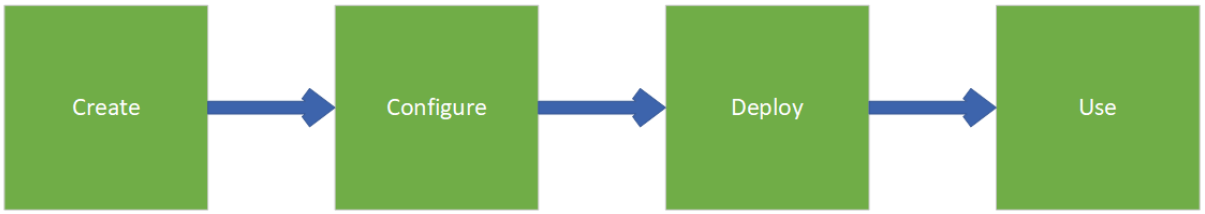
PF_TOTAL_SF: maximum number of SFs we wish to configure for the given PF/ECPF.
PF_SF_BAR_SIZE: size of each SF at the BAR2. The size is in powers of 2 in KB.
For example: PF_SF_BAR_SIZE=10 means each SF is taking 1MB of the BAR.
             PF_TOTAL_SF=14 means this PCI function can create up to 14 SFs.
             In total: FW will allocate 14MB of BAR2.
```

Perform a BlueField system-level reset for the `mlxconfig` settings to take effect.

11.7.3 SF Configuration

To use an SF, a 3-step setup sequence must be followed first:

1. Create.
2. Configure.
3. Deploy.



These steps can be performed using `mlxdevm` tool.

When working on top of an upstream-based kernel, on which the `mlxdevm` tool is unavailable, please refer to the Upstream Guide on Scalable Functions for instructions on using the `devlink` tool which should be used instead.

11.7.3.1 Configuration Using mlxdevm Tool

1. Create the SF.
   SFs are managed using the `mlxdevm` tool supplied with iproute2 package. The tool is found at `/opt/mellanox/iproute2/sbin/mlxdevm`.
   An SF is created using the `mlxdevm` tool. The SF is created by adding a port of `pcisf` flavor.
   To create an SF port representor, run:

   ```
   /opt/mellanox/iproute2/sbin/mlxdevm port add pci/<pci_address> flavour pcisf pfnum <corresponding pfnum>
   sfnum <sfnum>
   ```

   Each SF must have a unique number (`<sfnum>`).

   For example:

```
/opt/mellanox/iproute2/sbin/mlxdevm port add pci/0000:03:00.0 flavour pcisf pfnum 0 sfnum 4
```

Output example:

```
pci/0000:30:00.0/229409: type eth netdev eth0 flavour pcisf controller 0 pfnum 0 sfnum 4
   function:
    hw_addr 00:00:00:00:00:00 state inactive opstate detached roce true max_uc_macs 128 trust off
```

The number 229409 is required to complete the following two steps (i.e., configuration and deployment).

`pci/0000:03:00.0/229409` is called the SF index.

`pci/<pci_address>/<sf_index>` can be replaced with `<representor_name>`. For example:

```
pci/0000:03:00.0/229409 = en3f0pf0sf4
```

To see information about the created SF such as its MAC address, trust mode, or state (active/inactive), run the following command:

```
/opt/mellanox/iproute2/sbin/mlxdevm port show
```

Output example:

```
pci/0000:30:00.0/229409: type eth netdev en3f0pf0sf4 eth0 flavor pcisf controller 0 pfnum 0 sfnum 4
    function:
      hw_addr 00:00:00:00:00:00 state inactive opstate detached roce true max_uc_macs 128 trust off
```

⚠ SF number ≥1000 is reserved for the virtio-net controller.

⚠ When an SF is added on the external controller (e.g., BlueField) users must supply the controller number. In a single host BlueField case, there is only one controller starting with controller number 1. The following is an example of adding an SF for PF0 of external controller 1:

```
$ mlxdevm port add pci/0000:03:00.0 flavour pcisf pfnum 0 sfnum 88 controller 1
pci/0000:03:00.0/32768: type eth netdev eth6 flavour pcisf controller 1 pfnum 0 sfnum 88
 splittable false
  function:
    hw_addr 00:00:00:00:00:00 state inactive opstate detached
```

2. Configure the SF.
   A subfunction representor (SF port representor) is created but it is not deployed yet. Users should configure the hardware address (e.g., MAC address), set trust mode to on, and activate the SF before deploying it.
   The following steps can be executed as separate commands (at any order) or combined as one:
   - To configure the hardware address, run:

     ```
     /opt/mellanox/iproute2/sbin/mlxdevm port function set pci/<pci_address>/<sf_index>  hw_addr <MAC
     address>
     ```

- To set the trust mode to on, run:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/<pci_address>/<sf_index> trust on
```

> A trusted function has additional privileges (e.g., the ability to update steering database).

> To modify the trust mode of an SF, the SF must first be deactivated. The correct sequence is to deactivate the SF, change the trust mode setting, and then reactivate the SF.

- To activate the created SF, run:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/<pci_address>/<sf_index> state active
```

Alternatively, to configure the MAC address, set trust mode on, and set the state as active, run:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/<pci_address>/<sf_index>  hw_addr <mac_address>
trust on state active
```

For example:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/229409 hw_addr 00:00:00:00:04:0
 trust on state active
```

> The SF capabilities above must be set before deploying the SF.

3. Deploy the SF.
   To unbind the SF from the default config driver and bind the actual SF driver, run:

```
echo mlx5_core.sf.<next_serial> >  /sys/bus/auxiliary/drivers/mlx5_core.sf_cfg/unbind
echo mlx5_core.sf.<next_serial>  > /sys/bus/auxiliary/drivers/mlx5_core.sf/bind
```

For example:

```
echo mlx5_core.sf.4  > /sys/bus/auxiliary/drivers/mlx5_core.sf_cfg/unbind
echo mlx5_core.sf.4  > /sys/bus/auxiliary/drivers/mlx5_core.sf/bind
```

> `<next_serial>` is a number produced by the firmware when creating the SF (this is the gvmi number of the SF). `mlxdevm` tool when creating the SF. To obtain it, refer to the useful commands provided below.

An application interested in using the SF netdevice and RDMA device must monitor the RDMA and netdevices either through udev monitor or poll the sysfs hierarchy of the SF's auxiliary device.

Useful commands:

- To see the available sub-functions, run:

```
$ devlink dev show
```

For example, if you run the command before creating, configuring, and deploying the SF (using the steps detailed earlier), the output would appear as follows:

```
pci/0000:03:00.0
pci/0000:03:00.1
auxiliary/mlx5_core.sf.2
auxiliary/mlx5_core.sf.3
```

After creating, configuring, and deploying the SF, the output would be:

```
pci/0000:03:00.0
pci/0000:03:00.1
auxiliary/mlx5_core.sf.2
auxiliary/mlx5_core.sf.3
auxiliary/mlx5_core.sf.4
```

Note that the `<next_serial>` number is 4 for the created SF.

- To see the `sfnum` of each sub-function, run:

```
cat /sys/bus/auxiliary/devices/mlx5_core.sf.<next_serial>/sfnum
```

For example:

```
cat /sys/bus/auxiliary/devices/mlx5_core.sf.4/sfnum
```

Example output:

```
cat /sys/bus/auxiliary/devices/mlx5_core.sf.4/sfnum
4
```

- To remove an SF, you must first make its state inactive and only then remove the SF representor.
  To make the SF's state inactive, run:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/<pci_address>/<sf_index> state inactive
```

To delete the SF port representor, run:

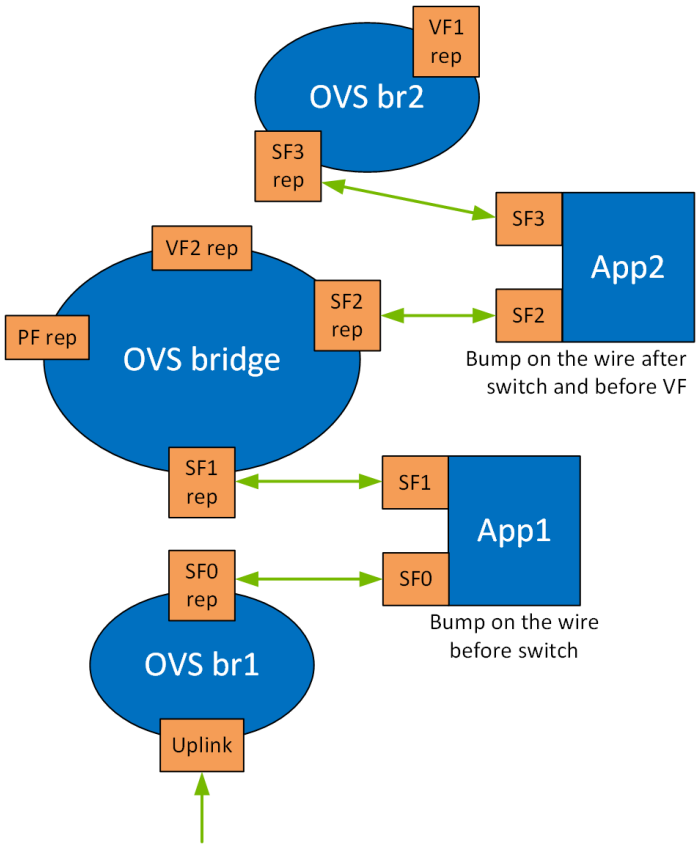
```
/opt/mellanox/iproute2/sbin/mlxdevm port del pci/<pci_address>/<sf_index>
```

For example:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/229409 state inactive
```

```
/opt/mellanox/iproute2/sbin/mlxdevm port del pci/0000:03:00.0/229409
```

4. Use the SF.



Running the application on the DPU requires OVS configuration. By creating SFs, an SF representor for the OVS is also created and named `en3f0pf*sf*`. Therefore, each representor needs to be connected to the correct OVS bridge.

> ⚠ Two SFs related to the same PCIe are necessary for the configuration in the illustration.

The following example configures 2 SFs and adds their representors to the OVS.

a. Create, configure, and deploy the SFs. Run:

```
/opt/mellanox/iproute2/sbin/mlxdevm port add pci/0000:03:00.0 flavour pcisf pfnum 0 sfnum 4
/opt/mellanox/iproute2/sbin/mlxdevm port add pci/0000:03:00.0 flavour pcisf pfnum 0 sfnum 5
```

Using the command `mlxdevm port show`, you can see the SF indices of the created SFs.

```
/opt/mellanox/iproute2/sbin/mlxdevm port show
```

Output example:

```
pci/0000:30:00.0/229409: type eth netdev en3f0pf0sf4 flavour pcisf controller 0 pfnum 0 sfnum 4
   function:
    hw_addr 00:00:00:00:00:00 state inactive opstate detached roce true max_uc_macs 128 trust off
pci/0000:30:00.0/229410: type eth netdev en3f0pf0sf5 flavour pcisf controller 0 pfnum 0 sfnum 5
   function:
```

```
    hw_addr 00:00:00:00:00:00 state inactive opstate detached roce true max_uc_macs 128 trust off
```

b. Configure the MAC address, set trust mode on, and activate the created SFs:

```
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/229409 hw_addr
02:25:f2:8d:a2:4c trust on state active
/opt/mellanox/iproute2/sbin/mlxdevm port function set pci/0000:03:00.0/229410 hw_addr
02:25:f2:8d:a2:5c trust on state active
```

Using `ifconfig`, you may see that there are 2 added network interfaces: `en3f0pf0sf4` and `en3f0pf0sf5` for the two respective SF port representors.

c. Delete existing OVS bridges (optional).
For example, run the following command to delete an OVS bridge called `ovsbr1`:

```
ovs-vsctl del-br ovsbr1
```

d. Create two bridges `sf_bridge1` and `sf_bridge2` and configure them as follows:

```
ovs-vsctl add-br sf_bridge1
ovs-vsctl add-br sf_bridge2
ovs-vsctl add-port sf_bridge1 p0
ovs-vsctl add-port sf_bridge2 pf0hpf
```

e. Add the port representors to the OVS bridges:

```
ovs-vsctl add-port sf_bridge1 en3f0pf0sf4
ovs-vsctl add-port sf_bridge2 en3f0pf0sf5
```

The OVS bridges after adding the SF representors:

```
Bridge sf_bridge1
     Port p0
         Interface p0
     Port sf_bridge1
         Interface sf_bridge1
             type: internal
     Port en3f0pf0sf4
         Interface en3f0pf0sf4
Bridge sf_bridge2
     Port sf_bridge2
         Interface sf_bridge2
             type: internal
     Port en3f0pf0sf5
         Interface en3f0pf0sf5
     Port pf0hpf
         Interface pf0hpf
ovs_version: "2.14.1"
```

The interface might be down by default. Remember to `ifconfing` the interface to "up" status.

> ⚠ When deleting the SF port representor, you must also de-attach it from the bridge it is connected to using the command `ovs-vsctl port-del en3f0pf0sf*`. Otherwise, the port representor will still be connected to the bridge but would not be recognizable.

To run the application, use the following command to initialize the SFs during runtime:

```
*Executable_binary* -a auxiliary:mlx5_core.sf.* -a auxiliary:mlx5_core.sf.*
```

For example:

```
doca_<app_name> -a auxiliary:mlx5_core.sf.4 -a auxiliary:mlx5_core.sf.5 -- [application_flags]
```

11.8 DOCA TLS Offload Guide

This guide provides an overview and configuration steps of TLS hardware offloading via kernel-TLS, using hardware capabilities of NVIDIA® BlueField® DPU.

11.8.1 Introduction

Transport layer security (TLS) is a cryptographic protocol designed to provide communications security over a computer network. The protocol is widely used in applications such as email, instant messaging, and voice over IP (VoIP), but its use in securing HTTPS remains the most publicly visible.

The TLS protocol aims primarily to provide cryptography, including privacy (confidentiality), integrity, and authenticity using certificates, between two or more communicating computer applications. It runs in the application layer and is itself composed of two layers: the TLS record and the TLS handshake protocols.

TLS works over TCP and consists of 3 phases:

1. Handshake – establishment of a connection
2. Application – sending and receiving encrypted packets
3. Termination – connection termination

11.8.1.1 TLS Handshake

In the handshake phase, the client and server decide on which cipher suites they will use, and exchange keys and certificates according to the following flow:

1. Client hello, provides the server at a minimum with the following:
    - A key exchange algorithm, to determine how symmetric keys are exchanged
    - An authentication or digital signature algorithm, which dictates how server authentication and client authentication (if required) are implemented
    - A bulk encryption cipher, which is used to encrypt the data
    - A hash/MAC (message authentication code) function, which determines how data integrity checks are carried out
    - The version of the protocol it understands
    - The cipher suites it is capable of working with
    - A unique random number, which is important to guard against replay attacks
2. Server hello:
    - Selects a cipher suite
    - Generates its own random number
    - Assigns a session ID to the TLS connection
    - Sends enough information to complete a key exchange—most often, this means sending a certificate including an RSA public key
3. Client:
    - Responsible for completing the key exchange using the information the server provided

At this point, the connection is secured, both sides have agreed on an encryption algorithm, a MAC algorithm, and respective keys.

11.8.1.2 kTLS

The Linux kernel provides TLS offload infrastructure. kTLS (kernel TLS) offloads TLS handling from the user-space to the kernel-space.

kTLS has 3 modes of operation:

- SW – all operation is handled in kernel (i.e., handshake, encryption, decryption)
- HW-offload (the focus of this guide) – handshake and error handling are performed in software. Packets are encrypted/decrypted in hardware. In this case, there is an additional offload from the kernel to the hardware.
- HW-record – all operations are handled by the hardware (driver and firmware) including the handshake. It also handles its own TCP session. This option is currently not supported.

It is important to understand that Rx (receiving) and Tx (sending) can have two separate modes. For example, Rx can be dealt in SW mode but Tx in HW-offload mode (i.e., the hardware will only encrypt but not decrypt).

11.8.1.3 HW-offloading kTLS

In general, the TLS HW-offload performs best and provides optimal value on longer lived sessions, with relatively large packets. Scaling in terms of concurrent connections and connections per second is use-case dependent (e.g., the amount of active concurrent connections from the overall open concurrent connections is material).

It is necessary to learn the following terms before proceeding:

- The transport interface send (TIS) object is responsible for performing all transport-related operations of the transmit side. Messages from Send Queues (SQs) get segmented and transmitted by the TIS including all transport required implications. For example, in the case of a large send offload, the TIS is responsible for the segmentation. The NVIDIA® ConnectX® hardware uses a TIS object to save and access the TLS crypto information and state of an offloaded Tx kTLS connection.
- The transport interface receive (TIR) object is responsible for performing all transport-related operations on the receive side. TIR performs the packet processing and reassembly and is also responsible for demultiplexing the packets into different receive queues (RQs).
- Both TIS and TIR hold the data encryption key (DEK).

11.8.1.3.1 kTLS Offload Flow in High Level

⚠ The following flow does not include resync and errors.

1. Establishes a TLS connection with remote host (server or client) by handling a TLS handshake by kernel on current host.
2. Initializes the following state for each connection, Rx and Tx:
    - Crypto secrets (e.g., public key)
    - Crypto processing state
    - Record metadata (e.g., record sequence number, offset)
    - Expected TCP sequence number

Tx flow:

1. Packets belonging to device offloaded sockets arrive to the kernel and it does not encrypt them.
2. Kernel performs record framing and marks the packet with a connection identifier.
3. Kernel sends packets to the device driver for offloading.
4. Device checks that the sequence number matches the state in the TIS and performs encryption and authentication.

Rx flow:

1. When the connection is created, a HW steering rule is added to steer packets to their respective TIR.
2. Device receives the packet then validates and checks that sequence number of TCP matches the state in the TIR.
3. Performs decryption and authentication, and indicates in the CQE (completion queue entry).
4. Kernel understands that the packet is already decrypted so it does not decrypt it itself and passes it on to the user-space.

11.8.1.3.2 Resync and Error Handling

When the sequence number does not match expectations or if any other error occurs, the hardware gives control back to the SW which handles the problem.

See more about kTLS modes, resync, and error handling in the Linux Kernel documentation.

11.8.2 Prerequisites

All commands in this section should be performed on host (not on BlueField) unless stated otherwise.

11.8.2.1 Checking Hardware Support for Crypto Acceleration

To check if the BlueField or ConnectX have crypto acceleration, run the following command from host:

```
host> mst start # turn on mst driver
host> flint -d <device under /dev/mst/ directory> dc | grep Crypto
```

The output should include `Crypto Enabled`. For example:

```
host> flint -d  /dev/mst/mt41686_pciconf0 dc | grep Crypto
....
;;Description = NVIDIA BlueField-2 E-Series Eng. sample DPU; 200GbE single-port QSFP56; PCIe Gen4 x16; Secure Boot
Disabled; Crypto Enabled; 16GB on-board DDR; 1GbE OOB management
....
```

11.8.2.2 Kernel Requirements

- Operating system must be either:
  - FreeBSD 13.0+.

- A Linux distribution built on Linux kernel version 5.3 or later for Tx support and version 5.9 or later for Rx support. We recommend using the latest version when possible for the best available optimizations.

  > ⚠ TIS Pool optimization is added to Linux kernel version 6.0. Instead of creating TIS per new connection, unused TIS from previous connection, will be recycled. This will improve Tx connection rate. No further installations required beyond installing the kernel itself.

- Check the current kernel version on the host. Run:

```
host> uname -r
```

- The kernel must be configured to support TLS by setting the options `TLS_DEVICE` and `MLX5_TLS` to `y`. To check if TLS is configured, run:

```
host> cat /boot/config-$(uname -r) | grep TLS
```

Example output:

```
host> cat /boot/config-5.4.0-121-generic | grep TLS
...
CONFIG_TLS_DEVICE=y
CONFIG_MLX5_TLS=y
...
```

If the current kernel does not support one of the options, you can change the configurations and recompile, or build a new kernel.

> ⚠ Follow the build instructions provided with the kernel provider.

Schematic flow for building a Linux kernel:

a. Enter the Linux kernel directory downloaded (usually in `/usr/src/`):

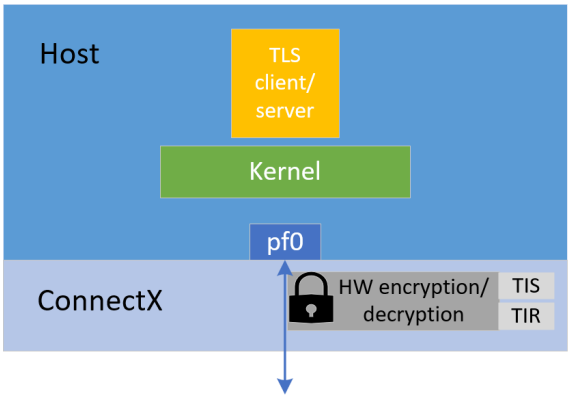
```
host> make menuconfig # Set TLS_DEVICE=y and MLX5_TLS=y in options. Setting location in the menu
can be found by pressing '/' and typing 'setting'.
host> make -j <num-of-cores> && make -j <num-of-cores> modules_install && make -j <num of cores>
install
```

b. Update the grub to the new configured kernel then reboot.

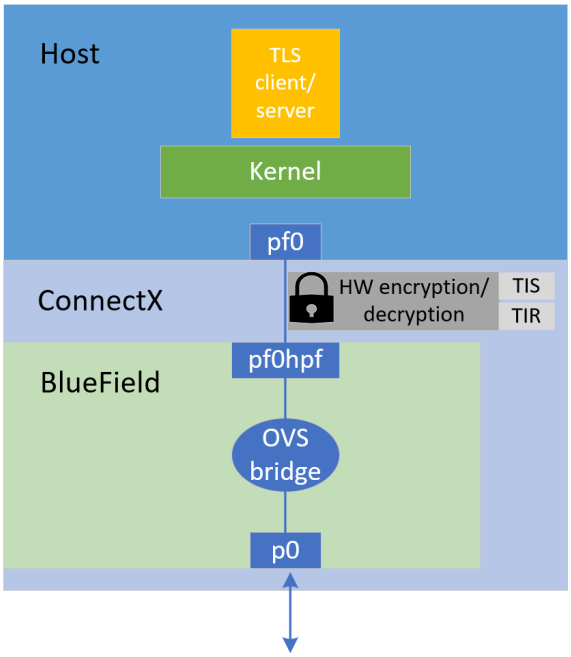
11.8.3 Configurations and Useful Commands

11.8.3.1 TLS Setup

Host + ConnectX Setup



Host + BlueField Setup



11.8.3.2 Finding NVIDIA Interfaces

```
host> mst start          # if mst driver is not loaded.
host> mst status -v
```

NVIDIA's netdev interfaces are found be under the `NET` column.

For example:

```
host> mst status -v
....
DEVICE_TYPE             MST                           PCI       RDMA            NET                     NUMA
BlueField2(rev:0)       /dev/mst/mt41686_pciconf0.1   b1:00.1   mlx5_1          net-ens5f1              1

BlueField2(rev:0)       /dev/mst/mt41686_pciconf0     b1:00.0   mlx5_0          net-ens5f0              1
```

In this example, the interfaces `ens5f1` and `ens5f0` are NVIDIA's netdev interfaces.

11.8.3.3 Configuring TLS Offload

- To check if the offload option is on or off, run:

```
host> ethtool -k $iface | grep tls
```

Example output:

```
tls-hw-tx-offload: on
tls-hw-rx-offload: off
tls-hw-record: off [fixed]
```

> ⚠ `tls-hw-record` is not required for the device as kTLS does not support "HW Record" mode.

- To turn Tx offload on or off:

```
host> ethtool -K $iface tls-hw-tx-offload <on | off>
```

- To turn Rx offload on or off:

```
host> ethtool -K $iface tls-hw-rx-offload <on | off>
```

11.8.3.4 Configuring OVS Bridge on BlueField

When the host is connected to a BlueField device, an OVS bridge must be configured on the BlueField so traffic passes bidirectionally from host to uplink. If no OVS bridge is configured, the host is isolated from the network (see diagram above).

> ⚠ On BlueField image version 3.7.0 or higher the default OVS configuration can be used without additional modifications.

To configure the OVS bridge on BlueField, run the following commands on BlueField:

```
dpu> for br in $(ovs-vsctl list-br); do ovs-vsctl del-br $br; done # erasing existing bridges
dpu> ovs-vsctl add-br ovs-br0 && ovs-vsctl add-port ovs-br0 p0 && ovs-vsctl add-port ovs-br0 pf0hpf
dpu> ovs-vsctl add-br ovs-br1 && ovs-vsctl add-port ovs-br1 p1 && ovs-vsctl add-port ovs-br1 pf1hpf
dpu> ovs-vsctl set Open_vSwitch . other_config:hw-offload=true && systemctl restart openvswitch-switch
```

Where `p0` / `p1` are the uplink interfaces and `pf0hpf` / `pf1hpf` are the interfaces facing the host.

11.8.4 Common Use Cases

11.8.4.1 OpenSSL

OpenSSL is an all-around cryptography library that offers open-source application of the TLS protocol. It is the main library for using kTLS and other applications since Nginx depends on it as their base library.

> ⚠ The kTLS and HW offloading do not depend on OpenSSL. Any program that can implement a TLS stack can be run instead. However, because of the vast use of OpenSSL, this guide addresses installation recommendations.

kTLS is supported only in OpenSSL version 3.2.0 or higher, and only on the supported kernel versions. The supported OpenSSL version is available for download from distro packages, or it can be downloaded and compiled from the OpenSSL GitHub.

> ⛔ Many modules depend on OpenSSL. Changing the default version may cause problems. Adding `--prefix=/var/tmp/ssl --openssldir=/var/tmp/ssl` in the `./Configure` command below may prevent the built OpenSSL from becoming the default one used by the system. Make sure the directory of the OpenSSL you build manually is not located in any paths listed in the PATH environment variable.

1. Check the version of the default OpenSSL:

```
host> openssl version
```

2. Follow OpenSSL installation instructions from OpenSSL's supplied guides. During the configuration process, make sure to set the `enable-ktls` option before building it by running it from within the OpenSSL directory (works in version 3.2.0 and higher). For example:

```
host> ./Configure linux-$(uname -p) enable-ktls --prefix=/var/tmp/ssl --openssldir=/var/tmp/ssl # Add
"threads" as well for multithread support
```

3. Check if kTLS is enabled in OpenSSL by running the following command from within the OpenSSL directory, and check whether `ktls` is listed under `Enabled features`:

```
host> perl configdata.pm --dump | less
```

If OpenSSL has been downloaded manually, the OpenSSL executable would be located in the `/<openssl-dir>/apps/` directory. For example, checking the version from within OpenSSL directory is done using the command `./apps/openssl version`.

⚠ Installing a new OpenSSL requires recompiling user tools that were configured over OpenSSL (e.g., Nginx).

⚠ In OpenSSL's master source code, there is a feature "Support for kTLS Zero-Copy sendfile() on Linux" (Zero-Copy commit). If the Zero-Copy option is set, `SSL_sendfile()` uses the Zero-Copy TX mode which means that the data itself is not copied from the user space to Kernel space. This gives a performance boost when used with kTLS hardware offload. Be aware that invalid TLS records may be transmitted if the file is changed while being sent.

11.8.4.2 Nginx

Nginx is a free and open-source software web server that can also be used as a reverse proxy, load balancer, mail proxy and HTTP cache. Nginx can be configured to depend on OpenSSL library and therefore Nginx could have the great advantages of TLS HW-offload on ConnectX-6 Dx, ConnectX-7 or the DPU.

11.8.4.2.1 Prerequisites

Refer to the OpenSSL section for setting OpenSSL.

11.8.4.2.2 Configuration

1. Install dependencies. For Ubuntu distribution, for example:

```
host> apt install libpcre3 libpcre3-dev
```

2. Clone Nginx's repository and enter directory:

```
host> git clone https://github.com/nginx/nginx.git && cd nginx
```

3. Configure Nginx components to support kTLS:

```
host> ./auto/configure --with-openssl=/<insert_path_to_openssl_directory> --with-debug --with-
http_ssl_module --with-openssl-opt="enable-ktls -DOPENSSL_LINUX_TLS -g3"
```

4. Build Nginx:

```
host> make -j <num of cores> && sudo make -j <num-of-cores> install
```

> ⚠ If `make` fails with a `deprecated openssl functions` error, remove `-Werror` for `CFLAGS` in objs/Makefile and try again.

5. Add the following lines to the end of the `/usr/local/nginx/conf/nginx.conf` file (before the last closing bracket):

```
server {
    listen 443 ssl default_server reuseport;
    server_name localhost;
    root /tmp/nginx/docs/html/;

    include /etc/nginx/default.d/*.conf;
    ssl_certificate /usr/local/nginx/conf/cert.pem;
    ssl_certificate_key /usr/local/nginx/conf/key.pem;
    ssl_ciphers ECDHE-RSA-AES128-GCM-SHA256;
    ssl_conf_command Options KTLS;
    ssl_protocols TLSv1.2;

 location / {
    index index.html;
 }

 error_page 404 /404.html;
    location = /40x.html {
 }

 error_page 500 502 503 504 /50x.html;
    location = /50x.html {
 }
}
```

6. Notice that the key and certificate of the Nginx server should be located in `/usr/local/nginx/conf/`. Therefore, after creating a key and certificate (as mentioned in section "Adding Certificate and Key") they should be copied to the aforementioned directory:

```
host> cp key.pem /usr/local/nginx/conf/ && cp cert.pem /usr/local/nginx/conf/
```

7. To run Nginx:

```
host> cd nginx && objs/nginx
```

This command starts Nginx Server in the background.

11.8.4.2.3 Stopping Nginx

```
host> pkill nginx
```

11.8.4.2.4 Wrk – Client

A simple client for requesting Nginx's server is "wrk". It can be installed by running the following:

```
host> git clone https://github.com/wg/wrk.git && cd wrk/ && make -j <num-of-cores>
```

11.8.4.2.5 Using Wrk

The following is an example of using the wrk client to request the page `index.html` from the Nginx server in address `4.4.4.4` (run within wrk's directory):

```
host> taskset -c 0 ./wrk -t1 -c10 -d30s https://4.4.4.4:443/index.html
```

⚠ Testing the kTLS offload (with or without hardware offload) is in the same manner as mentioned in section "Testing kTLS". TBD

11.8.5 Testing Offload via OpenSSL

This chapter demonstrates how to test the kTLS hardware offload.

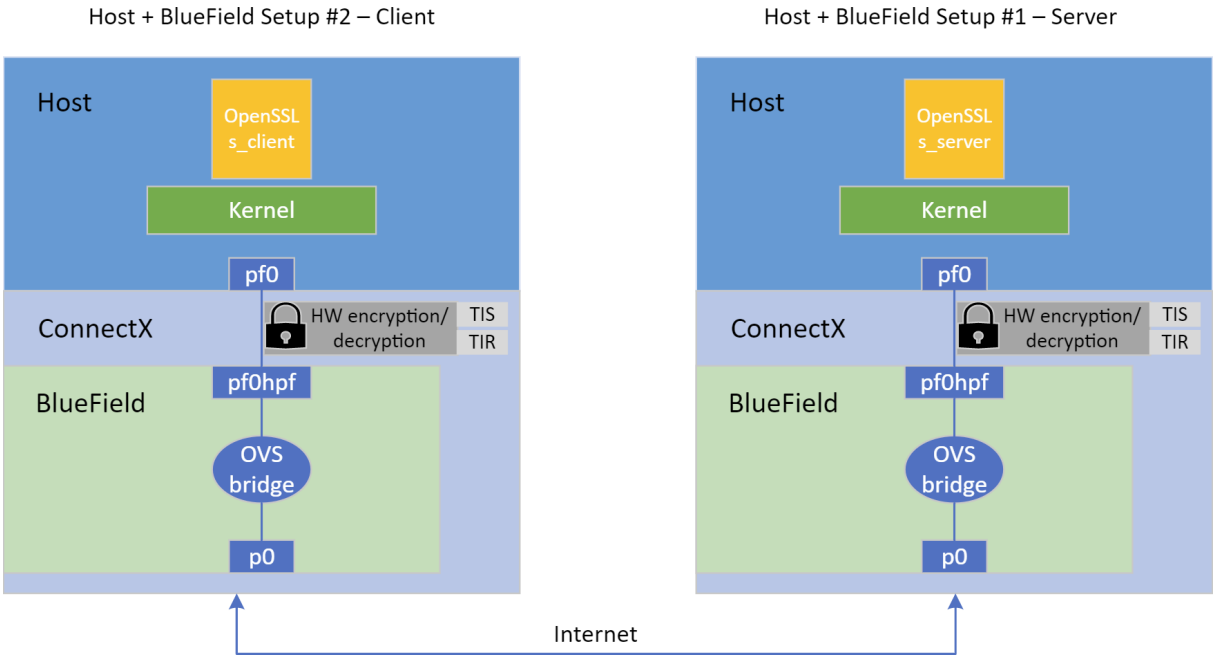
⚠ Make sure to refer to section "OpenSSL" before proceeding.

11.8.5.1 TLS Testing Setup

For testing purposes, a server and a client are required. The testing section only tests a single setup of a host and BlueField-2 or a host ConnectX which will participate either as a server or as a client. Setting a back-to-back setup of the same kind and installing the same OpenSSL version can help avoid misconfigurations. Nevertheless, it is required to have the same OpenSSL version on both the client and server.

Make sure the desired kTLS is configured as detailed in section "Configuring TLS Offload". To test hardware offload, make sure `tls-hw-tx-offload` and/or `tls-hw-rx-offload` are on. To test kTLS software mode, make sure to turn them off.

In addition, make sure both hosts (server and client) can communicate bidirectionally through ConnectX or BlueField. One can set the interface that supports the offload (on the host) with an IP, in same subnet. Make sure that when using BlueField, an OVS bridge is set on BlueField as shown in "Configuring OVS Bridge on BlueField".



11.8.5.2 Adding Certificate and Key

The server side should create a certificate and key. The client can also use a certificate, but it is not necessary for this test case. Run the following command in the installed OpenSSL directory and fill in all the requested details:

```
host> openssl req -x509 -newkey rsa:2048 -keyout key.pem -out cert.pem -days 365 -nodes
```

The following files are created:

- `key.pem` – private-key file used to generate the CSR and, later, to secure and verify connections using the certificate
- `cert.pem` – certificate signing request (CSR) file used to order your SSL certificate and, later, to encrypt messages that only its corresponding private key can decrypt

⚠ The server side should be run before client side so that client's request are answered by server.

11.8.5.3 Running Server Side

The following example works on OpenSSL version 3.1.0:

```
host> openssl s_server -key key.pem -cert cert.pem -tls1_2 -cipher ECDHE-RSA-AES128-GCM-SHA256 -accept 443 -ktls
```

⚠ Notice the `-ktls` flag.

⚠ Refer to official OpenSSL documentation on `s_server` for more information.

In this example, the key and certificate are provided, the cipher suite and TLS version are configured, and the server listens to port 443 and is instructed to use kTLS.

11.8.5.4 Running Client Side

The following example works on OpenSSL version 3.1.0:

```
host> openssl s_client -connect 4.4.4.4:443 -tls1_2 -ktls
```

Where 4.4.4.4 is the IP of the port/interface under test (e.g., `enp177s0f0np0`).

⚠ Refer to official OpenSSL documentation on `s_client` for more information.

11.8.5.5 Testing kTLS

After the connection is established (handshake is done), a prompt will open and the user, both on the client and server side, can send a message to other side in a chat-like manner. Messages should appear on the other side once they are received.

The following example checks kTLS hardware offload on the tested setup by tracking Rx and Tx TLS on device counters:

```
host> ethtool -S $iface | grep -i 'tx_tls_encrypted\|rx_tls_decrypted' # ($iface is the interface that offloads)
```

To check kTLS over kernel counters:

```
host> cat /proc/net/tls_stat
```

Output example:

⚠ The comments are not part of the output and are added as explanation.

```
host> cat /proc/net/tls_stat
TlsCurrTxSw                             0               # Current Tx connections opened in SW mode
TlsCurrRxSw                             0               # Current Rx connections opened in SW mode
TlsCurrTxDevice                         0               # Current Tx connections opened in HW-offload mode
TlsCurrRxDevice                         0               # Current Rx connections opened in HW-offload mode
TlsTxSw                                 2323828         # Accumulated number of Tx connections opened in SW mode
TlsRxSw                                 1               # Accumulated number of Rx connections opened in SW mode
TlsTxDevice                             12203652        # Accumulated number of Tx connections opened in HW-offload
mode
```

```
TlsRxDevice                     0               # Accumulated number of Rx connections opened in HW-offload
mode
TlsDecryptError                 0               # Failed record decryption (e.g., due to incorrect
authentication tag)
TlsRxDeviceResync               0               # Rx resyncs sent to HW's handling cryptography
TlsDecryptRetry                 0               # All Rx records re-decrypted due to TLS_RX_EXPECT_NO_PAD
misprediction
TlsRxNoPadViolation             0               # Data Rx records re-decrypted due to TLS_RX_EXPECT_NO_PAD
misprediction
```

More information about the kernel counters can be found in the Statistics section of the Kernel TLS documentation.

11.8.6 Optimizations over kTLS

11.8.6.1 XLIO

The NVIDIA accelerated IO (XLIO) software library boosts the performance of TCP/IP applications based on Nginx (e.g., CDN, DoH) and storage solutions as part of SPDK. XLIO is a user-space software library that exposes standard socket APIs **with kernel-bypass** architecture, enabling a hardware-based direct copy between an application's user-space memory and the network interface. In particular, XLIO can boost the performance of applications that use the kTLS hardware offload as OpenSSL and Nginx. Read more about XLIO in the NVIDIA XLIO Documentation and XLIO TLS HW-offload over kTLS in the TLS HW Offload section.

Even though XLIO is a kernel-bypass library, the kernel must support kTLS for the bypass to work properly.

11.8.7 Performance Tuning Options

TLS offload performance is related to how fast data can be pumped though the offload engine. In the case of user space applications, certain system configurations can be tuned to optimize its performance.

The following are items that can be tuned for optimal performance, mainly focusing on dedicating the server's work to the NUMA, or non-uniform memory access, cores:

Non-uniform memory access (NUMA) cores are cores with a dedicated memory for each of them, granting cores fast access to their own memory and slower access to others'. This architecture is best for scenarios when it is not necessary to share memory between cores.

1. Add NUMA cores of the NIC to the `isolcpus` kernel boot arguments for each server so that the kernel scheduler does not interrupt the core's running user thread. The following are examples of adding commands:
    a. Identify the NIC NUMA node (see NUMA column):

```
host> mst status -v
DEVICE_TYPE             MST                         PCI       RDMA      NET                   NUMA
ConnectX6DX(rev:0)    /dev/mst/mt4125_pciconf0 41:00.0    mlx5_0    net-enp65s0f0np0    1
```

    b. Identify the cores of the NIC NUMA node using the NUMA node number acquired from the previous output:

```
host> lscpu | grep "NUMA node1"
NUMA node1 CPU(s): 1,3,5,7,9,11,13,15,17,19,21,23
```

    c. Add the NIC NUMA cores to a grub file (e.g., `/etc/default/grub`) by adding the line `GRUB_CMDLINE_LINUX_DEFAULT="isolcpus=<NUMA-cores-from-previous-output>"`. For example:

```
GRUB_CMDLINE_LINUX_DEFAULT="isolcpus=1,3,5,7,9,11,13,15,17,19,21,23"
```

    d. Update grub:

```
host> sudo update-grub
```

    e. Reboot and check that the configuration has been applied:

```
host> cat /proc/cmdline
BOOT_IMAGE=/vmlinuz-5.10.12 root=UUID=1879326c-711f-4f95-a974-d732af14ef04 ro department=general
user_notifier=dovd osi_string None BOOTIF=01-90-b1-1c-14-02-44 quiet splash
isolcpus=1,3,5,7,9,11,13,15,17,19,21,23
```

2. Disable `irqbalance` service:

> ⚠ Interrupt request, or IRQ, determines what hardware interrupts arrive to each core.

```
host> service irqbalance stop
```

3. Run `set_irq_affinity.sh` to redistribute IRQs to various cores.

> ⚠ The script is within MLNX_OFED's sources:
>
> a. You can find it in MLNX_OFED downloads.
>
> b. Under "Download" select the correct version and download the "SOURCES" `.tgz` file.
>
> c. Extract the `.tgz`.
>
> d. Under SOURCES, extract the `mlnx_tools`.

You should find both files `set_irq_affinity.sh` and its helper file `common_irq_affinity.sh` under the `sbin` directory.

```
host> ./set_irq_affinity.sh <ConnectX_or_BlueField_network_interface>
```

4. Set the interface RSS to the number of cores to use:

```
host> ethtool -X <ConnectX_or_BlueField_network_interface> equal <number_of_isolcpus_cores>
```

5. Set the interface queues for number of cores to use:

```
host> ethtool -L <ConnectX_or_BlueField_network_interface> combined <number_of_isolcpus_cores>
```

6. Pin the application with `taskset` to the `isolcpus` cores used. For example:

```
host> taskset -c 1,3,5,7,9,11,13,15,17,19,21,23 openssl s_server -key key.pem -cert cert.pem -tls1_2
-cipher ECDHE-RSA-AES128-GCM-SHA256 -accept 443 -ktls
```

11.9 DOCA Virtual Functions User Guide

This guide provides an overview and configuration of virtual functions for NVIDIA® BlueField® and demonstrates a use case for running the DOCA applications over x86 host.

11.9.1 Introduction

Single root IO virtualization (SR-IOV) is a technology that allows a physical PCIe device to present itself multiple times through the PCIe bus. This technology enables multiple virtual instances of the device with separate resources. NVIDIA adapters are able to expose virtual instances or functions (VFs) for each port individually. These virtual functions can then be provisioned separately.

Each VF can be seen as an additional device connected to the physical interface or function (PF). It shares the same resources with the PF, and its number of ports equals those of the PF.

SR-IOV is commonly used in conjunction with an SR-IOV-enabled hypervisor to provide virtual machines direct hardware access to network resources, thereby increasing its performance.

There are several benefits to running applications on the host. For example, one may want to utilize a strong and high-resource host machine, or to start DOCA integration on the host before offloading it to the BlueField DPU.

The configuration in this document allows the entire application to run on the host's memory, while utilizing the HW accelerators on BlueField.

When VFs are enabled on the host, VF representors are visible on the Arm side which can be bridged to corresponding PF representors (e.g., the uplink representor and the host representor). This allows the application to only scan traffic forwarded to the VFs as configured by the user and to behave as a simple "bump-on-the-wire". DOCA installed on the host allows access to the hardware capabilities of the BlueField DPU without comprising features which use HW offload/steering elements embedded inside the eSwitch.

11.9.2 Prerequisites

To run all the reference applications over the host, you must install the host DOCA package. Refer to the DOCA Installation Guide for Linux for more information on host installation.
VFs must be configured as trusted for the hardware jump action to work as intended. The following steps configure "trusted" mode for VFs:

1. Delete all existing VFs
    a. To delete all VFs on a PF run the following on the host:

    ```
    host $ echo 0 > /sys/class/net/<physical_function>/device/sriov_numvfs
    ```

    For example:

    ```
    host $ echo 0 > /sys/class/net/ens1f0/device/sriov_numvfs
    ```

2. Delete all existing SFs.

    Refer to BlueField Scalable Function User Guide for instructions on deleting SFs.

3. Stop the main driver on the host:

    ```
    host $ /etc/init.d/openibd stop
    ```

4. Before creating the VFs, set them to "trusted" mode on the device by running the following commands on the DPU side.
    a. Setting VFs on port 0:

```
host $ mlxreg -d /dev/mst/mt41686_pciconf0 --reg_id 0xc007 --reg_len 0x40 --indexes
"0x0.0:32=0x80000000" --yes --set "0x4.0:32=0x1"
```

b. Setting VFs on port 1:

```
host $ mlxreg -d /dev/mst/mt41686_pciconf0.1 --reg_id 0xc007 --reg_len 0x40 --indexes
"0x0.0:32=0x80000000" --yes --set "0x4.0:32=0x1"
```

⚠ These commands set trusted mode for all created VFs/SFs after their execution on the DPU.

⚠ Setting trusted mode should be performed once per reboot.

5. Restart the main driver on the host by running the following command:

```
host $ /etc/init.d/openibd restart
```

11.9.3 VF Creation

1. Make sure mst driver is running:

```
host $ sudo mst status
```

If it is not loaded, run:

```
host $ sudo mst start
```

2. Enable SR-IOV. Run:

```
host $ sudo mlxconfig -y -d /dev/mst/mt41686_pciconf0 s SRIOV_EN=1
```

3. Set number of VFs. Run:

```
host $ sudo mlxconfig -y -d /dev/mst/mt41686_pciconf0 s NUM_OF_VFS=X
```

⚠ Perform a BlueField system reboot for the `mlxconfig` settings to take effect.

```
host $ echo X > /sys/class/net/<physical_function>/device/sriov_numvfs
```

For example:

```
host $ sudo mlxconfig -y -d /dev/mst/mt41686_pciconf0 s NUM_OF_VFS=2
host $ reboot
host $ echo 2 > /sys/class/net/ens1f0/device/sriov_numvfs
```

After enabling VF, the representor appears on the DPU. The function itself is seen at the x86 side.

4. To verify that the VFs have been created. Run:

```
host $ lspci | grep Virtual
b1:00.3 Ethernet controller: Mellanox Technologies ConnectX Family mlx5Gen Virtual Function (rev 01)
b1:00.4 Ethernet controller: Mellanox Technologies ConnectX Family mlx5Gen Virtual Function (rev 01)
b1:01.3 Ethernet controller: Mellanox Technologies ConnectX Family mlx5Gen Virtual Function (rev 01)
```

⚠ 2 new virtual Ethernet devices are created in this example.

11.9.4 Running DOCA Application on Host

⚠ Allocate the required number of VFs as explained previously.

⚠ Allocate any other resources as specified by the application (e.g., huge pages).

The following is the CLI example for running a reference application over the host using VF:

```
doca_<app_name> -a "pci address VF0" -a "pci address VF1" -c 0xff -- [application flags]
```

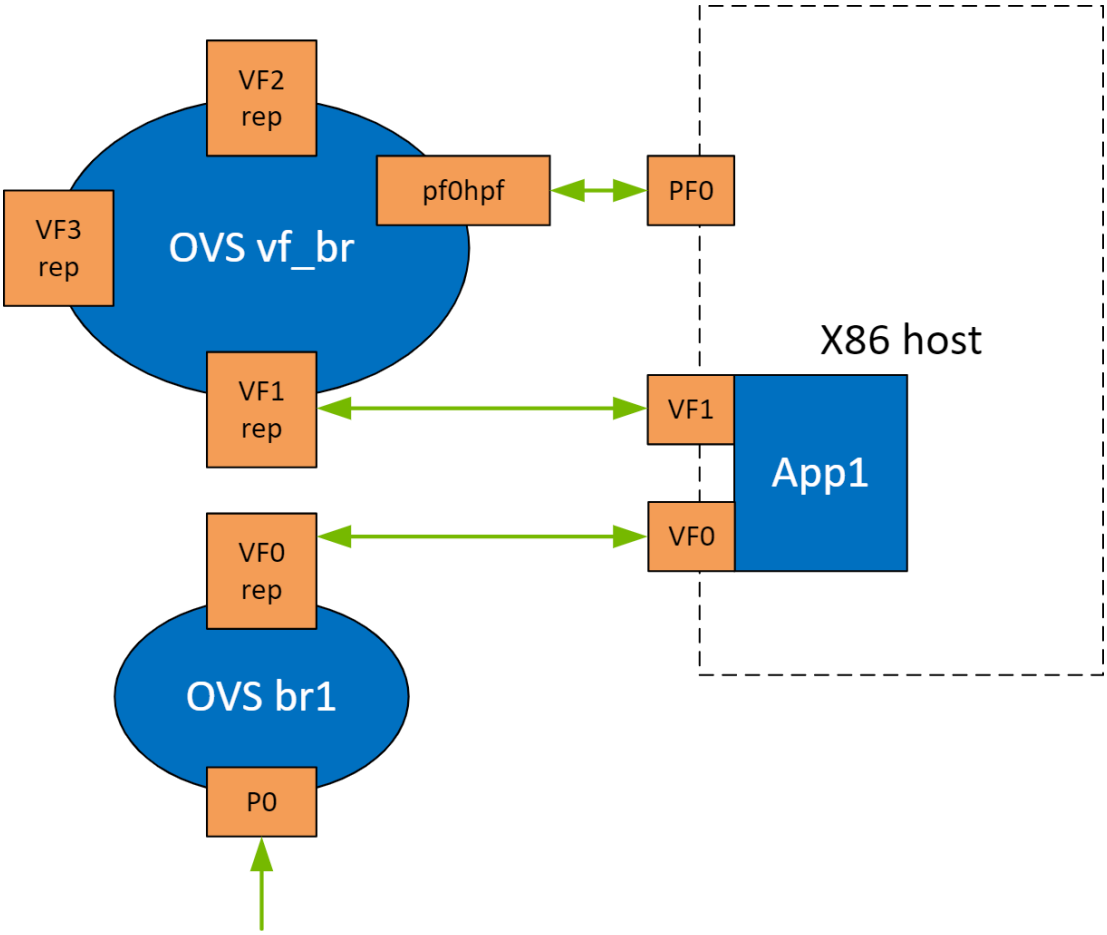
The following is an example with specific PCIe addresses for the VFs:

```
doca_<app_name> -a b1:00.3 -a b1:00.4 -c 0xff -- -l 60
```

⚠ By default, a DPDK application initializes all the cores of the device. This is usually unnecessary and may even cause unforeseeable issues. It is recommended to limit the number of cores, especially when using an AMD-based system, to 16 cores using the `-c` flag when running DPDK.

11.9.5 Topology Example

The following is a topology example for running the application over the host.



Configure the OVS on BlueField as follows:

```
Bridge vf_br:
    Port vf_br
        Interface vf_br
            type: internal
    Port pf0hpf
        Interface pf0hpf
   Port pf0vf1
        Interface pf0vf1
Bridge ovsbr1
   Port ovsbr1
        Interface ovsbr1
            type: internal
   Port p0
        Interface p0
   Port pf0vf0
        Interface pf0vf0
```

When enabling a new VF over the host, VF representors are created on the Arm side. The first OVS bridge connects the uplink connection (`p0`) to the new VF representor (`pf0vf0`), and the second bridge connects the second VF representor (`pf0vf1`) to the host representors (`pf0phf`). On the host, the 2 PCIe addresses of the newly created function must be initialized when running the applications.

When traffic is received (e.g., from the uplink), the following occurs:

1. Traffic is received over `p0` .
2. Traffic is forwarded to `pf0vf0` .

3. Application "listens" to `pf0vf0` and `pf0vf1` and can, therefore, acquire the traffic from `pf0vf0`, inspect it, and forward to `pf0vf1`.
4. Traffic is forwarded from `pf0vf1` to `pf0hpf`.

11.9.6 VF Creation on Adapter Card

> ⚠ Supported only for NVIDIA® ConnectX®-6 Dx based adapter cards and higher.

The following steps are required only when running DOCA applications on an adapter card.

1. Set trust level for all VFs. Run:

```
host $ mlxreg -d /dev/mst/mt4125_pciconf0 --reg_name VHCA_TRUST_LEVEL --yes --set
"all_vhca=0x1,trust_level=0x1" --indexes "vhca_id=0x0,all_vhca=0x0"
```

2. Create X VFs (X being the required number of VFs) and run the following to turn on trusted mode for the created VFs:

```
echo ON | tee /sys/class/net/enp1s0f0np0/device/sriov/X/trust
```

   For example, if you are creating 2 VFs, the following commands should be used:

```
echo ON | tee /sys/class/net/enp1s0f0np0/device/sriov/0/trust
echo ON | tee /sys/class/net/enp1s0f0np0/device/sriov/1/trust
```

3. Create a VF representor using the following command, replace the PCIe address with the PCIe address of the created VF:

```
echo 0000:17:00.2 > /sys/bus/pci/drivers/mlx5_core/unbind
echo 0000:17:00.2 > /sys/bus/pci/drivers/mlx5_core/bind
```

11.10 BlueField SR-IOV

This page explains the NVIDIA BlueField SR-IOV solution, detailing how to configure asymmetric Virtual Functions (VFs) per Embedded CPU Function (ECPF) and host Physical Function (PF) to enable scalable network virtualization.

11.10.1 Introduction

The NVIDIA® BlueField® SR-IOV solution is based on asymmetric VF and enables per-ECPF and per PF control over number of VF allocation.

ECPF VFs are intended to be used in switchdev mode. Like SFs and host VFs, ECPF VFs have a representor. Representor naming for ECPF VFs start after the host VFs. For example, if the host has 32 VFs enabled, then the host VF representors are named `pf0vf0` - `pf0vf31`, and the Arm representors continue at `pf0vf32` onward.

11.10.2 Enabling BlueField SR-IOV

To enable BlueField SR-IOV, apply the following configuration in the BlueField OS:

```
mlxconfig -d 03:00.0 -y s PF_NUM_OF_VF_VALID=1
```

⚠ Once `PF_NUM_OF_VF_VALID` is set, the `NUM_OF_VFS` mlxconfig option is not relevant and the user must set `PF_NUM_OF_VF` for each host and EC function. It is recommended for the number of VFs for each ECPF and each host PF be the same.

The BlueField should now support setting asymmetric VF configuration per port.

11.10.3 Configuring VF Limits

The following are examples for configuring the number of VFs per port:

1. In the BlueField, issue the following commands to configure 32 VFs per port:

   ```
   bf> mlxconfig -d 03:00.0 -y s PF_NUM_OF_VF=32
   bf> mlxconfig -d 03:00.1 -y s PF_NUM_OF_VF=32
   ```

   ⚠ The BlueField ECPF driver in the BlueField's Arm OS limits the number of VFs it supports to 32 per port.

2. In the host OS, issue the following commands to configure up to 126 VFs per port:

   ```
   host> mlxconfig -d 03:00.0 -y s PF_NUM_OF_VF=126
   host> mlxconfig -d 03:00.1 -y s PF_NUM_OF_VF=126
   ```

11.10.4 Applying Configuration

To apply the configuration, perform a BlueField system reboot for the `mlxconfig` settings to take effect.

11.10.5 Instantiating VFs

Create ECPF VFs:

```
echo 1 > /sys/class/net/p0/device/sriov_numvfs
```

11.10.6 Limitations and Legacy Support

BlueField SR-IOV VFs do not support the following legacy SR-IOV functionalities:

- Virtual switch tagging (VF VLAN)
- Spoof check
- VF trust
- VF rate

11.11 fTPM over OP-TEE

This page provides an overview and configuration instructions for using fTPM over the OP-TEE on NVIDIA® BlueField®-3 DPUs (and higher) to deliver secure, hardware-isolated cryptographic services and protected storage without requiring a separate dedicated chip.

11.11.1 Introduction

> ⚠ fTMP over OP-TEE is supported on BlueField DPUs only on host OS Ubuntu 22.04 or Oracle Linux.

The Trusted Computing Group (TCG) is responsible for the specifications governing the trusted platform module (TPM). In many systems, the TPM provides integrity measurements, health checks and authentication services.

Attributes of a TPM:

- Support for bulk (symmetric) encryption in the platform
- High quality random numbers
- Cryptographic services
- Protected persistent store for small amounts of data, sticky bits, monotonic counters, and extendible registers
- Protected pseudo-persistent store for unlimited amounts of keys and data
- Extensive choice of authorization methods to access protected keys and data

- Platform identities
- Support for platform privacy
- Signing and verifying digital signatures
- Certifying the properties of keys and data
- Auditing the usage of keys and data

With TPM 2.0., the TCG creates a library specification describing all the commands or features that could be implemented and may be necessary in servers, laptops, or embedded systems. Each platform can select the features needed and the level of security or assurance required. This flexibility allows the newest TPMs to be applied to many embedded applications.

Firmware TPM (fTPM) is implemented in protected software. The code runs on the main CPU so that a separate chip is not required. While running like any other program, the code is in a protected execution environment called a trusted execution environment (TEE) which is separate from the rest of the programs running on the CPU. By doing this, secrets (e.g., private keys perhaps needed by the TPM but should not be accessed by others) can be kept in the TEE creating a more secure environment.

> fTPM provides similar functionality to a chip-based TPM, but does not require extra hardware. It complies with the official TCG reference implementation of the TPM 2.0 specification. The source code of this implementation is located here.

> fTPM fully supports TPM2 Tools and the TCG TPM2 Software Stack (TSS).

Characteristics of an fTPM:

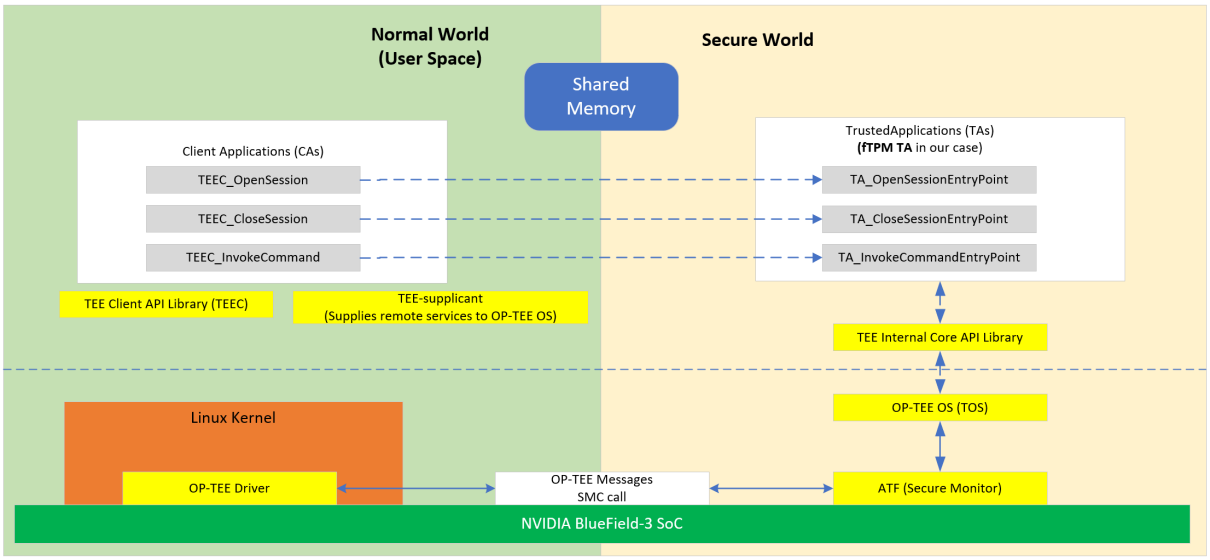
- Emulated TPM using an isolated hardware environment
- Executes in an open-source trusted execution environment (OP-TEE)
- fTPM trusted application (TA) is part of the OP-TEE binary. This allows early access on bootup, runs only in secure DRAM.

  > Currently, the only TA supported is fTPM.

- fTPM is not a task waiting to be woken up. It only executes when TPM primitives are forwarded to it from the user space. It is guaranteed shielded execution via the TEE OS and, when invoked via the TEE Dispatcher, runs to completion.

11.11.2 Architecture and Secure Storage

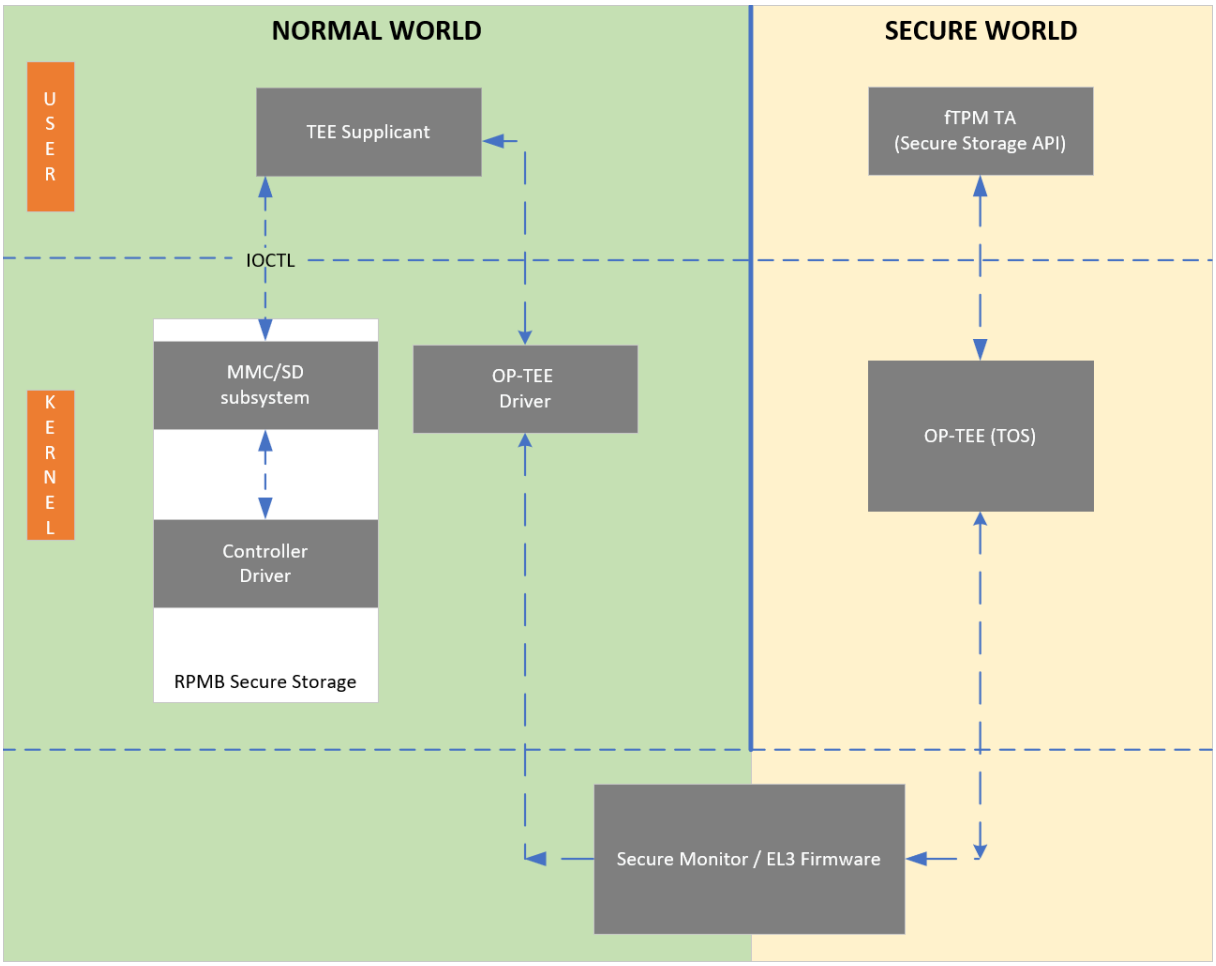
The fTPM TA is the only TA BlueField-3 currently supports. Any TA loaded by OP-TEE must be signed (signing done externally) and then authenticated by OP-TEE before being allowed to load and execute.



A replay-protected memory block (RPMB) is provided as a means for a system to store data to the specific memory area in an authenticated and replay-protected manner, making it readable and writable only after a successful authentication read/write accesses. The RPMB is a dedicated partition available on the eMMC, which makes it possible to store and retrieve data with integrity and authenticity support. A signed access to an RPMB is supported by first programming authentication key information to the eMMC memory (shared secret). The RPMB authentication key is programmed into BlueField at manufacturing time.

> RPMB features a 4MB partition secure storage for BlueField-3.

There is no eMMC controller driver in OP-TEE. All device operations have to go through the normal world via the TEE-supplicant daemon, which relies on the Linux kernel's ioctl interface to access the device. All writes to the RPMB are atomic, authenticated, and encrypted. The RPMB partition stores data in an authenticated, replay-protected manner, making it a perfect complement to fTPM for storing and protecting data.



11.11.3 Enabling OP-TEE on BlueField-3

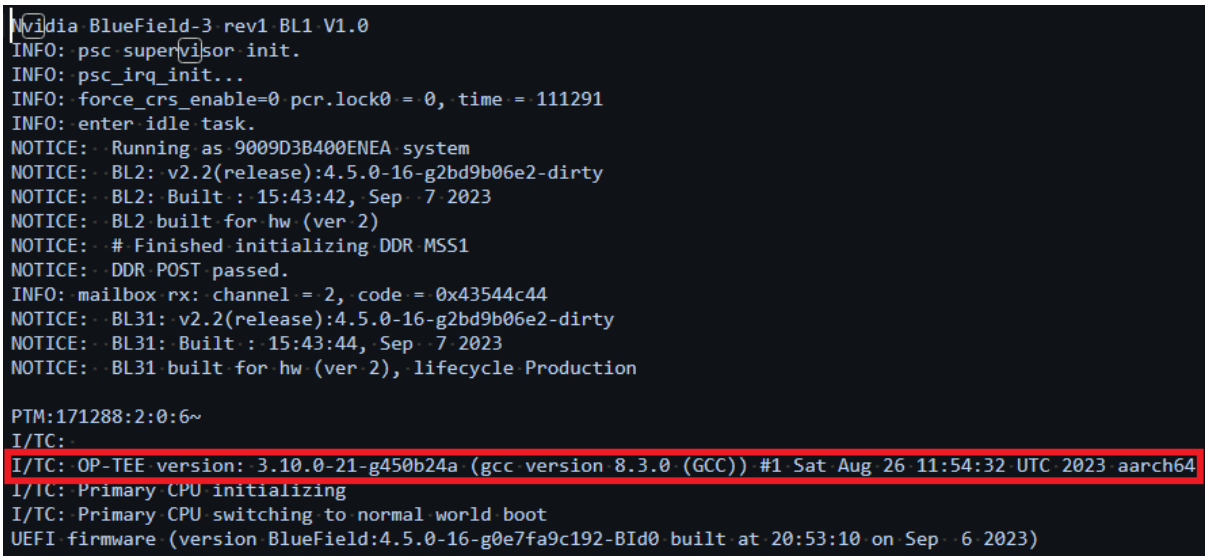
Enable OP-TEE in the UEFI menu:

1. ESC into the UEFI on BlueField boot.
2. Navigate to Device Manager > System Configuration.
3. Check "Enable OP-TEE".
4. Save the change and reset/reboot.
5. Upon reboot OP-TEE is enabled.

> ⚠ OP-TEE is essentially dormant (does not have an OS scheduler) and reacts to external inputs.

11.11.4 Verifying BlueField-3 is Running OP-TEE

Users can see the OP-TEE version during BlueField-3 boot:



The following indicators should all be present if fTPM over OP-TEE is enabled:

- Check "dmesg" for the OP-TEE driver initializing

```
root@localhost ~]# dmesg | grep tee
[    5.646578] optee: probing for conduit method.
[    5.653282] optee: revision 3.10 (450b24ac)
[    5.653991] optee: initialized driver
```

- Verify that the following kernel modules are loaded (running):

```
[root@localhost ~]# lsmod | grep tee
tpm_ftpm_tee           16384  0
optee                  49152  1
tee                    49152  3 optee,tpm_ftpm_tee
```

- Verify that the proper devices are created/available (4 in total):

```
[root@localhost ~]# ls -l /dev/tee*
crw------- 1 root root 234,  0 Sep  8 18:24 /dev/tee0
crw------- 1 root root 234, 16 Sep  8 18:24 /dev/teepriv0

[root@localhost ~]# ls -l /dev/tpm*
crw-rw---- 1 tss root  10,   224 Sep  8 18:24 /dev/tpm0
crw-rw---- 1 tss tss  252, 65536 Sep  8 18:24 /dev/tpmrm0
```

- Verify that the required processes are running (3 in total):

```
[root@localhost ~]# ps axu | grep tee
root         707  0.0  0.0  76208  1372 ?        Ssl  14:42   0:00 /usr/sbin/tee-supplicant
root         715  0.0  0.0      0     0 ?        I<   14:42   0:00 [optee_bus_scan]

[root@localhost ~]# ps axu | grep tpm
root         124  0.0  0.0      0     0 ?        I<   18:24   0:00 [tpm_dev_wq]
```
