In certain fabric configurations, InfiniBand packets belonging to the same QP may traverse different network paths from source to destination. This can lead to packets arriving out of order.

Instead of dropping these packets and triggering retransmissions, this feature enables them to be accepted and placed directly into host memory, even if they arrive out of order. This improves overall performance by:

- Enhancing network utilization
- Reducing latency

When out-of-order messages are received, data is placed in host memory in the order it arrives, without requiring strict in-order delivery.

For setup instructions, refer to the community post HowTo Configure Adaptive Routing and SHIELD.

5.6.2.1.10 IB Router

An InfiniBand (IB) router enables communication between two or more IB subnets. This allows the network to scale beyond 40,000 end-ports, supports separation and fault resilience across subnet "islands," and facilitates connectivity between subnets with different topologies.

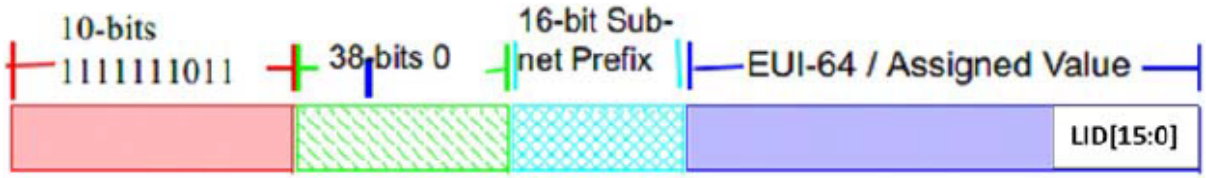
Forwarding between subnets is performed using Global Routing Header (GRH) lookup. The router's basic functionality includes:

- Removing the existing Layer 2 Local Routing Header (LRH)
- Performing routing
- Looking up the routing table using the GID extracted from the GRH

- Constructing a new LRH for the destination, based on the routing table

The DLID in the new LRH is derived using a simplified GID-to-LID mapping, where LID = the lower 16 bits of the GID. This approach eliminates the need for ARP queries or lookups.

Local Unicast GID Format

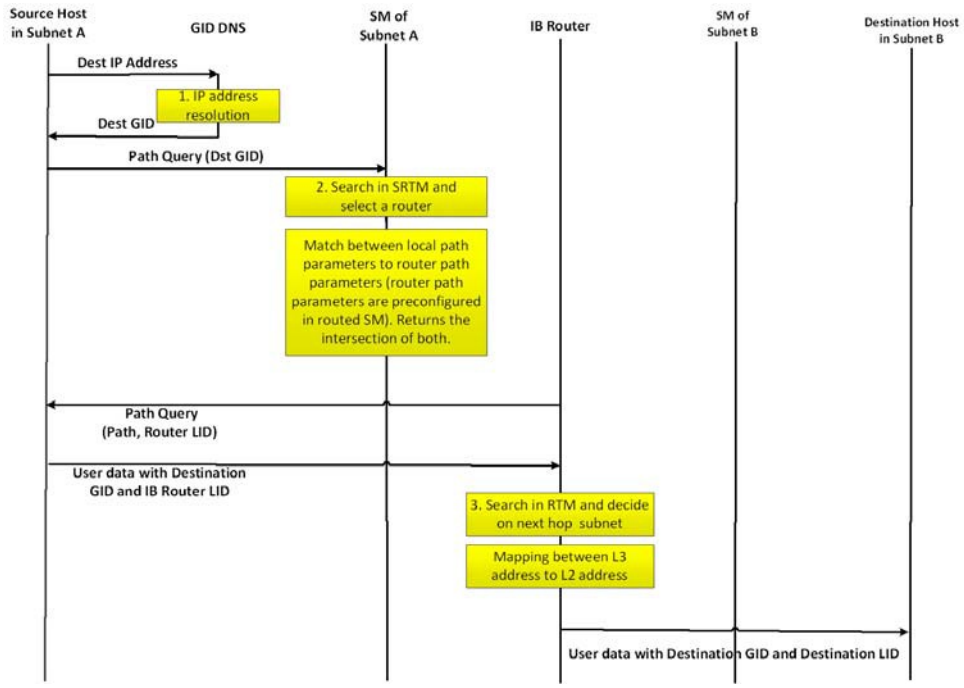


To enable this mechanism, the Subnet Manager (SM) assigns an alias GID to each host. The alias GID format is:

```
alias GID = {subnet_prefix[127:64], reserved[63:16], LID[15:0]}
```

Hosts must use these alias GIDs when transmitting traffic to peers located in remote subnets.

Host-to-Host IB Router Unicast Flow



For information on the architecture and functionality of IB Router, refer to IB Router Architecture and Functionality Community post.

For information on IB Router configuration, refer to HowTo Configure IB Routers Community post.

5.6.2.1.11 MAD Congestion Control

Subnet Administration (SA) Management Datagrams (MADs) are General Management Packets (GMPs) used to communicate with the SA entity within an InfiniBand subnet. The SA is typically part of the subnet manager and exists as a single active instance. As a result, congestion at the SA communication level can occur.

Congestion control is handled by limiting the number of outstanding MADs, which are MADs that have been sent but have not yet received a response. A FIFO queue holds additional SA MADs whose transmission is delayed due to exceeding the `max_outstanding` threshold.

The length of this queue is controlled by `queue_size`, which helps prevent excessive memory use. If the FIFO queue becomes full, new SA MADs are dropped, and the drops counter is incremented.

Each queued MAD also has an associated timeout (`time_sa_mad`). When this timeout expires, the MAD is removed from the queue, and the user is notified of the expiration.

This feature is implemented per CA port, and configuration is available via sysfs:

```
/sys/class/infiniband/mlx5_0/mad_sa_cc/
    1/
        drops
        max_outstanding
        queue_size
        time_sa_mad
    2/
        drops
        max_outstanding
        queue_size
        time_sa_mad
```

5.6.2.1.11.1 Usage Examples

- To print the current value:

```
cat /sys/class/infiniband/mlx5_0/mad_sa_cc/1/max_outstanding
# Output: 16
```

- To change the current value:

```
echo 32 > /sys/class/infiniband/mlx5_0/mad_sa_cc/1/max_outstanding
cat /sys/class/infiniband/mlx5_0/mad_sa_cc/1/max_outstanding
# Output: 32
```

- To reset the drops counter:

```
echo 0 > /sys/class/infiniband/mlx5_0/mad_sa_cc/1/drops
```

Valid parameter ranges:

Parameter	Range	Default Values
`max_oustanding`	1–2^20	16
`queue_size`	16–2^20	16
`time_sa_mad`	1 ms–10000	20 ms

5.6.2.2 Ethernet Network

The chapter contains the following sections:

- Ethernet Interface
- Ethernet QoS
- Ethtool
- Checksum Offload
- Ignore FCS Errors
- RDMA over Converged Ethernet
- Flow Control
- Explicit Congestion Notification
- RSS Support
- Time Stamping
- Flow Steering
- Wake-on-LAN
- Q-in-Q Tunneling
- VLAN Stripping in Linux Verbs
- Offloaded Traffic Sniffer
- Dump Configuration
- Local Loopback Disable
- kTLS Offloads
- IPsec Crypto Offload
- IPsec Packet Offload
- MACsec Full Offload

5.6.2.2.1 Ethernet Interface

5.6.2.2.1.1 Port Type Management Configuration

Ports of ConnectX-4 adapter cards and above can be individually configured to work as InfiniBand or Ethernet ports. If you wish to change the port type, use the mlxconfig script after the driver is loaded.

For further information on how to set the port type, please refer to the MFT User Manual.

5.6.2.2.1.2 Counters

Counters are used to provide information about how well an operating system, an application, a service, or a driver is performing. The counter data help determine system bottlenecks and fine-tune the system and application performance. The operating system, network, and devices provide counter data that an application can consume to provide users with a graphical view of how well the system is performing.

The counter index is a Queue Pair (QP) attribute given in the QP context. Multiple QPs may be associated with the same counter set. If multiple QPs share the same counter, the counter value will represent the cumulative total.

RoCE Counters

- RoCE counters are available only through sysfs located under:
  - `# /sys/class/infiniband/<device>/ports/*/hw_counters/`
  - `# /sys/class/infiniband/<device>/hw_counters/`
  - `# /sys/class/infiniband/<device>/ports/*/counters/`

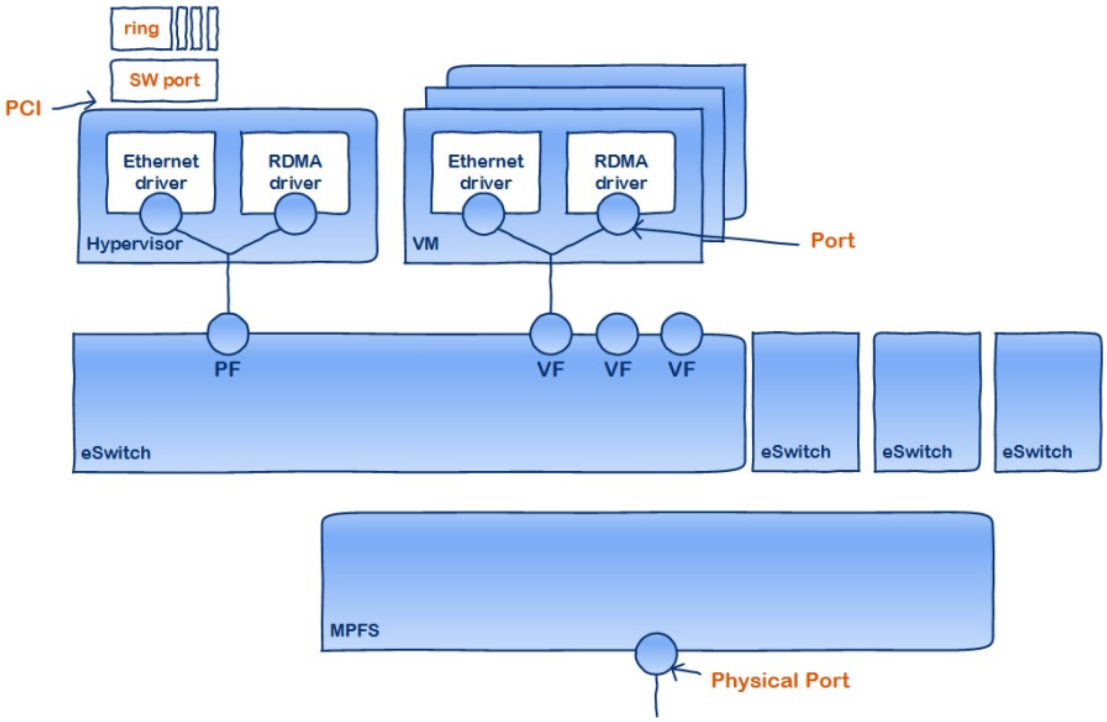
For mlx5 port and RoCE counters, refer to the Understanding mlx5 Linux Counters community post.

SR-IOV Counters

PFs can also read VFs' port counters through sysfs located under `/sys/class/net/<interface_name>/device/sriov/<index>/stats/`.

ethtool Counters

The ethtool counters are counted in different places, according to which they are divided into groups. Each counters group may also have different counter types.



For the full list of supported ethtool counters, refer to the Understanding mlx5 ethtool Counters community post.

5.6.2.2.1.3 Persistent Naming

To avoid network interface renaming after boot or driver restart, set the desired constant interface name in the `/etc/udev/rules.d/70-persistent-net.rules` file.

- Example for Ethernet interfaces:

```
PCI device 15b3:1019 (mlx5_core)
SUBSYSTEM=="net", ACTION=="add", DRIVERS=="?*", ATTR{address}=="00:02:c9:fa:c3:50", ATTR{dev_id}=="0x0",
ATTR{type}=="1", KERNEL=="eth*", NAME="eth1"
SUBSYSTEM=="net", ACTION=="add", DRIVERS=="?*", ATTR{address}=="00:02:c9:fa:c3:51", ATTR{dev_id}=="0x0",
ATTR{type}=="1", KERNEL=="eth*", NAME="eth2"
SUBSYSTEM=="net", ACTION=="add", DRIVERS=="?*", ATTR{address}=="00:02:c9:e9:56:a1", ATTR{dev_id}=="0x0",
ATTR{type}=="1", KERNEL=="eth*", NAME="eth3"
SUBSYSTEM=="net", ACTION=="add", DRIVERS=="?*", ATTR{address}=="00:02:c9:e9:56:a2", ATTR{dev_id}=="0x0",
ATTR{type}=="1", KERNEL=="eth*", NAME="eth4"
```

- Example for IPoIB interfaces:

```
SUBSYSTEM=="net", ACTION=="add", DRIVERS=="?*", ATTR{dev_id}=="0x0", ATTR{type}=="32", NAME="ib0"
SUBSYSTEM=="net", ACTION=="add", DRIVERS=="?*", ATTR{dev_id}=="0x1", ATTR{type}=="32", NAME="ib1"
```

5.6.2.2.1.4 Interrupt Request (IRQ) Naming

Once IRQs are allocated by the driver, they are named `mlx5_comp<x>@pci:<pci_addr>`. The IRQ name is constant and is not affected by the interface state.

The mlx5_core driver allocates all IRQs during loading time to support the maximum possible number of channels. Once the driver is up, no further IRQs are freed or allocated. Changing the number of working channels does not re-allocate or free the IRQs.

5.6.2.2.2 Ethernet QoS

Quality of service (QoS) is a mechanism of assigning a priority to a network flow (socket, `rdma_cm` connection) and manage its guarantees, limitations and its priority over other flows. This is accomplished by mapping the user's priority to a hardware TC (traffic class) through a 2/3 stage process. The TC is assigned with the QoS attributes and the different flows behave accordingly.

5.6.2.2.2.1 Mapping Traffic to Traffic Classes

Mapping traffic to TCs consists of several actions which are user controllable, some controlled by the application itself and others by the system/network administrators. The following is the general mapping traffic to Traffic Classes flow:

1. The application sets the required type of service (ToS).
2. The ToS is translated into a Socket Priority (`sk_prio`).
3. The `sk_prio` is mapped to a user priority (UP) by the system administrator (some applications set `sk_prio` directly).
4. The UP is mapped to TC by the network/system administrator.
5. TCs hold the actual QoS parameters

QoS can be applied on the following types of traffic. However, the general QoS flow may vary among them:

- Plain Ethernet – Applications use regular inet sockets and the traffic passes via the kernel Ethernet driver
- RoCE – Applications use the RDMA API to transmit using Queue Pairs (QPs)
- Raw Ethernet QP – Application use VERBs API to transmit using a Raw Ethernet QP

5.6.2.2.2.2 Plain Ethernet Quality of Service Mapping

Applications use regular inet sockets and the traffic passes via the kernel Ethernet driver. The following is the Plain Ethernet QoS mapping flow:

1. The application sets the ToS of the socket using setsockopt (IP_TOS, value).
2. ToS is translated into the sk_prio using a fixed translation:

```
TOS 0 <=> sk_prio 0
TOS 8 <=> sk_prio 2
TOS 24 <=> sk_prio 4
TOS 16 <=> sk_prio 6
```

3. The Socket Priority is mapped to the UP in the following conditions:

a. If the underlying device is a VLAN device, egress_map is used controlled by the vconfig command. This is per VLAN mapping.
b. If the underlying device is not a VLAN device, the mapping is done in the driver.

4. The UP is mapped to the TC as configured by the mlnx_qos tool or by the lldpad daemon if DCBX is used.

⚠ Socket applications can use setsockopt (SK_PRIO, value) to directly set the `sk_prio` of the socket. In this case, the ToS to `sk_prio` fixed mapping is not needed. This allows the application and the administrator to utilize more than the 4 values possible via ToS.

⚠ In the case of a VLAN interface, the UP obtained according to the above mapping is also used in the VLAN tag of the traffic.

5.6.2.2.2.3 RoCE Quality of Service Mapping

Applications use RDMA-CM API to create and use QPs. The following is the RoCE QoS mapping flow:

1. The application sets the ToS of the QP using the rdma_set_option option(RDMA_OPTION_ID_TOS, value).
2. ToS is translated into the Socket Priority (sk_prio) using a fixed translation:

```
TOS 0 <=> sk_prio 0
TOS 8 <=> sk_prio 2
TOS 24 <=> sk_prio 4
TOS 16 <=> sk_prio 6
```

3. The Socket Priority is mapped to the User Priority (UP) using the tc command.
   - In the case of a VLAN device where the parent real device is used for the purpose of this mapping
   - If the underlying device is a VLAN device, and the parent real device was not used for the mapping, the VLAN device's egress_map is used

4. UP is mapped to the TC as configured by the mlnx_qos tool or by the lldpad daemon if DCBX is used.

⚠ With RoCE, there can only be 4 predefined ToS values for the purpose of QoS mapping.

5.6.2.2.2.4 Map Priorities with set_egress_map

For RoCE old kernels that do not support set_egress_map, use the tc_wrap script to map between sk_prio and UP. Use tc_wrap with option -u. For example:

```
tc_wrap -i <ethX> -u <skprio2up mapping>
```

5.6.2.2.2.5 Quality of Service Properties

The different QoS properties that can be assigned to a TC are:

- Strict Priority
- Enhanced Transmission Selection (ETS)
- Rate Limit
- Trust State
- Receive Buffer
- DCBX Control Mode

Strict Priority

When setting a TC's transmission algorithm to be 'strict', then this TC has absolute (strict) priority over other TC strict priorities coming before it (as determined by the TC number: TC 7 is the highest priority, TC 0 is lowest). It also has an absolute priority over nonstrict TCs (ETS).
This property needs to be used with care, as it may easily cause starvation of other TCs. A higher strict priority TC is always given the first chance to transmit. Only if the highest strict priority TC has nothing more to transmit, will the next highest TC be considered.
Nonstrict priority TCs will be considered last to transmit.
This property is extremely useful for low latency low bandwidth traffic that needs to get immediate service when it exists, but is not of high volume to starve other transmitters in the system.

Enhanced Transmission Selection (ETS)

Enhanced Transmission Selection standard (ETS) exploits the time periods in which the offered load of a particular Traffic Class (TC) is less than its minimum allocated bandwidth by allowing the difference to be available to other traffic classes.
After servicing the strict priority TCs, the amount of bandwidth (BW) left on the wire may be split among other TCs according to a minimal guarantee policy.
If, for instance, TC0 is set to 80% guarantee and TC1 to 20% (the TCs sum must be 100), then the BW left after servicing all strict priority TCs will be split according to this ratio. Since this is a minimum guarantee, there is no maximum enforcement. This means, in the same example, that if TC1 did not use its share of 20%, the reminder will be used by TC0.
ETS is configured using the mlnx_qos tool (mlnx_qos) which allows you to:

- Assign a transmission algorithm to each TC (strict or ETS)
- Set minimal BW guarantee to ETS TCs
  Usage:

```
mlnx_qos -i \[options\]
```

Rate Limit

Rate limit defines a maximum bandwidth allowed for a TC. Please note that 10% deviation from the requested values is considered acceptable.

Trust State

Trust state enables prioritizing sent/received packets based on packet fields.
The default trust state is PCP. Ethernet packets are prioritized based on the value of the field (PCP/DSCP).
For further information on how to configure Trust mode, please refer to HowTo Configure Trust State on NVIDIA Adapters community post.

> ⚠ Setting the Trust State mode shall be done before enabling SR-IOV in order to propagate the Trust State to the VFs.

Receive Buffer

By default, the receive buffer configuration is controlled automatically. Users can override the receive buffer size and receive buffer's xon and xoff thresholds using mlnx_qos tool.
For further information, please refer to HowTo Tune the Receive buffers on NVIDIA Adapters community post.

DCBX Control Mode

DCBX settings, such as "ETS" and "strict priority" can be controlled by firmware or software. When DCBX is controlled by firmware, changes of QoS settings cannot be done by the software. The DCBX control mode is configured using the mlnx_qos -d os/fw command.
For further information on how to configure the DCBX control mode, please refer to mlnx_qos community post.

5.6.2.2.2.6 Quality of Service Tools

mlnx_qos

mlnx_qos is a centralized tool used to configure QoS features of the local host. It communicates directly with the driver thus does not require setting up a DCBX daemon on the system.
The mlnx_qos tool enables the administrator of the system to:

- Inspect the current QoS mappings and configuration
  The tool will also display maps configured by TC and vconfig set_egress_map tools, in order to give a centralized view of all QoS mappings.
- Set UP to TC mapping
- Assign a transmission algorithm to each TC (strict or ETS)
- Set minimal BW guarantee to ETS TCs
- Set rate limit to TCs
- Set DCBX control mode
- Set cable length
- Set trust state

For an unlimited ratelimit, set the ratelimit to 0.

Usage:

```
mlnx_qos -i <interface> \[options\]
```

Options:

--version	Show the program's version number and exit
-h, --help	Show this help message and exit
-f LIST, --pfc=LIST	Set priority flow control for each priority. LIST is a comma separated value for each priority starting from 0 to 7. Example: 0,0,0,0,1,1,1,1 enable PFC on TC4-7
-p LIST, --prio_tc=LIST	Maps UPs to TCs. LIST is 8 comma-separated TC numbers. Example: 0,0,0,0,1,1,1,1 maps UPs 0-3 to TC0, and UPs 4-7 to TC1
-s LIST, --tsa=LIST	Transmission algorithm for each TC. LIST is comma separated algorithm names for each TC. Possible algorithms: strict, ets and vendor. Example: vendor,strict,ets,ets,ets,ets,ets,ets sets TC0 to vendor, TC1 to strict, TC2-7 to ets
-t LIST, --tcbw=LIST	Set the minimally guaranteed %BW for ETS TCs. LIST is comma-separated percents for each TC. Values set to TCs that are not configured to ETS algorithm are ignored but must be present. Example: if TC0,TC2 are set to ETS, then 10,0,90,0,0,0,0,0will set TC0 to 10% and TC2 to 90%. Percents must sum to 100
-r LIST, --ratelimit=LIST	Rate limit for TCs (in Gbps). LIST is a comma-separated Gbps limit for each TC. Example: 1,8,8 will limit TC0 to 1Gbps, and TC1,TC2 to 8 Gbps each
-d DCBX, --dcbx=DCBX	Set dcbx mode to firmware controlled(fw) or OS controlled(os). Note, when in OS mode, mlnx_qos should not be used in parallel with other dcbx tools, such as lldptool
--trust=TRUST	set priority trust state to pcp or dscp

--dscp2prio=DSCP2PRIO	Set/del a (dscp,prio) mapping. Example 'set,30,2' maps dscp 30 to priority 2. 'del,30,2' resets the dscp 30 mapping back to the default setting priority 0
--cable_len=CABLE_LEN	Set cable_len for buffer's xoff and xon thresholds
-i INTF, --interface=INTF	Interface name
-a	Show all interface's TCs

Get current configuration:

```
ofed_scripts/utils/mlnx_qos -i ens1f0
DCBX mode: OS controlled
Priority trust state: dscp
dscp2prio mapping:
        prio:0 dscp:07,06,05,04,03,02,01,00,
        prio:1 dscp:15,14,13,12,11,10,09,08,
        prio:2 dscp:23,22,21,20,19,18,17,16,
        prio:3 dscp:31,30,29,28,27,26,25,24,
        prio:4 dscp:39,38,37,36,35,34,33,32,
        prio:5 dscp:47,46,45,44,43,42,41,40,
        prio:6 dscp:55,54,53,52,51,50,49,48,
        prio:7 dscp:63,62,61,60,59,58,57,56,
Cable len: 7
PFC configuration:
        priority 0 1 2 3 4 5 6 7
        enabled 0 0 0 0 0 0 0 0
tc: 0 ratelimit: unlimited, tsa: vendor
         priority: 1
tc: 1 ratelimit: unlimited, tsa: vendor
         priority: 0
tc: 2 ratelimit: unlimited, tsa: vendor
         priority: 2
tc: 3 ratelimit: unlimited, tsa: vendor
         priority: 3
tc: 4 ratelimit: unlimited, tsa: vendor
         priority: 4
tc: 5 ratelimit: unlimited, tsa: vendor
         priority: 5
tc: 6 ratelimit: unlimited, tsa: vendor
         priority: 6
tc: 7 ratelimit: unlimited, tsa: vendor
         priority: 7
```

Set rate limit (3Gb/s for tc0 4Gb/s for tc1 and 2Gb/s for tc2):

```
# mlnx_qos -i <interface> -p 0,1,2 -r 3,4,2
tc: 0 ratelimit: 3 Gbps, tsa: strict
         up:  0
                 skprio: 0
                 skprio: 1
                 skprio: 2 (tos: 8)
                 skprio: 3
                 skprio: 4 (tos: 24)
                 skprio: 5
                 skprio: 6 (tos: 16)
                 skprio: 7
                 skprio: 8
                 skprio: 9
                 skprio: 10
                 skprio: 11
                 skprio: 12
                 skprio: 13
                 skprio: 14
                 skprio: 15
         up:  3
         up:  4
         up:  5
         up:  6
         up:  7
tc: 1 ratelimit: 4 Gbps, tsa: strict
         up:  1
tc: 2 ratelimit: 2 Gbps, tsa: strict
         up:  2
```

Configure QoS
(map UP 0,7 to tc0,1,2,3 to tc1 and 4,5,6 to tc2. Set tc0,tc1 as ets and tc2 as strict. Divide ets 30% for tc0 and 70% for tc1):

```
# mlnx_qos -i <interface> -s ets,ets,strict -p 0,1,1,1,2,2,2 -t 30,70
tc: 0 ratelimit: 3 Gbps, tsa: ets, bw: 30%
         up:  0
                 skprio: 0
                 skprio: 1
                 skprio: 2 (tos: 8)
                 skprio: 3
                 skprio: 4 (tos: 24)
                 skprio: 5
                 skprio: 6 (tos: 16)
                 skprio: 7
                 skprio: 8
                 skprio: 9
                 skprio: 10
                 skprio: 11
                 skprio: 12
                 skprio: 13
                 skprio: 14
                 skprio: 15
  up:  7
tc: 1 ratelimit: 4 Gbps, tsa: ets, bw: 70%
         up:  1
         up:  2
         up:  3
tc: 2 ratelimit: 2 Gbps, tsa: strict
         up:  4
         up:  5
         up:  6
```

tc and tc_wrap.py

The tc tool is used to create 8 Traffic Classes (TCs).
The tool will either use the sysfs (/sys/class/net/<ethX>/qos/tc_num) or the tc tool to create the TCs.

Usage

```
tc_wrap.py -i <interface> \[options\]
```

Options

--version	show program's version number and exit
-h, --help	show this help message and exit
-u SKPRIO_UP, --skprio_up=SKPRIO_UP	maps sk_prio to priority for RoCE. LIST is <=16 comma separated priority. index of element is sk_prio
-i INTF, --interface=INTF	Interface name

Example

Run:

```
tc_wrap.py -i enp139s0
```

Output:

```
Tarrfic classes are set to 8

UP  0
    skprio: 0 (vlan 5)
UP  1
```

```
    skprio: 1 (vlan 5)
UP  2
    skprio: 2 (vlan 5 tos: 8)
UP  3
    skprio: 3 (vlan 5)
UP  4
    skprio: 4 (vlan 5 tos: 24)
UP  5
    skprio: 5 (vlan 5)
UP  6
    skprio: 6 (vlan 5 tos: 16)
UP  7
    skprio: 7 (vlan 5)
```

Additional Tools

tc tool compiled with the sch_mqprio module is required to support kernel v2.6.32 or higher. This is a part of iproute2 package v2.6.32-19 or higher. Otherwise, an alternative custom sysfs interface is available.

- mlnx_qos tool (package: ofed-scripts) requires python version 2.5 < = X
- tc_wrap.py (package: ofed-scripts) requires python version 2.5 < = X

5.6.2.2.2.7 Packet Pacing

ConnectX-4 and above devices allow packet pacing (traffic shaping) per flow. This capability is achieved by mapping a flow to a dedicated send queue and setting a rate limit on that Send queue.
Note the following:

- Up to 512 send queues are supported
- 16 different rates are supported
- The rates can vary from 1 Mbps to line rate in 1 Mbps resolution
- Multiple queues can be mapped to the same rate (each queue is paced independently)
- It is possible to configure rate limit per CPU and per flow in parallel

System Requirements

- Driver v3.3 or higher
- Linux kernel v4.1 or higher
- ConnectX-4 or ConnectX-4 Lx adapter cards with an official firmware version

Packet Pacing Configuration

> ⚠ This configuration is non-persistent and does not survive driver restart.

1. Firmware Activation:

   To activate Packet Pacing in the firmware:

   First, make sure MFT service (mst) is started:

   ```
   # mst start
   ```

   Then run:

```
#echo "MLNX_RAW_TLV_FILE" > /tmp/mlxconfig_raw.txt
#echo "0x00000004 0x0000010c 0x00000000 0x00000001" >> /tmp/mlxconfig_raw.txt
#yes | mlxconfig -d <mst_dev> -f /tmp/mlxconfig_raw.txt set_raw > /dev/null
#reboot /mlxfwreset
```

To deactivate Packet Pacing in the firmware, run:

```
#echo "MLNX_RAW_TLV_FILE" > /tmp/mlxconfig_raw.txt
#echo "0x00000004 0x0000010c 0x00000000 0x00000000" >> /tmp/mlxconfig_raw.txt
#yes | mlxconfig -d <mst_dev >-f /tmp/mlxconfig_raw.txt set_raw > /dev/null
#reboot /mlxfwreset
```

2. Driver Activation:
   There are two operation modes for Packet Pacing:

   a. Rate limit per CPU core:
      When XPS is enabled, traffic from a CPU core will be sent using the corresponding send queue. By limiting the rate on that queue, the transmit rate on that CPU core will be limited. For example:

      ```
      echo 300 > /sys/class/net/ens2f1/queues/tx-0/tx_maxrate
      ```

      In this case, the rate on Core 0 (tx-0) is limited to 300Mbit/sec.

   b. Rate limit per flow:

      i. The driver allows opening up to 512 additional send queues using the following command:

      ```
      ethtool -L ens2f1 other 1200
      ```

      In this case, 1200 additional queues are opened

      ii. Create flow mapping.
      Users can map a certain destination IP and/or destination layer 4 Port to a specific send queue. The match precedence is as follows:

      - IP + L4 Port
      - IP only
      - L4 Port only
      - No match (the flow would be mapped to default queues)

      To create flow mapping:
      Configure the destination IP. Write the IP address in hexadecimal representation to the relevant sysfs entry. For example, to map IP address 192.168.1.1 (0xc0a80101) to send queue 310, run the following command:

      ```
      echo 0xc0a80101 > /sys/class/net/ens2f1/queues/tx-310/flow_map/dst_ip
      ```

      To map Destination L4 3333 port (either TCP or UDP) to the same queue, run:

      ```
      echo 3333 > /sys/class/net/ens2f1/queues/tx-310/flow_map/dst_port
      ```

From this point on, all traffic destined to the given IP address and L4 port will be sent using send queue 310. All other traffic will be sent using the original send queue.

iii. Limit the rate of this flow using the following command:

```
echo 100 > /sys/class/net/ens2f1/queues/tx-310/tx_maxrate
```

⚠ Each queue supports only a single IP+Port combination.

5.6.2.2.3 Ethtool

Ethtool is a standard Linux utility for controlling network drivers and hardware, particularly for wired Ethernet devices. It can be used to:

- Get identification and diagnostic information
- Get extended device statistics
- Control speed, duplex, auto-negotiation and flow control for Ethernet devices
- Control checksum offload and other hardware offload features
- Control DMA ring sizes and interrupt moderation
- Flash device firmware using a .mfa2 image

Ethtool Supported Options

Options	Description
ethtool --set-priv-flags eth<x> <priv flag> <on/off>	Enables/disables driver feature matching the given private flag.
ethtool --show-priv-flags eth<x>	Shows driver private flags and their states (ON/OFF).
ethtool -a eth<x>	Queries the pause frame settings.
ethtool -A eth<x> [rx on|off] [tx on|off]	Sets the pause frame settings.
ethtool -c eth<x>	Queries interrupt coalescing settings.
ethtool -C eth<x> [pkt-rate-low N] [pkt-rate-high N] [rx-usecs-low N] [rx-usecs-high N]	Sets the values for packet rate limits and for moderation time high and low values.
ethtool -C eth<x> [rx-usecs N] [rx-frames N]	Sets the interrupt coalescing setting. rx-frames will be enforced immediately, rx-usecs will be enforced only when adaptive moderation is disabled. **Note**: usec settings correspond to the time to wait after the *last* packet is sent/received before triggering an interrupt.
ethtool -C eth<x> adaptive-rx on|off	Enables/disables adaptive interrupt moderation. By default, the driver uses adaptive interrupt moderation for the receive path, which adjusts the moderation time to the traffic pattern.

Options	Description
ethtool -C eth<x> adaptive-tx on|off	**Note**: Supported by mlx5e for ConnectX-4 and above adapter cards. Enables/disables adaptive interrupt moderation. By default, the driver uses adaptive interrupt moderation for the transmit path, which adjusts the moderation parameters (time/frames) to the traffic pattern.
ethtool -g eth<x>	Queries the ring size values.
ethtool -G eth<x> [rx <N>] [tx <N>]	Modifies the ring size.

ethtool -i eth<x>	Checks driver and device information.
	For example:
	`driver: mlx5_core`
	`version: 5.1-0.4.0`
	`firmware-version: 4.6.4046 (MT_QEMU000000)`
	`expansion-rom-version:`
	`bus-info: 0000:07:00.0`
	`supports-statistics: yes`
	`supports-test: yes`
	`supports-eeprom-access: no`
	`supports-register-dump: no`
	`supports-priv-flags: yes`

ethtool -k eth<x>	Queries the stateless offload status.
ethtool -K eth<x> [rx on|off] [tx on|off] [sg on|off] [tso on|off] [lro on|off] [gro on|off] [gso on|off] [rxvlan on|off] [txvlan on|off] [ntuple on/off] [rxhash on/off] [rx-all on/off] [rx-fcs on/off]	Sets the stateless offload status. TCP Segmentation Offload (TSO), Generic Segmentation Offload (GSO): increase outbound throughput by reducing CPU overhead. It works by queuing up large buffers and letting the network interface card split them into separate packets. Large Receive Offload (LRO): increases inbound throughput of high-bandwidth network connections by reducing CPU overhead. It works by aggregating multiple incoming packets from a single stream into a larger buffer before they are passed higher up the networking stack, thus reducing the number of packets that have to be processed. LRO is available in kernel versions < 3.1 for untagged traffic. Hardware VLAN insertion Offload (txvlan): When enabled, the sent VLAN tag will be inserted into the packet by the hardware. **Note**: LRO will be done whenever possible. Otherwise GRO will be done. Generic Receive Offload (GRO) is available throughout all kernels. Hardware VLAN Striping Offload (rxvlan): When enabled received VLAN traffic will be stripped from the VLAN tag by the hardware. RX FCS (rx-fcs): Keeps FCS field in the received packets.Sets the stateless offload status. RX FCS validation (rx-all): Ignores FCS validation on the received packets.
ethtool -l eth<x>	Shows the number of channels.

<table>
<tr><th>Options</th><th>Description</th></tr>
<tr><td>ethtool -L eth<x> [rx <N>] [tx <N>]</td><td>Sets the number of channels.
Notes:
This also resets the RSS table to its default distribution, which is uniform across the cores on the NUMA (non-uniform memory access) node that is closer to the NIC.
For ConnectX®-4 cards, use ethtool -L eth<x> combined <N> to set both RX and TX channels.</td></tr>
<tr><td>ethtool -m|--dump-module-eeprom eth<x> [raw on|off] [hex on|off] [offset N] [length N]</td><td>Queries/decodes the cable module eeprom information.</td></tr>
<tr><td>ethtool -p|--identify DEVNAME</td><td>Enables visual identification of the port by LED blinking [TIME-IN-SECONDS].</td></tr>
<tr><td>ethtool -p|--identify eth<x> <LED duration></td><td>Allows users to identify interface's physical port by turning the ports LED on for a number of seconds.
Note: The limit for the LED duration is 65535 seconds.</td></tr>
<tr><td>ethtool -S eth<x></td><td>Obtains additional device statistics.</td></tr>
<tr><td>ethtool -s eth<x> advertise <N> autoneg on</td><td>Changes the advertised link modes to requested link modes <N>
To check the link modes' hex values, run <code><man ethtool></code> and to check the supported link modes, run <code>ethtool eth<x></code>
For advertising new link modes, make sure to configure the entire bitmap as follows:<table><tr><td>200GAUI-4 / 200GBASE-CR4/KR4</td><td>0x7c000000000000000</td></tr><tr><td>100GAUI-2 / 100GBASE-CR2 / KR2</td><td>0x3E00000000000000</td></tr><tr><td>CAUI-4 / 100GBASE-CR4 / KR4</td><td>0xF000000000</td></tr><tr><td>50GAUI-1 / LAUI-1/ 50GBASE-CR / KR</td><td>0x1F0000000000000</td></tr><tr><td>50GAUI-2 / LAUI-2/ 50GBASE-CR2/KR2</td><td>0x10C00000000</td></tr><tr><td>XLAUI-4/XLPPI-4 // 40G</td><td>0x7800000</td></tr><tr><td>25GAUI-1/ 25GBASE-CR / KR</td><td>0x380000000</td></tr><tr><td>XFI / XAUI-1 // 10G</td><td>0x7C0000181000</td></tr><tr><td>5GBASE-R</td><td>0x1000000000000</td></tr><tr><td>2.5GBASE-X / 2.5GMII</td><td>0x820000000000</td></tr><tr><td>1000BASE-X / SGMII</td><td>0x20000020020</td></tr></table>Notes:
Both previous and new link modes configurations are supported, however, they must be run separately.
Any link mode configuration on Kernels below v5.1 and ConnectX-6 HCAs will result in the advertisement of the full capabilities.
<code><autoneg on></code> only sends a hint to the driver that the user wants to modify advertised link modes and not speed.</td></tr>
<tr><td>ethtool -s eth<x> msglvl [N]</td><td>Changes the current driver message level.</td></tr>
</table>

Options	Description
ethtool -s eth<x> speed <SPEED> autoneg off	Changes the link speed to requested <SPEED>. To check the supported speeds, run `ethtool eth<x>`. **Note**: <autoneg off> does not set autoneg OFF, it only hints the driver to set a specific speed.
ethtool -t eth<x>	Performs a self-diagnostics test.
ethtool -T eth<x>	Shows time stamping capabilities
ethtool -x eth<x>	Retrieves the receive flow hash indirection table.
ethtool -X eth<x> equal a b c...	Sets the receive flow hash indirection table. **Note**: The RSS table configuration is reset whenever the number of channels is modified (using ethtool -L command).
ethtool --show-fec eth<x>	Queries current Forward Error Correction (FEC) encoding in case FEC is supported. **Note**: An output of "baser" implies Firecode encoding.
ethtool --set-fec eth<x> encoding auto|off|rs|baser	Configures Forward Error Correction (FEC). **Note**: 'baser' encoding applies to the Firecode encoding, and 'auto' regards the HCA's default.
ethtool -f|--flash <devname> FILE [N]	Flash firmware image on the device using the specified .mfa2 file (FILE). By default, the command flashes all the regions on the device unless a region number (N) is specified.

5.6.2.2.4 Checksum Offload

The following "receive IP/L4 checksum offload" modes are supported.

- `CHECKSUM_UNNECESSARY` – When this mode is used, the driver indicates to the Linux networking stack that the hardware successfully validated the IP and L4 checksum so the Linux networking stack does not need to deal with IP/L4 checksum validation.
- `CHECKSUM_COMPLETE` – When this mode is used, the driver still reports to the OS the calculated by hardware checksum value. This allows accelerating checksum validation in Linux networking stack, since it does not have to calculate the whole checksum including payload by itself.
- `CHECKSUM_NONE` – When this mode is used, the driver indicates to the Linux networking stack that it must calculate and validate the IP/L4 checksum.

5.6.2.2.5 Ignore FCS Errors

Upon packet reception, the Frame Check Sequence (FCS) field undergoes checksum validation. If the validation fails, the packet is dropped.

When the FCS option is enabled (disabled by default), the device skips FCS validation, accepting packets regardless of whether the FCS is valid. This behavior can be useful in

specific diagnostic or experimental scenarios, but enabling FCS is generally not recommended for production environments.

To enable or disable FCS validation, use the `ethtool` option:

```
ethtool --offload <interface> rx-fcs on|off
```

5.6.2.2.6 RDMA over Converged Ethernet

Remote Direct Memory Access (RDMA) enables direct memory-to-memory data transfers between servers, bypassing CPU involvement. RoCE (RDMA over Converged Ethernet) extends RDMA functionality to lossless Ethernet networks, delivering high-throughput, ultra-low latency communication.

With advancements in reliable Ethernet technologies, the NVIDIA® ConnectX® Ethernet adapter family supports RDMA transport over 10GigE and 40GigE networks. By offloading RDMA services to hardware, these adapters significantly reduce CPU load and latency—making them ideal for performance-critical applications like financial systems, databases, storage, and content delivery networks.

5.6.2.2.6.1 Key Considerations for RoCE

When deploying RDMA applications over Ethernet, consider the following:

- No Subnet Manager (SM) – Unlike InfiniBand, RoCE does not require an SM. However, certain operations (e.g., multicast group joins) must be handled differently, even though the API remains unchanged.
- No LID (Local ID) – As LID is specific to InfiniBand, it is not set for RoCE ports and appears as zero in queries.
- No APM (Alternate Path Migration) – RoCE does not support APM, as it relies on InfiniBand-specific mechanisms.
- Manual Path Record Setup – Since path querying is not possible without an SM, users must manually populate the path record structure before establishing a connection. Using RDMA-CM is strongly recommended, as it automates path record handling.
- Priority Mapping via VLAN Tags – VLAN-tagged Ethernet frames use a 3-bit priority field derived from the 3 least significant bits of the InfiniBand Service Level (SL) field.
- RoCE Traffic Counters – RoCE traffic is offloaded by hardware and is not visible in standard Ethernet interface counters. Instead, RoCE traffic statistics can be found at:

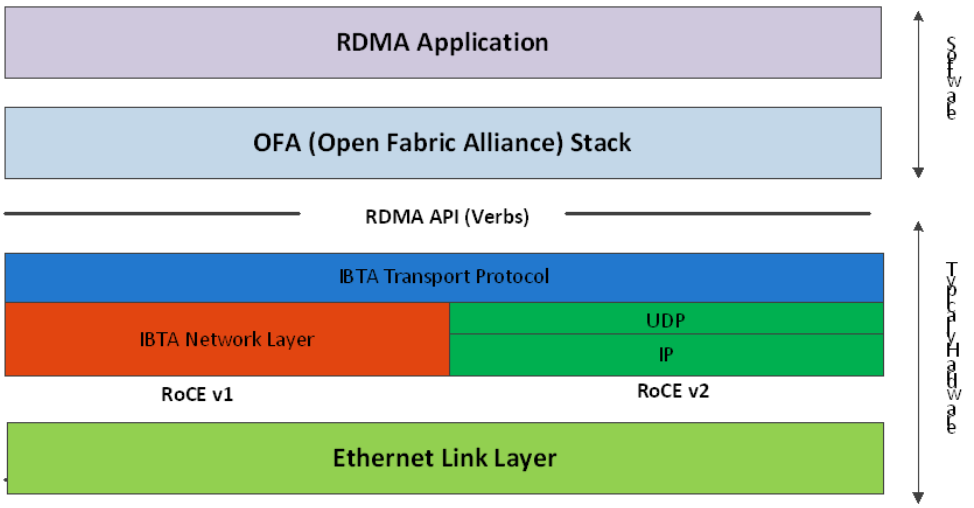
  ```
  /sys/class/infiniband/<device>/ports/<port number>/counters/
  ```

5.6.2.2.6.2 RoCE Modes

RoCE encapsulates IB transport in one of the following Ethernet packets:

- **RoCEv1** - uses a dedicated ethertype (`0x8915`)
- **RoCEv2** - encapsulates RDMA in UDP/IP packets, using UDP port `4791`

RoCEv1 and RoCEv2 Protocol Stack



RoCEv1

RoCEv1 uses a dedicated Ethernet EtherType (`0x8915`). It may include or omit VLAN tags and adheres to the standard Ethernet MTU. It is a Layer 2 protocol and is limited to communication within the same Ethernet broadcast domain.

RoCEv2

RoCEv2 extends RDMA to Layer 3 networks by encapsulating RDMA traffic in UDP/IP packets. This allows traffic to traverse IP routers and use standard IP routing. Key features include:

- IP Header – Enables routing across IP networks.
- UDP Header – Used for stateless encapsulation; destination port `4791` .
- Source Port Field – Can serve as an opaque flow ID to assist with ECMP (Equal-Cost Multi-Path) routing.

Since the packet format change occurs at the wire level and does not affect the RDMA API, applications can operate seamlessly over RoCEv1 or RoCEv2 without modification.

> ⚠ Both RoCEv1 and RoCEv2 are supported by default. The driver associates GID indexes with both modes, creating one entry per version.
>
> For deployment examples, see the Recommended Network Configuration Examples For RoCE Deployment community post.

5.6.2.2.6.3 GID Table Population

GID (Global Identifier) table entries are automatically created when an IP address is configured on an Ethernet device associated with a RoCE port. Each GID entry includes:

- GID value
- GID type (e.g., RoCEv1, RoCEv2)
- Associated network device

By default, each RoCE-capable port has two GID entries with the same value but different types (RoCEv1 and RoCEv2). GID format can be:

- IPv4 GID – An IPv4-mapped IPv6 address
- IPv6 GID – A native IPv6 address

The Layer 3 header depends on the GID type:

- For RoCEv2 – IPv4 or IPv6
- For RoCEv1 – Uses IPv4 GIDs as-is, with GRH if required

Accessing GID Table via Sysfs

The GID (Global Identifier) table is exposed to userspace via `sysfs` and provides details for each GID entry associated with a RoCE-capable port:

- GID value:

```
/sys/class/infiniband/{device}/ports/{port}/gids/{index}
```

- GID type (e.g., RoCEv1 or RoCEv2):

```
/sys/class/infiniband/{device}/ports/{port}/gid_attrs/types/{index}
```

- Associated network device:

```
/sys/class/infiniband/{device}/ports/{port}/gid_attrs/ndevs/{index}
```

Each file in this directory represents a GID index and contains the corresponding GID value.

Setting the RoCE Mode for a QP

For devices supporting both RoCEv1 and RoCEv2, selecting the desired mode depends on the Queue Pair (QP) type:

RC/UC QPs (Connected QPs)

To transition a connected QP from INIT to RTR state, you must provide an Address Vector (AV). Among its attributes, the AV must include the GID index from the port's GID table to define the source GID for the QP.

The GID type at the specified index will determine the RoCE mode (v1 or v2) for the QP.

UD QPs (Unconnected QPs)

UD QPs use GIDs for addressing, but since they are connectionless, setting the GID index in the AV similarly determines the RoCE version used for sending packets.

Setting RoCE Mode of RDMA_CM Applications

The `RDMA_CM` interface simplifies connection management by requiring only the active side to specify the IP address of the passive peer.

- The `RDMA_CM` stack selects a source GID from the local GID table.
- Since multiple entries may have the same GID value (but different types), the GID type must be specified for accurate lookup.

Configuring RDMA_CM GID Type

`RDMA_CM` uses a global module setting to determine which GID type to use when resolving the local GID. This can be controlled using the `cma_roce_mode` utility:

- To print current RoCE mode for a port:

```
cma_roce_mode -d <device> -p <port>
```

- To set RoCE mode (1 for RoCEv1, 2 for RoCEv2):

```
cma_roce_mode -d <device> -p <port> -m <1|2>
```

This affects `RDMA_CM` applications by defining how the source GID is selected during connection establishment.

GID Table Example

The following is an example of the GID table.

DEV	PORT	INDEX	GID	IPv4	Type	Netdev
`mlx5_0`	1	0	`fe80:0000:0000:0000:ba59:9fff:fe1a:e3ea`		v1	`p4p1`
`mlx5_0`	1	1	`fe80:0000:0000:0000:ba59:9fff:fe1a:e3ea`		v2	`p4p1`
`mlx5_0`	1	2	`0000:0000:0000:0000:0000:ffff:0a0a:0a01`	`10.10.10.1`	v1	`p4p1`
`mlx5_0`	1	3	`0000:0000:0000:0000:0000:ffff:0a0a:0a01`	`10.10.10.1`	v2	`p4p1`
`mlx5_1`	1	0	`fe80:0000:0000:0000:ba59:9fff:fe1a:e3eb`		v1	`p4p2`
`mlx5_1`	1	1	`fe80:0000:0000:0000:ba59:9fff:fe1a:e3eb`		v2	`p4p2`

Where:

- Entries on port 1 index 0/1 are the default GIDs, one for each supported RoCE type
- Entries on port 1 index 2/3 belong to IP address 192.168.1.70 on eth1
- Entries on port 1 index 4/5 belong to IP address 193.168.1.70 on eth1.100
- Packets from a QP that is associated with these GID indexes will have a VLAN header (VID=100)
- Entries on port 1 index 6/7 are IPv6 GID. Packets from a QP that is associated with these GID indexes will have an IPv6 header

5.6.2.2.6.4 RoCE Lossless Ethernet Configuration

To function reliably, RoCE requires a form of flow control. While it is possible to use global flow control, this is normally undesirable, for performance reasons.

The normal and optimal way to use RoCE is to use Priority Flow Control (PFC). To use PFC, it must be enabled on all endpoints and switches in the flow path.

5.6.2.2.6.5 Installing and Loading the Driver

To install and load the driver:

1. Install MLNX_OFED (See Installation section for further details).
   RoCE is installed as part of mlx5 and other modules upon driver's installation.

   > ⚠ The list of the modules that will be loaded automatically upon boot can be found in the configuration file `/etc/infiniband/openib.conf`.

2. Query for the device's information. Example:

```
ibv_devinfo MLNX_OFED_LINUX-5.0-2.1.8.0:
```

3. Display the existing MLNX_OFED version.

```
ofed_info -s
hca_id: mlx5_0
        transport:                      InfiniBand (0)
        fw_ver:                         16.28.0578
        node_guid:                      ec0d:9a03:0044:3764
        sys_image_guid:                 ec0d:9a03:0044:3764
        vendor_id:                      0x02c9
        vendor_part_id:                 4121
        hw_ver:                         0x0
        board_id:                       MT_0000000009
        phys_port_cnt:                  1
                port:   1
                        state:                  PORT_ACTIVE (4)
                        max_mtu:                4096 (5)
                        active_mtu:             1024 (3)
                        sm_lid:                 0
                        port_lid:               0
                        port_lmc:               0x00
                        link_layer:             Ethernet
```

Output notes:

The port's state is: Ethernet is in PORT_ACTIVE state	The port state can also be obtained by running the following command: `# cat /sys/class/infiniband/mlx5_0/ports/1/state: ACTIVE`
link_layer parameter shows that port 1 is Ethernet	The link_layer can also be obtained by running the following command: `# cat /sys/class/infiniband/mlx5_0/ports/1/ link_layer Ethernet`
The fw_ver parameter shows that the firmware version is 16.28.0578.	The firmware version can also be obtained by running the following command: `# cat /sys/class/infiniband/mlx5_0/fw_ver 16.28.0578`

Associating InfiniBand Ports to Ethernet Ports

The mlx5_ib driver holds a reference to the net device for getting notifications about the state of the port, as well as using the mlx5_core driver to resolve IP addresses to MAC that are required for address vector creation. However, RoCE traffic does not go through the mlx5_core driver; it is completely offloaded by the hardware.

```
# ibdev2netdev
mlx5_0 port 1 <===> eth2
#
```

Configuring an IP Address to the netdev Interface

To configure an IP address to the netdev interface:

1. Configure an IP address to the netdev interface on both sides of the link.

```
# ifconfig eth2 20.4.3.220
# ifconfig eth2
eth2    Link encap:Ethernet HWaddr 00:02:C9:08:E8:11
    inet addr:20.4.3.220 Bcast:20.255.255.255 Mask:255.0.0.0
    UP BROADCAST MULTICAST MTU:1500 Metric:1
    RX packets:0 errors:0 dropped:0 overruns:0 frame:0
    TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
    collisions:0 txqueuelen:1000
    RX bytes:0 (0.0 b) TX bytes:0 (0.0 b)
```

2. Make sure that ping is working.

```
ping 20.4.3.219
PING 20.4.3.219 (20.4.3.219) 56(84) bytes of data.
64 bytes from 20.4.3.219: icmp_seq=1 ttl=64 time=0.873 ms
64 bytes from 20.4.3.219: icmp_seq=2 ttl=64 time=0.198 ms
64 bytes from 20.4.3.219: icmp_seq=3 ttl=64 time=0.167 ms
20.4.3.219 ping statistics —
3 packets transmitted, 3 received, 0% packet loss, time 2000ms rtt min/avg/max/mdev = 0.167/0.412/0.873/
0.326 ms
```

Adding VLANs

To add VLANs:

1. Make sure that the 8021.q module is loaded.

```
modprobe 8021q
```

2. Add VLAN.

```
# vconfig add eth2 7
Added VLAN with VID == 7 to IF -:eth2:-
#
```

3. Configure an IP address.

```
ifconfig eth2.7 7.4.3.220
```

Defining Ethernet Priority (PCP in 802.1q Headers)

1. Define Ethernet priority on the server.

```
# ibv_rc_pingpong -g 1 -i 2 -l 4
local address: LID 0x0000, QPN 0x1c004f, PSN 0x9daf6c, GID fe80::202:c900:708:e799
remote address: LID 0x0000, QPN 0x1c004f, PSN 0xb0a49b, GID fe80::202:c900:708:e811
8192000 bytes in 0.01 seconds = 4840.89 Mbit/sec
1000 iters in 0.01 seconds = 13.54 usec/iter
```

2. Define Ethernet priority on the client.

```
# ibv_rc_pingpong -g 1 -i 2 -l 4 sw419
local address: LID 0x0000, QPN 0x1c004f, PSN 0xb0a49b, GID fe80::202:c900:708:e811
remote address: LID 0x0000, QPN 0x1c004f, PSN 0x9daf6c, GID fe80::202:c900:708:e799
8192000 bytes in 0.01 seconds = 4855.96 Mbit/sec
1000 iters in 0.01 seconds = 13.50 usec/iter
```

Using rdma_cm Tests

1. Use rdma_cm test on the server.

```
# ucmatose
cmatose: starting server
initiating data transfers
completing sends
receiving data transfers
data transfers complete
cmatose: disconnecting
disconnected
test complete
return status 0
#
```

2. Use rdma_cm test on the client.

```
# ucmatose -s 20.4.3.219
cmatose: starting client
cmatose: connecting
receiving data transfers
sending replies
data transfers complete
test complete
return status 0
#
```

This server-client run is without PCP or VLAN because the IP address used does not belong to a VLAN interface. If you specify a VLAN IP address, then the traffic should go over VLAN.

5.6.2.2.6.6 Type Of Service (ToS)

The TOS field for `rdma_cm` sockets can be set using the `rdma_set_option()` API, just as it is set for regular sockets. If a TOS is not set, the default value (0) is used.

ToS Kernel Implementation

Modern Linux kernels (v2.6.39+) no longer use hard-coded bit shifting to determine service levels. Instead, the kernel uses a two-step mapping process:

1. TOS to Linux Priority: The TOS byte is interpreted using RFC 1349 service bits to derive a Linux Socket Priority (`sk_prio`).
2. Linux Priority to Hardware Resources: The Linux Priority is then mapped to the InfiniBand SL and VLAN Priority Code Point (PCP).

Step 1: TOS to Linux Priority Mapping

The bit pattern extracted from the TOS value is mapped to a Linux priority as shown below:

TOS Value	Linux Priority	Traffic Class
0x0–0x6	0	Best Effort
0x8–0xE	2	Bulk Data
0x10–0x16	6	Interactive
0x18–0x1E	4	Interactive Bulk

Step 2: Priority to SL and PCP

Once the Linux Priority is determined, the hardware driver maps it to specific network headers based on the interface configuration:

- Service level (SL): The Linux Priority is mapped to an SL based on the `tc mqprio` configuration. If `mqprio` is not configured, the SL is derived from the VLAN device. If neither mapping is present, the SL defaults to 0. Note that this is independent of the hardware's priority-to-TC mapping.
- VLAN PCP: For traffic on a tagged VLAN interface, the PCP is determined by the `tc mqprio` configuration on the upper network device. If `mqprio` is not configured, the PCP is derived from the VLAN interface's egress map (configured via `ip link` or `vconfig`).

DSCP

A configuration entry exists in the RDMA-CM `configfs` that allows users to select a default TOS for RDMA-CM QPs. This is useful for users who want to control the TOS field without modifying their source code.

Applications that set the TOS explicitly using the `rdma_set_option` API will override the `configfs` value and continue to work as expected. For further information about DSCP marking, refer to the "HowTo Set Egress ToS/DSCP on RDMA CM QPs" community post.

5.6.2.2.6.7 RoCE LAG

RoCE LAG is a feature meant for mimicking Ethernet bonding for IB devices and is available for dual port cards only.
This feature is supported on kernel versions 4.9 and above.

RoCE LAG mode is entered when both Ethernet interfaces are configured as a bond in one of the following modes:

- active-backup (mode 1)
- balance-xor (mode 2)
- 802.3ad (LACP) (mode 4)

Any change of bonding configuration that negates one of the above rules (i.e, bonding mode is not 1, 2 or 4, or both Ethernet interfaces that belong to the same card are not the only slaves
of the bond interface), will result in exiting RoCE LAG mode and the return to normal IB device per port configuration.
Once RoCE LAG is enabled, instead of having two IB devices; mlx5_0 and mlx5_1, there will be one device named mlx5_bond_0.
For information on how to configure RoCE LAG, refer to HowTo Configure RoCE over LAG (ConnectX-4/ConnectX-5/ConnectX-6) Community post.

5.6.2.2.6.8 Disabling RoCE

By default, RoCE is enabled on all mlx5 devices. When RoCE is enabled, all traffic to UDP port 4791 is treated as RoCE traffic by the device.

In case you are only interested in Ethernet (no RDMA) and wish to enable forwarding of traffic to this port, you can disable RoCE through sysfs:

```
echo <0|1> > /sys/devices/{pci-bus-address}/roce_enable
```

> ⚠ Once RoCE is disabled, only Ethernet traffic will be supported. Therefore, there will be no GID tables and only Raw Ethernet QPs will be supported.

The current RoCE state can be queried by sysfs:

```
cat /sys/devices/{pci-bus-address}/roce_enable
```

5.6.2.2.6.9 Enabling/Disabling RoCE on VMs via VFs

By default, when configuring VFs on the hypervisor, all VFs will be enabled with RoCE. This means they require more OS memory (from the VM). In case you are only interested in Ethernet (no RDMA) on the VM, and you wish to save the VM memory, you can disable

RoCE on the VF from the hypervisor. In addition, by disabling RoCE, a VM can have the capability of utilizing the RoCE UDP port (4791) for standard UDP traffic.

For details on how to enable/disable RoCE on a VF, refer to HowTo Enable/Disable RoCE on VMs via VFs Community post.

5.6.2.2.6.10 Force DSCP

This feature enables setting a global traffic_class value for all RC QPs, or setting a specific traffic class based on several matching criteria.

Usage

- To set a single global traffic class to be applied to all QPs, write the desired global traffic_class value to /sys/class/infiniband/<dev>/tc/<port>/traffic_class.
  Note the following:
  - Negative values indicate that the feature is disabled. traffic_class value can be set using ibv_modify_qp()
  - Valid values range between 0 - 255

> ⚠ The ToS field is 8 bits, while the DSCP field is 6 bits. To set a DSCP value of X, you need to multiply this value by 4 (SHIFT 2). For example, to set DSCP value of 24, set the ToS bit to 96 (24x4=96).

- To set multiple traffic class values based on source and/or destination IPs, write the desired rule to /sys/class/infiniband/<dev>/tc/<port>/traffic_class. For example:

```
echo "tclass=16,src_ip=1.1.1.2,dst_ip=1.1.1.0/24" > /sys/class/infiniband/mlx5_0/tc/1/traffic_class
```

  Note: Adding "tclass" prefix to tclass value is optional.

In the example above, traffic class 16 will be set to any QP with source IP 1.1.1.2 and destination IP 1.1.1.0/24.
Note that when setting a specific traffic class, the following rule precedence will apply:

- If a global traffic class value is set, it will be applied to all QPs
- If no global traffic class value is set, and there is a rule with matching source and destination IPs applicable to at least one QP, it will be applied
- Rules only with matching source and/or destination IPs have no defined precedence over other rules with matching source and/or destination IPs

Notes:

- A mask can be provided when using destination IPv4 addresses
- The rule precedence is not affected by the order in which rules are inserted
- Overlapping rules are entirely up to the administrator.
- "tclass=-1" will remove the rule from the database

5.6.2.2.6.11 Force Time to Live (TTL)

This feature enables setting a global TTL value for all RC QPs.
Write the desired TTL value to /sys/class/infiniband/<dev>/tc/<port>/ttl. Valid values range between 0 - 255

5.6.2.2.7 Flow Control

5.6.2.2.7.1 Priority Flow Control (PFC)

Priority Flow Control (PFC) IEEE 802.1Qbb applies pause functionality to specific classes of traffic on the Ethernet link. For example, PFC can provide lossless service for the RoCE traffic and best-effort service for the standard Ethernet traffic. PFC can provide different levels of service to specific classes of Ethernet traffic (using IEEE 802.1p traffic classes).

Configuring PFC on ConnectX-4 and above

1. Enable PFC on the desired priority:

   ```
   mlnx_qos -i <ethX> --pfc <0/1>,<0/1>,<0/1>,<0/1>,<0/1>,<0/1>,<0/1>,<0/1>
   ```

   Example (Priority=4):

   ```
   mlnx_qos -i eth1 --pfc 0,0,0,0,1,0,0,0
   ```

2. Create a VLAN interface:

   ```
   vconfig add <ethX> <VLAN_ID>
   ```

   Example (VLAN_ID=5):

   ```
   vconfig add eth1 5
   ```

3. Set egress mapping:
   a. For Ethernet traffic:

      ```
      vconfig set_egress_map <vlan_einterface> <skprio> <up>
      ```

      Example (skprio=3, up=5):

      ```
      vconfig set_egress_map eth1.5 3 5
      ```

4. Create 8 Traffic Classes (TCs):

   ```
   tc_wrap.py -i <interface>
   ```

5. Enable PFC on the switch.
   For information on how to enable PFC on your respective switch, please refer to

Switch FC/PFC Configuration sections in the RDMA/RoCE Solutions Community page.

PFC Configuration Using LLDP DCBX

PFC Configuration on Hosts

PFC Auto-Configuration Using LLDP Tool in the OS

1. Start lldpad daemon on host.

```
lldpad -d
```

OR

```
service lldpad start
```

2. Send lldpad packets to the switch.

```
lldptool set-lldp -i <ethX>  adminStatus=rxtx
lldptool -T -i <ethX>   -V  sysName enableTx=yess
lldptool -T -i <ethX>   -V  portDesc enableTx=yess
lldptool -T -i <ethX>   -V  sysDesc enableTx=yess
lldptool -T -i <ethX>   -V sysCap enableTx=yess
lldptool -T -i <ethX>   -V mngAddr enableTx=yess
lldptool -T -i <ethX>   -V PFC enableTx=yes;
lldptool -T -I <ethX>   -V CEE-DCBX enableTx=yess
```

3. Set the PFC parameters.

   - For the CEE protocol, use dcbtool:

   ```
   dcbtool sc <ethX> pfc pfcup:<xxxxxxxx>
   ```

   Example:

   ```
   dcbtool sc eth6 pfc pfcup:01110001
   ```

   where:

[pfcup:xxxxxxxx]	Enables/disables priority flow control. From left to right (priorities 0-7) - x can be equal to either 0 or 1. 1 indicates that the priority is configured to transmit priority pause.

   - For IEEE protocol, use lldptool:

   ```
   lldptool -T -i <ethX> -V PFC enabled=x,x,x,x,x,x,x,x
   ```

   Example:

   ```
   lldptool -T -i eth2 -V PFC enabled=1,2,4
   ```

   where:

enabled	Displays or sets the priorities with PFC enabled. The set attribute takes a comma-separated list of priorities to enable, or the string none to disable all priorities.

PFC Auto-Configuration Using LLDP in the Firmware (for mlx5 driver)

There are two ways to configure PFC and ETS on the server:

1. **Local Configuration** - Configuring each server manually.
2. **Remote Configuration** - Configuring PFC and ETS on the switch, after which the switch will pass the configuration to the server using LLDP DCBX TLVs.
   There are two ways to implement the remote configuration using mlx5 driver:
   a. Configuring the adapter firmware to enable DCBX.
   b. Configuring the host to enable DCBX.

For further information on how to auto-configure PFC using LLDP in the firmware, refer to the HowTo Auto-Config PFC and ETS on ConnectX-4 via LLDP DCBX Community post.

PFC Configuration on Switches

1. In order to enable DCBX, LLDP should first be enabled:

```
switch (config) # lldp
show lldp interfaces ethernet remote
```

2. Add DCBX to the list of supported TLVs per required interface.
   For IEEE DCBX:

```
switch (config) # interface 1/1
switch (config interface ethernet 1/1) # lldp tlv-select dcbx
```

   For CEE DCBX:

```
switch (config) # interface 1/1
switch (config interface ethernet 1/1) # lldp tlv-select dcbx-cee
```

3. [**Optional**] Application Priority can be configured on the switch, with the required ethertype and priority. For example, IP packet, priority 1:

```
switch (config) # dcb application-priority 0x8100 1
```

4. Make sure PFC is enabled on the host (for enabling PFC on the host, refer to PFC Configuration on Hosts section above). Once it is enabled, it will be passed in the LLDP TLVs.
5. Enable PFC with the desired priority on the Ethernet port.

```
dcb priority-flow-control enable force
dcb priority-flow-control priority <priority> enable
interface ethernet <port> dcb priority-flow-control mode on force
```

   Example - Enabling PFC with priority 3 on port 1/1:

```
dcb priority-flow-control enable force
dcb priority-flow-control priority 3 enable
interface ethernet 1/1 dcb priority-flow-control mode on force
```

Priority Counters

Several ingress and egress counters per priority are supported. Run ethtool -S to get the full list of port counters.

ConnectX-4 Counters

- Rx and Tx Counters:
  - Packets
  - Bytes
  - Octets
  - Frames
  - Pause
  - Pause frames
  - Pause Duration
  - Pause Transition

Example

```
# ethtool -S eth35 | grep prio4
     prio4_rx_octets: 62147780800
     prio4_rx_frames: 14885696
     prio4_tx_octets: 0
     prio4_tx_frames: 0
     prio4_rx_pause: 0
     prio4_rx_pause_duration: 0
     prio4_tx_pause: 26832
     prio4_tx_pause_duration: 14508
     prio4_rx_pause_transition: 0
```

The Pause counters in ConnectX-4 are visible via ethtool only for priorities on which PFC is enabled.

PFC Storm Prevention

PFC storm prevention enables toggling between default and auto modes.
The stall prevention timeout is configured to 8 seconds by default. Auto mode sets the stall prevention timeout to be 100 msec.
The feature can be controlled using sysfs in the following directory: /sys/class/net/eth*/settings/ pfc_stall_prevention

- To query the PFC stall prevention mode:

  ```
  cat /sys/class/net/eth*/settings/pfc_stall_prevention
  ```

  Example

  ```
  $ cat /sys/class/net/ens6/settings/pfc_stall_prevention
  default
  ```

- To configure the PFC stall prevention mode:

  ```
  echo <option> /sys/class/net/<interface>/settings/pfc_stall_prevention
  ```

The following two counters were added to the ethtool -S:

- tx_pause_storm_warning_events - when the device is stalled for a period longer than a pre-configured watermark, the counter increases, allowing the debug utility an insight into current device status.
- tx_pause_storm_error_events - when the device is stalled for a period longer than a pre-configured timeout, the pause transmission is disabled, and the counter increase.

5.6.2.2.7.2 Dropless Receive Queue (RQ)

Dropless RQ feature enables the driver to notify the FW when SW receive queues are overloaded. This scenario takes place when the handling of SW receive queue is slower than the handling of the HW receive queues.
When this feature is enabled, a packet that is received while the receive queue is full will not be immediately dropped. The FW will accumulate these packets assuming posting of new WQEs will resume shortly. If received WQEs are not posted after a certain period of time, out_of_buffer counter will increase, indicating that the packet has been dropped.
This feature is disabled by default. In order to activate it, ensure that Flow Control feature is also enabled.

To enable the feature, run:

```
ethtool --set-priv-flags ens6 dropless_rq on
```

To get the feature state, run:

```
ethtool --show-priv-flags DEVNAME
```

Output example:

```
Private flags for DEVNAME:
rx_cqe_moder   : on
rx_cqe_compress: off
sniffer        : off
dropless_rq    : off
hw_lro         : off
```

To disable the feature, run:

```
ethtool --set-priv-flags ens6 dropless_rq off
```

5.6.2.2.8 Explicit Congestion Notification

Explicit congestion notification (ECN), an extension to the IP protocol, enables reliable communication by signaling congestion without dropping packets. To ensure reliable operation, all nodes along the communication path (including routers) must support ECN.

ECN is represented by two bits in the traffic control IP header and is implemented in this context for RoCE v2.

5.6.2.2.8.1 Enabling ECN

To enable ECN on the hosts:

1. Enable ECN in sysfs.

```
/sys/class/net/<interface>/ecn/<protocol>/enable/<X>
```

2. Query the attribute.

```
cat /sys/class/net/<interface>/ecn/<protocol>/params/<requested attribute>
```

3. Modify the attribute.

```
echo <value> /sys/class/net/<interface>/ecn/<protocol>/params/<requested attribute>
```

ECN supports the following algorithms:

- `r_roce_ecn_rp` - Reaction point
- `r_roce_ecn_np` - Notification point

Each algorithm has a set of relevant parameters and statistics, which are defined per device, per port, per priority.

To query whether ECN is enabled per Priority X:

```
cat /sys/class/net/<interface>/ecn/<protocol>/enable/X
```

To read ECN configurable parameters:

```
cat /sys/class/net/<interface>/ecn/<protocol>/requested attributes
```

To enable ECN for each priority per protocol:

```
echo 1 > /sys/class/net/<interface>/ecn/<protocol>/enable/X
```

To modify ECN configurable parameters:

```
echo <value> > /sys/class/net/<interface>/ecn/<protocol>/requested attributes
```

Where:

- X – priority {0..7}
- protocol – `roce_rp` ; `roce_np`
- Requested attributes – Next Slide for each protocol.

5.6.2.2.9 RSS Support

The device supports using XOR as the RSS distribution function, in addition to the default Toeplitz function.

The XOR function provides better distribution across the driver's receive queues for a small number of streams, ensuring each TCP/UDP stream is assigned to a different queue.

To switch between the Toeplitz and XOR RSS hash functions, use the `sysfs` interface at: `/sys/class/net/eth*/settings/hfunc`.

To query the operational and supported hash functions:

```
cat /sys/class/net/eth*/settings/hfunc
```

Example:

```
cat /sys/class/net/eth2/settings/hfunc
Operational hfunc: toeplitz
Supported hfuncs: xor toeplitz
```

To change the operational hash function:

```
echo xor > /sys/class/net/eth*/settings/hfunc
```

5.6.2.2.9.1 RSS Verbs Support

Receive Side Scaling (RSS) technology allows spreading incoming traffic between different receive descriptor queues. Assigning each queue to different CPU cores allows better load balancing of the incoming traffic and improves performance.
This technology was extended to user space by the verbs layer and can be used for RAW ETH QP.

5.6.2.2.9.2 RSS Flow Steering

Steering rules classify incoming packets and deliver a specific traffic type (e.g. TCP/UDP, IP only) or a specific flow to "RX Hash" QP. "RX Hash" QP is responsible for spreading the traffic it handles between the Receive Work Queues using RX hash and Indirection Table. The Receive Work Queue can point to different CQs that can be associated with different CPU cores.

5.6.2.2.9.3 Verbs

The following verbs should be used to achieve this task in both control and data path. Details per verb should be referenced from its man page.

- `ibv_create_wq`, `ibv_modify_wq`, `ibv_destory_wq`

- `ibv_create_rwq_ind_table`, `ibv_destroy_rwq_ind_table`
- `ibv_create_qp_ex` with specific RX configuration to create the "RX hash" QP

5.6.2.2.10 Time Stamping

Time stamping is the process of keeping track of the creation of a packet. A time-stamping service supports assertions of proof that a datum existed before a particular time. Incoming packets are time-stamped before they are distributed on the PCI depending on the congestion in the PCI buffers. Outgoing packets are time-stamped very close to placing them on the wire.

5.6.2.2.10.1 Configuring Time Stamping

Time stamping is off by default and should be enabled before use.

Enabling Time Stamping for Socket

To enable time stamping for a socket, call `setsockopt()` with `SO_TIMESTAMPING` and with the following flags:

`SOF_TIMESTAMPING_TX_HARDWARE`	Try to obtain send time-stamp in hardware
`SOF_TIMESTAMPING_TX_SOFTWARE`	If `SOF_TIMESTAMPING_TX_HARDWARE` is off or fails, then do it in software
`SOF_TIMESTAMPING_RX_HARDWARE`	Return the original, unmodified time-stamp as generated by the hardware
`SOF_TIMESTAMPING_RX_SOFTWARE`	If `SOF_TIMESTAMPING_RX_HARDWARE` is off or fails, then do it in software
`SOF_TIMESTAMPING_RAW_HARDWARE`	Return original raw hardware time-stamp
`SOF_TIMESTAMPING_SYS_HARDWARE`	Return hardware time-stamp transformed into the system time base
`SOF_TIMESTAMPING_SOFTWARE`	Return system time-stamp generated in software
`SOF_TIMESTAMPING_TX/RX`	Determine how time-stamps are generated
`SOF_TIMESTAMPING_RAW/SYS`	Determine how they are reported

Enabling Time Stamping for Network Device

To enable time stamping for a network device, admin privileged users may enable/disable time stamping through calling ioctl (sock, SIOCSH-WTSTAMP, &ifreq) with the following values:

- Send side time sampling, enabled by `ifreq.hwtstamp_config.tx_type` when:

```
/* possible values for hwtstamp_config->tx_type */
enum hwtstamp_tx_types {
        /*
         * No outgoing packet will need hardware time stamping;
         * should a packet arrive which asks for it, no hardware
         * time stamping will be done.
```

```
         */
        HWTSTAMP_TX_OFF,

        /*
         * Enables hardware time stamping for outgoing packets;
         * the sender of the packet decides which are to be
         * time stamped by setting %SOF_TIMESTAMPING_TX_SOFTWARE
         * before sending the packet.
         */
        HWTSTAMP_TX_ON,
/*
         * Enables time stamping for outgoing packets just as
         * HWTSTAMP_TX_ON does, but also enables time stamp insertion
         * directly into Sync packets. In this case, transmitted Sync
         * packets will not received a time stamp via the socket error
         * queue.
         */
        HWTSTAMP_TX_ONESTEP_SYNC,
};
Note: for send side time stamping currently only HWTSTAMP_TX_OFF and
HWTSTAMP_TX_ON are supported.
```

- Receive side time sampling, enabled by `ifreq.hwtstamp_config.rx_filter` when:

```
/* possible values for hwtstamp_config->rx_filter */
enum hwtstamp_rx_filters {
        /* time stamp no incoming packet at all */
        HWTSTAMP_FILTER_NONE,

        /* time stamp any incoming packet */
        HWTSTAMP_FILTER_ALL,
      /* return value: time stamp all packets requested plus some others */
        HWTSTAMP_FILTER_SOME,

        /* PTP v1, UDP, any kind of event packet */
        HWTSTAMP_FILTER_PTP_V1_L4_EVENT,
        /* PTP v1, UDP, Sync packet */
        HWTSTAMP_FILTER_PTP_V1_L4_SYNC,
        /* PTP v1, UDP, Delay_req packet */
        HWTSTAMP_FILTER_PTP_V1_L4_DELAY_REQ,
        /* PTP v2, UDP, any kind of event packet */
        HWTSTAMP_FILTER_PTP_V2_L4_EVENT,
        /* PTP v2, UDP, Sync packet */
        HWTSTAMP_FILTER_PTP_V2_L4_SYNC,
        /* PTP v2, UDP, Delay_req packet */
        HWTSTAMP_FILTER_PTP_V2_L4_DELAY_REQ,

        /* 802.AS1, Ethernet, any kind of event packet */
        HWTSTAMP_FILTER_PTP_V2_L2_EVENT,
        /* 802.AS1, Ethernet, Sync packet */
        HWTSTAMP_FILTER_PTP_V2_L2_SYNC,
        /* 802.AS1, Ethernet, Delay_req packet */
        HWTSTAMP_FILTER_PTP_V2_L2_DELAY_REQ,

        /* PTP v2/802.AS1, any layer, any kind of event packet */
        HWTSTAMP_FILTER_PTP_V2_EVENT,
        /* PTP v2/802.AS1, any layer, Sync packet */
        HWTSTAMP_FILTER_PTP_V2_SYNC,
        /* PTP v2/802.AS1, any layer, Delay_req packet */
        HWTSTAMP_FILTER_PTP_V2_DELAY_REQ,
};
Note: for receive side time stamping currently only HWTSTAMP_FILTER_NONE and
HWTSTAMP_FILTER_ALL are supported.
```

Getting Time Stamping

Once time stamping is enabled time stamp is placed in the socket Ancillary data. recvmsg() can be used to get this control message for regular incoming packets. For send time stamps the outgoing packet is looped back to the socket's error queue with the send time-stamp(s) attached. It can be received with recvmsg (`flags=MSG_ERRQUEUE`). The call returns the original outgoing packet data including all headers prepended down to and including the link layer, the `scm_time-stamping` control message and a `sock_extended_err` control message with `ee_errno==ENOMSG` and `ee_origin==SO_EE_ORIGIN_TIMESTAMPING`. A socket with such a pending bounced packet is ready for reading as far as select() is concerned. If the outgoing packet has to be fragmented, then only the first fragment is time stamped and returned to the sending socket.

⚠ When time stamping is enabled, VLAN stripping is disabled. For more info please refer to `Documentation/networking/timestamping.txt` in kernel.org.

⚠ On ConnectX-4 adapters and above, when time stamping is enabled, RX CQE compression is disabled (features are mutually exclusive).

Time Stamping Capabilities via ethtool

To display time-stamping capabilities via ethtool:

```
ethtool -T eth<x>
```

Example output:

```
ethtool -T eth0
Time stamping parameters for p2p1:
Capabilities:
                                hardware-transmit           (SOF_TIMESTAMPING_TX_HARDWARE)
                                software-transmit           (SOF_TIMESTAMPING_TX_SOFTWARE)
                                hardware-receive            (SOF_TIMESTAMPING_RX_HARDWARE)
                                software-receive            (SOF_TIMESTAMPING_RX_SOFTWARE)
                                software-system-clock       (SOF_TIMESTAMPING_SOFTWARE)
                                hardware-raw-clock          (SOF_TIMESTAMPING_RAW_HARDWARE)
PTP Hardware Clock: 1
Hardware Transmit Timestamp Modes:
off                              (HWTSTAMP_TX_OFF)
on                               (HWTSTAMP_TX_ON)

Hardware Receive Filter Modes:
none                            (HWTSTAMP_FILTER_NONE)
all                             (HWTSTAMP_FILTER_ALL)
```

For more details on PTP Hardware Clock, please refer to: https://www.kernel.org/doc/Documentation/ptp/ptp.txt

Steering PTP Traffic to Single RX Ring

As a result of Receive Side Steering (RSS) PTP traffic coming to UDP ports 319 and 320, it may reach the user space application in an out of order manner. In order to prevent this, PTP traffic needs to be steered to single RX ring using ethtool.

Example:

```
# ethtool -u ens7
8 RX rings available
Total 0 rules
# ethtool -U ens7 flow-type udp4 dst-port 319 action 0 loc 1
# ethtool -U ens7 flow-type udp4 dst-port 320 action 0 loc 0
# ethtool -u ens7
8 RX rings available
Total 2 rules
Filter: 0
Rule Type: UDP over IPv4
Src IP addr: 0.0.0.0 mask: 255.255.255.255
Dest IP addr: 0.0.0.0 mask: 255.255.255.255
TOS: 0x0 mask: 0xff
Src port: 0 mask: 0xffff
Dest port: 320 mask: 0x0
Action: Direct to queue 0
Filter: 1
Rule Type: UDP over IPv4
Src IP addr: 0.0.0.0 mask: 255.255.255.255
Dest IP addr: 0.0.0.0 mask: 255.255.255.255
TOS: 0x0 mask: 0xff
Src port: 0 mask: 0xffff
Dest port: 319 mask: 0x0
Action: Direct to queue 0
```

Tx Port Time Stamping

> ⚠ This feature is supported on ConnectX-6 Dx and above adapter cards only.

Transmitted packet time-stamping accuracy can be improved when using a timestamp generated at the port level instead of a timestamp generated upon CQE creation. Tx port time stamping better reflects the actual time of a packet's transmission.

Normal Send queues (SQs) are open with CQE time-stamp support. When this feature is enabled, the driver is expected to open extra Tx port time-stamped SQ per traffic class (TC).

The stream must meet the following conditions in order to be transmitted through a Tx port time-stamped SQ.

1. `SKBTX_HW_TSTAMP` flag was set at `tx_flag` (`SO_TIMESTAMPING` was set via `setsockopt()` or similarly)
2. Packet type is:
    - Non-IP, with EtherType of PTP over IEEE 802.3 (0x88f7); or
    - UDP over IPv4/IPv6

This feature is disabled by default in order to avoid extra SQ memory allocations. The feature can be enabled or disabled using the following command:

```
ethtool --set-priv-flags <ifs-name> tx_port_ts <on/off>
```

PTP Cyc2time Hardware Translation Offload

> ⚠ This feature is supported on ConnectX-6 Dx and above adapter cards only.

The device timestamp operates in one of two modes: real-time or free-running internal time.

- Free-Running Internal Time Mode – In this mode, the device clock cannot be edited. Driver or user space must adjust the timestamps to real-time nanoseconds.
- Real-Time Mode – In this mode, the hardware clock can be adjusted, providing timestamps already translated into real-time nanoseconds.

Both modes are global per device. Once a mode is configured, all clock-related features (e.g., PPS, CQE TS, PCIe BAR) operate exclusively with the selected clock mode.

By default, the hardware is set to free-running internal time mode. The driver adjusts the hardware real-time clock based on PTP daemon clock updates.

Only Physical Functions (PFs) can modify the hardware real-time clock. Adjustments from Virtual Functions (VFs) are ignored (treated as no-operations). If multiple PFs attempt to modify the clock, the device selects one as the designated clock provider. If

the designated provider fails to send updates within a specific period, the device may replace it with another PF. Other inputs during this period are also treated as no-operations.

Timestamp Format

CQE hardware timestamp format for ConnectX-6 Dx and ConnectX-6 Lx NICs is 64 bit, as follows:

```
{32bit sec, 32 bit nsec}
```

Configuration

To enable the feature:

1. Set `REAL_TIME_CLOCK_ENABLE` in `NV_CONFIG` via mlxconfig
2. Restart the driver.

Limitations

- Administrator must restart the driver and perform a FW reset for the configuration to take effect. Otherwise, mismatch between HW and driver timestamp mode might occur.
- Once real time mode is activated on a given device (see configuration section), version 5.3 or newer must run on all device functions. Any older driver running on a device function at this configuration will fail to open any traffic queues (RDMA or ETH), hence becoming dysfunctional.
- In real time mode, all device functions must be PTP-synchronized by a single clock domain—do not use multiple GMs for different functions on the same device.
- Regarding hardware clock ownership, the hardware is configured only from a single elected function; other function settings are ignored by the device. There is no indication as to which function is the hardware-clock's owner. After an internal timeout without modifying the hardware clock, a function losses the hardware-clock's ownership and is open to be grasped by any of the functions.
- All PFs/VFs within the same device must sync to the same 1588 master clock. If multiple masters are used, the device will use a single elected function. This might lead to wrong clock representation by device, wrong 1588 TLVs and hiccups on replacement of elected function.
- This feature is supported on ConnectX-6 Dx and above adapter cards only.

5.6.2.2.10.2 RoCE Time Stamping

RoCE time stamping allows you to stamp packets when they are sent to the wire/ received from the wire. The time-stamp is given in raw hardware cycles but could be easily converted into hardware referenced nanoseconds based time. Additionally, it enables you to query the hardware for the hardware time, thus stamp other application's event and compare time.

Query Capabilities

Time stamping is available if and only the hardware reports it is capable of reporting it. To verify whether RoCE time stamping is available, run `ibv_query_device_ex`.

For further information, please see ibv_query_device_ex manual page.

Creating a Time Stamping Completion Queue

To get time stamps, a suitable extended completion queue (CQ) must be created via a special call to ibv_create_cq_ex verb.

For further information, please see ibv_create_cq_ex manual page.

> ⚠ Time Stamping in not available when CQE zipping is used.

Querying the Hardware Time

Querying the hardware for time is done via the `ibv_query_rt_values_ex` verb. For example:

For further information, please see ibv_query_rt_values_ex manual page.

5.6.2.2.10.3 One Pulse Per Second (1PPS)

1PPS is a time synchronization feature that allows the adapter to be able to send or receive 1 pulse per second on a dedicated pin on the adapter card using an SMA connector (SubMiniature version A). Only one pin is supported and could be configured as 1PPS in or 1PPS out.

For further information, refer to HowTo Test 1PPS on NVIDIA Adapters Community post.

5.6.2.2.11 Flow Steering

Flow steering is a new model which steers network flows based on flow specifications to specific QPs. Those flows can be either unicast or multicast network flows. In order to maintain flexibility, domains and priorities are used. Flow steering uses a methodology of flow attribute, which is a combination of L2-L4 flow specifications, a destination QP and a priority. Flow steering rules may be inserted either by using ethtool or by using InfiniBand verbs. The verbs abstraction uses different terminology from the flow attribute (ibv_flow_attr), defined by a combination of specifications (struct ibv_flow_spec_*).

5.6.2.2.11.1 Flow Steering Support

All flow steering features are enabled in the supported adapter cards.

5.6.2.2.11.2 Flow Domains and Priorities

Flow steering defines the concept of domain and priority. Each domain represents a user agent that can attach a flow. The domains are prioritized. A higher priority domain will always supersede a lower priority domain when their flow specifications overlap. Setting a lower priority value will result in a higher priority.
In addition to the domain, there is a priority within each of the domains. Each domain can have at most 2^12 priorities in accordance with its needs.
The following are the domains at a descending order of priority:

- **User Verbs** allows a user application QP to be attached to a specified flow when using `ibv_create_flow` and `ibv_destroy_flow` verbs
  - `ibv_create_flow`

    ```
    struct ibv_flow *ibv_create_flow(struct ibv_qp *qp, struct ibv_flow_attr
    *flow)
    ```

    Input parameters:
    - `struct ibv_qp` - the attached QP.
    - `struct ibv_flow_attr` - attaches the QP to the flow specified. The flow contains mandatory control parameters and optional L2, L3 and L4 headers. The optional headers are detected by setting the size and `num_of_specs` fields:
      `struct ibv_flow_attr` can be followed by the optional flow headers structs:

      ```
      struct ibv_flow_spec_eth
      struct ibv_flow_spec_ipv4
      struct ibv_flow_spec_tcp_udp
      struct ibv_flow_spec_ipv6
      ```

      For further information, please refer to the `ibv_create_flow` man page.
  - `ibv_destroy_flow`

    ```
    int ibv_destroy_flow(struct ibv_flow *flow_id)
    ```

    Input parameters:
    `ibv_destroy_flow` requires struct `ibv_low` which is the return value of `ibv_create_flow` in case of success.
    Output parameters:
    Returns 0 on success, or the value of errno on failure.
    For further information, please refer to the `ibv_destroy_flow` man page.

5.6.2.2.11.3 Ethtool

Ethtool domain is used to attach an RX ring, specifically its QP to a specified flow. Please refer to the most recent ethtool man page for all the ways to specify a flow.

Examples:

- ethtool –U eth5 flow-type ether dst 00:11:22:33:44:55 loc 5 action 2
  All packets that contain the above destination MAC address are to be steered into rx-ring 2 (its underlying QP), with priority 5 (within the ethtool domain)
- ethtool –U eth5 flow-type tcp4 src-ip 1.2.3.4 dst-port 8888 loc 5 action 2
  All packets that contain the above destination IP address and source port are to be steered into rx- ring 2. When destination MAC is not given, the user's destination MAC is filled automatically.
- ethtool -U eth5 flow-type ether dst 00:11:22:33:44:55 vlan 45 m 0xf000 loc 5 action 2
  All packets that contain the above destination MAC address and specific VLAN are steered into ring 2. Please pay attention to the VLAN's mask 0xf000. It is required in order to add such a rule.
- ethtool –u eth5
  Shows all of ethtool's steering rule

When configuring two rules with the same priority, the second rule will overwrite the first one, so this ethtool interface is effectively a table. Inserting Flow Steering rules in the kernel requires support from both the ethtool in the user space and in kernel (v2.6.28).

5.6.2.2.11.4 Accelerated Receive Flow Steering (aRFS)

Receive Flow Steering (RFS) and Accelerated Receive Flow Steering (aRFS) are kernel features currently available in most distributions. For RFS, packets are forwarded based on the location of the application consuming the packet. aRFS boosts the speed of RFS by adding support for the hardware. By usingaRFS(unlike RFS), the packets are directed to a CPU that is local to the thread running the application.

aRFSis an in-kernel-logic responsible for load balancing between CPUs by attaching flows to CPUs that are used by flow's owner applications. This domain allows the aRFS mechanism to use the flow steering infrastructure to support the aRFS logic by implementing the ndo_rx_flow_steer, which, in turn, calls the underlying flow steering mechanism with the aRFS domain.

To configure RFS:

Configure the RFS flow table entries (globally and per core).
Note: The functionality remains disabled until explicitly configured (by default it is 0).

- The number of entries in the global flow table is set as follows:

/proc/sys/net/core/rps_sock_flow_entries

- The number of entries in the per-queue flow table are set as follows:

  /sys/class/net/<dev>/queues/rx-<n>/rps_flow_cnt

Example:

```
# echo 32768 > /proc/sys/net/core/rps_sock_flow_entries
# NUM_CHANNELS=`ethtool -l ens6 | grep "Combined:" | tail -1 | awk '{print $2}'`
# for f in `seq 0 $((NUM_CHANNELS-1))`; do echo 32768 > /sys/class/net/ens6/queues/rx-$f/rps_flow_cnt; done
```

To Configure aRFS:

The aRFS feature requires explicit configuration in order to enable it. Enabling the aRFS requires enabling the 'ntuple' flag via the ethtool.
For example, to enable ntuple for eth0, run:

```
ethtool -K eth0 ntuple on
```

aRFS requires the kernel to be compiled with the `CONFIG_RFS_ACCEL` option. This option is available in kernels 2.6.39 and above. Furthermore, aRFS requires Device Managed Flow Steering support.

RFS cannot function if LRO is enabled. LRO can be disabled via ethtool.

5.6.2.2.11.5 Flow Steering Dump Tool

The mlx_fs_dump is a python tool that prints the steering rules in a readable manner. Python v2.7 or above, as well as pip, anytree and termcolor libraries are required to be installed on the host.

Running example:

```
./ofed_scripts/utils/mlx_fs_dump -d /dev/mst/mt4115_pciconf0
FT: 9 (level: 0x18, type: NIC_RX)
+-- FG: 0x15 (MISC)
    |-- FTE: 0x0 (FWD) to (TIR:0x7e) out.ethtype:IPv4 out.ip_prot:UDP out.udp_dport:0x140
    +-- FTE: 0x1 (FWD) to (TIR:0x7e) out.ethtype:IPv4 out.ip_prot:UDP out.udp_dport:0x13f
...
```

For further information on the mlx_fs_dump tool, please refer to mlx_fs_dump Community post.

5.6.2.2.12 Wake-on-LAN

Wake-on-LAN (WoL) is a technology that allows a network professional to remotely power on a computer or to wake it up from sleep mode.

- To enable WoL:

```
ethtool -s <interface> wol g
```

- To get WoL:

```
ethtool <interface> | grep Wake-on Wake-on: g
```

Where `g` is the magic packet activity.

5.6.2.2.13 Q-in-Q Tunneling

Q-in-Q tunneling (hardware-accelerated 802.1ad VLAN) enables the creation of a Layer 2 Ethernet connection between two servers. It allows segregation of different VLAN traffic on a link or bundling multiple VLANs into a single VLAN. This is achieved by adding a service VLAN tag before the user's existing 802.1Q VLAN tags.

> For details on Q-in-Q support in virtualized environments (SR-IOV), refer to "Q-in-Q Encapsulation per VF in Linux".

To enable device support for accelerated 802.1ad VLAN:

1. Turn on the new ethtool private flag `phv-bit` (disabled by default).

```
$ ethtool --set-priv-flags eth1 phv-bit on
```

   Enabling this flag sets the `phv_en` port capability.

2. Change the interface device features by turning on the ethtool device feature `tx-vlan-stag-hw-insert` (disabled by default).

```
$ ethtool -K eth1 tx-vlan-stag-hw-insert on
```

   Once the private flag and the ethtool device feature are set, the device will be ready for 802.1ad VLAN acceleration.

> The `phv-bit` private flag setting is available for the PF only. The VF can use the VLAN acceleration by setting the `tx-vlan-stag-hw-insert` parameter only if the private flag `phv-bit` is enabled by the PF. If the PF enables/disables the `phv-bit` flag after the VF driver is up, the configuration will take place only after the VF driver is restarted.

5.6.2.2.14 VLAN Stripping in Linux Verbs

> This capability is now accessible from userspace using the verbs.

VLAN stripping adds access to the device's ability to offload the Customer VLAN (cVLAN) header stripping from an incoming packet, thus achieving acceleration of VLAN handing in receive flow.

It is configured per WQ option. You can either enable it upon creation or modify it later using the appropriate verbs (`ibv_create_wq` / `ibv_modify_wq`).

5.6.2.2.15 Offloaded Traffic Sniffer

> To be able to activate this feature, make sure libpcap library v1.9 or above is installed on your setup.
>
> To download libpcap, please visit https://www.tcpdump.org/.

Offloaded Traffic Sniffer allows bypass kernel traffic (such as RoCE, VMA, and DPDK) to be captured by existing packet analyzer, such as tcpdump.

To capture the interface's bypass kernel traffic, run tcpdump on the RDMA device.

For examples on how to dump RDMA traffic using the Inbox tcpdump tool for ConnectX-4 adapter cards and above, click here.

> Note that enabling Offloaded Traffic Sniffer can cause bypass kernel traffic speed degradation.

> In case you do not wish to install libpcap on your setup, you can use docker to run the tcpdump. For further information, please see https://hub.docker.com/r/mellanox/tcpdump-rdma.

5.6.2.2.16 Dump Configuration

This feature helps dumping driver and firmware configuration using ethtool. It creates a backup of the configuration files into a specified dump file.

5.6.2.2.16.1 Dump Parameters (Bitmap Flag)

The following bitmap parameters are used to set the type of dump. If a value is not set, the default value used is "0".

Bitmap Parameters

Value	Description
1	MST dump
2	Ring dump (Software context information for SQs, EQs, RQs, CQs)
3	MST dump + Ring dump (1+2)
4	Clear this parameter

5.6.2.2.16.2 Configuration

In order to configure this feature, follow the steps below:

1. Set the dump bitmap parameter by running -W (uppercase) with the desired bitmap parameter value (see Bitmap Parameters table above). In the following example, the bitmap parameter value is 3.

```
ethtool -W ens1f0 3
```

2. Dump the file by running -w (lowercase) with the desired configuration file name.

```
ethtool -w ens1f0 data /tmp/dump.bin
```

3. [**Optional**] To get the bitmap parameter value, version and size of the dump, run the command above without the file name.

```
ethtool -w ens1f0
flag: 3, version: 1, length: 4312
```

4. To open the dump file, run:

```
mlnx_dump_parser -f /tmp/dump.bin -m mst_dump_demo.txt -r ring_dump_demo.txt
Version: 1 Flag: 3 Number of blocks: 123 Length 327584
MCION module number: 0 status: | present |
DRIVER VERSION: 1-23 (03 Mar 2015)
DEVICE NAME 0000:81:00.0:ens1f0
Parsing Complete!
```

where:

-f	For the file to be parsed (the file that was just created)
-m	For the mst dump file

-r	For the ring dump file

For further information, refer to HowTo Dump Driver Configuration (via ethtool) Community post.

Output:

```
# mlnx_dump_parser -f /tmp/dump.bin -m mst_dump_demo.txt -r ring_dump_demo.txt
Version: 1 Flag: 3 Number of blocks: 123 Length 327584
MCION module number: 0 status: | present |
DRIVER VERSION: 1-23 (03 Mar 2015)
DEVICE NAME 0000:81:00.0:ens1f0
Parsing Complete!
```

5. Open the files.
   a. The MST dump file will look as follows. In order to analyze it, contact NVIDIA Support.

```
cat mst_dump_demo.txt
0x00000000 0x01002000
0x00000004 0x00000000
0x00000008 0x00000000
0x0000000c 0x00000000
0x00000010 0x00000000
0x00000014 0x00000000
0x00000018 0x00000000
...
```

   b. The Ring dump file can help developers debug ring-related issues, and it looks as follows:

```
# cat ring_dump_demo.txt
SQ TYPE: 3, WQN: 102, PI: 0, CI: 0, STRIDE: 6, SIZE: 1024...
SQ TYPE: 3, WQN: 102, PI: 0, CI: 0, STRIDE: 6, SIZE: 1024, WQE_NUM: 65536, GROUP_IP: 0
CQ TYPE: 5, WQN: 20, PI: 0, CI: 0, STRIDE: 6, SIZE: 1024, WQE_NUM: 1024, GROUP_IP: 0
RQ TYPE: 4, WQN: 103, PI: 15, CI: 0, STRIDE: 5, SIZE: 16, WQE_NUM: 512, GROUP_IP: 0
CQ TYPE: 5, WQN: 21, PI: 0, CI: 0, STRIDE: 6, SIZE: 16384, WQE_NUM: 16384, GROUP_IP: 0
EQ TYPE: 6, CI: 1, SIZE: 0, IRQN: 109, EQN: 19, NENT: 2048, MASK: 0, INDEX: 0, GROUP_ID: 0
SQ TYPE: 3, WQN: 106, PI: 0, CI: 0, STRIDE: 6, SIZE: 1024, WQE_NUM: 65536, GROUP_IP: 1
CQ TYPE: 5, WQN: 23, PI: 0, CI: 0, STRIDE: 6, SIZE: 1024, WQE_NUM: 1024, GROUP_IP: 1
RQ TYPE: 4, WQN: 107, PI: 15, CI: 0, STRIDE: 5, SIZE: 16, WQE_NUM: 512, GROUP_IP: 1
CQ TYPE: 5, WQN: 24, PI: 0, CI: 0, STRIDE: 6, SIZE: 16384, WQE_NUM: 16384, GROUP_IP: 1
EQ TYPE: 6, CI: 1, SIZE: 0, IRQN: 110, EQN: 20, NENT: 2048, MASK: 0, INDEX: 1, GROUP_ID: 1
SQ TYPE: 3, WQN: 110, PI: 0, CI: 0, STRIDE: 6, SIZE: 1024, WQE_NUM: 65536, GROUP_IP: 2
CQ TYPE: 5, WQN: 26, PI: 0, CI: 0, STRIDE: 6, SIZE: 1024, WQE_NUM: 1024, GROUP_IP: 2
RQ TYPE: 4, WQN: 111, PI: 15, CI: 0, STRIDE: 5, SIZE: 16, WQE_NUM: 512, GROUP_IP: 2
CQ TYPE: 5, WQN: 27, PI: 0, CI: 0, STRIDE: 6, SIZE: 16384, WQE_NUM: 16384, GROUP_IP: 2
...
```

5.6.2.2.17 Local Loopback Disable

Local Loopback Disable allows users to force the disablement of local loopback on the virtual port (vport). This disables both unicast and multicast loopback in the hardware.

- To enable Local Loopback Disable, run:

```
echo 1 > /sys/class/net/<ifname>/settings/force_local_lb_disable"
```

- To disable Local Loopback Disable, run:

```
echo 0 > /sys/class/net/<ifname>/settings/force_local_lb_disable"
```

When turned off, the driver configures the loopback mode according to its own logic.

5.6.2.2.18 kTLS Offloads

This feature is supported on NVIDIA® ConnectX®-6 Dx and NVIDIA® BlueField®-2 crypto devices onwards.

Transport Layer Security (TLS) is a widely-deployed protocol used for securing TCP connections on the Internet. TLS is also a required feature for HTTP/2, the latest web standard. Kernel implementation of TLS (kTLS) provides new opportunities for offloading the protocol into the hardware.

TLS data-path offload allows the NIC to accelerate encryption, decryption and authentication of AES-GCM. TLS offload handles data as it goes through the device without storing any data, but only updating context. If the packet cannot be encrypted/decrypted by the device, then a software fallback handles the packet.

5.6.2.2.18.1 Establishing a kTLS Connection

To avoid unnecessary complexity in the kernel, the TLS handshake is kept in the user space. A full TLS connection using the socket is done using the following scheme:

1. Call `connect()` or `accept()` on a standard TCP file descriptor.
2. Use a user space TLS library to complete a handshake.
3. Create a new KTLS socket file descriptor.
4. Extract the TLS Initialization Vectors (IVs), session keys, and sequence IDs from the TLS library. Use the `setsockopt` function on the kTLS file descriptor (FD) to pass them to the kernel.
5. Use standard `read()`, `write()`, `sendfile()` and `splice()` system calls on the KTLS FD.

Drivers can offer Tx and Rx packet encryption/decryption offload from the kernel into the NIC hardware. Upon receipt of a non-data TLS message (a control message), the kTLS socket returns an error, and the message is left on the original TCP socket instead. The kTLS socket is automatically unattached. Transfer of control back to the original encrypted FD is done by calling `getsockopt` to receive the current sequence numbers, and inserting them into the TLS library.

5.6.2.2.18.2 Kernel Support

For support in the kernel, make sure the following flags are set as follows.

- `CONFIG_TLS=y`
- `CONFIG_TLS_DEVICE=y | m`

For kTLS **Tx** device offloads with OFED drivers, kernel TLS module (kernel/net/tls) must be aligned to kernel v5.3 and above.

For kTLS **Rx** device offloads with OFED drivers, kernel TLS module (kernel/net/tls) must be aligned to kernel v5.9 and above.

5.6.2.2.18.3 Configuring kTLS Offloads

To enable kTLS Tx offload, run:

```
ethtool -K <ifs> tls-hw-tx-offload on
```

To enable kTLS Rx offload, run:

```
ethtool -K <ifs> tls-hw-rx-offload on
```

For further information on TLS offloads, please visit the following kernel documentation:

- Kernel TLS Offload
- Kernel TLS

5.6.2.2.18.4 OpenSSL with kTLS Offload

OpenSSL version 3.0.0 or above is required to support kTLS TX/RX offloads.

Supported OpenSSL version is available to download from distro packages, or can be downloaded and compiled from the OpenSSL github.

For a configuration example, please refer to the DOCA TLS Offload Guide.

5.6.2.2.19 IPsec Crypto Offload

This feature is supported on crypto-enabled products of NVIDIA® BlueField®-2 DPUs, and NVIDIA® ConnectX®-6 Dx and ConnectX-7 adapters (but not of ConnectX-6).

Newer/future crypto-enabled DPU and adapter product generations should also support the feature, unless explicitly stated in their documentation.

For BlueField-2 and ConnectX-6 Dx devices only: If your target application will utilize bandwidth of 100Gb/s or higher, where a substantial part of the bandwidth will be allocated for IPsec traffic, please refer to the *NVIDIA BlueField-2 DPUs Product Release Notes* or *NVIDIA ConnectX-6 Dx Adapters Product Release Notes* to learn about a potential bandwidth limitation. To access the relevant product release notes, please contact your NVIDIA sales representative.

IPsec crypto offload feature, also known as IPsec inline offload or IPsec aware offload feature enables the user to offload IPsec crypto encryption and decryption operations to the hardware.

The hardware implementation only supports AES-GCM encryption scheme.

5.6.2.2.19.1 Enabling IPsec Crypto Offload

To enable the feature, support in both kernel and adapter firmware is required.

- To add IPsec crypto offload support in the kernel, set the following flags accordingly:

```
CONFIG_XFRM_OFFLOAD=y
CONFIG_INET_ESP_OFFLOAD=m
CONFIG_INET6_ESP_OFFLOAD=m
```

  These flags are enabled by default in RedHat 8 and Ubuntu 18.04.0.

- To check whether IPsec crypto offload is supported in firmware, look for the following string in the dmesg:

```
mlx5e: IPSec ESP acceleration enabled
```

5.6.2.2.19.2 Configuring Security Associations for IPsec Offloads

To program the inline offload security associations (SA), add the option `offload dev <netdev interface> dir out/in` in the `ip xfrm state` command for transmitting and receiving SA.

- Transmit inline offload SA xfrm command example:

```
sudo ip xfrm state add src 192.168.1.64/24 dst 192.168.1.65/24 proto esp spi 0x46dc6204 reqid 0x46dc6204
 mode transport aead 'rfc4106(gcm(aes))'
0x60bd6c3eafba371a46411830fd56c53af93883261ed1fb26767820ff493f43ba35b0dcca 128 offload dev p4p1 dir out sel
src 192.168.1.64 dst 192.168.1.65
```

- Receive inline offload SA xfrm command example:

```
sudo ip xfrm state add src 192.168.1.65/24 dst 192.168.1.64/24 proto esp spi 0xaea0846c reqid 0xaea0846c
 mode transport aead 'rfc4106(gcm(aes))'
0x81d5c3167c912c1dd50dab0cb4b6d815b6ace8844304db362215a258cd19deda8f89deda 128 offload dev p4p1 dir in sel
src 192.168.1.65 dst 192.168.1.64
```

Example of setting xfrm policies:

- First server:

```
+ sudo ip xfrm state add src 192.168.1.64/24 dst 192.168.1.65/24 proto esp spi 0x28f39549 reqid 0x28f39549
 mode transport aead 'rfc4106(gcm(aes))'
0x492e8ffe718a95a00c1893ea61afc64997f4732848ccfe6ea07db483175cb18de9ae411a 128 offload dev enp4s0 dir out
sel src 192.168.1.64 dst 192.168.1.65
+ sudo ip xfrm state add src 192.168.1.65/24 dst 192.168.1.64/24 proto esp spi 0x622a73b4 reqid 0x622a73b4
 mode transport aead 'rfc4106(gcm(aes))'
0x093bfee2212802d626716815f862da31bcc7d9c44cfe3ab8049e7604b2feb1254869d25b 128 offload dev enp4s0 dir in
sel src 192.168.1.65 dst 192.168.1.64
+ sudo ip xfrm policy add src 192.168.1.64 dst 192.168.1.65 dir out tmpl src 192.168.1.64/24 dst
192.168.1.65/24 proto esp reqid 0x28f39549 mode transport
+ sudo ip xfrm policy add src 192.168.1.65 dst 192.168.1.64 dir in tmpl src 192.168.1.65/24 dst
192.168.1.64/24 proto esp reqid 0x622a73b4 mode transport
+ sudo ip xfrm policy add src 192.168.1.65 dst 192.168.1.64 dir fwd tmpl src 192.168.1.65/24 dst
192.168.1.64/24 proto esp reqid 0x622a73b4 mode transport
```

- Second server:

```
+ ssh -A -t root@1-csi-0921d /bin/bash
+ set -e
+ '[' 0 == 1 ']'
+ sudo ip xfrm state add src 192.168.1.64/24 dst 192.168.1.65/24 proto esp spi 0x28f39549 reqid 0x28f39549
 mode transport aead 'rfc4106(gcm(aes))'
0x492e8ffe718a95a00c1893ea61afc64997f4732848ccfe6ea07db483175cb18de9ae411a 128 offload dev enp4s0 dir in
sel src 192.168.1.64 dst 192.168.1.65
+ sudo ip xfrm state add src 192.168.1.65/24 dst 192.168.1.64/24 proto esp spi 0x622a73b4 reqid 0x622a73b4
 mode transport aead 'rfc4106(gcm(aes))'

sel src 192.168.1.65 dst 192.168.1.64
+ sudo ip xfrm policy add src 192.168.1.65 dst 192.168.1.64 dir out tmpl src 192.168.1.65/24 dst
192.168.1.64/24 proto esp reqid 0x622a73b4 mode transport
+ sudo ip xfrm policy add src 192.168.1.64 dst 192.168.1.65 dir in tmpl src 192.168.1.64/24 dst
192.168.1.65/24 proto esp reqid 0x28f39549 mode transport
+ sudo ip xfrm policy add src 192.168.1.64 dst 192.168.1.65 dir fwd tmpl src 192.168.1.64/24 dst
192.168.1.65/24 proto esp reqid 0x28f39549 mode transport
+ echo 'IPSec tunnel configured successfully'
```

5.6.2.2.20 IPsec Packet Offload

⚠ This feature is supported on crypto-enabled products of BlueField-2 DPUs, as well as on ConnectX-6 Dx, ConnectX-6 Lx and ConnectX-7 adapter cards. Note that it is not supported on ConnectX-6 cards.

Newer/future crypto-enabled DPU and adapter product generations should also support this feature, unless explicitly stated otherwise in their documentation.

⚠ When using NVIDIA® BlueField®-2 DPUs and NVIDIA® ConnectX®-6 Dx adapters only: If your target application utilizes 100Gb/s or a higher bandwidth, where a substantial part of the bandwidth is allocated for IPsec traffic, please refer to the relevant DPU or adapter card Product Release Notes to learn about a potential bandwidth limitation. To access the Release Notes, visit NVIDIA Networking's documentation website, or contact your NVIDIA sales representative.

⚠ ConnectX-6 Dx adapters only support Full Offload: Encrypted Overlay (where a Hypervisor controls IPsec offload - See for example OVS IPsec - https://docs.openvswitch.org/en/latest/tutorials/ipsec/) in a Linux OS with NVIDIA drivers.

⚠ This feature requires Linux kernel v6.6, or higher.

⚠ IPsec tunnel mode is supported in alpha-level when controlled by VM (VF capability) only.

This feature is designed to enable IPsec full offload in switchdev mode. The `ip-xfrm` command is used to configure IPsec states and policies, and it is similar to legacy mode configuration. However, there are several limitations to the use of full offload in this mode:

1. Only IPsec Transport Mode and Tunnel Mode are supported.
2. The first IPsec TX state/policy is not allowed to be offloaded if any offloaded TC rule exists, and the same applies for the first RX state/policy. More specifically, IPsec RX/TX tables must be created before offloading any TC rule. For this reason, it is a common practice to configure IPsec rules before adding any TC rule.

Following is an example for IPsec configuration with a VXLan tunnel:

- Enable switchdev mode:

```
echo 1 > /sys/class/net/$PF0 /device/sriov_numvfs
echo 0000:08:00.2 > /sys/bus/pci/drivers/mlx5_core/unbind
devlink dev param set pci/0000:08:00.0 name flow_steering_mode value dmfs cmode runtime
devlink dev eswitch set pci/0000:08:00.0 mode switchdev
echo 0000:08:00.2 > /sys/bus/pci/drivers/mlx5_core/bind
```

- Configure PF/VF/REP netdevices, and place a VF in a namespace:

```
ifconfig $PF $LOCAL_TUN/16 up
ip l set dev $PF mtu 2000

ifconfig $REP up
ip netns add ns0
ip link set dev $VF netns ns0
ip netns exec ns0 ifconfig $VF $IP/16 up
```

- Configure IPsec states and policies:

```
ip xfrm state add src $LOCAL_TUN/16 dst $REMOTE_IP/16 proto esp spi 0xb29ed314 reqid 0xb29ed314 mode
transport aead 'rfc4106(gcm(aes))' 0x20f01f80a26f633d85617465686c32552c92c42f 128 offload packet dev $PF
dir out sel src $LOCAL_TUN/16 dst $REMOTE_IP/16 flag esn replay-window 64
ip xfrm state add src $REMOTE_IP/16 dst $LOCAL_TUN/16 proto esp spi 0xc35aa26e reqid 0xc35aa26e mode
transport aead 'rfc4106(gcm(aes))' 0x6cb228189b4c6e82e66e46920a2cde39187de4ba 128 offload packet dev $PF
dir in sel src $REMOTE_IP/16 dst $LOCAL_TUN/16 flag esn replay-window 64

ip xfrm policy add src $LOCAL_TUN dst $REMOTE_IP offload packet dev $PF dir out tmpl src $LOCAL_TUN/16 dst
$REMOTE_IP/16 proto esp reqid 0xb29ed314 mode transport priority 12
ip xfrm policy add src $REMOTE_IP dst $LOCAL_TUN offload packet dev $PF dir in tmpl src $REMOTE_IP/16 dst
$LOCAL_TUN/16 proto esp reqid 0xc35aa26e mode transport priority 12
```

- Configure Openvswitch:

```
ovs-vsctl add-br br-ovs
ovs-vsctl add-port br-ovs $REP
ovs-vsctl add-port br-ovs vxlan1 -- set interface vxlan1 type=vxlan options:local_ip=$LOCAL_TUN
options:remote_ip=$REMOTE_IP options:key=$VXLAN_ID options:dst_port=4789
```

5.6.2.2.20.1 IPsec Full Offload for RDMA Traffic

This IPsec Full Offload for RDMA Traffic option provides a significant performance improvement compared to the software IPsec counterpart, and enables the use of IPsec over RoCE packets, which are outside the network stack and cannot be used without full hardware offload. As a result, users can leverage the benefits of the IPsec protocol with RoCE V2, even when using SR-IOV VFs.

The configuration steps for this feature should be identical to the steps mentioned above, but if this feature is supported, the traffic that will be sent can also be RoCEV2 IPsec traffic.

To configure this feature:

1. Enable IPsec over VF. For more information, please see IPsec Functionality.
2. Configure IPsec policies and states on the relevant VF net device. This should be identical to the software configuration of IPsec rules, which can be done using one of the following implementation options:

Command	Offload Request Parameter
iproute2 ip xfrm	offload packet
libreswan	nic-offload=packet
strongswan [1]	

1. For an example of using strongSwan configuration, refer to the DOCA East-West Overlay Encryption Application.

4. Configure an SR-IOV VF normally, and add its OVS/TC rules.

> ⚠ For this feature to work, DMFS steering mode must be enabled.

- The following is a full minimalistic configuration example using iproute, whereas PF0 is the netdevice PF, F0_REP is the VF representor, and NIC is the VF netdevice to configure IPsec over:

```
1.  echo 1 > /sys/class/net/$PF0 /device/sriov_numvfs
2.  echo 0000:08:00.2 > /sys/bus/pci/drivers/mlx5_core/unbind
3.  devlink dev eswitch set pci/0000:08:00.0 mode switchdev
4.  devlink dev param set pci/0000:08:00.0 name flow_steering_mode value dmfs cmode runtime
5.  devlink port function set pci/0000:08:00.0/1 ipsec_packet enable
6.  echo 0000:08:00.2 > /sys/bus/pci/drivers/mlx5_core/bind
7.  tc qdisc add dev $PF0 ingress
tc qdisc add dev $VF0_REP ingress
tc filter add dev $PF0 parent ffff: protocol 802.1q chain 0 flower vlan_id 10 vlan_ethtype 802.1q cvlan_id
5 action vlan pop action vlan pop  action mirred egress redirect dev $VF0_REP

tc filter add dev $VF0_REP parent ffff: protocol all chain 0 flower action vlan push protocol 802.1q id 5
 action vlan push protocol 802.1q id 10 action mirred egress redirect dev $PF0

8.  ifconfig $PF0 $PF_IP/24 up
ifconfig $NIC $LOC_IP/$SUB_NET up
```

```
ip link set dev $VF_REP up
9.  ip  xfrm state flush
ip  xfrm policy flush
```

- Configure IPsec states and policies:

```
#states
ip  -4 xfrm state add src $LOC_IP/$SUB_NET dst $REMOTE_IP/$SUB_NET proto esp spi 1000 reqid 10000 aead
'rfc4106(gcm(aes))' 0x010203047aeaca3f87d060a12f4a4487d5a5c335 128 mode transport sel src $LOC_IP dst
$REMOTE_IP offload packet dev $NIC dir out
ip  -4 xfrm state add src $REMOTE_IP/$SUB_NET dst $LOC_IP/$SUB_NET proto esp spi 1001 reqid 10001 aead
'rfc4106(gcm(aes))' 0x010203047aeaca3f87d060a12f4a4487d5a5c335 128 mode transport sel src $REMOTE_IP dst
$LOC_IP offload packet dev $NIC dir in
#policies
ip  -4 xfrm policy add src $LOC_IP dst $REMOTE_IP offload packet dev $NIC dir out tmpl src $LOC_IP/$SUB_NET
dst $REMOTE_IP/$SUB_NET proto esp reqid 10000 mode transport
ip  -4 xfrm policy add src $REMOTE_IP dst $LOC_IP offload packet dev $NIC dir in tmpl src $REMOTE_IP/
$SUB_NET dst $LOC_IP/$SUB_NET proto esp reqid 10001 mode transport
ip  -4 xfrm policy add src $REMOTE_IP dst $LOC_IP dir fwd tmpl src $REMOTE_IP/$SUB_NET dst $LOC_IP/$SUB_NET
proto esp reqid 10001 mode transport
```

Note that the configuration above is for one side only, yet IPsec must be configured for both sides in order for them to communicate properly. The configuration for the other side should be almost identical, but Step 9 would be configured in an asymmetrical way, meaning the first policy would look the following, and all other states/policies would be adjusted accordingly:

```
ip -4 xfrm state add src $LOC_IP/$SUB_NET dst $REMOTE_IP/$SUB_NET proto esp spi 1001 reqid 10001 aead
'rfc4106(gcm(aes))' 0x010203047aeaca3f87d060a12f4a4487d5a5c335 128 mode transport sel src $LOC_IP dst $REMOTE_IP
offload packet dev $NIC dir out
```

Once this step is completed, you can send any RoCE traffic of your choice between the two machines with configured IPsec. For example, `ibv_rc_pingpong -g 3 -d VF_device :` on one side, and `ibv_rc_pingpong -g 3 -d VF_device $IP_OF_OTHER_SIDE :` on the other side.

Finally, you can verify that the traffic was encrypted using IPsec by using the ipsec counters:

```
ethtool -S VF_NETDEV | grep ipsec
```

5.6.2.2.21 MACsec Full Offload

> ⚠ MACsec full offload is supported at alpha level only.

MACsec Full offload feature, also known as MACsec inline Full offload, enables the user to offload MACsec crypto encryption and decryption, MACsec headers encapsulation and decapsulation, and Anti replay operations to the hardware.

> ⚠ Hardware implementation supports GCM-AES & GCM-AES-XPN encryption schemes and is supported with ConnectX-7 onwards.

⚠ MACsec introduced in MOFED v5.9 requires a minimal Kernel version of 6.1.

To enable the feature, support in both kernel and adapter firmware is required.

For support in the kernel, make sure the following flags are set as follows:

- `CONFIG_MACSEC=y`
- `CONFIG_MLX5_EN_MACSEC=y`

For support in firmware, use version xx.34.0364 and up.

5.6.2.2.21.1 Configurations

IProute2 Configuration

Configuring Physical Interface

- Client side:

```
ip address flush <physical_device>
ip address add <client_physical_device_ip> dev <physical interface>
ip link set dev <physical_device> up
```

- Server side:

```
ip address flush <physical_device>
ip address add <server_physical_device_ip> dev <physical interface>
ip link set dev <physical_device> up
```

Add MACsec Device

- Client side:

```
ip link add link <physical_device> <macsec_device> type macsec sci <client_sci> client on
```

- Server side:

```
ip link add link <physical_device> <macsec_device> type macsec sci <server_sci> client on
```

Offload MACsec Device

- Client side:

```
ip macsec offload <macsec_device> mac
```

- Server side:

```
ip macsec offload <macsec_device> mac
```

Add MACsec rules:

- Client side:

```
ip macsec add <macsec_device> tx sa <sa_num>pn <inital_packet_number>on key <client_key_id> <client_key>
ip macsec add <macsec_device> rx sci <server_sci> on
ip macsec add <macsec_device> rx sci <server_sci>sa <sa_num> pn <inital_packet_number> on key
<server_key_id> <server_key>
```

- Server side:

```
ip macsec add <macsec_device> tx sa <sa_num>pn <inital_packet_number>on key <server_key_id> <server_key>
ip macsec add <macsec_device> rx sci <client_sci> on
ip macsec add <macsec_device> rx sci <client_sci>sa <sa_num> pn <inital_packet_number> on key
<client_key_id> <client_key>
```

Configure MACsec device IPs:

- Client side:

```
ip address flush <macsec_device>
ip address add <client_macsec_device_ip> dev <macsec_device>
ip link set dev <macsec_device> up
```

- Server side:

```
ip address flush <macsec_device>
ip address add <server_macsec_device_ip> dev <macsec_device>
ip link set dev <macsec_device> up
```

Configuration Example

Client side:

```
ip address flush enp8s0f0
ip address add 1.1.1.1/24 dev enp8s0f0
ip link set dev enp8s0f0 up
ip link add link enp8s0f0 macsec0 type macsec sci 1 encrypt on
ip macsec offload macsec0 mac
ip macsec add macsec0 tx sa 0 pn 1 on key 00 dffafc8d7b9a43d5b9a3dfbbf6a30c16
ip macsec add macsec0 rx sci 2 on
ip macsec add macsec0 rx sci 2 sa 0 pn 1 on key 00 ead3664f508eb06c40ac7104cdae4ce5
ip address flush macsec0
ip address add 2.2.2.1/24 dev macsec0
ip link set dev macsec0 up
```

Server side:

```
ip link del macsec0
ip address flush enp8s0f0
ip address add 1.1.1.2/24 dev enp8s0f0
ip link set dev enp8s0f0 up
ip link add link enp8s0f0 macsec0 type macsec sci 2 encrypt on
ip macsec offload macsec0 mac
ip macsec add macsec0 tx sa 0 pn 1 on key 00 ead3664f508eb06c40ac7104cdae4ce5
ip macsec add macsec0 rx sci 1 on
ip macsec add macsec0 rx sci 1 sa 0 pn 1 on key 00 dffafc8d7b9a43d5b9a3dfbbf6a30c16
ip address flush macsec0
ip address add 2.2.2.2/24 dev macsec0
ip link set dev macsec0 up
```

Use `ip macsec show` command to check configuration.

To verify traffic is offloaded, check MACsec counters by running `ethtool -S <physical_device> | grep macsec`.

Refer to the Linux Manual page for more information.

5.6.2.3 DPU

This section contains the following pages:

- QoS Configuration
- Shared RQ Mode

5.6.2.3.1 QoS Configuration

To learn more about port QoS configuration, refer to this community post.

When working in Embedded Host mode, using `mlnx_qos` on both the host and Arm will result with undefined behavior. Users must only use `mlnx_qos` from the Arm. After changing the QoS settings from Arm, users must restart the mlx5 driver on host.

When configuring QoS using DCBX, the `lldpad` service from the NVIDIA® BlueField® networking platform's (DPU or SuperNIC) side must be disabled if the configurations are not done using tools other than `lldpad`.

This section explains how to configure QoS group and settings using devlink located under `/opt/mellanox/iproute2/sbin/`. It is applicable to host PF/VF and Arm side SFs. The following uses VF as example.

The settings of a QoS group include creating/deleting a QoS group and modifying its `tx_max` and `tx_share` values. The settings of VF QoS include modifying its `tx_max` and `tx_share` values, assigning a VF to a QoS group, and unassigning a VF from a QoS group. This section focuses on the configuration syntax.

Please refer to section "Limit and Bandwidth Share Per VF" in the MLNX_OFED User Manual for detailed explanation on vPort QoS behaviors.

5.6.2.3.1.1 devlink port function rate add

	`devlink port function rate add <DEV>/<GROUP_NAME>` Adds a QoS group.	
Syntax Description	DEV/GROUP_NAME	Specifies group name in string format

Example	This command adds a new QoS group named `12_group` under device `pci/0000:03:00.0`: `devlink port function rate add pci/0000:03:00.0/12_group`
Notes	

5.6.2.3.1.2 devlink port function rate del

	`devlink port function rate del <DEV>/<GROUP_NAME>` Deletes a QoS group.	
Syntax Description	DEV/GROUP_NAME	Specifies group name in string format
Example	This command deletes QoS group `12_group` from device `pci/0000:03:00.0`: `devlink port function rate del pci/0000:03:00.0/12_group`	
Notes		

5.6.2.3.1.3 devlink port function rate set tx_max tx_share

	`devlink port function rate set {<DEV>/<GROUP_NAME> | <DEV>/<PORT_INDEX>} tx_max <TX_MAX> [tx_share <TX_SHARE>]` Sets `tx_max` and `tx_share` for QoS group or devlink port.	
Syntax Description	DEV/GROUP_NAME	Specifies the group name to operate on
	DEV/PORT_INDEX	Specifies the devlink port to operate on
	TX_MAX	`tx_max` bandwidth in MB/s
	TX_SHARE	tx_share bandwidth in MB/s

Example	This command sets `tx_max` to 2000MB/s and `tx_share` to 500MB/s for the `12_group` QoS group:
	`devlink port function rate set pci/0000:03:00.0/12_group tx_max 2000MBps tx_share 500MBps`
	This command sets `tx_max` to 2000MB/s and `tx_share` to 500MB/s for the VF represented by port index 196609:
	`devlink port function rate set pci/0000:03:00.0/196609 tx_max 200MBps tx_share 50MBps`
	This command displays a mapping between VF devlink ports and netdev names:
	`$ devlink port`
	In the output of this command, VFs are indicated by `flavour pcivf`.	

Notes		

5.6.2.3.1.4 devlink port function rate set parent

	`devlink port function rate set <DEV>/<PORT_INDEX> {parent <PARENT_GROUP_NAME>}` Assigns devlink port to a QoS group.	
Syntax Description	DEV/PORT_INDEX	Specifies the devlink port to operate on
	PARENT_GROUP_NAME	parent group name in string format
Example	This command assigns this function to the QoS group `12_group`: `devlink port function rate set pci/0000:03:00.0/196609 parent 12_group`	
Notes		

5.6.2.3.1.5 devlink port function rate set noparent

	`devlink port function rate set <DEV>/<PORT_INDEX> noparent` Ungroups a devlink port.	
Syntax Description	DEV/PORT_INDEX	Specifies the devlink port to operate on
Example	This command ungroups this function: `devlink port function rate set pci/0000:03:00.0/196609 noparent`	
Notes		

5.6.2.3.1.6 devlink port function rate show

	`devlink port function rate show [<DEV>/<GROUP_NAME> | <DEV>/<PORT_INDEX>]` Displays QoS information QoS group or devlink port.	
Syntax Description	DEV/GROUP_NAME	Specifies the group name to display
	DEV/PORT_INDEX	Specifies the devlink port to display

Example	This command displays the QoS info of all QoS groups and devlink ports on the system:
	`devlink port function rate show`
	`pci/0000:03:00.0/12_group type node tx_max 2000MBps tx_share 500MBps`
	`pci/0000:03:00.0/196609 type leaf tx_max 200MBps tx_share 50MBps parent 12_group`
	This command displays QoS info of `12_group`:
	`devlink port function rate show pci/0000:03:00.0/12_group`
	`pci/0000:03:00.0/12_group type node tx_max 2000MBps tx_share 500MBps`	

Notes	If a QoS group name or devlink port are not specified, all QoS groups and devlink ports are displayed.	

5.6.2.3.2 Shared RQ Mode

When creating 1 send queue (SQ) and 1 receive queue (RQ), each representor consumes ~3MB memory per single channel. Scaling this to the desired 1024 representors (SFs and/or VFs) would require ~3GB worth of memory for single channel. A major chunk of the 3MB is contributed by RQ allocation (receive buffers and SKBs). Therefore, to make efficient use of memory, shared RQ mode is implemented so PF/VF/SF representors share receive queues owned by the uplink representor.

The feature is enabled by default. To disable it:

1. Edit the field `ALLOW_SHARED_RQ` in `/etc/mellanox/mlnx-bf.conf` as follows:

```
ALLOW_SHARED_RQ="no"
```

2. Restart the driver. Run:

```
/etc/init.d/openibd restart
```

To connect from the host to NVIDIA® BlueField® networking platform (DPU or SuperNIC) in shared RQ mode, please refer to section Verifying Connection from Host to BlueField.

⚠ PF/VF representor to PF/VF communication on the host is not possible.

The following behavior is observed in shared RQ mode:

- It is expected to see a `0` in the `rx_bytes` and `rx_packets` and valid `vport_rx_packets` and `vport_rx_bytes` after running traffic. Example output:

```
# ethtool -S pf0hpf
NIC statistics:
     rx_packets: 0
     rx_bytes: 0
     tx_packets: 66946
     tx_bytes: 8786869
     vport_rx_packets: 546093
     vport_rx_bytes: 321100036
     vport_tx_packets: 549449
     vport_tx_bytes: 321679548
```

- Ethtool usage – in this mode, it is not possible to change/set the ring or coalesce parameters for the RX side using ethtool. Changing channels also only affects the TX side.

5.6.2.4 Storage Protocols

There are several storage protocols that use the advantage of InfiniBand and RDMA for performance reasons (high throughput, low latency and low CPU utilization). In this chapter we will discuss the following protocols:

- **SCSI RDMA Protocol (SRP)** is designed to take full advantage of the protocol off-load and RDMA features provided by the InfiniBand architecture.
- **iSCSI Extensions for RDMA (iSER)** is an extension of the data transfer model of iSCSI, a storage networking standard for TCP/IP. It uses the iSCSI components while taking the advantage of the RDMA protocol suite. ISER is implemented on various stor- age targets such as TGT, LIO, SCST and out of scope of this manual. For various ISER targets configuration steps, troubleshooting and debugging, as well as other implementation of storage protocols over RDMA (such as Ceph over RDMA, nbdX and more) refer to Storage Solutions on the Community website.
- **Lustre** is an open-source, parallel distributed file system, generally used for large-scale cluster computing that supports many requirements of leadership class HPC simulation environments.
- **NVM Express™ over Fabrics (NVME-oF)**
    - NVME-oF is a technology specification for networking storage designed to enable NVMe message-based commands to transfer data between a host computer and a target solid-state storage device or system over a network such as Ethernet, Fibre Channel, and InfiniBand. Tunneling NVMe commands through an RDMA fabric provides a high throughput and a low latency. This is an alternative to the SCSi based storage networking protocols.
    - NVME-oF Target Offload is an implementation of the new NVME-oF standard Target (server) side in hardware. Starting from ConnectX-5 family cards, all regular IO requests can be processed by the HCA, with the HCA sending IO requests directly to a real NVMe PCI device, using peer-to-peer PCI communications. This means that excluding connection management and error flows, no CPU utilization will be observed during NVME-oF traffic. For further information, please refer to Storage Solutions on the Community website (enterprise-support.nvidia.com/s/).

5.6.2.4.1 SRP - SCSI RDMA Protocol

The SCSI RDMA Protocol (SRP) is designed to take full advantage of the protocol offload and RDMA features provided by the InfiniBand architecture. SRP allows a large body of SCSI software to be readily used on InfiniBand architecture. The SRP Initiator controls the connection to an SRP Target in order to provide access to remote storage devices across an InfiniBand fabric. The kSRP Target resides in an IO unit and provides storage services.

5.6.2.4.1.1 SRP Initiator

This SRP Initiator is based on open source from OpenFabrics (www.openfabrics.org) that implements the SCSI RDMA Protocol-2 (SRP-2). SRP-2 is described in Document # T10/1524-D available from http://www.t10.org.

The SRP Initiator supports

- Basic SCSI Primary Commands -3 (SPC-3) (www.t10.org/ftp/t10/drafts/spc3/spc3r21b.pdf)
- Basic SCSI Block Commands -2 (SBC-2) (www.t10.org/ftp/t10/drafts/sbc2/sbc2r16.pdf)
- Basic functionality, task management and limited error handling

⚠ This package, however, does not include an SRP Target.

Loading SRP Initiator

To load the SRP module either:

- Execute the `modprobe ib_srp` command after the OFED driver is up.

or

1. Change the value of `SRP_LOAD` in `/etc/infiniband/openib.conf` to "`yes`".
2. Run `/etc/init.d/openibd restart` for the changes to take effect.

⚠ When loading the `ib_srp` module, it is possible to set the module parameter `srp_sg_tablesize.` This is the maximum number of gather/scatter entries per I/O (default: 12).

SRP Module Parameters

When loading the SRP module, the following parameters can be set (viewable by the "modinfo ib_srp" command):

`cmd_sg_entries`	Default number of gather/scatter entries in the SRP command (default is 12, max 255)
`allow_ext_sg`	Default behavior when there are more than cmd_sg_entries S/G entries after mapping; fails the request when false (default false)
`topspin_workarounds`	Enable workarounds for Topspin/Cisco SRP target bugs
`reconnect_delay`	Time between successive reconnect attempts. Time between successive reconnect attempts of SRP initiator to a disconnected target until dev_loss_tmo timer expires (if enabled), after that the SCSI target will be removed
`fast_io_fail_tmo`	Number of seconds between the observation of a transport layer error and failing all I/O. Increasing this timeout allows more tolerance to transport errors, however, doing so increases the total failover time in case of serious transport failure. Note: fast_io_fail_tmo value must be smaller than the value of recon- nect_delay

dev_loss_tmo	Maximum number of seconds that the SRP transport should insulate transport layer errors. After this time has been exceeded the SCSI target is removed. Normally it is advised to set this to -1 (disabled) which will never remove the scsi_host. In deployments where different SRP targets are connected and disconnected frequently, it may be required to enable this timeout in order to clean old scsi_hosts representing targets that no longer exists

Constraints between parameters:

- dev_loss_tmo, fast_io_fail_tmo, reconnect_delay cannot be all disabled or negative values.
- reconnect_delay must be positive number.
- fast_io_fail_tmo must be smaller than SCSI block device timeout.
- fast_io_fail_tmo must be smaller than dev_loss_tmo.

SRP Remote Ports Parameters

Several SRP remote ports parameters are modifiable online on existing connection.

To modify dev_loss_tmo to 600 seconds:

```
echo 600 > /sys/class/srp_remote_ports/port-xxx/dev_loss_tmo
```

To modify fast_io_fail_tmo to 15 seconds:

```
echo 15 > /sys/class/srp_remote_ports/port-xxx/fast_io_fail_tmo
```

To modify reconnect_delay to 10 seconds:

```
echo 20 > /sys/class/srp_remote_ports/port-xxx/reconnect_delay
```

Manually Establishing an SRP Connection

The following steps describe how to manually load an SRP connection between the Initiator and an SRP Target. “Automatic Discovery and Connection to Targets” section explains how to do this automatically.

- Make sure that the ib_srp module is loaded, the SRP Initiator is reachable by the SRP Target, and that an SM is running.
- To establish a connection with an SRP Target and create an SRP (SCSI) device for that target under /dev, use the following command:

```
echo -n id_ext=[GUID value],ioc_guid=[GUID value],dgid=[port GID value],\
pkey=ffff,service_id=[service[0] value] > \
/sys/class/infiniband_srp/srp-mlx[hca number]-[port number]/add_target
```

See **“**SRP Tools - ibsrpdm, srp_daemon and srpd Service Script**”** section for instructions on how the parameters in this echo command may be obtained.

Notes:

- Execution of the above “echo” command may take some time
- The SM must be running while the command executes
- It is possible to include additional parameters in the echo command:
    - max_cmd_per_lun - Default: 62
    - max_sect (short for max_sectors) - sets the request size of a command
    - io_class - Default: 0x100 as in rev 16A of the specification (In rev 10 the default was 0xff00)
    - tl_retry_count - a number in the range 2..7 specifying the IB RC retry count. Default: 2
    - comp_vector, a number in the range 0..n-1 specifying the MSI-X completion vector. Some HCA's allocate multiple (n) MSI-X vectors per HCA port. If the IRQ affinity masks of these interrupts have been configured such that each MSI-X interrupt is handled by a different CPU then the comp_vector parameter can be used to spread the SRP completion workload over multiple CPU's.
    - cmd_sg_entries, a number in the range 1..255 that specifies the maximum number of data buffer descriptors stored in the SRP_CMD information unit itself. With allow_ext_sg=0 the parameter cmd_sg_entries defines the maximum S/G list length for a single SRP_CMD, and commands whose S/G list length exceeds this limit after S/G list collapsing will fail.
    - initiator_ext - see "Multiple Connections from Initiator InfiniBand Port to the Target" section.
- To list the new SCSI devices that have been added by the echo command, you may use either of the following two methods:
    - Execute “fdisk -l”. This command lists all devices; the new devices are included in this listing.
    - Execute “dmesg” or look at /var/log/messages to find messages with the names of the new devices.

SRP sysfs Parameters

Interface for making ib_srp connect to a new target. One can request ib_srp to connect to a new target by writing a comma-separated list of login parameters to this sysfs attribute. The supported parameters are:

id_ext	A 16-digit hexadecimal number specifying the eight byte identifier extension in the 16-byte SRP target port identifier. The target port identifier is sent by ib_srp to the target in the SRP_LOGIN_REQ request.
ioc_guid	A 16-digit hexadecimal number specifying the eight byte I/O controller GUID portion of the 16-byte target port identifier.
dgid	A 32-digit hexadecimal number specifying the destination GID.
pkey	A four-digit hexadecimal number specifying the InfiniBand partition key.
service_id	A 16-digit hexadecimal number specifying the InfiniBand service ID used to establish communication with the SRP target. How to find out the value of the service ID is specified in the documentation of the SRP target.

max_sect	A decimal number specifying the maximum number of 512-byte sectors to be transferred via a single SCSI command.
max_cmd_per_lun	A decimal number specifying the maximum number of outstanding commands for a single LUN.
io_class	A hexadecimal number specifying the SRP I/O class. Must be either 0xff00 (rev 10) or 0x0100 (rev 16a). The I/O class defines the format of the SRP initiator and target port identifiers.
initiator_ext	A 16-digit hexadecimal number specifying the identifier extension portion of the SRP initiator port identifier. This data is sent by the initiator to the target in the SRP_LOGIN_REQ request.
cmd_sg_entries	A number in the range 1..255 that specifies the maximum number of data buffer descriptors stored in the SRP_CMD information unit itself. With allow_ext_sg=0 the parameter cmd_sg_entries defines the maxi- mum S/G list length for a single SRP_CMD, and commands whose S/G list length exceeds this limit after S/G list collapsing will fail.
allow_ext_sg	Whether ib_srp is allowed to include a partial memory descriptor list in an SRP_CMD instead of the entire list. If a partial memory descriptor list has been included in an SRP_CMD the remaining memory descriptors are communicated from initiator to target via an additional RDMA transfer. Setting allow_ext_sg to 1 increases the maximum amount of data that can be transferred between initiator and target via a single SCSI command. Since not all SRP target implementations support partial memory descriptor lists the default value for this option is 0.
sg_tablesize	A number in the range 1..2048 specifying the maximum S/G list length the SCSI layer is allowed to pass to ib_srp. Specifying a value that exceeds cmd_sg_entries is only safe with partial memory descriptor list support enabled (allow_ext_sg=1).
comp_vector	A number in the range 0..n-1 specifying the MSI-X completion vector. Some HCA's allocate multiple (n) MSI-X vectors per HCA port. If the IRQ affinity masks of these interrupts have been configured such that each MSI-X interrupt is handled by a different CPU then the comp_vector parameter can be used to spread the SRP completion workload over multiple CPU's.
tl_retry_count	A number in the range 2..7 specifying the IB RC retry count.

SRP Tools - ibsrpdm, srp_daemon and srpd Service Script

The OFED distribution provides two utilities: ibsrpdm and srp_daemon:

- They detect targets on the fabric reachable by the Initiator (Step 1)
- Output target attributes in a format suitable for use in the above “echo” command (Step 2)
- A service script srpd which may be started at stack startup

The utilities can be found under /usr/sbin/, and are part of the srptools RPM that may be installed using the OFED installation. Detailed information regarding the various options for these utilities are provided by their man pages.
Below, several usage scenarios for these utilities are presented.

ibsrpdm

ibsrpdm has the following tasks:

1. Detecting reachable targets.

a. To detect all targets reachable by the SRP initiator via the default umad device (/sys/class/infiniband_mad/umad0), execute the following command:

```
ibsrpdm
```

This command will result into readable output information on each SRP Target detected. Sample:

```
    IO Unit Info:
         port LID:        0103
         port GID:        fe80000000000000002c90200402bd5
         change ID:       0002
         max controllers: 0x10
      controller[  1]
          GUID:      0002c90200402bd4
          vendor ID: 0002c9
          device ID: 005a44
          IO class : 0100
          ID:        LSI Storage Systems SRP Driver 200400a0b81146a1
          service entries: 1
          service[  0]: 200400a0b81146a1 / SRP.T10:200400A0B81146A1
```

b. To detect all the SRP Targets reachable by the SRP Initiator via another umad device, use the following command:

```
ibsrpdm -d <umad device>
```

2. Assisting in SRP connection creation.
   a. To generate an output suitable for utilization in the “echo” command in “Manually Establishing an SRP Connection” section, add the ‘-c’ option to ibsrpdm:

```
ibsrpdm -c
```

Sample output:

```
id_ext=200400A0B81146A1,ioc_guid=0002c90200402bd4,
dgid=fe80000000000000002c90200402bd5,pkey=ffff,service_id=200400a0b81146a1
```

   b. To establish a connection with an SRP Target using the output from the ‘ibsrpdm -c’ example above, execute the following command:

```
echo -n id_ext=200400A0B81146A1,ioc_guid=0002c90200402bd4,
dgid=fe80000000000000002c90200402bd5,pkey=ffff,service_id=200400a0b81146a1 > /sys/
class/infiniband_srp/srp-mlx5_0-1/add_target
```

The SRP connection should now be up; the newly created SCSI devices should appear in the listing obtained from the ‘`fdisk -l`’ command.

3. Discover reachable SRP Targets given an InfiniBand HCA name and port, rather than by just running `/sys/class/infiniband_mad/umad<N>` where `<N>` is a digit.

srpd

The srpd service script allows automatic activation and termination of the srp_daemon utility on all system live InfiniBand ports.

srp_daemon

srp_daemon utility is based on ibsrpdm and extends its functionality. In addition to the ibsrpdm functionality described above, srp_daemon can:

- Establish an SRP connection by itself (without the need to issue the “echo” command described in “Manually Establishing an SRP Connection” section)
- Continue running in background, detecting new targets and establishing SRP connections with them (daemon mode)
- Discover reachable SRP Targets given an infiniband HCA name and port, rather than just by `/dev/umad<N>` where `<N>` is a digit
- Enable High Availability operation (together with Device-Mapper Multipath)
- Have a configuration file that determines the targets to connect to:

1. srp_daemon commands equivalent to ibsrpdm:

```
"srp_daemon -a -o" is equivalent to "ibsrpdm"
"srp_daemon -c -a -o" is equivalent to "ibsrpdm -c"
```

   Note: These srp_daemon commands can behave differently than the equivalent ibsrpdm command when /etc/srp_daemon.conf is not empty.
2. srp_daemon extensions to ibsrpdm.
   - To discover SRP Targets reachable from the HCA device <InfiniBand HCA name> and the port <port num>, (and to generate output suitable for 'echo'), execute:

     ```
     host1# srp_daemon -c -a -o -i <InfiniBand HCA name> -p <port number>
     ```

     Note: To obtain the list of InfiniBand HCA device names, you can either use the ibstat tool or run ‘ls /sys/class/infiniband’.
   - To both discover the SRP Targets and establish connections with them, just add the -e option to the above command.
   - Executing srp_daemon over a port without the -a option will only display the reachable targets via the port and to which the initiator is not connected. If executing with the -e option it is better to omit -a.
   - It is recommended to use the -n option. This option adds the initiator_ext to the connecting string (see "Multiple Connections from Initiator InfiniBand Port to the Target" section).
   - srp_daemon has a configuration file that can be set, where the default is / etc/srp_daemon.conf. Use the -f to supply a different configuration file that configures the targets srp_daemon is allowed to connect to. The configuration file can also be used to set values for additional parameters (e.g., max_cmd_per_lun, max_sect).
   - A continuous background (daemon) operation, providing an automatic ongoing detection and connection capability. See "Automatic Discovery and Connection to Targets" section.

- Make sure the ib_srp module is loaded, the SRP Initiator can reach an SRP Target, and that an SM is running.
- To connect to all the existing Targets in the fabric, run "`srp_daemon -e -o`". This utility will scan the fabric once, connect to every Target it detects, and then exit.

  > ⚠ srp_daemon will follow the configuration it finds in /etc/srp_daemon.conf. Thus, it will ignore a target that is disallowed in the configuration file.

- To connect to all the existing Targets in the fabric and to connect to new targets that will join the fabric, execute srp_daemon -e. This utility continues to execute until it is either killed by the user or encounters connection errors (such as no SM in the fabric).
- To execute SRP daemon as a daemon on all the ports:
  - srp_daemon.sh (found under /usr/sbin/). srp_daemon.sh sends its log to /var/log/srp_daemon.log.
  - Start the srpd service script, run service srpd start

For the changes in openib.conf to take effect, run:

```
/etc/init.d/openibd restart
```

Multiple Connections from Initiator InfiniBand Port to the Target

Some system configurations may need multiple SRP connections from the SRP Initiator to the same SRP Target: to the same Target IB port, or to different IB ports on the same Target HCA.
In case of a single Target IB port, i.e., SRP connections use the same path, the configuration is enabled using a different initiator_ext value for each SRP connection. The initiator_ext value is a 16-hexadecimal-digit value specified in the connection command.

Also in case of two physical connections (i.e., network paths) from a single initiator IB port to two different IB ports on the same Target HCA, there is need for a different initiator_ext value on each path. The conventions is to use the Target port GUID as the initiator_ext value for the relevant path.

If you use srp_daemon with -n flag, it automatically assigns initiator_ext values according to this convention. For example:

```
id_ext=200500A0B81146A1,ioc_guid=0002c90200402bec,\
dgid=fe8000000000000002c90200402bed,pkey=ffff,\ service_id=200500a0b81146a1,initiator_ext=ed2b400002c90200
```

Notes:

- It is recommended to use the -n flag for all srp_daemon invocations.
- ibsrpdm does not have a corresponding option.

- srp_daemon.sh always uses the -n option (whether invoked manually by the user, or automatically at startup by setting SRP_DAEMON_ENABLE to yes).

High Availability (HA)

High Availability works using the Device-Mapper (DM) multipath and the SRP daemon. Each initiator is connected to the same target from several ports/HCAs. The DM multipath is responsible for joining together different paths to the same target and for failover between paths when one of them goes offline. Multipath will be executed on newly joined SCSI devices.
Each initiator should execute several instances of the SRP daemon, one for each port. At startup, each SRP daemon detects the SRP Targets in the fabric and sends requests to the ib_srp module to connect to each of them. These SRP daemons also detect targets that subsequently join the fabric, and send the ib_srp module requests to connect to them as well.

Operation

When a path (from port1) to a target fails, the ib_srp module starts an error recovery process. If this process gets to the reset_host stage and there is no path to the target from this port, ib_srp will remove this scsi_host. After the scsi_host is removed, multipath switches to another path to this target (from another port/HCA).
When the failed path recovers, it will be detected by the SRP daemon. The SRP daemon will then request ib_srp to connect to this target. Once the connection is up, there will be a new scsi_host for this target. Multipath will be executed on the devices of this host, returning to the original state (prior to the failed path).

Manual Activation of High Availability

Initialization - execute after each boot of the driver:

1. Execute `modprobe dm-multipath`
2. Execute `modprobe ib-srp`
3. Make sure you have created file /etc/udev/rules.d/91-srp.rules as described above
4. Execute for each port and each HCA:

   ```
   srp_daemon -c -e -R 300 -i <InfiniBand HCA name> -p <port number>
   ```

   This step can be performed by executing srp_daemon.sh, which sends its log to /var/log/srp_daemon.log.

Now it is possible to access the SRP LUNs on /dev/mapper/.

> ⚠ It is possible for regular (non-SRP) LUNs to also be present; the SRP LUNs may be identified by their names. You can configure the /etc/multipath.conf file to change multipath behavior.

⚠ It is also possible that the SRP LUNs will not appear under /dev/mapper/. This can occur if the SRP LUNs are in the black-list of multipath. Edit the 'blacklist' section in /etc/multipath.conf and make sure the SRP LUNs are not blacklisted.

Automatic Activation of High Availability

- Start srpd service, run:

```
service srpd start
```

- From the next loading of the driver it will be possible to access the SRP LUNs on /dev/mapper/

  ⚠ It is possible that regular (not SRP) LUNs are also present. SRP LUNs may be identified by their name.

- It is possible to see the output of the SRP daemon in /var/log/srp_daemon.log

5.6.2.4.1.2 Shutting Down SRP

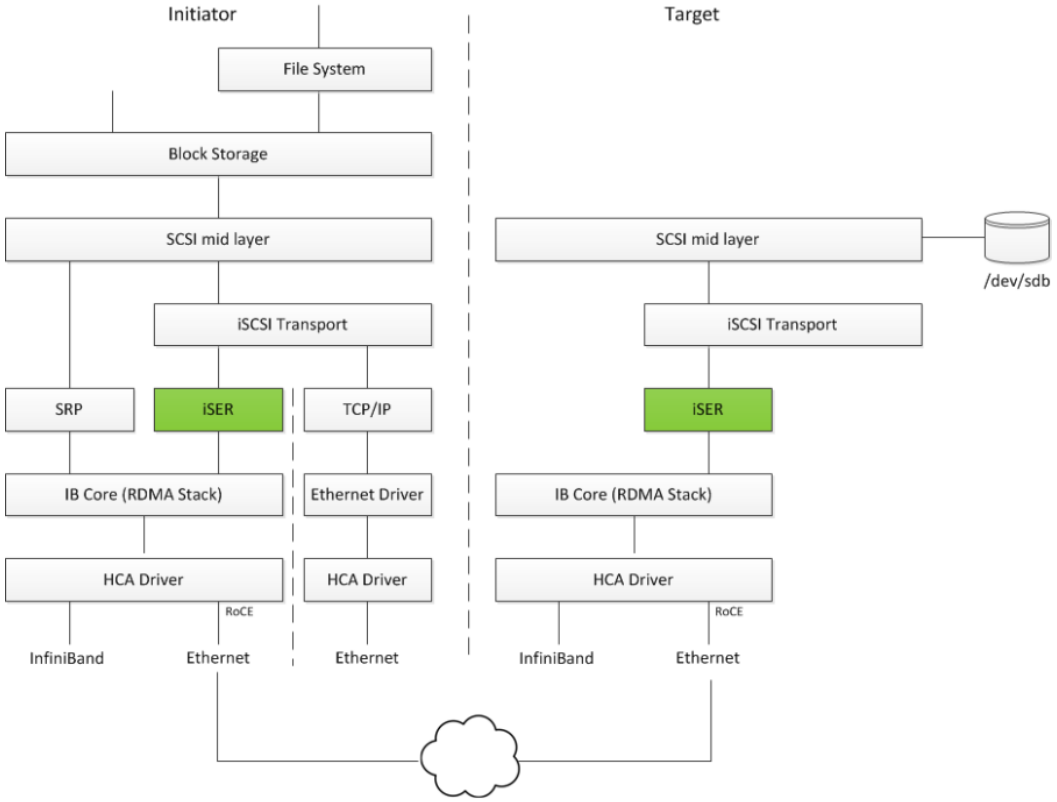
SRP can be shutdown by using "rmmod ib_srp", or by stopping the OFED driver ("/etc/init.d/openibd stop"), or as a by-product of a complete system shutdown.
Prior to shutting down SRP, remove all references to it. The actions you need to take depend on the way SRP was loaded. There are three cases:

1. Without High Availability
   When working without High Availability, you should unmount the SRP partitions that were mounted prior to shutting down SRP.
2. After Manual Activation of High Availability
   If you manually activated SRP High Availability, perform the following steps:
   a. Unmount all SRP partitions that were mounted.
   b. Stop service srpd (Kill the SRP daemon instances).
   c. Make sure there are no multipath instances running. If there are multiple instances, wait for them to end or kill them.
   d. Run: `multipath -F`
3. After Automatic Activation of High Availability
   If SRP High Availability was automatically activated, SRP shutdown must be part of the driver shutdown ("/etc/init.d/openibd stop") which performs Steps 2-4 of case b above. However, you still have to unmount all SRP partitions that were mounted before driver shutdown.

5.6.2.4.2 iSER - iSCSI Extensions for RDMA

iSCSI Extensions for RDMA (iSER) enhances the iSCSI protocol by integrating it with RDMA, enabling direct data transfers to and from SCSI buffers without intermediate copying.

By leveraging the RDMA protocol suite, iSER provides higher bandwidth for block storage transfers with zero-copy efficiency. This approach eliminates the overhead of TCP/IP processing while maintaining full compatibility with the iSCSI protocol.



There are three target implementation of ISER:

- Linux SCSI target framework (tgt)
- Linux-IO target (LIO)
- Generic SCSI target subsystem for Linux (SCST)

Each target can operate in either TCP or iSER transport mode.

iSER also supports RoCE without requiring additional configuration. To bond RoCE interfaces, set the `fail_over_mac` option in the bonding driver (see "Bonding IPoIB").

In the network stack, RDMA/RoCE is positioned below the iSER layer. To run iSER, ensure that the RDMA layer is properly configured and validated, whether over Ethernet or InfiniBand. For guidance on troubleshooting RDMA, refer to "HowTo Enable, Verify and Troubleshoot RDMA" community article.

5.6.2.4.2.1 iSER Initiator

The iSER initiator is controlled through the iSCSI interface available from the iscsi-initiator-utils package.

To discover and log into iSCSI targets, as well as access and manage the open-iscsi database use the `iscasiadm` utility, a command-line tool.

To enable iSER as a transport protocol use "`I iser`" as a parameter of the `iscasiadm` command.

Example for discovering and connecting targets over iSER:

```
iscsiadm -m discovery -o new -o old -t st -I iser -p <ip:port> -l
```

Note that the target implementation (e.g. LIO, SCST, TGT) does not affect he initiator process and configuration.

5.6.2.4.2.2 iSER Targets

> ⚠ Setting the iSER target is out of scope of this manual. For guidelines of how to do so, please refer to the relevant target documentation (e.g. stgt, targetcli).

Targets settings such as timeouts and retries are set the same as any other iSCSI targets.

> ⚠ If targets are set to auto connect on boot, and targets are unreachable, it may take a long time to continue the boot process if timeouts and max retries are set too high.

For various configuration, troubleshooting and debugging examples, refer to Storage Solutions on the Community website.

5.6.2.4.3 Lustre

Lustre is an open-source, parallel distributed file system, generally used for large-scale cluster computing that supports many requirements of leadership class HPC simulation environments.

Lustre Compilation for MLNX_OFED:

> ⚠ This procedure applies to RHEL/SLES OSs supported by Lustre. For further information, please refer to Lustre Release Notes.

To compile Lustre version 2.4.0 and higher:

```
$ ./configure --with-o2ib=/usr/src/ofa_kernel/default/
$ make rpms
```

To compile older Lustre versions:

```
$ EXTRA_LNET_INCLUDE="-I/usr/src/ofa_kernel/default/include/ -include /usr/src/ofa_kernel/default/include/linux/
compat-2.6.h" ./configure --with-o2ib=/usr/src/ofa_kernel/default/
$ EXTRA_LNET_INCLUDE="-I/usr/src/ofa_kernel/default/include/ -include /usr/src/ofa_kernel/default/include/linux/
compat-2.6.h" make rpms
```

For full installation example, refer to HowTo Install NVIDIA OFED driver for Lustre Community post.

5.6.2.4.4 NVME-oF - NVM Express over Fabrics

5.6.2.4.4.1 NVME-oF

NVME-oF enables NVMe message-based commands to transfer data between a host computer and a target solid-state storage device or system over a network such as Ethernet, Fibre Channel, and InfiniBand. Tunneling NVMe commands through an RDMA fabric provides a high throughput and a low latency.
For information on how to configure NVME-oF, please refer to the HowTo Configure NVMe over Fabrics Community post.

> ⚠ The --with-nvmf installation option should **not** be specified, if nvme-tcp kernel module is used. In this case, the native Inbox nvme-tcp kernel module will be loaded.

5.6.2.4.4.2 NVME-oF Target Offload

> ⚠ This feature is only supported for ConnectX-5 adapter cards family and above.

NVME-oF Target Offload is an implementation of the new NVME-oF standard Target (server) side in hardware. Starting from ConnectX-5 family cards, all regular IO requests can be processed by the HCA, with the HCA sending IO requests directly to a real NVMe PCI device, using peer-to-peer PCI communications. This means that excluding connection management and error flows, no CPU utilization will be observed during NVME-oF traffic.

- For instructions on how to configure NVME-oF target offload, refer to HowTo Configure NVME-oF Target Offload Community post.
- For instructions on how to verify that NVME-oF target offload is working properly, refer to Simple NVMe-oF Target Offload Benchmark Community post.

5.6.2.5 Virtualization

The chapter contains the following sections:

- SR-IOV
- Paravirtualization
- VXLAN Hardware Stateless Offloads
- Q-in-Q Encapsulation per VF in Linux
- 802.1Q Double-Tagging
- Scalable Functions

5.6.2.5.1 SR-IOV

Single Root I/O Virtualization (SR-IOV) enables a single physical PCIe device to expose multiple virtual instances on the PCIe bus. Each instance, known as a virtual function (VF), acts as an independent PCIe device while sharing the physical function (PF)'s resources.

NVIDIA® ConnectX® adapters support up to 127 VFs per port, each of which can be provisioned and managed independently. SR-IOV is typically used with an SR-IOV-enabled hypervisor to provide virtual machines with direct hardware access to network interfaces, improving throughput and reducing CPU overhead.

This section describes how to configure SR-IOV in a Red Hat Enterprise Linux (RHEL) environment using ConnectX VPI adapters.

5.6.2.5.1.1 System Requirements

To configure and use SR-IOV, ensure the following prerequisites are met:

- Installed MLNX_OFED driver
- A server or blade with an SR-IOV-capable BIOS
- A hypervisor that supports SR-IOV (for example, Red Hat Enterprise Linux Server 6 or later)
- An ConnectX VPI adapter supporting SR-IOV

5.6.2.5.1.2 BIOS and Kernel Setup

> The figures used in this section are for illustration purposes only. For further information, refer to your BIOS User Manual.

1. Enable "SR-IOV" in the system BIOS.

2. Enable "Intel Virtualization Technology" (VT-d).

3. Install a hypervisor that supports SR-IOV.
4. Update the GRUB configuration to enable IOMMU:

   Example for Intel systems (`/boot/grub/grub.conf`):

```
default=0
timeout=5
splashimage=(hd0,0)/grub/splash.xpm.gz
hiddenmenu
title Red Hat Enterprise Linux Server (4.x.x)
        root (hd0,0)
        kernel /vmlinuz-4.x.x ro root=/dev/VolGroup00/LogVol00 rhgb quiet
        intel_iommu=on        initrd /initrd-4.x.x.img
```

Ensure the parameter `intel_iommu=on` is present. On newer systems using `/boot/grub2/grub.cfg`, add the parameter to the line starting with `linux16`.

5.6.2.5.1.3 Configuring SR-IOV (Ethernet)

For configuration details, refer to the community guide HowTo Configure SR-IOV for ConnectX-4/ConnectX- 5/ConnectX-6 with KVM (Ethernet).

5.6.2.5.1.4 Configuring SR-IOV (InfiniBand)

1. Install MLNX_OFED for Linux with SR-IOV support.
2. Verify SR-IOV enablement in the firmware:

```
mlxconfig -d /dev/mst/mt4115_pciconf0 q
```

Example output:

```
SRIOV_EN                    1
NUM_OF_VFS                  8
```

To modify these settings, if needed:

```
mlxconfig -d /dev/mst/mt4115_pciconf0 set SRIOV_EN=1 NUM_OF_VFS=16
```

3. Reboot the server.
4. Create VFs. Depending on your kernel version, use one of the following sysfs files:
   - Standard (for newer kernels):

```
echo <num_vfs> > /sys/class/infiniband/mlx5_0/device/sriov_numvfs
```

   - Legacy (for older kernels):

```
echo <num_vfs> > /sys/class/infiniband/mlx5_0/device/mlx5_num_vfs
```

The `sriov_numvfs` file is only present if `intel_iommu=on` was set in GRUB.

Rules:

- You can change the number of VFs only when none are assigned.
- If VFs are assigned to VMs, the count cannot be changed.

- Unloading the PF driver removes SR-IOV only if no VFs are assigned.
- When the PF driver is reloaded, assigned VFs become operational again (the VF driver may need to be restarted).

5. Verify VF creation.

```
lspci | grep Mellanox
```

Example output:

```
08:00.0 Infiniband controller: Mellanox Technologies MT27700 Family [ConnectX-4]
08:00.1 Infiniband controller: Mellanox Technologies MT27700 Family [ConnectX-4]
08:00.2 Infiniband controller: Mellanox Technologies MT27700 Family [ConnectX-4 Virtual Function]
08:00.3 Infiniband controller: Mellanox Technologies MT27700 Family [ConnectX-4 Virtual Function]
08:00.4 Infiniband controller: Mellanox Technologies MT27700 Family [ConnectX-4 Virtual Function]
08:00.5 Infiniband controller: Mellanox Technologies MT27700 Family [ConnectX-4 Virtual Function]
```

6. Configure each VF. Sysfs entries are available under `/sys/class/infiniband/mlx5_<PF_INDEX>/device/sriov/`. Example output:

```
sriov/
    0/
        node
        port
        policy
    1/
        node
        port
        policy
    2/
        node
        port
        policy
```

- Node GUID:

```
echo 00:11:22:33:44:55:1:0 > /sys/class/infiniband/mlx5_0/device/sriov/0/node
```

- Port GUID:

```
echo 00:11:22:33:44:55:2:0 > /sys/class/infiniband/mlx5_0/device/sriov/0/port
```

- Policy (`/sys/class/infiniband/<PF>/device/sriov/<index>/policy`) – Defines VF port behavior. Options:

Value	Description
Down	Port state remains down
Up	Sets port to *Initialize*, allowing the SM to bring it up
Follow	Mirrors the physical port's state

By default, all VF policies initialize as `Down`, except `VPort0`, which defaults to `Follow`.

7. Enable virtualization in OpenSM by adding the following to `/etc/opensm/opensm.conf`:

```
virt_enabled 2
```

> ⚠ OpenSM and related InfiniBand tools (e.g., `iblinkinfo`, `ibqueryerr`) must run on the PF, not the VF. In multi-PF configurations, OpenSM should run on `host0`.

VF Initialization and Binding

Because the same `mlx5_core` driver handles both PFs and VFs, the PF driver attempts to initialize all VFs by default.
To assign a VF to a virtual machine, unbind it from the PF driver first:

1. Identify the VF PCIe address:

```
lspci -D
```

Example:

```
0000:09:00.2
```

2. Unbind from PF driver:

```
echo 0000:09:00.2 > /sys/bus/pci/drivers/mlx5_core/unbind
```

3. Bind again (if needed):

```
echo 0000:09:00.2 > /sys/bus/pci/drivers/mlx5_core/bind
```

PCIe BDF Mapping of PFs and VFs

PCIe addresses are sequential across PFs and VFs.

For example, if the card's PCIe slot is `05:00` and it has two ports:

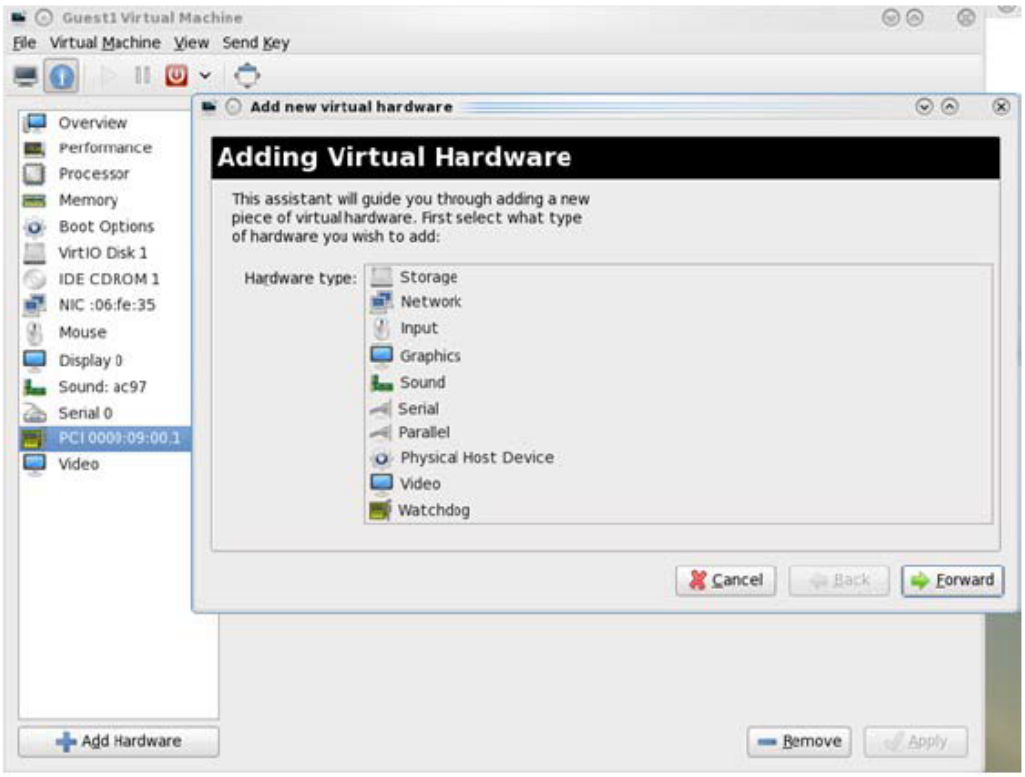
Function	PCIe BDF Range	Description
PF0	05:00.0	PF for port 0
PF1	05:00.1	PF for port 1
VFs for PF0	05:00.2–05:00.4	VFs 0–2 for PF0 (`mlx5_0`)
VFs for PF1	05:00.5–05:00.7	VFs 0–2 for PF1 (`mlx5_1`)

5.6.2.5.1.5 Additional SR-IOV Configurations

Assigning VF to Virtual Machine

This section describes how to attach an SR-IOV VF to a VM on a Red Hat KVM host using `virt-manager` (RHEL/KVM).

1. Run the virt-manager.
2. Double-click the VM and open its Properties.
3. Go to Details → Add Hardware → PCI Host Device.



4. Select the NVIDIA VF by its PCIe address (e.g., `00:03.1`).
5. Reboot the VM if it's running; otherwise, start it.
6. Inside the guest, verify the device is present:

```
lspci | grep Mellanox
```

Example:

```
01:00.0 Infiniband controller: Mellanox Technologies MT28800 Family [ConnectX-5 Ex]
```

7. (Optional) Configure the guest interface (e.g., via `/etc/sysconfig/network-scripts/ifcfg-ethX`).

> ⚠ VF MACs are randomly assigned by default; you don't need to set one unless you require a stable MAC.

Ethernet VF Configuration (Host)

You can configure VFs via `iproute2` (preferred) or `sysfs`.

- Using ip (preferred)

```
ip link set { dev <PF_DEVICE> | group <DEVGROUP> } [ up | down ] \
  vf <NUM> [ mac <LLADDR> ] [ vlan <VLANID> [ qos <VLAN-QOS> ] ] \
  [ spoofchk { on | off } ] \
  [ state { enable | disable | auto } ]
```

- Using sysfs (example layout, ConnectX-4)

```
/sys/class/net/<PF>/device/sriov/<VF>/
    config
    link_state
    mac
    mac_list
    max_tx_rate
    min_tx_rate
    spoofcheck
    stats
    trunk
    trust
```

VLAN Modes: VGT vs VST

- VGT (VLAN Guest Tagging) – Guest tags/untags its own traffic. *(Default)*
- VST (VLAN Switch Tagging) – Hypervisor enforces a VLAN/QoS for the VF; outgoing untagged/priority-tagged traffic is tagged by the hypervisor; incoming VLAN tags are stripped.

Configure VST:

```
ip link set dev <PF_DEVICE> vf <NUM> vlan <VLAN_ID> [qos <QOS>]
# Example:
ip link set dev eth2 vf 2 vlan 10 qos 3    # enable VST with VLAN 10, QoS 3
ip link set dev eth2 vf 2 vlan 0           # revert to VGT
```

Additional Ethernet VF Options

- Guest MAC (set a stable MAC before the guest driver loads):

```
ip link set dev <PF_DEVICE> vf <NUM> mac <LLADDR>
```

> ⚠ For legacy/ConnectX-4 guests (no random MAC), always configure via `ip link`.

- Spoof checking (kernel ≥ 3.1):

```
ip link set dev <PF_DEVICE> vf <NUM> spoofchk [on | off]
```

- Guest link state:

```
ip link set dev <PF_DEVICE> vf <UM> state [enable| disable| auto]
```

VF Statistics (sysfs)

Virtual function statistics can be queried via sysfs:

```
cat /sys/class/infiniband/mlx5_2/device/sriov/2/stats
tx_packets : 5011
tx_bytes   : 4450870
tx_dropped : 0
rx_packets : 5003
rx_bytes   : 4450222
rx_broadcast : 0
rx_multicast : 0
tx_broadcast : 0
tx_multicast : 8
rx_dropped : 0
```

Mapping VFs to Ports

Use `ip link` (v2.6.34~3+):

```
ip link
```

Example (excerpt):

```
61: p1p1: ...
    vf 0 MAC 00:00:00:00:00:00, vlan 4095, spoof checking off, link-state auto
    vf 38 MAC ff:ff:ff:ff:ff:ff, vlan 65535, spoof checking off, link-state disable
```

A MAC of `ff:ff:ff:ff:ff:ff` indicates the VF is not assigned to this net device's port.

You can still configure such VFs from this PF; changes apply to the VF's actual port owner.

RoCE Support

RoCE is supported on VFs and can be used with VLANs. The hypervisor GID table has 16 entries; the remaining 112 entries are shared across VFs. With >56 VFs, some may have only a single GID entry, which is insufficient if a VF's Ethernet interface is assigned an IP. Plan VF counts accordingly.

VGT+ (Virtual Guest Tagging Plus)

VGT+ lets a VF tag its own packets while enforcing an administrative VLAN trunk policy that defines which VLANs are allowed.

- No default VLAN is defined by VGT+.
- Outgoing packets are forwarded only if they match allowed VLANs.
- Incoming packets are delivered to the VF only if allowed by policy.

> ⚠ In SR-IOV, the default operating mode is VGT.

Enable VGT+ (set allowed VLAN ranges):

```
# Enable VLAN range(s) on VF 0 of PF eth5:
echo "add <start_vid> <end_vid>" > /sys/class/net/eth5/device/sriov/0/trunk

# Examples:
echo "add 4 15"  > /sys/class/net/eth5/device/sriov/0/trunk
echo "add 17 17" > /sys/class/net/eth5/device/sriov/0/trunk

# VLAN 0 means untagged and priority-tagged traffic is allowed.
# Disable VGT+ (remove all VLANs):
echo "rem 0 4095" > /sys/class/net/eth5/device/sriov/0/trunk
# Remove a specific range/ID:
echo "rem 4 15"   > /sys/class/net/eth5/device/sriov/0/trunk
echo "rem 17 17"  > /sys/class/net/eth5/device/sriov/0/trunk
```

SR-IOV Advanced Security

MAC Anti-Spoofing

Prevents a VF from sending frames with a MAC different from the one assigned by the admin. Disabled by default.

- Using `ip` (kernel ≥ 3.10):

```
ip link set ens785f1 vf 0 spoofchk on   # enable
ip link set ens785f1 vf 0 spoofchk off  # disable
```

- Using sysfs:

```
echo "ON"  > /sys/class/net/ens785f1/device/sriov/0/spoofcheck
echo "OFF" > /sys/class/net/ens785f1/device/sriov/0/spoofcheck
```

> ⚠ This setting is non-persistent across driver restarts.

Rate Limit per VF

See HowTo Configure Rate Limit per VF for ConnectX-4/ConnectX-5/ConnectX-6 Community post. Per-VF files (e.g., `/sys/class/net/<ifname>/device/sriov/<vf_num>/max_tx_rate`) still apply.

Rate Limit per Group of VFs

Group VFs and apply a group rate limit; effective VF limit is the min of the VF's own limit and the group's available bandwidth share.

```
# Enable VLAN range(s) on VF 0 of PF eth5:
echo "add <start_vid> <end_vid>" > /sys/class/net/eth5/device/sriov/0/trunk

# Examples:
echo "add 4 15"  > /sys/class/net/eth5/device/sriov/0/trunk
echo "add 17 17" > /sys/class/net/eth5/device/sriov/0/trunk

# VLAN 0 means untagged and priority-tagged traffic is allowed.
# Disable VGT+ (remove all VLANs):
echo "rem 0 4095" > /sys/class/net/eth5/device/sriov/0/trunk
# Remove a specific range/ID:
```

```
echo "rem 4 15"   > /sys/class/net/eth5/device/sriov/0/trunk
echo "rem 17 17"  > /sys/class/net/eth5/device/sriov/0/trunk
```

Configuration outline:

1. When supported, the driver exposes `/sys/class/net/<ifname>/device/sriov/groups/` .
2. All VFs start in group 0.
3. Move a VF to a group:

```
echo 7 > /sys/class/net/<ifname>/device/sriov/5/group
```

4. Set group max rate:

```
echo 5000 > /sys/class/net/<ifname>/device/sriov/groups/7/max_tx_rate
```

5. Inspect VF/group:
    - VF stats include group ID:

```
cat /sys/class/net/<ifname>/device/sriov/<vf_num>/stats
```

    - Group config shows current rate limit and member count:

```
cat /sys/class/net/<ifname>/device/sriov/groups/<group_id>/config
```

Bandwidth Guarantee per Group of VFs

Guarantee a minimum transmit rate per group; ensure the sum of group minimums ≤ line rate.

Example (40 Gb/s link):

```
echo 20000 > /sys/class/net/<ifname>/device/sriov/group/1/min_tx_rate
echo 5000 > /sys/class/net/<ifname>/device/sriov/group/2/min_tx_rate
echo 15000 > /sys/class/net/<ifname>/device/sriov/group/3/min_tx_rate
```

- Group 1: 20 Gb/s
- Group 2: 5 Gb/s
- Group 3: 15 Gb/s
- Groups with 0 have no guarantee.

> ⚠ You can still set per-VF min rates to split a group's guarantee among member VFs (sum should not exceed the group minimum).

Privileged VFs

Trusted VFs can receive a limited set of PF-like privileges (e.g., entering promiscuous mode).

- Using `ip` (kernel ≥ 4.5):

```
ip link set ens785f1 vf 0 trust on
ip link set ens785f1 vf 0 trust off
```

- Using sysfs:

```
echo "ON"  > /sys/class/net/ens785f1/device/sriov/0/trust
echo "OFF" > /sys/class/net/ens785f1/device/sriov/0/trust
```

Probed VFs

Probing VFs consumes resources. Disable probing if you don't need to monitor VMs:

- Kernel ≥ 4.12 (preferred) – use `sriov_drivers_autoprobe` (PCIe sysfs).
- Older kernels – use `mlx5_core` module param `probe_vf`:

```
echo 0 > /sys/module/mlx5_core/parameters/probe_vf
```

For more information on how to probe VFs, see HowTo Configure and Probe VFs on mlx5 DriversCommunity post.

VF Promiscuous and All-Multicast Modes

⚠ Only trusted VFs can enable these modes.

- Promiscuous Mode (receive unmatched and all multicast traffic):

```
ifconfig eth2 promisc     # enable
ifconfig eth2 -promisc    # disable
```

- All-Multicast Mode (receive all multicast on the port):

```
ifconfig eth2 allmulti    # enable
ifconfig eth2 -allmulti   # disable
```

5.6.2.5.1.6 Uninstalling the SR-IOV Driver

1. Detach all VFs from VMs or stop the VMs that use VFs.

   ⛔ Stopping the driver while VMs are using VFs may hang the host.

2. Run the uninstall script:

   ```
   /usr/sbin/ofed_uninstall.sh
   ```

   Follow the prompts. Example output (truncated):

   ```
   This program will uninstall all OFED packages on your machine.
   Do you want to continue? [y/N]: y
   ...
   ```

3. Reboot the server.

5.6.2.5.1.7 SR-IOV Live Migration

> ⚠ This feature is supported in Ethernet mode only.

Live migration refers to the process of moving a guest virtual machine (VM) running on one physical host to another host without disrupting normal operations or causing other adverse effects for the end user.

Using the Migration process is useful for:

- load balancing
- hardware independence
- energy saving
- geographic migration
- fault tolerance

Migration works by sending the state of the guest virtual machine's memory and any virtualized devices to a destination host physical machine. Migrations can be performed live or not, in the live case, the migration will not disrupt the user operations and it will be transparent to it as explained in the sections below.

Non-Live Migration

When using the non-live migration process, the Hypervisor suspends the guest virtual machine, then moves an image of the guest virtual machine's memory to the destination host physical machine. The guest virtual machine is then resumed on the destination host physical machine, and the memory the guest virtual machine used on the source host physical machine is freed. The time it takes to complete such a migration depends on the network bandwidth and latency. If the network is experiencing heavy use or low bandwidth, the migration will take longer then desired.

Live Migration

When using the Live Migration process, the guest virtual machine continues to run on the source host physical machine while its memory pages are transferred to the destination host physical machine. During migration, the Hypervisor monitors the source for any changes in the pages it has already transferred and begins to transfer these changes when all of the initial pages have been transferred.

It also estimates transfer speed during migration, so when the remaining amount of data to transfer will take a certain configurable period of time, it will suspend the original guest virtual machine, transfer the remaining data, and resume the same guest virtual machine on the destination host physical machine.

MLX5 VF Live Migration

The purpose of this section is to demonstrate how to perform basic live migration of a QEMU VM with an MLX5 VF assigned to it. This section does not explains how to create VMs either using libvirt or directly via QEMU.

Requirements

The below are the requirements for working with MLX5 VF Live Migration.

Components	Description
Adapter Cards	• ConnectX-7 ETH • BlueField-3 as NIC ⚠ The same PSID must be used on both the source and the target hosts (identical cards, same CAPs and features are needed), and have the same firmware version.
Firmware	• 28.41.1000 • 32.41.1000
Kernel	Linux v6.7 or newer
User Space Tools	iproute2 version 6.2 or newer
QEMU	QEMU 8.1 or newer
Libvirt	Libvirt 8.6 or newer

Setup

NVCONFIG

SR-IOV should be enabled and be configured to support the required number of VFs as of enabling live migration. This can be achieved by the below command:

```
mlxconfig -d *<PF_BDF>* s SRIOV_EN=1 NUM_OF_VFS=4 VF_MIGRATION_MODE=2
```

where:

SRIOV_EN	Enable Single-Root I/O Virtualization (SR-IOV)
NUM_OF_VFS	The total number of Virtual Functions (VFs) that can be supported, for each PF.
VF_MIGRATION_MODE	Defines support for VF migration. • 0x0: DEVICE_DEFAULT • 0x1: MIGRATION_DISABLED • 0x2: MIGRATION_ENABLED

Kernel Configuration

Needs to be compiled with driver MLX5_VFIO_PCI enabled. (i.e. CONFIG_MLX5_VFIO_PCI).

To load the driver, run:

```
modprobe mlx5_vfio_pci
```

QEMU

Needs to be compiled with VFIO_PCI enabled (this is enabled by default).

Host Preparation

As stated earlier, creating the VMs is beyond the scope of this guide and we assume that they are already created. However, the VM configuration should be a migratable configuration, similarly to how it is done without SRIOV VFs.

> ⚠ The below steps should be done before running the VMs.

Over libvirt

1. Set the PF in the "switchdev" mode.

```
devlink dev eswitch set pci/<PF_BDF> mode switchdev
```

2. Create the VFs that will be assigned to the VMs.

```
echo "1" > /sys/bus/pci/devices/<PF_BDF>/sriov_numvfs
```

3. Set the VFs as migration capable.
    a. See the name of the VFs, run:

```
devlink port show
```

    b. Unbind the VFs from mlx5_core, run:

```
echo '<VF_BDF>' > /sys/bus/pci/drivers/mlx5_core/unbind
```

    c. Use devlink to set each VF as migration capable, run:

```
devlink port function set pci/<PF_BDF>/1 migratable enable
```

4. Assign the VFs to the VMs.

    a. Edit the VMs XML file, run:

```
virsh edit <VM_NAME>
```

    b. Assign the VFs to the VM by adding the following under the "devices" tag:

```
<hostdev mode='subsystem' type='pci' managed='no'>
  <driver name='vfio'/>
    <source>
      <address domain='0x0000' bus='0x08' slot='0x00' function='0x2'/>
    </source>
  <address type='pci' domain='0x0000' bus='0x09' slot='0x00' function='0x0'/>
</hostdev>
```

> ⚠ The domain, bus, slot and function values above are dummy values, replace them with your VFs values.

5. Set the destination VM in incoming mode.
    a. Edit the destination VM XML file, run:

```
virsh edit <VM_NAME>
```

b. Set the destination VM in migration incoming mode by adding the following under "domain" tag:

```
<domain type='kvm' xmlns:qemu='http://libvirt.org/schemas/domain/qemu/1.0'>
  [...]
  <qemu:commandline>
    <qemu:arg value='--incoming'/>
    <qemu:arg value='tcp:<DEST_IP>:<DEST_PORT>'/>
  </qemu:commandline>
</domain>
```

> ⚠ To be able to save the file, the above `"xmlns:qemu"` attribute of the "domain" tag must be added as well.

6. Bind the VFs to mlx5_vfio_pci driver.

a. Detach the VFs from libvirt management, run:

```
virsh nodedev-detach pci_<VF_BDF>
```

b. Unbind the VFs from vfio-pci driver (the VFs are automatically bound to it after running "virsh nodedev-detach"), run:

```
echo '<VF_BDF>' > /sys/bus/pci/drivers/vfio-pci/unbind
```

c. Set driver override, run:

```
echo 'mlx5_vfio_pci' > /sys/bus/pci/devices/<VF_BDF>/driver_override
```

d. Bind the VFs to mlx5_vfio_pci driver, run:

```
echo '<VF_BDF>' > /sys/bus/pci/drivers/mlx5_vfio_pci/bind
```

Directly over QEMU

1. Set the PF in "switchdev" mode.

```
devlink dev eswitch set pci/<PF_BDF> mode switchdev
```

2. Create the VFs that will be assigned to the VMs.

```
echo "1" > /sys/bus/pci/devices/<PF_BDF>/sriov_numvfs
```

3. Set the VFs as migration capable.

a. See the name of the VFs, run:

```
devlink port show
```

b. Unbind the VFs from mlx5_core, run:

```
echo '<VF_BDF>' > /sys/bus/pci/drivers/mlx5_core/unbind
```

c. Use devlink to set each VF as migration capable, run:

```
devlink port function set pci/<PF_BDF>/1 migratable enable
```

4. Bind the VFs to mlx5_vfio_pci driver:
   a. Set driver override, run:

```
echo 'mlx5_vfio_pci' > /sys/bus/pci/devices/<VF_BDF>/driver_override
```

   b. Bind the VFs to mlx5_vfio_pci driver, run:

```
echo '<VF_BDF>' > /sys/bus/pci/drivers/mlx5_vfio_pci/bind
```

Running the Migration

Over libvirt

1. Start the VMs in source and in destination, run:

```
virsh start <VM_NAME>
```

2. Enable switchover-ack QEMU migration capability. Run the following commands both in source and destination:

```
virsh qemu-monitor-command <VM_NAME> --hmp "migrate_set_capability return-path on"
```

```
virsh qemu-monitor-command <VM_NAME> --hmp "migrate_set_capability switchover-ack on"
```

3. **[Optional]** Configure the migration bandwidth and downtime limit in source side:

```
virsh qemu-monitor-command <VM_NAME> --hmp "migrate_set_parameter max-bandwidth <VALUE>"
virsh qemu-monitor-command <VM_NAME> --hmp "migrate_set_parameter downtime-limit <VALUE>"
```

4. Start migration by running the migration command in source side:

```
virsh qemu-monitor-command <VM_NAME> --hmp "migrate -d tcp:<DEST_IP>:<DEST_PORT>"
```

5. Check the migration status by running the info command in source side:

```
virsh qemu-monitor-command <VM_NAME> --hmp "info migrate"
```

When the migration status is "completed" it means the migration has finished successfully.

Directly over QEMU

1. Start the VM in source with the VF assigned to it:

```
qemu-system-x86_64 [...] -device vfio-pci,host=<VF_BDF>,id=mlx5_1
```

2. Start the VM in destination with the VF assigned to it and with the "incoming" parameter:

```
qemu-system-x86_64 [...] -device vfio-pci,host=<VF_BDF>,id=mlx5_1 -incoming tcp:<DEST_IP>:<DEST_PORT>
```

3. Enable switchover-ack QEMU migration capability. Run the following commands in QEMU monitor, both in source and destination:

```
migrate_set_capability return-path on
```

```
migrate_set_capability switchover-ack on
```

4. **[Optional]** Configure the migration bandwidth and downtime limit in source side:

```
migrate_set_parameter max-bandwidth <VALUE>
migrate_set_parameter downtime-limit <VALUE>
```

5. Start migration by running the migration command in QEMU monitor in source side:

```
migrate -d tcp:<DEST_IP>:<DEST_PORT>
```

6. Check the migration status by running the info command in QEMU monitor in source side:

```
info migrate
```

> ⚠ When the migration status is "completed" it means the migration has finished successfully.

Migration with MultiPort vHCA

Enables the usage of a dual port Virtual HCA (vHCA) to share RDMA resources (e.g., MR, CQ, SRQ, PDs) across the two Ethernet (RoCE) NIC network ports and display the NIC as a dual port device.

MultiPort vHCA (MPV) VF is made of 2 "regular" VFs, one VF of each port. Creating a migratable MPV VF requires the same steps as regular VF (see steps in section Over libvirt). The steps should be performed on each of the NIC ports. MPV VFs traffic cannot be configured with OVS. TC rules must be defined to configure the MPV VFs traffic.

Notes

> ⚠ In ConnectX-7 adapter cards, migration cannot run in parallel on more than 4 VFs. It is the administrator's responsibility to control that.

⚠ Live migration requires same firmware version on both the source and the target hosts.

5.6.2.5.2 Paravirtualization

The following steps demonstrate how to enable paravirtualization networking support on RHEL 7.x systems without NetworkManager, using a manually configured bridge.

1. Create a configuration file for the bridge interface (`bridge0`):

```
vim /etc/sysconfig/network-scripts/ifcfg-bridge0
```

Example contents:

```
DEVICE=bridge0
TYPE=Bridge
IPADDR=12.195.15.1
NETMASK=255.255.0.0
BOOTPROTO=static
ONBOOT=yes
NM_CONTROLLED=no
DELAY=0
```

2. Modify the configuration of the physical Ethernet interface (in this example, `eth5`) to associate it with the bridge:

```
vim /etc/sysconfig/network-scripts/ifcfg-eth5
```

Example contents:

```
DEVICE=eth5
BOOTPROTO=none
STARTMODE=on
HWADDR=00:02:c9:2e:66:52
TYPE=Ethernet
NM_CONTROLLED=no
ONBOOT=yes
BRIDGE=bridge0
```

3. Apply the configuration changes by restarting the network service:

```
service network restart
```

⚠ This will temporarily disrupt network connectivity.

4. Once the bridge is active, you can assign it to a virtual machine (VM). After booting the VM, verify that the virtual interface is using the bridged connection:

```
ifconfig -a
```

Example output:

```
eth6      Link encap:Ethernet  HWaddr 52:54:00:E7:77:99
          inet addr:13.195.15.5  Bcast:13.195.255.255  Mask:255.255.0.0
          inet6 addr: fe80::5054:ff:fee7:7799/64 Scope:Link
          UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1
```

```
          RX packets:481 errors:0 dropped:0 overruns:0 frame:0
          TX packets:450 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:1000
          RX bytes:22440 (21.9 KiB)  TX bytes:19232 (18.7 KiB)
```

5.6.2.5.3 VXLAN Hardware Stateless Offloads

VXLAN (Virtual Extensible LAN) technology addresses scalability and isolation challenges in modern data center networks by encapsulating Layer 2 frames within Layer 3 packets. However, this encapsulation introduces performance challenges that require extending traditional stateless offload capabilities to VXLAN traffic.

The ConnectX® family of adapter cards provides hardware acceleration for VXLAN-encapsulated packets, offering the same stateless offloads typically available for non-encapsulated traffic. VXLAN packets are encapsulated using an outer UDP header.

The following stateless offloads are supported for VXLAN traffic:

- Checksum Generation
  - Inner IP checksum
  - Inner TCP/UDP checksum
- Checksum Validation
  - Inner IP checksum
  - Inner TCP/UDP checksum
- TSO (TCP Segmentation Offload)
  - Supported for inner TCP payloads
- RSS (Receive Side Scaling)
  - Flow distribution based on inner packet attributes (e.g., IP addresses, TCP/UDP ports)
- Receive Queue Selection
  - Inner frames can be steered to specific Queue Pairs (QPs) for advanced traffic steering and isolation

5.6.2.5.3.1 Enabling VXLAN Hardware Stateless Offloads

VXLAN offload is enabled by default for ConnectX-4 family devices running the minimum required firmware version and a kernel version that includes VXLAN support.

To confirm if the current setup supports VXLAN, run:

```
ethtool -k $DEV | grep udp_tnl
```

Example:

```
ethtool -k ens1f0 | grep udp_tnl
tx-udp_tnl-segmentation: on
```

ConnectX-4 family devices support configuring multiple UDP ports for VXLAN offload. Ports can be added to the device by configuring a VXLAN device from the OS command line using the `ip` command.

> ⚠ If you configure multiple UDP ports for offload and exceed the total number of ports supported by hardware, then those additional ports will still function properly, but will not benefit from any of the stateless offloads.

Example:

```
ip link add vxlan0 type vxlan id 10 group 239.0.0.10 ttl 10 dev ens1f0 dstport 4789
ip addr add 192.168.4.7/24 dev vxlan0
ip link set up vxlan0
```

> ⚠ dstport' parameters are not supported in Ubuntu 14.4.

The VXLAN ports can be removed by deleting the VXLAN interfaces.

Example:

```
ip link delete vxlan0
```

5.6.2.5.3.2 Important Note

VXLAN tunneling adds an encapsulation overhead of 50 bytes per packet, comprising:

- 14 bytes – Ethernet header
- 20 bytes – Outer IP header
- 8 bytes – UDP header
- 8 bytes – VXLAN header

This overhead must be accounted for to prevent packet fragmentation or drops.

> ⚠ VXLAN adds 50 bytes of encapsulation overhead. To avoid fragmentation or packet loss, you must account for this overhead by adjusting the MTU:
>
> - Option 1: Decrease the MTU on the sending interface (e.g., VM virtio-net, host veth). For example: Use MTU 1450 instead of 1500.
> - Option 2: Increase the MTU on the physical uplink. For example: Use MTU 1550 instead of 1500.

5.6.2.5.4 Q-in-Q Encapsulation per VF in Linux

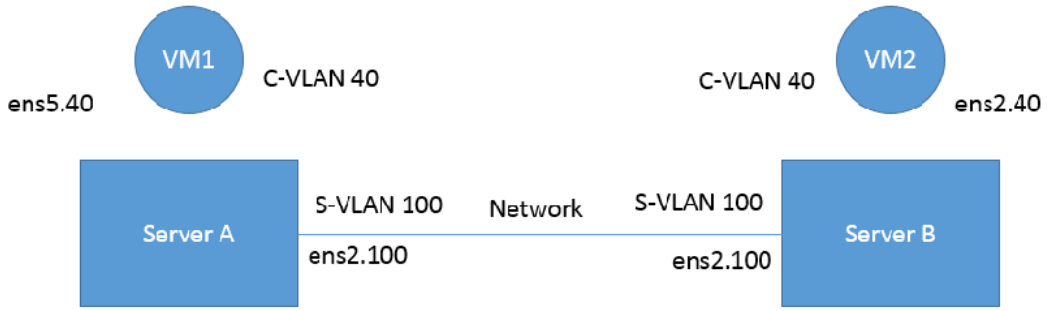
> ⚠ This feature is supported on ConnectX-5 and ConnectX-6 adapter cards only.

This section explains how to configure IEEE 802.1ad Q-in-Q VLAN tagging (S-VLAN) for a hypervisor on a per-VF basis. A VM connected to the VF via SR-IOV can transmit traffic with or without a C-VLAN tag.

When a VF is configured for VST Q-in-Q encapsulation, the adapter hardware automatically inserts an S-VLAN tag into outgoing packets from the VF to the physical port. For incoming packets, the hardware removes the S-VLAN tag before delivering the traffic to the VF.

5.6.2.5.4.1 Setup

The setup assumes there are two servers equipped with ConnectX-5/ConnectX-6 adapter cards.



5.6.2.5.4.2 Prerequisites

- Kernel must be of v3.10 or higher, or custom/inbox kernel must support vlan-stag
- Firmware version 16/20.21.0458 or higher must be installed for ConnectX-5/ ConnectX-6 HCAs
- The server should be enabled in SR-IOV and the VF should be attached to a VM on the hypervisor.
- Network Considerations - the network switches may require increasing the MTU (to support 1522 MTU size) on the relevant switch ports.

5.6.2.5.4.3 Configuring Q-in-Q Encapsulation per Virtual Function for ConnectX-5/ ConnectX-6

1. Add the required S-VLAN (QinQ) tag (on the hypervisor) per port per VF. There are two ways to add the S-VLAN:
   a. By using sysfs:

```
echo '100:0:802.1ad' > /sys/class/net/ens1f0/device/sriov/0/vlan
```

   b. By using the ip link command (available only when using the latest Kernel version):

```
ip link set dev ens1f0 vf 0 vlan 100 proto 802.1ad
```

   Check the configuration using the ip link show command:

```
# ip link show ens1f0
 ens1f0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT qlen 1000
    link/ether ec:0d:9a:44:37:84 brd ff:ff:ff:ff:ff:ff
    vf 0 MAC 00:00:00:00:00:00, vlan 100, vlan protocol 802.1ad, spoof checking off, link-state
auto, trust off
    vf 1 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 2 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 3 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 4 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
```

2. **Optional:** Add S-VLAN priority. Use the qos parameter in the ip link command (or sysfs):

```
ip link set dev ens1f0 vf 0 vlan 100 qos 3 proto 802.1ad
```

   Check the configuration using the ip link show command:

```
# ip link show ens1f0
ens1f0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT qlen 1000
    link/ether ec:0d:9a:44:37:84 brd ff:ff:ff:ff:ff:ff
    vf 0 MAC 00:00:00:00:00:00, vlan 100, qos 3, vlan protocol 802.1ad, spoof checking off, link-state
auto, trust off
    vf 1 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 2 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 3 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 4 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
```

3. Create a VLAN interface on the VM and add an IP address.

```
ip link add link ens5 ens5.40 type vlan protocol 802.1q id 40
ip addr add 42.134.135.7/16 brd 42.134.255.255 dev ens5.40
ip link set dev ens5.40 up
```

4. To verify the setup, run ping between the two VMs and open Wireshark or tcpdump to capture the packet.

5.6.2.5.5 802.1Q Double-Tagging

This section describes the configuration of 802.1Q double-tagging support to the hypervisor per Virtual Function (VF). The Virtual Machine (VM) attached to the VF (via SR-IOV) can send traffic with or without C-VLAN. Once a VF is configured to VST encapsulation, the adapter's hardware will insert C-VLAN to any packet from the VF to the physical port. On the receive side, the adapter hardware will strip the C-VLAN from any packet coming from the wire to that VF.

5.6.2.5.5.1 Configuring 802.1Q Double-Tagging per Virtual Function

1. Add the required C-VLAN tag (on the hypervisor) per port per VF. There are two ways to add the C-VLAN:
   a. By using sysfs:

```
echo '100:0:802.1q' > /sys/class/net/ens1f0/device/sriov/0/vlan
```

   b. By using the ip link command (available only when using the latest Kernel version):

```
ip link set dev ens1f0 vf 0 vlan 100
```

Check the configuration using the ip link show command:

```
# ip link show ens1f0
 ens1f0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT qlen 1000
    link/ether ec:0d:9a:44:37:84 brd ff:ff:ff:ff:ff:ff
    vf 0 MAC 00:00:00:00:00:00, vlan 100, spoof checking off, link-state auto, trust off
    vf 1 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 2 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 3 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
    vf 4 MAC 00:00:00:00:00:00, spoof checking off, link-state auto, trust off
```

2. Create a VLAN interface on the VM and add an IP address.

```
# ip link add link ens5 ens5.40 type vlan protocol 802.1q id 40
# ip addr add 42.134.135.7/16 brd 42.134.255.255 dev ens5.40
# ip link set dev ens5.40 up
```

3. To verify the setup, run ping between the two VMs and open Wireshark or tcpdump to capture the packet.

5.6.2.5.6 Scalable Functions

Scalable function is a lightweight function that has a parent PCI function on which it is deployed. Scalable functions are useful for containers where netdevice and RDMA devices of a scalable function can be assigned to a container. This way, the container can get complete offload capabilities of an eswitch, isolation and dedicated accelerated network device. For Step-by-Step Configuration instructions, follow the User Guide here.

5.6.2.6 Resiliency

The chapter contains the following sections:

- Reset Flow

5.6.2.6.1 Reset Flow

Reset Flow is activated by default. Once a "fatal device" error is recognized, both the HCA and the software are reset, the ULPs and user application are notified about it, and a recovery process is performed once the event is raised.

Currently, a reset flow can be triggered by a firmware assert with Recover Flow Request (RFR) only. Firmware RFR support should be enabled explicitly using mlxconfig commands.

- To query the current value, run:

```
mlxconfig -d /dev/mst/mt4115_pciconf0 query | grep SW_RECOVERY_ON_ERRORS
```

- To enable RFR bit support, run:

```
mlxconfig -d /dev/mst/mt4115_pciconf0 set SW_RECOVERY_ON_ERRORS=true
```

5.6.2.6.1.1 Kernel ULPs

Once a "fatal device" error is recognized, an `IB_EVENT_DEVICE_FATAL` event is created, ULPs are notified about the incident, and outstanding WQEs are simulated to be returned with "flush in error" message to enable each ULP to close its resources and not get stuck via calling its `remove_one` callback as part of "Reset Flow".

Once the unload part is terminated, each ULP is called with its `add_one` callback, its resources are re-initialized and it is re-activated.

5.6.2.6.1.2 User Space Applications (IB/RoCE)

Once a "fatal device" error is recognized an `IB_EVENT_DEVICE_FATAL` event is created, applications are notified about the incident and relevant recovery actions are taken.

Applications that ignore this event enter a zombie state, where each command sent to the kernel is returned with an error, and no completion on outstanding WQEs is expected.

The expected behavior from the applications is to register to receive such events and recover once the above event is raised. Same behavior is expected in case the NIC is unbounded from the PCI and later is rebounded. Applications running over RDMA CM should behave in the same manner once the `RDMA_CM_EVENT_DEVICE_REMOVAL` event is raised.

The following is an example of using the unbind/bind for NIC defined by `0000:04:00.0`:

```
echo 0000:04:00.0 > /sys/bus/pci/drivers/mlx5_core/unbind
echo 0000:04:00.0 > /sys/bus/pci/drivers/mlx5_core/bind
```

5.6.2.6.1.3 SR-IOV

If the PF recognizes the error, it notifies all the VFs about it by marking their communication channel with that information, consequently, all the VFs and the PF are reset.

If the VF encounters an error, only that VF is reset, whereas the PF and other VFs continue to work unaffected.

5.6.2.6.1.4 Forcing the VF to Reset

If an outside reset is forced by using the PCIe sysfs entry for a VF, a reset is executed on that VF once it runs any command over its communication channel.

For example, the following command can be used on a hypervisor to reset a VF defined by `0000:04:00.1`:

```
echo 1 >/sys/bus/pci/devices/0000:04:00.1/reset
```

5.6.2.6.1.5 Extended Error Handling (EEH)

Extended Error Handling (EEH) is a PowerPC mechanism that encapsulates AER, thus exposing AER events to the operating system as EEH events.

The behavior of ULPs and user space applications is identical to the behavior of AER.

5.6.2.6.1.6 CRDUMP

CRDUMP feature allows for taking an automatic snapshot of the device CR-Space in case the device's FW/HW fails to function properly.

Snapshots Triggers:

The snapshot is triggered after firmware detects a critical issue, requiring a recovery flow.

This snapshot can later be investigated and analyzed to track the root cause of the failure.

Currently, only the first snapshot is stored, and is exposed using a temporary virtual file. The virtual file is cleared upon driver reset.

When a critical event is detected, a message indicating CRDUMP collection will be printed to the Linux log. User should then back up the file pointed to in the printed message. The file location format is: `/proc/driver/mlx5_core/crdump/<pci address>`.

Snapshot should be copied by Linux standard tool for future investigation.

5.6.2.6.1.7 Firmware Tracer

This mechanism allows for the device's firmware/hardware to log important events into the event tracing system (/sys/kernel/debug/tracing) without requiring any NVIDIA tool.

> ⚠ To be able to use this feature, trace points must be enabled in the kernel.

This feature is enabled by default, and can be controlled using sysfs commands.

- To disable the feature:

```
echo 0 > /sys/kernel/debug/tracing/events/mlx5/fw_tracer/enable
```

- To enable the feature:

```
echo 1 > /sys/kernel/debug/tracing/events/mlx5/fw_tracer/enable
```

- To view FW traces using vim text editor:

```
vim /sys/kernel/debug/tracing/trace
```

5.6.2.7 Docker Containers

On Linux, Docker uses resource isolation of the Linux kernel, to allow independent "containers" to run within a single Linux kernel instance.
Docker containers are supported on MLNX_OFEDusing Docker runtime. Virtual RoCE and InfiniBand devices are supported using SR-IOV mode.

Currently, RDMA/RoCE devices are supported in the modes listed in the following table.

Orchestration and Clustering Tool	Version	Networking Mode	Link Layer	Virtualization Mode
Docker	Docker Engine 17.03 or higher	SR-IOV using SR-IOV plugin along with docker run wrapper tool	InfiniBand and Ethernet	SR-IOV
Kubernetes	Kubernetes 1.10.3 or higher	SR-IOV using device plugin, and using SR- IOV CNI plugin	InfiniBand and Ethernet	SR-IOV
		VXLAN using IPoIB bridge	InfiniBand	Shared HCA

5.6.2.7.1 Docker Using SR-IOV

This setup enables Docker containers to operate with SR-IOV (Single Root I/O Virtualization) for high-performance RDMA networking. It supports both InfiniBand and Ethernet link layers and is compatible with ConnectX-4, ConnectX-5, and ConnectX-6 adapter cards.

To ensure proper isolation of virtual RDMA devices within containers, the `docker_rdma_sriov` tool must be used.

Resources:

- SR-IOV Networking Plugin – Available on Docker Hub: rdma/sriov-plugin
- Container Tools Installer (includes `docker_rdma_sriov`) – Available on Docker Hub: rdma/container_tools_installer
- For detailed setup instructions, refer to the official guide: Docker RDMA SRIOV Networking with ConnectX-4/ConnectX-5/ConnectX-6

5.6.2.7.2 Kubernetes Using SR-IOV

To enable RDMA in a Kubernetes environment with SR-IOV networking, two key components are required:

5.6.2.7.2.1 RDMA Device Plugin

This plugin is responsible for exposing RDMA-capable devices to Kubernetes Pods. It ensures that RDMA resources (e.g., InfiniBand or RoCE VFs) are made available and consumable through Kubernetes scheduling.

5.6.2.7.2.2 SR-IOV CNI Plugin

The SR-IOV Container Network Interface (CNI) plugin provisions Virtual Function (VF) network devices into the Pods. When used in SR-IOV mode, the plugin handles:

- SR-IOV enablement
- GUID and MAC address configuration
- Privilege mode setup
- Trust mode setup

The plugin also manages VF allocation during Pod scheduling based on requests made via Kubernetes resource definitions.

5.6.2.7.3 Kubernetes with Shared HCA

A single RDMA device (HCA) can be shared among multiple Pods running on the same Kubernetes worker node. This is typically achieved using user-defined networks based on VXLAN or VETH interfaces.

These virtual networking devices allow multiple Pods to access the same physical HCA while maintaining isolation and flexibility in network topology.

> ⚠ This approach differs from SR-IOV, as it does not require allocating dedicated Virtual Functions (VFs) per Pod.

5.6.2.8 HPC-X

For detailed information about HPC-X®, refer to the HPC-X User Manual.

5.6.2.9 Fast Driver Unload

This feature enables optimizing mlx5 driver teardown time in shutdown and kexec flows.

The fast driver unload is disabled by default. To enable it, the `prof_sel` module parameter of mlx5_core module should be set to 3.

6 DOCA Reference Applications

This page provides an overview of the DOCA reference applications implemented on top of NVIDIA® BlueField®.

All the DOCA reference applications described in this section are governed under the BSD-3 software license agreement.

6.1 Introduction

DOCA reference applications are an educational resource provided as a guide on how to program on the NVIDIA BlueField networking platform using DOCA API.

> ⚠ The reference applications are not production-ready and should be used as reference only.

For instructions regarding the development environment and installation, refer to the DOCA Developer Guide and the DOCA Installation Guide for Linux respectively.

> ℹ For questions, comments, and feedback, please contact us at doca-feedback@nvidia.com.

6.1.1 Installation

DOCA applications are installed under `/opt/mellanox/doca/applications` with each application having its own dedicated folder. Each directory contains the source code and compilation files for the matching application.

6.1.2 Prerequisites

The DOCA SDK references (samples and applications) require the use of meson, with a minimal version requirement of 0.61.2. This version is already included as part of the packages provided by most Linux distributions, hence it is recommended to simply install it from packages:

- Ubuntu/Debian:

```
$ sudo apt install meson
```

- RHEL:

```
$ sudo yum install meson
```

In the rare case in which the version provided by the distribution is lower than the minimal required version of 0.61.2, one can install meson directly through pip instead of through packages:

```
$ sudo pip3 install meson==0.61.2
```

Unlike the package installation, in the case of installation through pip, users should also remember to install their compiler of choice as it won't be installed automatically.

6.1.3 Compilation

As applications are shipped alongside their sources, developers may want to modify some of the code during their development process and then recompile the applications. The files required for the compilation are the following:

- `/opt/mellanox/doca/applications/meson.build` – main compilation file for a project that contains all the applications
- `/opt/mellanox/doca/applications/meson_options.txt` – configuration file for the compilation process
- `/opt/mellanox/doca/applications/<application_name>/meson.build` – application-specific compilation definitions

To recompile all the reference applications:

1. Move to the applications directory:

```
cd /opt/mellanox/doca/applications
```

2. Prepare the compilation definitions:

```
meson /tmp/build
```

3. Compile all the applications:

```
ninja -C /tmp/build
```

> The generated applications are located under the `/tmp/build/` directory, using the following path `/tmp/build/<application_name>/doca_<application_name>`.

Compilation against DOCA's SDK relies on environment variables which are automatically defined per user session upon login. For more information, please refer to section "Meson Complains About Missing Dependencies" in the NVIDIA DOCA Troubleshooting Guide.

6.1.4 Developer Configurations

When recompiling the applications, meson compiles them by default in "debug" mode. Therefore, the binaries would not be optimized for performance as they would include the debug symbol. For comparison, the application binaries shipped as part of DOCA's installation are compiled in "release" mode. To compile the applications in something other than debug, please consult Meson's configuration guide.

The applications also offer developers the ability to use the DOCA log's `TRACE` level (`DOCA_LOG_TRC`) on top of the existing DOCA log levels. Enabling the `TRACE` log level during compilation activates various developer log messages left out of the release compilation. Activating the `TRACE` log level may be done through `enable_trace_log` in the `meson_options.txt` file, or directly from the command line:

1. Prepare the compilation definitions to use the trace log level:

```
meson /tmp/build -Denable_trace_log=true
```

2. Compile the applications:

```
ninja -C /tmp/build
```

6.2 Application Use of DOCA Libs

The following table maps DOCA reference applications to the libraries they make use of.

Application Category	Application	Library Category											
		BareMetal/Virtualized Cloud					Secure Cloud Gateway		Cloud Storage	Monitoring	Streaming	HPC

6.3 DOCA App Shield Agent Application Guide

6.3.1 Introduction

The App Shield Agent uses the DOCA App Shield library to monitor processes running on the host system. This security feature allows for the detection of core process corruption from a trusted, independent DPU, providing an intrusion detection system (IDS) that otherwise cannot be achieved from within the host itself.

The DOCA App Shield library enables the DPU to directly read, analyze, and verify the memory of the host, whether it's a bare metal system or a virtual machine. By using this library, the application calculates cryptographic hashes of non-writable memory pages, including those that are unloaded, for a specific process and its associated libraries. It then periodically re-verifies these pages to identify any unauthorized changes.

After each check, the application outputs a pass or fail attestation result, continuing the process until the first failure is detected. These results are logged to the console and also sent to the DOCA Telemetry Service (DTS) via inter-process communication (IPC).

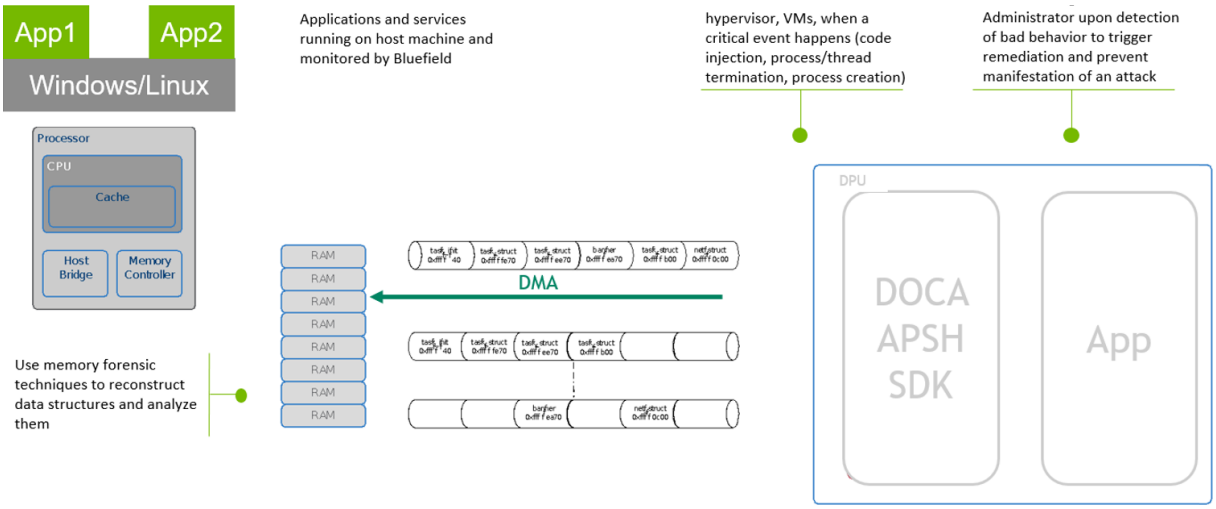
This guide illustrates how to implement secure process monitoring using the DOCA App Shield library, taking advantage of the BlueField DPU's capabilities, such as hardware-accelerated DMA and root-of-trust integrity enforcement.

6.3.2 System Design

The App Shield agent is designed to operate independently on the DPU's Arm core without impacting the host system's performance.

The host's role is minimal and primarily involves configuring the monitoring of a new process when necessary. This configuration includes generating the required ZIP and JSON files, which are then passed to the DPU. This setup is performed at the initial stage, often referred to as "time 0," when the host is still in a "safe" state.

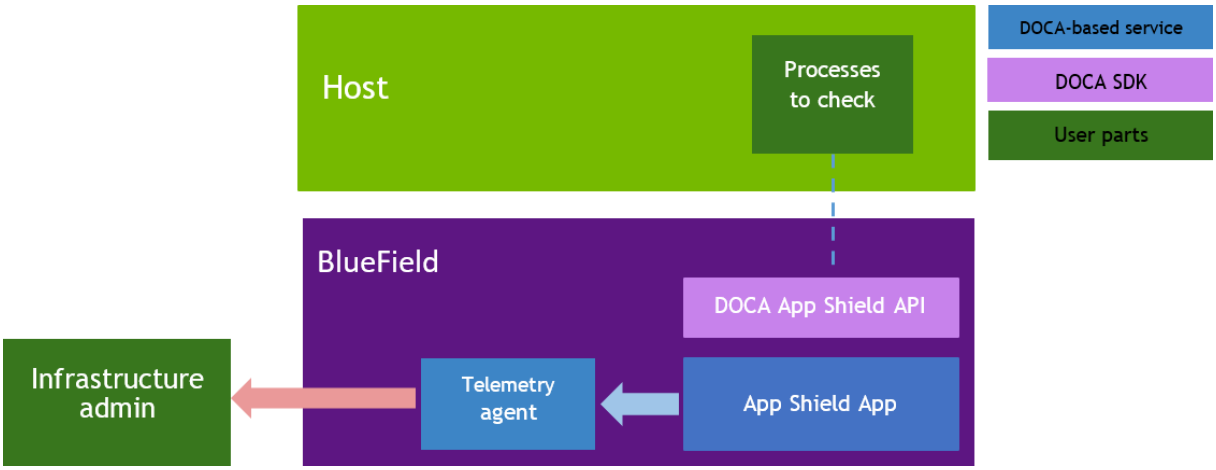
To generate these files, use the `doca_apsh_config.py` tool provided by DOCA App Shield. For detailed information, refer to DOCA App Shield.



6.3.3 Application Architecture

The user creates three mandatory files using the DOCA tool `doca_apsh_config.py` and copies them to the DPU. The application can report attestation results to the:

- File
- Terminal
- DTS



1. The files are generated by running `doca_apsh_config.py` on the host against the process at time zero.

   > ⚠ The actions 2-5 recur at regular time intervals.

2. The App Shield agent requests new attestation from DOCA App Shield library.
3. The DOCA App Shield library creates a new attestation:
   a. Scans and hashes process memory pages (that are currently in use).
   b. Compares the hash to the original hash.
   c. Creates attestation for each lib/exe involved in the process. Each of attestation includes the number of valid pages and the number of pages.
4. The App Shield agent searches each attestation for inconsistency between number of used pages and number of valid pages.
5. The App Shield agent reports results with a timestamp and scan count to:
   a. Local telemetry files – a folder and files representing the data a real DTS would have received. These files are used for the purposes of this example only as normally this data is not exported into user-readable files.
   b. DOCA log (without scan count).
   c. DTS IPC interface (even if no DTS is active).
6. The App Shield agent exits on first attestation failure.

6.3.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA App Shield
- DOCA Telemetry

Refer to their respective programming guide for more information.

6.3.5 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The sources of the application can be found under the application's directory: `/opt/mellanox/doca/applications/app_shield_agent/`.

6.3.5.1 Compiling All Applications

All DOCA applications are defined within a single meson project. Therefore, by default, the compilation process includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> `doca_app_shield_agent` is created under `/tmp/build/app_shield_agent/`.

6.3.5.2 Compiling Only the Current Application

To build only the App Shield Agent application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_app_shield_agent=true
ninja -C /tmp/build
```

> `doca_app_shield_agent` is created under `/tmp/build/app_shield_agent/`.

Alternatively, you can set the flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
    - Set `enable_all_applications` to `false`
    - Set `enable_app_shield_agent` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> `doca_app_shield_agent` is created under `/tmp/build/app_shield_agent/`.

6.3.6 Running the Application

6.3.6.1 Prerequisites

1. Configure the BlueField's firmware.
    a. On the BlueField system, configure the PF base address register and NVMe emulation. Run:

```
dpu> mlxconfig -d /dev/mst/mt41686_pciconf0 s PF_BAR2_SIZE=2 PF_BAR2_ENABLE=1
 NVME_EMULATION_ENABLE=1
```

    b. Perform a BlueField system reboot for the `mlxconfig` settings to take effect.
    c. You may verify these configurations using the following command:

```
dpu> mlxconfig -d /dev/mst/mt41686_pciconf0 q | grep -E "NVME|BAR"
```

2. Download target system (host/VM) symbols.
    - For Ubuntu:

```
host> sudo tee /etc/apt/sources.list.d/ddebs.list << EOF
deb http://ddebs.ubuntu.com/ $(lsb_release -cs) main restricted universe multiverse
deb http://ddebs.ubuntu.com/ $(lsb_release -cs)-updates main restricted universe multiverse
deb http://ddebs.ubuntu.com/ $(lsb_release -cs)-proposed main restricted universe multiverse
EOF
host> sudo apt install ubuntu-dbgsym-keyring
host> sudo apt-get update
host> sudo apt-get install linux-image-$(uname -r)-dbgsym
```

    - For CentOS:

```
host> yum install --enablerepo=base-debuginfo kernel-devel-$(uname -r) kernel-debuginfo-$(uname -r)
kernel-debuginfo-common-$(uname -m)-$(uname -r)
```

    - No action is needed for Windows

3. Perform IOMMU passthrough. This stage is only necessary if IOMMU is not enabled by default (for example, if the host is using an AMD CPU).

   ⚠ Skip this step if you are not sure whether it is needed. Return to it only if DMA fails with a message similar to the following in `dmesg`:

   ```
   host> dmesg
   [ 3839.822897] mlx5_core 0000:81:00.0: AMD-Vi: Event logged [IO_PAGE_FAULT domain=0x0047
   address=0x2a0aff8 flags=0x0000]
   ```

   a. Locate your OS's `grub` file (most likely `/boot/grub/grub.conf`, `/boot/grub2/grub.cfg`, or `/etc/default/grub`) and open it for editing. Run:

   ```
   host> vim /etc/default/grub
   ```

   b. Search for the line defining `GRUB_CMDLINE_LINUX_DEFAULT` and add the argument `iommu=pt`. For example:

   ```
   GRUB_CMDLINE_LINUX_DEFAULT="iommu=pt <intel/amd>_iommu=on"
   ```

   c. Run:

   ⚠ Prior to performing a power cycle, make sure to do a graceful shutdown.

   - For Ubuntu:

     ```
     host> sudo update-grub
     host> ipmitool power cycle
     ```

   - For CentOS:

     ```
     host> grub2-mkconfig -o /boot/grub2/grub.cfg
     host> ipmitool power cycle
     ```

   - For Windows targets, turn off Hyper-V capability.

4. Prepare target:

   a. Install DOCA on the target system.

   b. Create the ZIP and JSON files. Run:

   ```
   target-system> cd /opt/mellanox/doca/tools/
   target-system> python3 doca_apsh_config.py --pid <pid-of-process-to-monitor> --os <windows/linux>
   --path <path to dwarf2json executable  or pdbparse-to-json.py>
   target-system> cp /opt/mellanox/doca/tools/*.* <shared-folder-with-baremetal>
   dpu> scp <shared-folder-with-baremetal>/* <path-to-app-shield-binary>
   ```

   If the target system does not have DOCA installed, the script can be copied from the BlueField.

   The required `dwaf2json` and `pdbparse-to-json.py` are not provided with DOCA.

> If the kernel and process `.exe` have not changed, there no need to redo this step.

6.3.6.2 Application Execution

1. The App Shield Agent application is provided in source form, so it needs to be compiled before it can be executed.
   a. Application usage instructions:

```
Usage: doca_app_shield_agent [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pid                         Process ID of process to be attested
  -e, --ehm <path>                  Exec hash map path
  -m, --memr <path>                 System memory regions map
  -f, --vuid                        VUID of the System device
  -d, --dma                         DMA device name
  -o, --osym <path>                 System OS symbol map path
  -s, --osty <windows|linux>        System OS type - windows/linux
  -t, --time <seconds>              Scan time interval in seconds
```

   b. CLI example for running the application on the BlueField:

```
./doca_app_shield_agent -p 13577 -e hash.zip -m mem_regions.json -o symbols.json -f
MT2125X03335MLNXS0D0F0VF1 -d mlx5_0 -t 3 -s linux
```

> All used identifiers (`-f` , `-p` and `-d` flags) should match the identifier of the desired devices and processes.

6.3.6.3 Command Line Flags

6.3.6.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information

Short Flag	Long Flag	Description
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.3.6.3.2 Program Flags

Short Flag	Long Flag	Description
`p`	`pid`	PID of the process to be attested
`e`	`ehm`	Path to the pre-generated `hash.zip` file transferred from the host
`m`	`memr`	Path to the pre-generated `mem_regions.json` file transferred from the host

Short Flag	Long Flag	Description

`f`	`pcif`	System PCIe function vendor unique identifier (VUID) of the VF/PF exposed to the target system. Used for DMA operations.
		To obtain this argument, run:
		`target-system> lspci -vv | grep "\[VU\] Vendor specific:"`
		Example output:
		`[VU] Vendor specific: MT2125X03335MLNXS0D0F0`
		`[VU] Vendor specific: MT2125X03335MLNXS0D0F1`
		Two VUIDs are printed for each DPU connected to the target system. The first is of the DPU on `pf0` and the second is of the DPU on port `pf1`.
		⚠ Running this command on the DPU outputs VUIDs with an additional "EC" string in the middle. You must remove the "EC" to arrive at the correct VUID.
		The VUID of a VF allocated on PF0/1 is the VUID of the PF with an additional suffix, `VF<vf-number>`, where `vf-number` is the VF index +1.
		For example, for the output in the example above:
		• PF0 VUID = MT2125X03335MLNXS0D0F0
		• PF1 VUID = MT2125X03335MLNXS0D0F1
		• VUID of VF0 on PF0 = MT2125X03335MLNXS0D0F0VF1
		VUIDs are persistent even on reset.

`d`	`dma`	DMA device name to use
`o`	`osym`	Path to the pre-generated `symbols.json` file transferred from the host
`s`	`osty`	OS type (`windows` or `linux`) of the system where the process is running
`t`	`time`	Number of seconds to sleep between scans

6.3.6.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.3.7 Application Code Flow

1. Parse application argument.
   a. Initialize arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

   b. Register application parameters.

```
register_apsh_params();
```

c. Parse the arguments.

```
doca_argp_start();
```

2. Initialize DOCA App Shield lib context.
   a. Create lib context.

```
doca_apsh_create();
```

   b. Set DMA device for lib.

```
doca_devinfo_list_create();
doca_dev_open();
doca_devinfo_list_destroy();
doca_apsh_dma_dev_set();
```

   c. Start the context

```
doca_apsh_start();
apsh_system_init();
```

3. Initialize DOCA App Shield lib system context handler.
   a. Get the representor of the remote PCIe function exposed to the system.

```
doca_devinfo_remote_list_create();
doca_dev_remote_open();
doca_devinfo_remote_list_destroy();
```

   b. Create and start the system context handler.

```
doca_apsh_system_create();
doca_apsh_sys_os_symbol_map_set();
doca_apsh_sys_mem_region_set();
doca_apsh_sys_dev_set();
doca_apsh_sys_os_type_set();
doca_apsh_system_start();
```

4. Find target process by `pid`.

```
doca_apsh_processes_get();
```

5. Telemetry initialization.

```
telemetry_start();
```

   a. Initialize a new telemetry schema.
   b. Register attestation type event.
   c. Set up output to file (in addition to default IPC).
   d. Start the telemetry schema.
   e. Initialize and start a new DTS source with the `gethostname()` name as source ID.

6. Get initial attestation of the process.

```
doca_apsh_attestation_get();
```

7. Loop until attestation validation fail.

```
doca_apsh_attst_refresh();
/* validation logic */
doca_telemetry_exporter_source_report();
DOCA_LOG_INFO();
sleep();
```

8. DOCA App Shield Agent destroy.

```
doca_apsh_attestation_free();
doca_apsh_processes_free();
doca_apsh_system_destroy();
doca_apsh_destroy();
doca_dev_close();
doca_dev_remote_close();
```

9. Telemetry destroy.

```
telemetry_destroy();
```

10. Arg parser destroy.

```
doca_argp_destroy();
```

6.3.8 References

6.4 DOCA Bifurcated Driver Model Reference Application

This page provides an example of a Bifurcated Driver Model implementation using a multi-port eSwitch on top of the NVIDIA® BlueField® DPU.

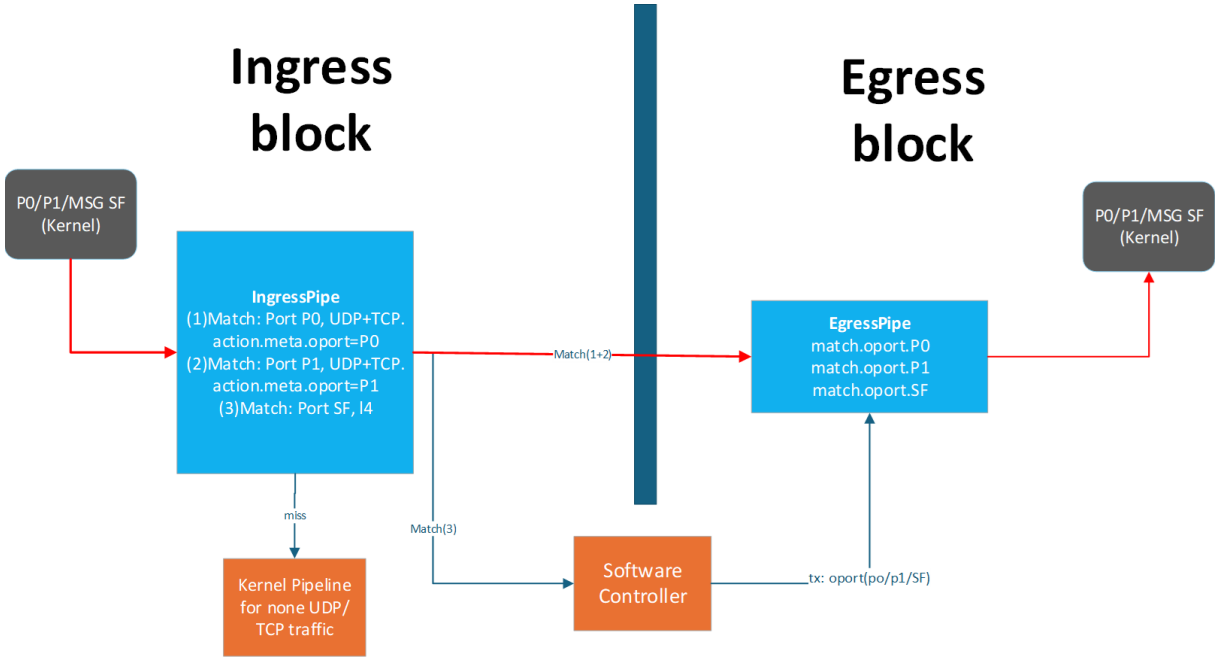
6.4.1 Introduction

The Bifurcated Driver Model leverages hardware capabilities to split incoming network traffic based on flow or packet type, allowing the standard Linux kernel driver and a DOCA-based application to operate simultaneously on the same network interface.

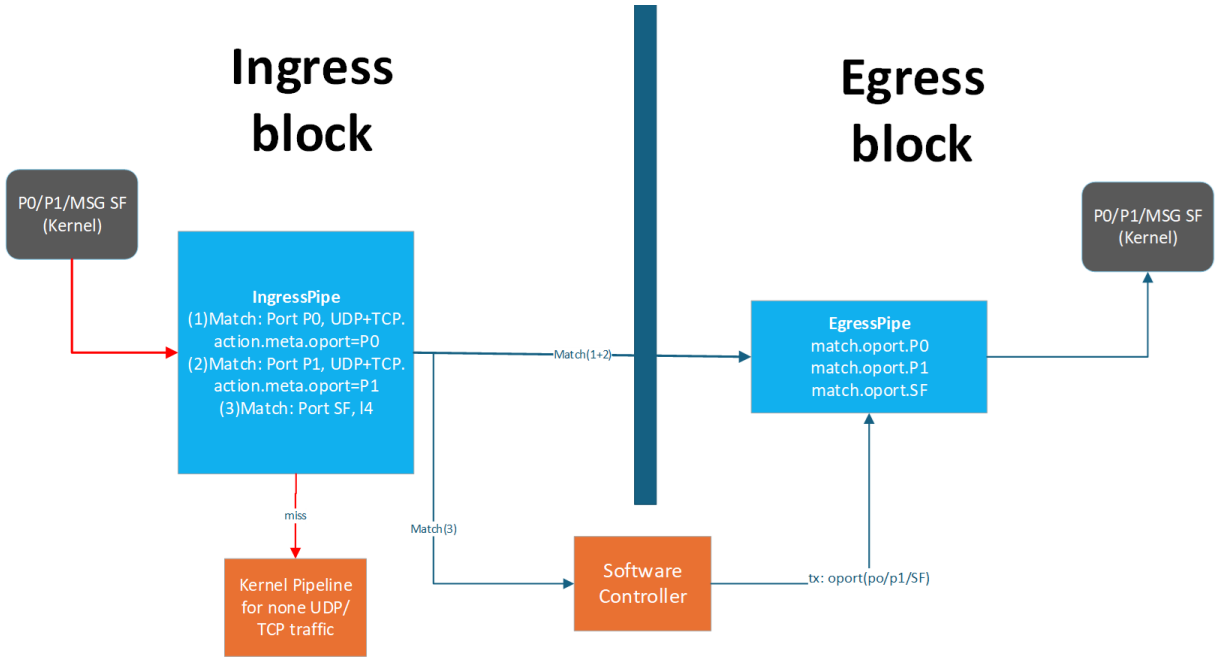
This architecture enables users to retain default kernel behavior for specific flows while implementing custom software logic for others. This application utilizes the DOCA Flow library to demonstrate efficient traffic forwarding between Physical Ports (wire) and Linux Ports (kernel).

6.4.2 System Design

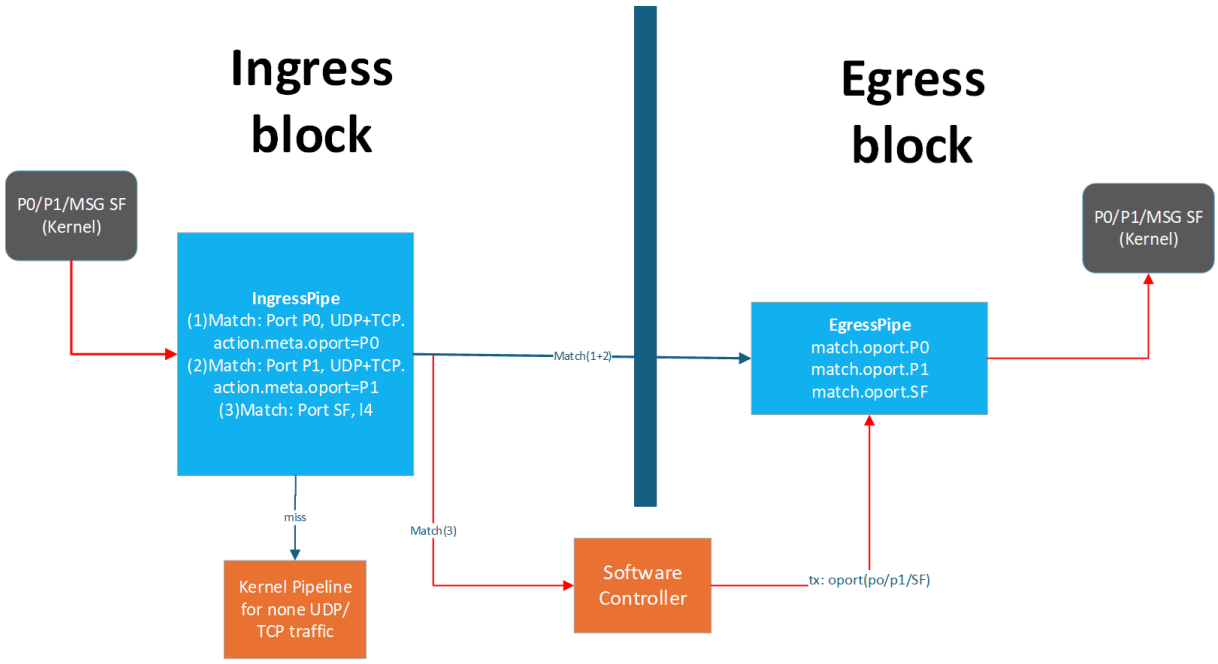
Port 0 ↔ Port 1 (Data Plane): High-volume traffic matching defined DOCA Flow rules are forwarded directly between Physical Port 0 and Physical Port 1. This bypasses the kernel network stack, remaining in the data plane for fast processing.



Port[0-1]↔ Kernel Pipeline (Control Plane): External traffic coming from Physical Port 0 or Physical Port 1 that is *not* TCP/UDP (e.g., ARP, ICMPv6, or specific control protocols) is missed and steered to the Linux Driver.



Kernel Port ↔ Kernel Port (Messaging): Internal Messaging traffic from the Linux Port is matched and steered to the Linux Representor Port, utilizing RSS for efficient kernel-space application processing.



6.4.3 Application Architecture

The Bifurcated Driver Model Reference Application consists of core logic that manages the DOCA Flow pipes and entries to implement traffic bifurcation.

1. Initialization: The application initializes DPDK and DOCA Flow resources, including ports and queues.
2. DOCA Flow Switch Configuration: setting DOCA Flow in a switch mode.
3. Port Setup: Creating DOCA Flow switch ports corresponding to the physical and Linux representor ports.
4. Default miss behavior: Unmatched packets are forwarded to the kernel, ensuring control plane protocols receive proper kernel processing.
5. Pipe Creation: Creates two pipes to implement the bifurcation logic:
    a. Egress Pipe (EGRESS domain): Matches on packet metadata (pkt_meta) and forwards packets to the corresponding port. Contains three entries:
        - $Metadata = PORT_P0 \rightarrow Forward\ to\ Physical\ Port\ 0$
        - $Metadata = PORT_LINUX \rightarrow Forward\ to\ Linux\ Port$
        - $Metadata = PORT_P1 \rightarrow Forward\ to\ Physical\ Port\ 1$
    b. Ingress Classifier Pipe (DEFAULT domain): Routes traffic based on source port_id and outer L4 protocol type, sets packet metadata, and forwards to either the egress pipe or RSS queues. Contains nine entries:

- $P0 + TCP/UDP \rightarrow Set\ metadata\ to\ P1, forward\ to\ egress\ pipe$
- $P1 + TCP/UDP \rightarrow Set\ metadata\ to\ P0, forward\ to\ egress\ pipe$
- $PORT_LINUX \rightarrow Forward\ to\ RSS\ queue$

6. Monitoring Configuration: Each pipe entry is configured with a non-shared counter resource to track packet statistics. The ingress root classifier pipe also enables a miss counter to monitor packets forwarded to the kernel.
7. Entry Processing: All flow entries are processed and offloaded to hardware.
8. Packet Processing: The main application loop demonstrates Linux port packet handling by receiving packets from queue 0, setting appropriate metadata, and transmitting them back through the switch port.
9. Statistics Collection: Upon completion, the application queries and displays per-entry packet counters for both ingress and egress pipes, along with the ingress miss counter, providing visibility into traffic patterns.

6.4.4 DOCA Libraries

This application leverages the following DOCA library:

- DOCA Flow – The core library used to program the hardware eSwitch to create the flow rules for traffic steering and bifurcation.

Refer to the respective programming guide for more information.

6.4.5 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/bifurcated_driver_model/
```

6.4.5.1 Compiling All Applications

To build all DOCA applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_bifurcated_driver_model` is created under `/tmp/build/applications/bifurcated_driver_model/`.

6.4.5.2 Recompiling Only the Current Application

To directly build only the Bifurcated Driver Model application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_bifurcated_driver_model=true
ninja -C /tmp/build
```

`doca_bifurcated_driver_model` is created under `/tmp/build/applications/bifurcated_driver_model/`.

6.4.6 Running the Application

The application is based on DOCA Flow and DPDK. Therefore, the user is required to allocate huge pages.

```
$ echo '1024' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

6.4.6.1 Application Execution

- Application usage instructions:

> The application is provided in source form, requiring compilation before execution.

```
Usage: doca_bifurcated_driver_model [DPDK Flags] -- [DOCA Flags] [Program Flags]
DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file
Program Flags:
  -a, --device                      device
```

```
  -r, --rep                       device representor
  -exp, --expert-mode             set expert mode
```

- This usage printout can be printed to the command line using the -h (or --help) options:

```
./doca_bifurcated_driver_model -- -h
```

> For additional information, refer to section "Command Line Flags".

- CLI example for running the application on BlueField:

```
cd /opt/mellanox/doca/applications/
./bifurcated_driver_model/doca_bifurcated_driver_model
 -- -l 60 -a pci/08:00.0 -r pci/08:00.0,pf0sf0 -r pci/08:00.1
```

> SFs must be enabled according to the BlueField Scalable Function User Guide.

- Before creating SFs on a specific physical port, it is important to verify the encap mode on the respective PF FDB. The default mode is basic. To check the encap mode, run:

```
cat /sys/class/net/p0/compat/devlink/encap
```

In this case, disable encap on the PF FDB before creating the SFs by running:

```
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode legacy
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode legacy
echo none > /sys/class/net/p0/compat/devlink/encap
echo none > /sys/class/net/p1/compat/devlink/encap
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode switchdev
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode switchdev
```

> If the encap mode is set to `basic` then the application fails upon initialization.

- The flag `-a pci/08:00.0` with representors `-r pci/08:00.0,pf0sf0 -r pci/08:00.1` is mandatory for proper usage of the application.
  - Modifying this flag will result in an unexpected behavior as only 2 ports are supported.
  - The SF number is arbitrary and configurable.
- The SF numbers must match the desired SF devices.
  - The device identifiers must match the desired network devices.
  - For additional information regarding the command line syntax of the device and device representor identifiers, refer to the matching section in the DOCA Arg Parser.

- For more information, refer to section "Running DOCA Application on Host" in DOCA Virtual Functions User Guide.

6.4.6.2 Command Line Flags

6.4.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.4.6.2.2 Program Flags

Flag Type	Short Flag	Long Flag	Description
Program flags	`a`	`device`	Device identifier
	`r`	`rep`	Device representor identifiers

Flag Type	Short Flag	Long Flag	Description
	`exp`	`expert-mode`	Set expert mode

6.4.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.4.7 Application Code Flow

The application initializes resources, sets up the flow pipes, and enters a processing loop.

1. Initialize logging:
    a. `doca_log_backend_create_standard();`
    b. `doca_log_backend_create_with_file_sdk();`
    c. `doca_log_backend_set_sdk_level();`
2. Argument Parsing Initialization:
    a. `doca_argp_init()` : Initialize arg parser.
    b. `register_doca_flow_switch_params()` : Register switch applications parameters.
3. Parse all command line arguments.
    a. `doca_argp_start();`
4. DOCA Flow devices initialization:
    a. `init_doca_flow_devs();`
5. DPDK & Port Initialization:
    a. `dpdk_queues_and_ports_init();`
6. DOCA Flow & Application Setup:
    a. `bifurcated_driver_model_init():`
        i. Initializes DOCA Flow:
        init_doca_flow();
        ii. Creates DOCA ports for all physical and Linux representor ports:
        init_doca_flow_switch_ports();
        iii. Set default miss behavior:
        doca_flow_port_update_default_miss();
        iv. Creates all necessary pipes: Ingress, and Egress pipes, defining the flow structure:
            1. `create_egress_pipe();`
            2. `add_egress_pipe_entries();`
            3. `create_ingress_classifier_pipe();`

4. `add_ingress_classifier_entries();`
    a. Data Plane (P0 ↔ P1): 4 entries for TCP/UDP forwarding
    b. Control Plane (Linux → RSS): 5 entries for various protocols
7. Process flow entries:
    a. `doca_flow_entries_process();`
8. Main processing loop
    a. `handle_rx_tx_pkts()`
9. Statistics collection:
    a. `print_flow_statistics();`
        i. `doca_flow_resource_query_entry()` : Query and display ingress entry counters.
        ii. `doca_flow_resource_query_pipe_miss()` : Query and display ingress miss counter.
10. Cleanup and destroy:
    a. `stop_doca_flow_ports()`
    b. `doca_flow_destroy()`
    c. `dpdk_queues_and_ports_fini()`
    d. `dpdk_fini()`
    e. `destroy_doca_flow_devs()`
    f. `doca_argp_destroy()`

6.5 DOCA DMA Copy Application Guide

This guide provides an example of a DMA Copy implementation on top of NVIDIA® BlueField® DPU.

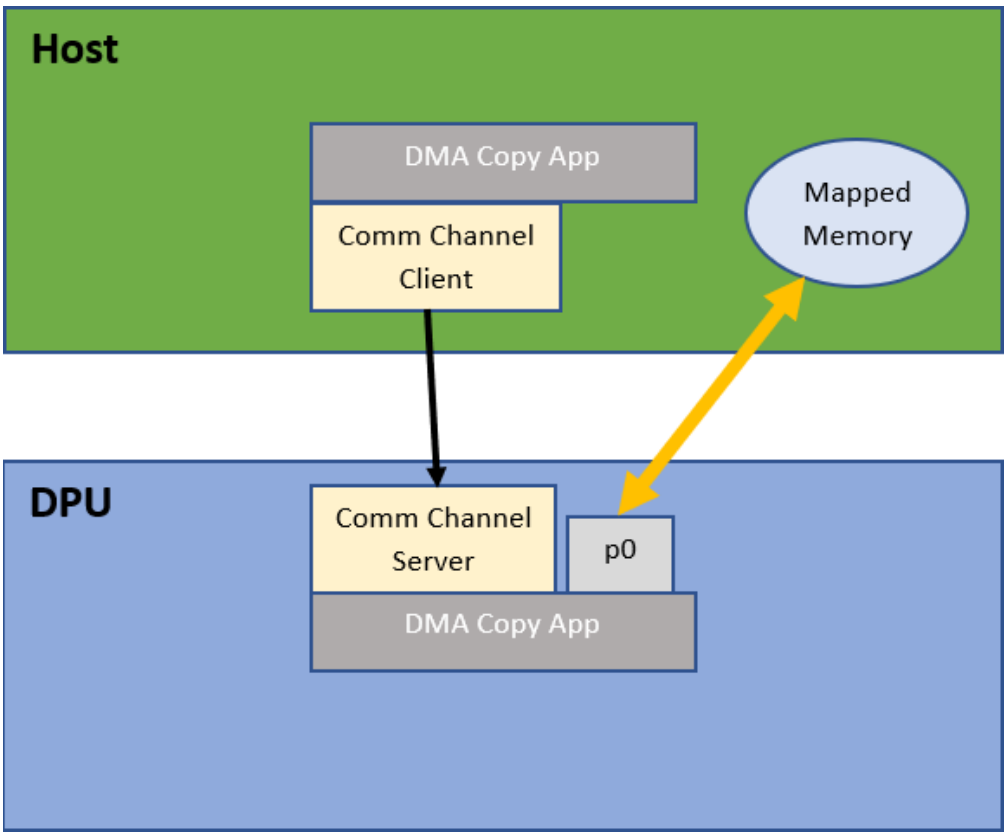
6.5.1 Introduction

DOCA DMA (direct memory access) Copy application transfers files (data path), up to the maximum supported size by the hardware, between the DPU and the x86 host using the DOCA DMA Library which provides an API to copy data between DOCA buffers using hardware acceleration, supporting both local and remote memory.

DOCA DMA allows complex memory copy operations to be easily executed in an optimized, hardware-accelerated manner.

6.5.2 System Design

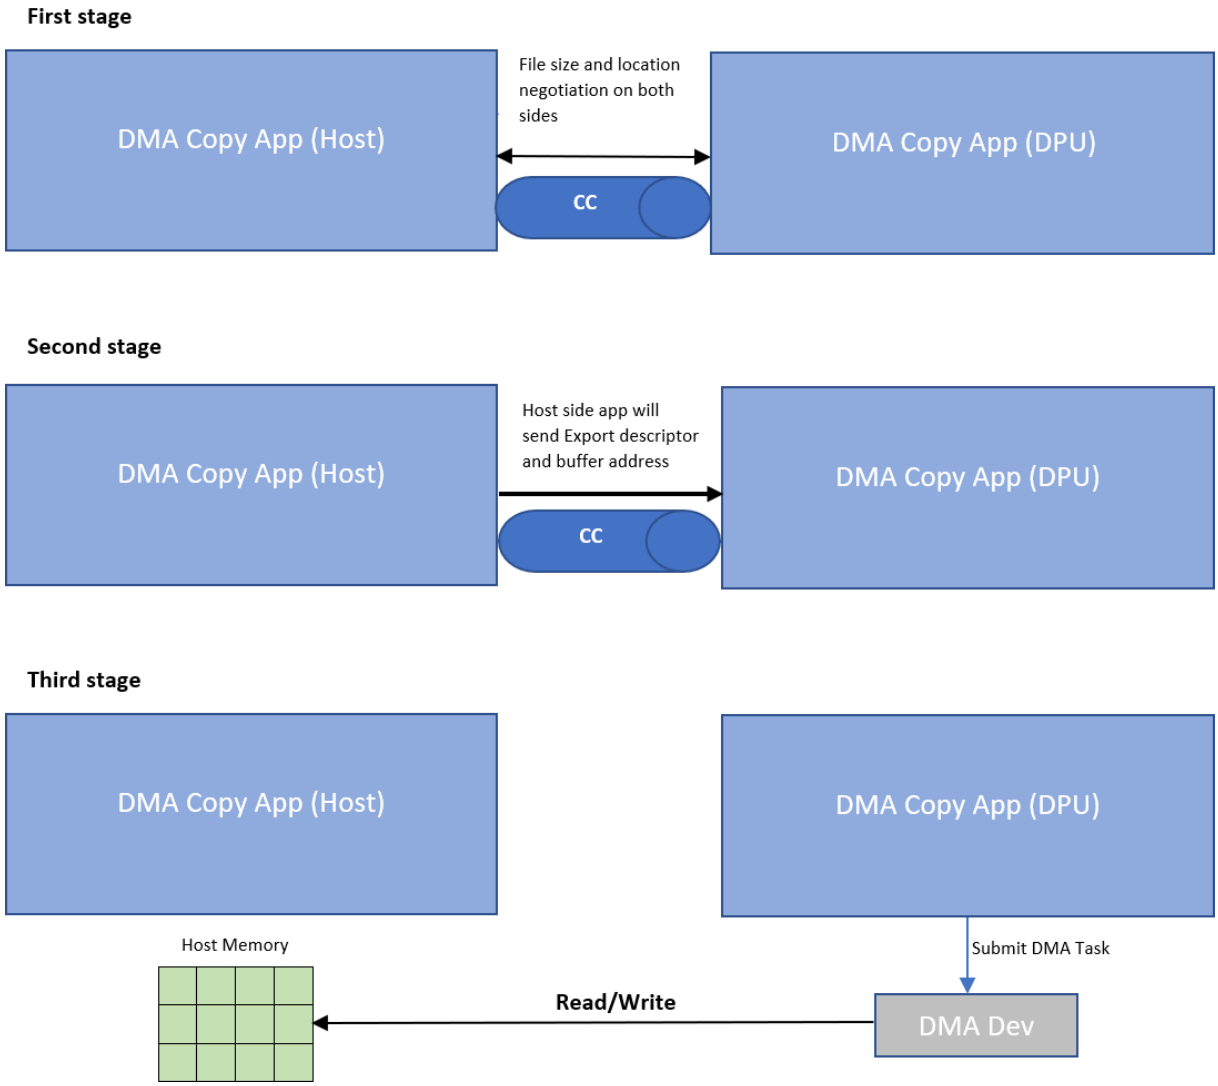
DOCA DMA Copy is designed to run on the instances of the BlueField DPU and x86 host. The DPU application must be the first to spawn as it opens the DOCA Comch server between the two sides on which all the necessary DOCA DMA library configuration files (control path) are transferred.



⚠ This reference application is designed for simplicity and clarity. Therefore, security-related requirements, such as isolation between the Host/DPU or among DPU processes, are out of scope and have not been addressed.

6.5.3 Application Architecture

DOCA DMA Copy runs on top of DOCA DMA to read/write directly from the host's memory without any user/kernel space context switches, allowing for a fast memory copy.



Flow:

1. The two sides initiate a short negotiation in which the file size and location are determined.
2. The host side creates the export descriptor with `doca_mmap_export_pci()` and sends it with the local buffer address and length on the Comch to the DPU side application.
3. The DPU side application uses the received export descriptor to create a remote memory map locally with `doca_mmap_create_from_export()` and the host buffer information to create a remote DOCA buffer.
4. From this point on, the DPU side application has all the necessary memory information and the DMA copy can take place.

6.5.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA DMA
- DOCA Comch

Refer to their respective programming guide for more information.

6.5.5 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

The installation of DOCA's reference applications contains the sources of the applications, alongside the matching compilation instructions. This allows for compiling the applications "as-is" and provides the ability to modify the sources, then compile a new version of the application.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The sources of the application can be found under the application's directory: `/opt/mellanox/doca/applications/dma_copy/`.

6.5.5.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_dma_copy` is created under `/tmp/build/dma_copy/`.

6.5.5.2 Compiling Only the Current Application

To directly build only the DMA Copy application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_dma_copy=true
ninja -C /tmp/build
```

> `doca_dma_copy` is created under `/tmp/build/dma_copy/`.

Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_dma_copy` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> `doca_dma_copy` is created under `/tmp/build/dma_copy/`.

6.5.6 Running the Application

6.5.6.1 Application Execution

The DMA Copy application is provided in source form. Therefore, a compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_dma_copy [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -f, --file                        Full path to file to be copied/created after a successful DMA copy
  -p, --pci-addr                    DOCA Comm Channel device PCI address
  -r, --rep-pci                     DOCA Comm Channel device representor PCI address (needed only on DPU)
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_dma_copy -h
```

For additional information, refer to section "Command Line Flags".

- CLI example for running the application on the BlueField:

```
./doca_dma_copy -p 03:00.0 -r 3b:00.0 -f received.txt
```

Both the DOCA Comch device PCIe address (`03:00.0`) and the DOCA Comch device representor PCIe address (`3b:00.0`) should match the addresses of the desired PCIe devices.

- CLI example for running the application on the host:

```
./doca_dma_copy -p 3b:00.0 -f send.txt
```

The DOCA Comch device PCIe address, `3b:00.0`, should match the address of the desired PCIe device.

6.5.6.2 Command Line Flags

6.5.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)

Short Flag	Long Flag	Description
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.5.6.2.2 Program Flags

Short Flag	Long Flag	Description
`f`	`file`	Full path to file to be copied/created after a successful copy. ⚠ This is a mandatory flag.
`p`	`pci-addr`	DOCA Comch device PCIe address. ⚠ This is a mandatory flag.
`r`	`rep-pci`	DOCA Comch device representor PCIe address. ⚠ This is a mandatory flag only on the DPU.

6.5.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.5.7 Application Code Flow

1. Parse application argument.
    a. Initialize arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

b. Register DMA Copy application parameters.

```
register_dma_copy_params();
```

c. Parse the arguments.

```
doca_argp_start();
```

2. Initialize Comch endpoint.

```
init_cc();
```

a. Create Comch endpoint.
b. Parse user PCIe address for Comch device.
c. Open Comch DOCA device.
d. Parse user PCIe address for Comch device representor (on DPU side).
e. Open Comch DOCA device representor (on DPU side).
f. Set Comch endpoint properties.

3. Open the DOCA hardware device from which the copy would be made.

```
open_dma_device();
```

a. Parse the PCIe address provided by the user.
b. Create a list of all available DOCA devices.
c. Find the appropriate DOCA device according to specific properties.
d. Open the device.

4. Create all required DOCA core objects.

```
create_core_objects();
```

5. Initiate DOCA core objects.

```
init_core_objects();
```

6. Start host/DPU DMA Copy.
   a. Host side application:

```
host_start_dma_copy();
```

i. Start negotiation with the DPU side application for the location and size of the file.
ii. Allocate memory for the DMA buffer.
iii. Export the memory map and send the output (export descriptor) to the DPU side application.
iv. Send the host local buffer memory address and length on the Comch to the DPU side application.
v. Wait for the DPU to notify that DMA Copy ended.

vi. Close all memory objects.
vii. Clean resources.

b. DPU side application:

```
dpu_start_dma_copy();
```

i. Start negotiation with the host side application for file location and size.
ii. Allocate memory for the DMA buffer.
iii. Receive the export descriptor on the Comch.
iv. Create the DOCA memory map for the remote buffer on the host.
v. Receive the host buffer information on the Comch.
vi. Create two DOCA buffers, one for the remote (host) buffer and one for the local buffer.
vii. Submit the DMA copy task.
viii. Send a host message to notify that DMA copy ended.
ix. Clean resources.

7. Destroy Comch.

```
destroy_cc();
```

8. Destroy DOCA core objects.

```
destroy_core_objects();
```

9. Arg parser destroy.

```
doca_argp_destroy();
```

6.6 DOCA DPA All-to-all Application Guide

This guide explains all-to-all collective operation example when accelerated using the DPA in NVIDIA® BlueField®-3 DPU.

6.6.1 Introduction

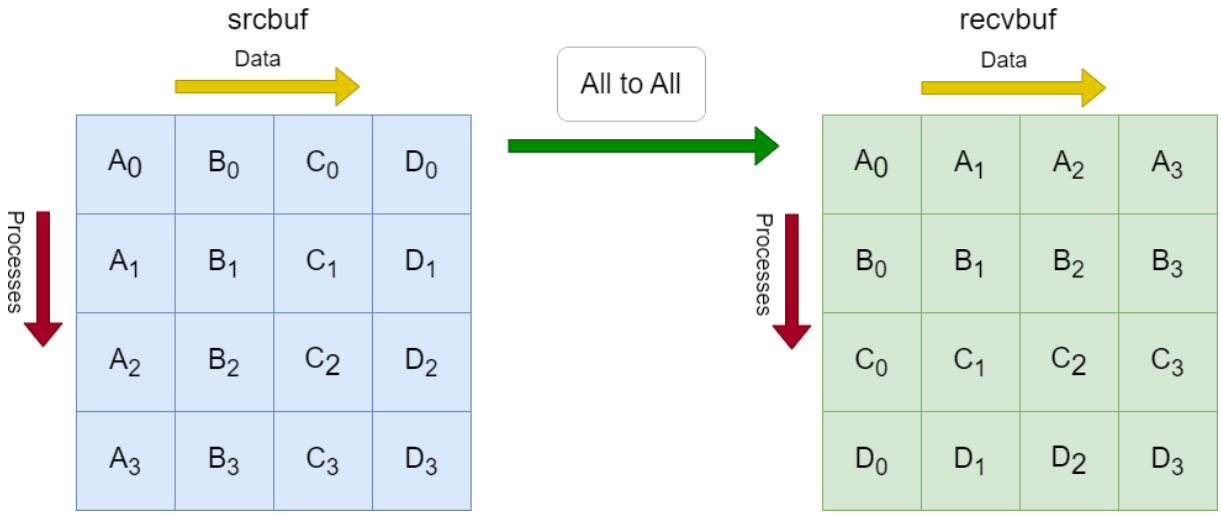
This reference application shows how the message passing interface (MPI) all-to-all collective can be accelerated on the Data Path Accelerator (DPA). In an MPI collective, all processes in the same job call the collective routine.

Given a communicator of *n* ranks, the application performs a collective operation in which all processes send and receive the same amount of data from all processes (hence all-to-all).

This document describes how to run the all-to-all example using the DOCA DPA API.

6.6.2 System Design

All-to-all is an MPI method. MPI is a standardized and portable message passing standard designed to function on parallel computing architectures. An MPI program is one where several processes run in parallel.

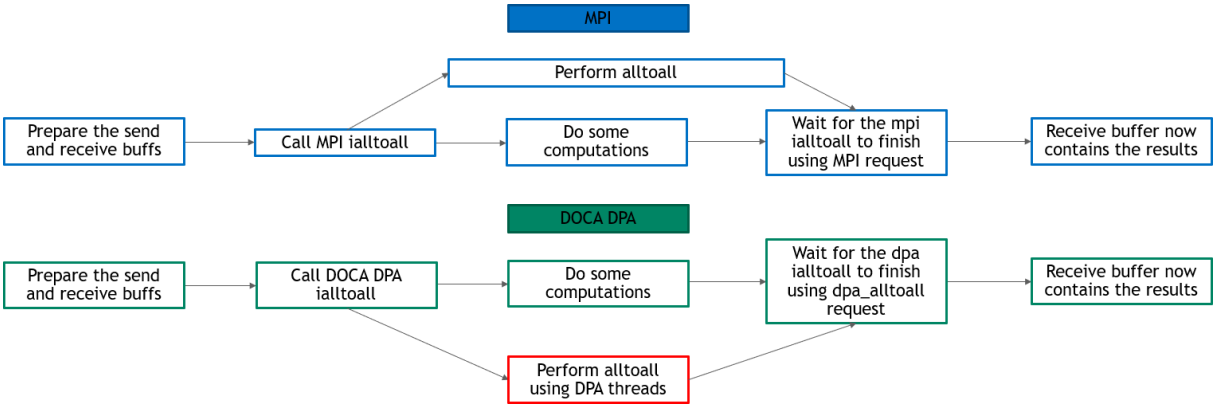


Each process in the diagram divides its local sendbuf into *n* blocks (4 in this example), each containing sendcount elements (4 in this example). Process *i* sends the *k*-th block of its local sendbuf to process *k* which places the data in the *i*-th block of its local recvbuf.

Implementing all-to-all method using DOCA DPA offloads the copying of the elements from the srcbuf to the recvbufs to the DPA, and leaves the CPU free to perform other computations.

6.6.3 Application Architecture

The following diagram describes the differences between host-based all-to-all and DPA all-to-all.



- In DPA all-to-all, DPA threads perform all-to-all and the CPU is free to do other computations
- In host-based all-to-all, CPU must still perform all-to-all at some point and is not completely free for other computations

6.6.4 DOCA Libraries

This application leverages the following DOCA library:

- DOCA DPA

Refer to its programming guide for more information.

6.6.5 Dependencies

- NVIDIA BlueField-3 platform is required
- The application can be run on target BlueField or on host.
- Open MPI version 4.1.5rc2 or greater (included in DOCA's installation).

6.6.6 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/dpa_all_to_all/
```

6.6.6.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

MPI is used for the compilation of this application. Make sure that MPI is installed on your setup (`openmpi` is provided as part of the installation of DOCA, as part of the `doca-all` and `doca-ofed` meta-packages).

Compiling the application requires updating the `LD_LIBRARY_PATH` and `PATH` environment variable to include MPI. For example, if `openmpi` is installed under `/usr/mpi/gcc/openmpi-4.1.7rc1`, then updating the environment variables should be like the following

```
export PATH=/usr/mpi/gcc/openmpi-4.1.7rc1/bin:${PATH}
export LD_LIBRARY_PATH=/usr/mpi/gcc/openmpi-4.1.7rc1/lib:${LD_LIBRARY_PATH}
```

To build all applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_dpa_all_to_all` is created under `/tmp/build/dpa_all_to_all/`.

6.6.6.2 Compiling DPA All-to-all Application Only

To directly build only all-to-all application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_dpa_all_to_all=true
ninja -C /tmp/build
```

`doca_dpa_all_to_all` is created under `/tmp/build/dpa_all_to_all/`.

Alternatively, one can set the desired flags in `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_dpa_all_to_all` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_dpa_all_to_all` is created under `/tmp/build/dpa_all_to_all/`.

6.6.7 Running the Application

6.6.7.1 Prerequisites

MPI is used to run this application. Make sure that MPI is installed on your setup (`openmpi` is provided as part of the installation of DOCA on the host, as part of the `doca-all` and `doca-ofed` meta-packages).

Running the application requires updating the `LD_LIBRARY_PATH` and `PATH` environment variable to include MPI. For example, if `openmpi` is installed under `/usr/mpi/gcc/openmpi-4.1.7rc1`, then updating the environment variables should be like the following:

```
export PATH=/usr/mpi/gcc/openmpi-4.1.7rc1/bin:${PATH}
export LD_LIBRARY_PATH=/usr/mpi/gcc/openmpi-4.1.7rc1/lib:${LD_LIBRARY_PATH}
```

6.6.7.2 Application Execution

DPA all-to-all application is provided in source form. Therefore, a compilation is required before application can be executed.

1. Application usage instructions:

```
Usage: doca_dpa_all_to_all [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -m, --msgsize <Message size>      The message size - the size of the sendbuf and recvbuf (in bytes). Must
be in multiplies of integer size. Default is size of one integer times the number of processes.
  -pf_devs, --pf-devices <PF device name> PF devices names that supports DPA, separated by comma without
spaces (max of two devices). If not provided then a random device will be chosen.
```

This usage printout can be printed to the command line using the `-h` (or `--help`) option:

```
./doca_dpa_all_to_all -h
```

The `rdma_devs` flag is only available when running the application from the target BlueField.

For additional information, please refer to section "Command Line Flags".

2. CLI example for running the application on host:

This is an MPI program, so use `mpirun` to run the application (with the `-np` flag to specify the number of processes to run).

- The following runs the DPA all-to-all application with 8 processes using the default message size (the number of processes, which is 8, times the size of 1 integer) with a random InfiniBand device:

```
mpirun -np 8 ./doca_dpa_all_to_all
```

- The following runs DPA all-to-all application with 8 processes, with 128 bytes as message size, and with `mlx5_0` and `mlx5_1` as the InfiniBand devices:

```
mpirun -np 8 ./doca_dpa_all_to_all -m 128 -pf_devs "mlx5_0,mlx5_1"
```

The application supports running with a maximum of 16 processes. If you try to run with more processes, an error is printed and the application exits.

6.6.7.3 Command Line Flags

6.6.7.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.6.7.3.2 Program Flags

Flag Type	Short Flag	Long Flag	Description
Program flags	`m`	`msgsize`	The message size. The size of the sendbuf and recvbuf (in bytes). Must be in multiples of an integer. The default is size of 1 integer times the number of processes.
	`pf_devs`	`pf-devices`	InfiniBand devices names that support DPA, separated by comma without spaces (max of two devices). If `NOT_SET` then a random InfiniBand device is chosen.

6.6.7.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.6.8 Application Code Flow

1. Initialize MPI.

```
MPI_Init(&argc, &argv);
```

2. Parse application arguments.
   a. Initialize arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

   b. Register the application's parameters.

```
register_all_to_all_params();
```

   c. Parse the arguments.

```
doca_argp_start();
```

      i. The `msgsize` parameter is the size of the sendbuf and recvbuf (in bytes). It must be in multiples of an integer and at least the number of processes times an integer size.
      ii. The `pf_devices_param` parameter is the names of the InfiniBand devices to use (must support DPA). It can include up to two devices names.

   d. Only let the first process (of rank 0) parse the parameters to then broadcast them to the rest of the processes.
3. Check and prepare the needed resources for the `all_to_all` call:

a. Check the number of processes (maximum is 16).
b. Check the `msgsize`. It must be in multiples of integer size and at least the number of processes times integer size.
c. Allocate the sendbuf and recvbuf according to `msgsize`.

4. Prepare the resources required to perform all-to-all method using DOCA DPA:

> The application uses MPI without an additional security layer. The data exported (for sync event, RDMA, and MMAP), as described in this step, should be passed over a secure channel in a production deployment.

a. Initialize DOCA DPA context(s):
   i. Open DOCA DPA device(s) (DOCA device that supports DPA).

```
open_dpa_devices();
```

   ii. Initialize DOCA DPA context using the opened device.

```
extern struct doca_dpa_app *dpa_all2all_app;

doca_dpa_create(pf_doca_device, &pf_doca_dpa);

doca_dpa_set_app(pf_doca_dpa, dpa_all2all_app);

doca_dpa_start(pf_doca_dpa);
```

1. When running from target BlueField: Initialize Extended DOCA DPA context using the opened RDMA device.

```
#ifdef DOCA_ARCH_DPU
    doca_dpa_device_extend(pf_doca_dpa, rdma_doca_device, &rdma_doca_dpa);
#else
    *rdma_doca_device = *pf_doca_device;
#endif
```

b. Initialize the required DOCA Sync Events for the all-to-all:
   i. One completion event for the kernel launch where the subscriber is CPU and the publisher is DPA.
   ii. Kernel events, published by remote peer and subscribed to by DPA, as the number of processes.

```
create_dpa_a2a_events() {
    // initialize completion event
    doca_sync_event_create(&comp_event);

    doca_sync_event_add_publisher_location_dpa(comp_event);

    doca_sync_event_add_subscriber_location_cpu(comp_event);

    doca_sync_event_start(comp_event);

    // initialize kernels events
    for (i = 0; i < resources->num_ranks; i++) {
        doca_sync_event_create(&(kernel_events[i]));

        doca_sync_event_add_publisher_location_remote_net(kernel_events[i]);

        doca_sync_event_add_subscriber_location_dpa(kernel_events[i]);

        doca_sync_event_start(kernel_events[i]);
    }
}
```

c. Prepare DOCA RDMAs and set them to work on DPA:

i. Create DOCA RDMAs as the number of processes/ranks.

```
for (i = 0; i < resources->num_ranks; i++) {
    doca_rdma_create(&rdma);

    rdma_as_doca_ctx = doca_rdma_as_ctx(rdma);

    doca_rdma_set_permissions(rdma);

    doca_rdma_set_grh_enabled(rdma);

    doca_ctx_set_datapath_on_dpa(rdma_as_doca_ctx, rdma_doca_dpa);

    doca_ctx_start(rdma_as_doca_ctx);
}
```

ii. Connect local DOCA RDMAs to the remote DOCA RDMAs.

```
connect_dpa_a2a_rdmas();
```

iii. Get DPA handles for local DOCA RDMAs (so they can be used by DPA kernel) and copy them to DPA heap memory.

```
for (int i = 0; i < resources->num_ranks; i++) {
    doca_rdma_get_dpa_handle(rdmas[i], &(rdma_handles[i]));
}

doca_dpa_mem_alloc(&dev_ptr_rdma_handles);

doca_dpa_h2d_memcpy(dev_ptr_rdma_handles, rdma_handles);
```

d. Prepare the memory required to perform all-to-all method using DOCA Mmap. This includes creating DPA memory handles for sendbuf and recvbuf, getting other processes recvbufs handles, and copying these memory handles and their remote keys and events handlers to DPA heap memory.

```
prepare_dpa_a2a_memory();
```

5. Launch `alltoall_kernel` using DOCA DPA kernel launch with all required parameters:
   a. Every MPI rank launches a kernel of up to `MAX_NUM_THREADS`. This example defines `MAX_NUM_THREADS` as 16.
   b. Launch `alltoall_kernel` using `kernel_launch`.

```
doca_dpa_kernel_launch_update_set();
```

   c. Each process should perform `num_ranks` RDMA write operations, with local and remote buffers calculated based on the rank of the process that is performing the RDMA write operation and the rank of the remote process that is being written to. The application iterates over the rank of the remote process.i
   Each process runs `num_threads` threads on this kernel, therefore the number of RDMA write operations (which is the number of processes) is divided by the number of threads.
   Each thread should wait on its local events to make sure that the remote processes have finished RDMA write operations.

```
for (i = thread_rank; i < num_ranks; i += num_threads) {
    doca_dpa_dev_rdma_post_write();
    doca_dpa_dev_rdma_signal_set();
}

for (i = thread_rank; i < num_ranks; i += num_threads) {
    doca_dpa_dev_sync_event_wait_gt();
}
```

RDMA operations should be executed over a secure channel in a production deployment, given the sensitivity arising from the nature of the protocol.

d. Wait until `alltoall_kernel` has finished.

```
doca_sync_event_wait_gt();
```

Add an MPI barrier after waiting for the event to make sure that all of the processes have finished executing `alltoall_kernel`.

```
MPI_Barrier();
```

After `alltoall_kernel` is finished, the recvbuf of all processes contains the expected output of all-to-all method.

6. Destroy `a2a_resources`:
   a. Free all DOCA DPA memories.

```
doca_dpa_mem_free();
```

   b. Destroy all DOCA Mmaps

```
doca_mmap_destroy();
```

   c. Destroy all DOCA RDMAs.

```
doca_ctx_stop();
doca_rdma_destroy();
```

   d. Destroy all DOCA Sync Events.

```
doca_sync_event_destroy();
```

   e. Destroy DOCA DPA context.

```
doca_dpa_destroy();
```

   f. Close DOCA device.

```
doca_dev_close();
```

6.7 DOCA East-West Overlay Encryption Application

This guide describes IPsec-based strongSwan solution on top of NVIDIA® BlueField® DPU.

> **Important note for NVIDIA® BlueField®-2 DPUs**
>
> If your target application utilizes 100Gb/s or higher bandwidth, where a substantial part of the bandwidth is allocated for IPsec traffic, please refer to the *NVIDIA BlueField-2 DPUs Product Release Notes* to learn about a potential bandwidth limitation. To access the relevant product release notes, please contact your NVIDIA sales representative.

6.7.1 Introduction

IPsec is used to set up encrypted connections between different devices. It helps keep data sent over public networks secure. IPsec is often used to set up VPNs, and it works by encrypting IP packets as well as authenticating the packets' originator.

IPsec contains the following main modules:

- Key exchange – a key is a string of random bytes that can be used for encryption and decryption of messages. IPsec sets up keys with a key exchange between the connected devices, so that each device can decrypt the other device's messages.
- Authentication – IPsec provides authentication for each packet which ensures that they come from a trusted source.
- Encryption – IPsec encrypts the payloads within each packet and possibly, based on the transport mode, the packet's IP header.
- Decryption – at the other end of the communication, packets are decrypted by the IPsec supported node.

IPsec supports two types of headers:

- Authentication header (AH) – AH protocol ensures that packets are from a trusted source. AH does not provide any encryption.

- Encapsulating security protocol (ESP) – ESP encrypts the payload for each packet as well as the IP header depending on the transport mode. ESP adds its own header and a trailer to each data packet.

IPsec support two types of transport mode:

- IPsec tunnel mode – used between two network nodes, each acting as tunnel initiator/terminator on a public network. In this mode, the original IP header and payload are both encrypted. Since the IP header is encrypted, an IP tunnel is added for network forwarding. At each end of the tunnel, the routers decrypt the IP headers to route the packets to their destinations.
- Transport mode – the payload of each packet is encrypted, but the original IP header is not. Intermediary network nodes are therefore able to view the destination of each packet and route the packet, unless a separate tunneling protocol is used.

strongSwan is an open-source IPsec-based VPN solution. For more information, refer to strongSwan documentation.

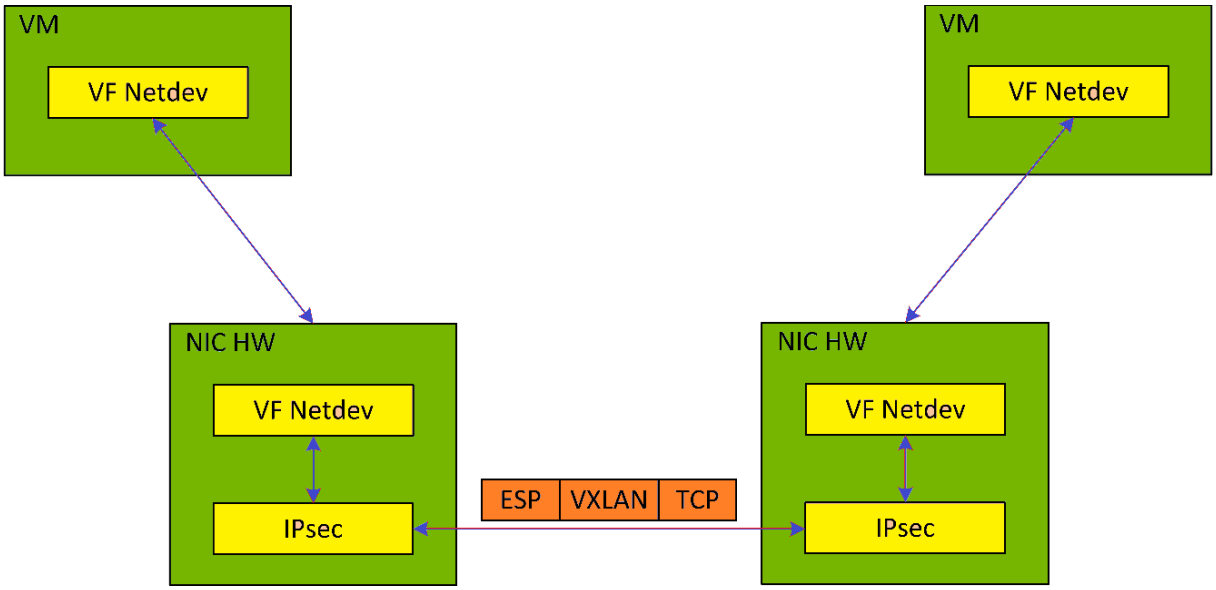
6.7.2 System Design

IPsec packet offload offloads both IPsec crypto (encrypt/decrypt) and IPsec encapsulation to the hardware.

The deployment model allows the IPsec offload to be transparent to the host with the benefits of securing legacy workloads (no dependency on host SW stack) and to zero CPU utilization on host.

IPsec packet offload configuration works with and is transparent to OVS offload. This means all packets from OVS offload are encrypted by IPsec rules.

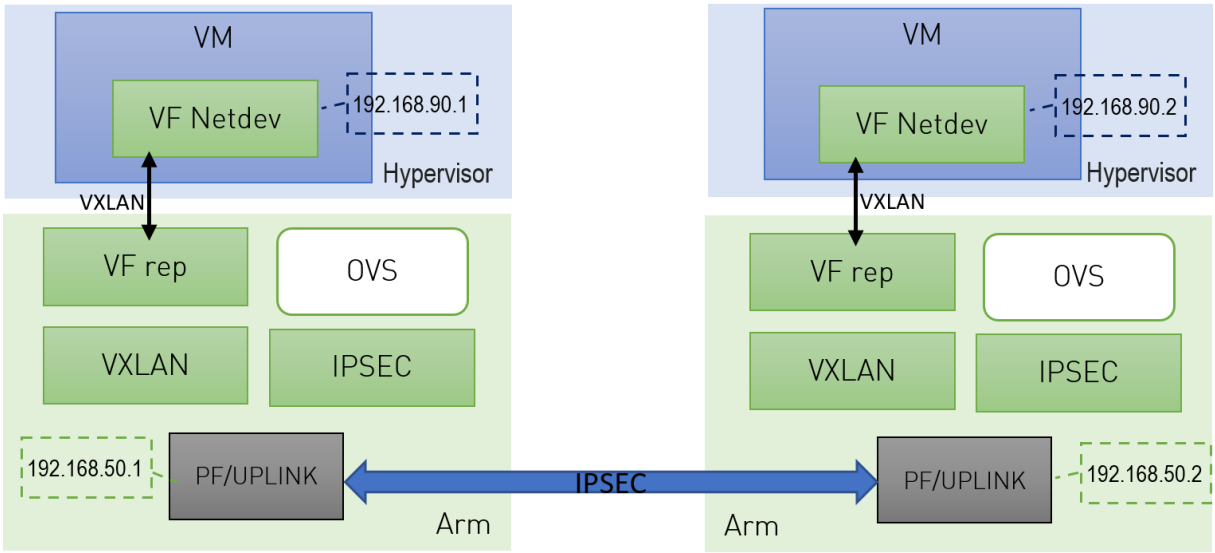
The following figure illustrates the interaction between IPsec packet offload and OVS VXLAN offload.



IPsec packet offload is only supported on Ubuntu Bluefield kernel 5.15

OVS offload and IPsec IPv6 do not work together.

6.7.3 Application Architecture



1. Configure strongSwan IPsec offload using `swanctl.conf` configuration file.
2. Traffic is sent from the host through BlueField.
3. Using OVS, the packets are encapsulated on ingress using tunnel protocols (VXLAN for example) to match IPsec configuration by strongSwan.

4. Set by strongSwan configuration file, traffic will be encrypted using the hardware offload.
5. Egress flow is decryption first, decapsulation of the tunnel header and forward to the relevant physical function.

6.7.4 DOCA Libraries

N/A

6.7.5 Dependencies

- NVIDIA® BlueField®-2 platform or higher is required
- BlueField Ubuntu BFB with kernel 5.15
- strongSwan version 5.9.10 or greater

6.7.5.1 Compiling and Installing strongSwan

> The following section provides instruction for compiling and installing NVIDIA's strongSwan fork (branch BF-5.9.10), but users can use the upstream strongSwan instructions (as long as the version is 5.9.10 or greater).

To compile and install strongswan from the source, perform these steps on BlueField (Arm cores):

1. Install dependencies:

```
sudo apt install dpkg-dev devscripts debhelper dh-autoreconf autoconf flex libtool gperf lzip yacc bison
flex m4 libgmp-dev libsystemd-dev -y
```

2. Clone and compile strongSwan:

```
$ git clone https://github.com/Mellanox/strongswan.git
$ cd strongswan
$ git checkout BF-5.9.10
$ dpkg-buildpackage -uc -us -b
```

This should create two `.deb` files in the parent folder, `strongswan_5.9.10-2.bf_arm64.deb` and `strongswan-swanctl_5.9.10-2.bf_arm64.deb`.

> **Warning:** strongSwan BF-5.9.10 is based on the official strongSwan 5.9.10 branch with added packaging and support for DOCA IPsec plugin. Refer to the DOCA IPsec Security Gateway Application Guide for more information regarding the strongSwan DOCA plugin.

3. Uninstall all old strongSwan and charon packages to prevent conflicts:

```
$ sudo dpkg -P --force-depends <packages>
```

Example:

```
$ sudo dpkg -P --force-depends libstrongswan libstrongswan-standard-plugins strongswan strongswan-charon
strongswan-libcharon strongswan-starter libcharon-extauth-plugins
```

> **Note:** Users can find all strongSwan and charon packages by running `dpkg -l | grep strongswan` and `dpkg -l | grep charon`.

4. Install the two strongSwan .deb files (they should've been created in the parent folder).

```
$ sudo dpkg -i ../strongswan_5.9.10-2.bf_arm64.deb ../strongswan-swanctl_5.9.10-2.bf_arm64.deb
```

6.7.6 Configuration Flow

The following section provides information on manually configuring IPsec packet offload in general and on using OVS IPsec with strongSwan specifically.

> **Warning:** There is a script, `east_west_overlay_encryption.sh` which performs the steps in this section automatically.

If you are working directly with the `ip xfrm` tool, use `/opt/mellanox/iproute2/sbin/ip` to benefit from IPsec packet offload support.

There are two parts in the configuration flow

1. Enabling IPsec packet offload mode.
2. Configuring the IPsec OVS bridge using one of three modes of authentication.

> **Warning:** An alternative for step two is configuring `swanctl.conf` files (configuration files for strongSwan) manually and using strongSwan directly instead of using IPsec OVS (which automatically generates `swanctl.conf` files) as explained in section "Configuring OVS IPsec Using strongSwan Manually".

6.7.6.1 Enabling IPsec Packet Offload

This section explicitly enables IPsec packet offload on the Arm cores before setting up offload-aware IPsec tunnels.

> ⚠ If an OVS VXLAN tunnel configuration already exists, stop `openvswitch` service prior to performing the steps below and restart the service afterwards.

Explicitly enable IPsec full offload on the Arm cores.

1. Set `IPSEC_FULL_OFFLOAD="yes"` in `/etc/mellanox/mlnx-bf.conf`.

   > ⚠ If `IPSEC_FULL_OFFLOAD` does not appear in `/etc/mellanox/mlnx-bf.conf` then you are probably using an old version of the BlueField image. Check the way of enabling IPsec full offload in a previous DOCA versions in the NVIDIA DOCA Documentation Archives.

2. Restart IB driver (rebooting also works). Run:

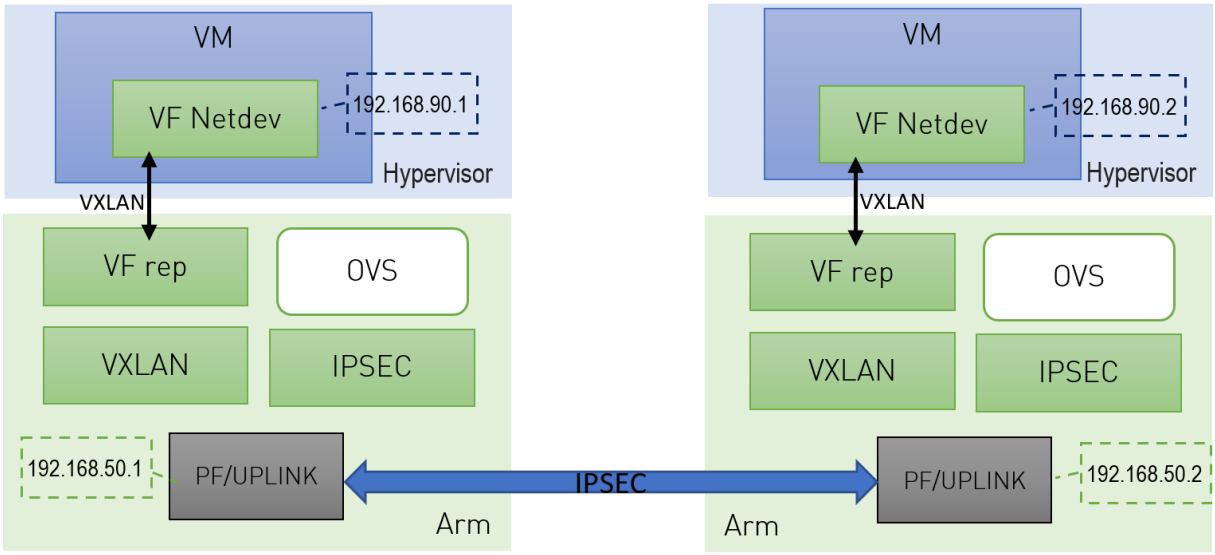
   ```
   /etc/init.d/openibd restart
   ```

> ⚠ To revert IPsec full offload mode, redo the procedure from step 1, only difference is to set `IPSEC_FULL_OFFLOAD="no"` in `/etc/mellanox/mlnx-bf.conf`.

6.7.6.2 Configuring OVS IPsec

> ⚠ Before proceeding with this section, make sure to follow the procedure in section "Enabling IPsec Packet Offload" for both DPUs.

This section configures OVS IPsec VXLAN tunnel which automatically generates the `swanctl.conf` files and runs strongSwan (the IPsec daemon). The following figure illustrates an example with two BlueField DPUs, Left and Right, operating with a secured VXLAN channel.



Two BlueField DPUs are required to build an OVS IPsec tunnel between the two hosts, Right and Left.

The OVS IPsec tunnel configures an unaware IPsec connection between the two hosts' InfiniBand devices. For the sake of this example, the host's InfiniBand network device is `HOST_PF`, and the DPU's host representor is `PF_REP` and the DPU's physical function `PF`.

This example sets up the following variables on both Arms:

```
# host_ip1=1.1.1.1
# host_ip2=1.1.1.2
# HOST_PF=ens7np0
# ip1=192.168.50.1
# ip2=192.168.50.2
# PF=p0
# PF_REP=pf0hpf
```

The name of the `HOST_PF` could be different in your machine. You may verify this by running:

```
host# ibdev2netdev
mlx5_0 port 1 ==> ens7np0 (Down)
mlx5_1 port 1 ==> ens8np1 (Down)
```

This example uses the first InfiniBand's (`mlx5_0`) network device which is `ens7np0`.

1. Configure IP addresses for the `HOST_PF`s of both hosts (x86):
   a. On `host_1`:

   ```
   # ifconfig $HOST_PF $host_ip1/24 up
   ```

   b. On `host_2`:

```
# ifconfig $HOST_PF $host_ip2/24 up
```

> ⚠ Step 1 is the only command that is performed on the host, the rest of the commands are performed on the Arm (DPU) side.

2. Configure IP addresses for the PFs of both Arms:
   a. On `Arm_1`:

```
# ifconfig $PF $ip1/24 up
```

   b. On `Arm_2`:

```
# ifconfig $PF $ip2/24 up
```

3. Start Open vSwitch. If your operating system is Ubuntu, run the following on both `Arm_1` and `Arm_2`:

```
# service openvswitch-switch start
```

   If your operating system is CentOS, run the following on both `Arm_1` and `Arm_2`:

```
# service openvswitch restart
```

4. Start OVS IPsec service. Run on both `Arm_1` and `Arm_2`:

```
# systemctl start openvswitch-ipsec.service
```

5. Set up OVS bridges in both DPUs. Run on both `Arm_1` and `Arm_2`:

```
# ovs-vsctl add-br vxlan-br
# ovs-vsctl add-port ovs-br $PF_REP
# ovs-vsctl set Open_vSwitch . other_config:hw-offload=true
```

> ⚠ Configuring `other_config:hw-offload=true` sets IPsec Packet offload. Setting it to `false` sets software IPsec.

> ⚠ The MTU of the MTU of the tunnel interface (PF) should be at least 50 bytes larger than the MTU of the endpoints of the tunnels above (PF_REP) to account for the size of the VXLAN tunnel header. For example, if the MTU of PF_REP is 1500 then the MTU of PF should be at least 1550.
>
> To configure the MTU of the PF:
>
> ```
> # ifconfig $PF mtu $PF_MTU up
> ```

6. Set up IPsec tunnel on the OVS bridge. Three authentication methods are possible, choose your preferred authentication method and follow the steps relevant to it. Note that the last two authentication methods requires you to create certificates (self-signed certificates or certificate authority certificates).

After the IPsec tunnel is set up using one of the three methods of authentication, strongSwan configuration is done automatically and the `swanctl.conf` files will be generated and strongSwan will run automatically.

6.7.6.2.1 Authentication Methods

The following subsections detail the possible authentication methods for setting up the IPsec tunnel on the OVS bridge.

6.7.6.2.1.1 Pre-shared Key

This method configures OVS IPsec using a pre-shared key. You must select a pre-shared key, for example:

```
psk=swordfish
```

1. Set up the VXLAN tunnel:
    a. On `Arm_1`, run:

```
# ovs-vsctl add-port vxlan-br tun -- \
            set interface tun type=vxlan \
                        options:local_ip=$ip1 \
                        options:remote_ip=$ip2 \
                        options:key=100 \
                        options:dst_port=4789 \
                        options:psk=$psk
```

    b. On `Arm_2`, run:

```
# ovs-vsctl add-port vxlan-br tun -- \
            set interface tun type=vxlan \
                        options:local_ip=$ip2 \
                        options:remote_ip=$ip1 \
                        options:key=100 \
                        options:dst_port=4789\
                        options:psk=$psk
```

6.7.6.2.1.2 Self-signed Certificate

This method configures OVS IPsec using self-signed certificates. You must generate self-signed certificates and keys. This example demonstrates how to generate self-signed certificates using `ovs-pki` but you may generate them in any other way while skipping step 1.

1. Generate self-signed certificates using `ovs-pki`:
    a. On `Arm_1`, run:

```
# ovs-pki req -u host_1
# ovs-pki self-sign host_1
```

After running this code you should have `host_1-cert.pem` and `host_1-privkey.pem`.

b. On `Arm_2`, run:

```
# ovs-pki req -u host_2
# ovs-pki self-sign host_2
```

After running this code you should have `host_2-cert.pem` and `host_2-privkey.pem`.

2. Configure the certificates and private keys:
   a. Copy the certificate of `Arm_1` to `Arm_2`, and the certificate of `Arm_2` to `Arm_1`.
   b. On each machine, move both `host_1-privkey.pem` and `host_2-cert.pem` to `/etc/swanctl/x509/` if on Ubuntu, or `/etc/strongswan/swanctl/x509/` if on CentOS.
   c. On each machine, move the local private key (`host_1-privkey.pem` on `Arm_1` and `host_2-privkey.pem` on `Arm_2`) to `/etc/swanctl/private` if on Ubuntu, or `/etc/strongswan/swanctl/private` if on CentOS.
3. Set up OVS `other_config` on both sides.
   a. On `A rm_1`:

```
# ovs-vsctl set Open_vSwitch . other_config:certificate=/etc/swanctl/x509/host_1-cert.pem \
  other_config:private_key=/etc/swanctl/private/host_1-privkey.pem
```

   b. On `Arm_2`:

```
# ovs-vsctl set Open_vSwitch . other_config:certificate=/etc/swanctl/x509/host_2-cert.pem \
  other_config:private_key=/etc/swanctl/private/host_2-privkey.pem
```

4. Set up the VXLAN tunnel:
   a. On `Arm_1`:

```
# ovs-vsctl add-port vxlan-br vxlanp0 -- set interface vxlanp0 type=vxlan options:local_ip=$ip1 \
  options:remote_ip=$ip2 options:key=100 options:dst_port=4789 \
  options:remote_cert=/etc/swanctl/x509/host_2-cert.pem
# service openvswitch-switch restart
```

   b. On `Arm_2`:

```
# ovs-vsctl add-port vxlan-br vxlanp0 -- set interface vxlanp0 type=vxlan options:local_ip=$ip2 \
  options:remote_ip=$ip1 options:key=100 options:dst_port=4789 \
  options:remote_cert=/etc/swanctl/x509/host_1-cert.pem
# service openvswitch-switch restart
```

⚠ In steps 3 and 4, if you are in CentOS you must change the path of the certificates to `/etc/strongswan/swanctl/x509/` and the path of the private keys to `/etc/strongswan/swanctl/private`.

6.7.6.2.1.3 CA-signed Certificate

This method configures OVS IPsec using certificate authority (CA)-signed certificates. You must generate CA-signed certificates and keys. The example demonstrates how to generate CA-signed certificates using `ovs-pki` but you may generate them in any other way while skipping step 1.

1. Generate CA-signed certificates using `ovs-pki`. For this method, all the certificates and the requests must be in the same directory during the certificate generating and signing. This example refers to this directory as `certsworkspace`.
   a. On `Arm_1`, run:

```
# ovs-pki init --force
# cp /var/lib/openvswitch/pki/controllerca/cacert.pem <path_to>/certsworkspace
# cd <path_to>/certsworkspace
# ovs-pki req -u host_1
# ovs-pki sign host1 switch
```

   After running this code, you should have `host_1-cert.pem`, `host_1-privkey.pem`, and `cacert.pm` in the `certsworkspace` folder.
   b. On `Arm_2`, run:

```
# ovs-pki init --force
# cp /var/lib/openvswitch/pki/controllerca/cacert.pem <path_to>/certsworkspace
# cd <path_to>/certsworkspace
# ovs-pki req -u host_2
# ovs-pki sign host_2 switch
```

   After running this code, you should have `host_2-cert.pem`, `host_2-privkey.pem`, and `cacert.pm` in the `certsworkspace` folder.
2. Configure the certificates and private keys:
   a. Copy the certificate of `Arm_1` to `Arm_2` and the certificate of `Arm_2` to `Arm_1`.
   b. On each machine, move both `host_1-privkey.pem` and `host_2-cert.pem` to `/etc/swanctl/x509/` if on Ubuntu, or `/etc/strongswan/swanctl/x509/` if on CentOS.
   c. On each machine, move the local private key (`host_1-privkey.pem` if on `Arm_1` and `host_2-privkey.pem` if on `Arm_2`) to `/etc/swanctl/private` if on Ubuntu, or `/etc/strongswan/swanctl/private` if on CentOS.
   d. On each machine, copy `cacert.pem` to the `x509ca` directory under `/etc/swanctl/x509ca/` if on Ubuntu, or `/etc/strongswan/swanctl/x509ca/` if on CentOS.

3. Set up OVS `other_config` on both sides.
    a. On `Arm_1`:

```
# ovs-vsctl set Open_vSwitch . \
        other_config:certificate=/etc/strongswan/swanctl/x509/host_1.pem \
        other_config:private_key=/etc/strongswan/swanctl/private/host_1-privkey.pem \
        other_config:ca_cert=/etc/strongswan/swanctl/x509ca/cacert.pem
```

    b. On `Arm_2`:

```
# ovs-vsctl set Open_vSwitch . \
        other_config:certificate=/etc/strongswan/swanctl/x509/host_2.pem \
        other_config:private_key=/etc/strongswan/swanctl/private/host_2-privkey.pem \
        other_config:ca_cert=/etc/strongswan/swanctl/x509ca/cacert.pem
```

4. Set up the tunnel:
    a. On `Arm_1`:

```
# ovs-vsctl add-port vxlan-br vxlanp0 -- set interface vxlanp0 type=vxlan options:local_ip=$ip1 \
options:remote_ip=$ip2 options:key=100 options:dst_port=4789 \ options:remote_name=host_2
# service openvswitch-switch restart
```

    b. On `Arm_2`:

```
# ovs-vsctl add-port vxlan-br vxlanp0 -- set interface vxlanp0 type=vxlan options:local_ip=$ip2 \
options:remote_ip=$ip1 options:key=100 options:dst_port=4789 \ options:remote_name=host_1
# service openvswitch-switch restart
```

In steps 3 and 4, if you are in CenOS you must change the path of the certificates to `/etc/strongswan/swanctl/x509/`, the path of the CA certificate to `/etc/strongswan/swanctl/x509ca/`, and the path of the private keys to `/etc/strongswan/swanctl/private/`.

6.7.6.3 Ensuring IPsec is Configured

Using `/opt/mellanox/iproute2/sbin/ip xfrm state show`, you should be able to see 4 IPsec states for the IPsec connection you configured with the keyword `in mode packet` meaning which means that you are in IPsec packet HW offload mode.

For example, after configuring IPsec using pre-shared key method, you would get something similar to the following on `Arm_1`:

```
# /opt/mellanox/iproute2/sbin/ip xfrm state show

src 192.168.50.1 dst 192.168.50.2
    proto esp spi 0xcc8bf8ad reqid 1 mode transport
    replay-window 0 flag esn
    aead rfc4106(gcm(aes)) 0x9f45cc4577e70c4e077bcc0c1473a782143e7ad199f58566519639d03b593b8996383f11 128
    anti-replay esn context:
     seq-hi 0x0, seq 0x0, oseq-hi 0x0, oseq 0x0
     replay_window 1, bitmap-length 1
     00000000
    crypto offload parameters: dev p0 dir out mode packet
    sel src 192.168.50.1/32 dst 192.168.50.2/32 proto udp sport 4789
src 192.168.50.2 dst 192.168.50.1
    proto esp spi 0xce8bf4b6 reqid 1 mode transport
    replay-window 0 flag esn
```

```
    aead rfc4106(gcm(aes)) 0xf2d0e335d9a64ef6e385a630a32b0e43bb52f581290cd34bbb8f7592d54f11657ed0258e 128
    anti-replay esn context:
     seq-hi 0x0, seq 0x0, oseq-hi 0x0, oseq 0x0
     replay_window 32, bitmap-length 1
     00000000
    crypto offload parameters: dev p0 dir in mode packet
    sel src 192.168.50.2/32 dst 192.168.50.1/32 proto udp dport 4789
src 192.168.50.1 dst 192.168.50.2
    proto esp spi 0xcb600a84 reqid 2 mode transport
    replay-window 0 flag esn
    aead rfc4106(gcm(aes)) 0x7fb26035299bcc9b973abea5d581acfbcf87cbf0bd053b745c4d95c62311f934010973f6 128
    anti-replay esn context:
     seq-hi 0x0, seq 0x0, oseq-hi 0x0, oseq 0x0
     replay_window 1, bitmap-length 1
     00000000
    crypto offload parameters: dev p0 dir out mode packet
    sel src 192.168.50.1/32 dst 192.168.50.2/32 proto udp dport 4789
src 192.168.50.2 dst 192.168.50.1
    proto esp spi 0xc137d5a0 reqid 2 mode transport
    replay-window 0 flag esn
    aead rfc4106(gcm(aes)) 0x28e3d12ad4e24aa9d9de9459de8ef8bb4379e8e12faac0054c5b629b6aa50fdeda8e4574 128
    anti-replay esn context:
     seq-hi 0x0, seq 0x0, oseq-hi 0x0, oseq 0x0
     replay_window 32, bitmap-length 1
     00000000
    crypto offload parameters: dev p0 dir in mode packet
    sel src 192.168.50.2/32 dst 192.168.50.1/32 proto udp sport 4789
```

After insuring that the IPsec connection is configured, you can send encrypted traffic between `host_1` and `host_2` using the `HOST_PF` s IP addresses.

6.7.6.4 Configuring OVS IPsec Using strongSwan Manually

This section configures an OVS VXLAN tunnel which then uses `swanctl.conf` files and runs strongSwan (the IPsec daemon) manually.

> ⚠ Before proceeding with this section, make sure to follow the procedure in section "Enabling IPsec Packet Offload" for both DPUs.

1. Build a VXLAN tunnel over OVS and connect the PF representor to the same OVS bridge.
   a. On `Arm_1`:

```
# ovs-vsctl add-br vxlan-br
# ovs-vsctl add-port vxlan-br PF_REP
# ovs-vsctl add-port vxlan-br vxlan11 -- set interface vxlan11 type=vxlan options:local_ip=$ip1 \
        options:remote_ip=$ip2 options:key=100 options:dst_port=4789 \
# ovs-vsctl set Open_vSwitch . other_config:hw-offload=true
```

   b. On `Arm_2`:

```
# ovs-vsctl add-br vxlan-br
# ovs-vsctl add-port vxlan-br PF_REP
# ovs-vsctl add-port vxlan-br vxlan11 -- set interface vxlan11 type=vxlan options:local_ip=$ip2 \
        options:remote_ip=$ip1 options:key=100 options:dst_port=4789 \
# ovs-vsctl set Open_vSwitch . other_config:hw-offload=true
```

2. If your operating system is Ubuntu, run on both `Arm_1` and `Arm_2`:

```
service openvswitch-switch start
```

   If your operating system is CentOS, run:

```
service openvswitch restart
```

3. Enable TC offloading for the PF. Run on both `Arm_1` and `Arm_2`:

```
# ethtool -K $PF hw-tc-offload on
```

4. Disable host PF as the port owner from Arm. Run on both `Arm_1` and `Arm_2`:

```
# mlxprivhost -d /dev/mst/mt${pciconf} --disable_port_owner r
```

> ⚠ To get `${pciconf}`, run the following on the DPU:
>
> ```
> # ls --color=never /dev/mst/ | grep --color=never '^m.*f0$' | cut -c 3-
> ```
>
> For example:
>
> ```
> # mlxprivhost -d /dev/mst/mt41686_pciconf0 --disable_port_owner r
> ```

5. Configure the `swanctl.conf` files for each machine. See section swanctl.conf Files.

> ⚠ Each machine should have exactly one . `swanctl.conf` file in `/etc/swanctl/conf.d/`.

6. Load the `swanctl.conf` files and initialize strongSwan. Run:
   a. On the `Arm_2`, run:

```
systemctl restart strongswan.service
swanctl --load-all
```

   b. On the `Arm_1`, run:

```
systemctl restart strongswan.service
swanctl --load-all
swanctl -i --child bf
```

Now the IPsec connection should be established.

6.7.6.5 swanctl.conf Files

strongSwan configures IPSec packet HW offload using a new value added to its configuration file `swanctl.conf`. The file should be placed under `sysconfdir` which by default can be found at `/etc/swanctl/swanctl.conf`.

The terms Left (BFL) and Right (BFR), in reference to the illustration under "Application Architecture", are used to identify the two nodes (or machines) that communicate.

⚠ Either side (BFL or BFR) can fulfill either role (initiator or receiver).

In this example, 192.168.50.1 is used for the left PF uplink and 192.168.50.2 for the right PF uplink.

```
connections {
   BFL-BFR {
      local_addrs  = 192.168.50.1
      remote_addrs = 192.168.50.2

      local {
        auth = psk
        id = host1
      }
      remote {
        auth = psk
        id = host2
      }
        children {
         bf-out {
            local_ts = 192.168.50.1/24 [udp]
            remote_ts = 192.168.50.2/24 [udp/4789]
            esp_proposals = aes128gcm128-x25519-esn
            mode = transport
            policies_fwd_out = yes
            hw_offload = packet
         }
         bf-in {
            local_ts = 192.168.50.1/24 [udp/4789]
            remote_ts = 192.168.50.2/24 [udp]
            esp_proposals = aes128gcm128-x25519-esn
            mode = transport
            policies_fwd_out = yes
            hw_offload = packet
         }
      }
      version = 2
      mobike = no
      reauth_time = 0
      proposals = aes128-sha256-x25519
   }
}

secrets {
   ike-BF {
      id-host1 = host1
      id-host2 = host2
      secret = 0sv+NkxY9LLZvwj4qCC2o/gGrWDF2d21jL
   }
}
```

The BFB installation will place two example `swanctl.conf` files for BFL and BFR (`BFL.swanctl.conf` and `BFR.swanctl.conf` respectively) in the strongSwan `conf.d` directory. Each node should have only one `swanctl.conf` file in its strongSwan `conf.d` directory.

Note that:

- "`hw_offload = packet`" is responsible for configuring IPsec packet offload
- Packet offload support has been added to the existing `hw_offload` field and preserves backward compatibility.
  For your reference:

Value	Description
no	Do not configure HW offload.
crypto	Configure crypto HW offload if supported by the kernel and hardware, fail if not supported.
yes	Same as crypto (considered legacy).
packet	Configure packet HW offload if supported by the kernel and hardware, fail if not supported.

Value	Description
auto	Configure packet HW offload if supported by the kernel and hardware, do not fail (perform fallback to crypto or no as necessary).

- Whenever the value of `hw_offload` is changed, strongSwan configuration must be reloaded.
- Switching to crypto HW offload requires setting up `devlink/ipsec_mode` to `none` beforehand.
- Switching to packet HW offload requires setting up
- `[udp/4789]` is crucial for instructing strongSwan to IPSec only VXLAN communication.
- Packet HW offload can only be done on what is streamed over VXLAN.

Mind the following limitations:

Fields	Limitation
reauth_time	Ignored if set
rekey_time	Do not use. Ignored if set.
rekey_bytes	Do not use. Not supported and will fail if it is set.
rekey_packets	Use for rekeying

6.7.7 Running the Application

6.7.7.1 Installation

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

6.7.7.2 Application Execution

Notes:

- IPsec daemons are started by `systemd strongswan.service`
- Use `systemctl [start | stop | restart]` to control IPsec daemons through `strongswan.service`. For example, to restart, run:

```
systemctl restart strongswan.service
```

This command effectively does the same thing as `ipsec restart`.

> Do not use the `ipsec` script (located under `/usr/sbin/ipsec`) to restart/stop/start the IPsec connection.

This subsection explains how to configure and set an IPsec connection using the script. To configure the IPsec connection, you need two DPUs, referred to as the initiator and receiver machines. There are no differences between the two machines except that the initiator is the one that initiates the connection between the two (and should run the script after the receiver).

The script is located under `/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh`.

6.7.7.2.1 Script Parameters

Parameter	Description	Valid Values	Use when	Notes
`side`	The side of the connection (receiver or initiator).	• `r|receiver` • `i|intitiator`	Always	This parameter must be always passed on the command line and cannot be passed in the JSON parameter file.
`j|json`	The JSON parameters file full path.	JSON file path, written according to the template demonstrated in the following file: `/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption_params.json`.	To pass the parameters as a JSON file	When running the script with JSON file, you cannot pass on the command line other parameters than the `side` and the JSON file.
`initiator_ip_addr`	The IP address of the initiator machine's port interface for the IPsec connection.	A valid IP address, ranging from 1.1.1.1 to 255.255.255.255.	Always	In the JSON file, it is set by default to 192.168.50.1.
`receiver_ip_addr`	The IP address of the receiver machine's port interface for the IPsec connection.	A valid IP address, ranging from 1.1.1.1 to 255.255.255.255.	Always	In the JSON file, it is set by default to 192.168.50.2.
`port_num`	The number of the port interface (p0/p1) for the IPsec connection.	0 or 1.	Always	In the JSON file, it is set by default to 0.

Parameter	Description	Valid Values	Use when	Notes
`auth_method`	the authentication method of IPsec. can be `psk` (pre-shared key), `ssc` (self-signed certificate) or `ca` (CA-signed certificate). Set by default to `psk`.	Can be `psk` (pre-shared key), `ssc` (self-signed certificate) or `ca` (CA-signed certificate).	Always	In the JSON file, it is set by default to `psk.`
`preshared_key`	The pre-shared key.	A sequence of characters (string).	The `auth_method` parameter is `psk`	In the JSON file it is set by default to `swordfish`. Both the initiator and receiver must configure the same `preshared_key`.
`initiator_cert_path`	The initiator's certificate.	Any valid self-signed or CA signed certificate. Must provide full path of certificate.	The `auth_method` parameter is `ssc` or `ca`	Both the initiator and receiver must configure the same `initiator_cert_path` .
`receiver_cert_path`	The receiver's certificate.	Any valid self-signed or CA signed certificate. Must provide full path of certificate.	The `auth_method` parameter is `ssc` or `ca`	Both the initiator and receiver must configure the same `receiver _cert_path` .
`initiator_key_path`	the initiator's private-key.	Any valid private key that is generated with the certificate. Must provide full path of private key.	The `side` parameter is set to `initiator` and the `auth_method` is set to `ssc` or `ca`	N/A
`receiver_key_path`	the receiver's private-key.	Any valid private key that is generated with the certificate. Must provide full path of private key.	The `side` parameter is set to `receiver` and the `auth_method` is set to `ssc` or `ca`	N/A

Parameter	Description	Valid Values	Use when	Notes
`initiator_cacert_path`	The initiator's CA certificate.	Any valid CA certificate. Must provide full path of certificate.	The `side` and `auth_method` parameters are set to `initiator` and `ca` respectively	N/A
`receiver_cacert_path`	The receiver's CA certificate.	Any valid CA certificate. Must provide full path of certificate.	The `side` and `auth_method` parameters are set to `receiver` and `ca` respectively	N/A
`initiator_cn`	The common name (CN) of the initiator's certificate.	Must be the same as the CN described in the initiator's certificate.	The `side` and `auth_method` parameters are set to `receiver` and `ca` respectively	N/A
`receiver_cn`	The CN of the receiver's certificate.	Must be the same as the CN described in the receiver's certificate.	The `side` and `auth_method` parameters are set to `initiator` and `ca` respectively	N/A

There are two ways of passing the parameters, either using the JSON parameters file or by passing the parameters on the command line.

6.7.7.2.2 Using JSON Parameters File

In this method, you must configure the parameters file and the then run the script:

1. Configure the JSON parameters file located under `/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption_params.json` or create a JSON file according to the template of `east_west_overlay_encryption_params.json` for the script according to the explanation under section "Script Parameters".
2. Run the script on the receiver's DPU with the JSON file:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh --side=r --
json=/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption_params.json
```

3. Run the script on the initiator's DPU:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh --side=i --
json=/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption_params.json
```

   You may now send encrypted data over the PF interface (192.168.50.[1|2]) configured for VXLAN.

6.7.7.2.3 Passing Parameters on Command Line

In this method, you do not need to configure the parameters file and can run the script with the appropriate parameters.

6.7.7.2.3.1 Passing Parameters for Pre-shared Key Authentication Method

1. Run the script on the receiver's DPU:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh --side=r --
initiator_ip_addr=INITIATOR_IP_ADDRESS --receiver_ip_addr=RECEIVER_IP_ADDRESS --port_num=PORT_NUM \
--auth_method=psk --preshared_key=PRESHARED_KEY
```

2. Run the script on the initiator's DPU:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh --side=i --
initiator_ip_addr=INITIATOR_IP_ADDRESS --receiver_ip_addr=RECEIVER_IP_ADDRESS --port_num=PORT_NUM \
--auth_method=psk --preshared_key=PRESHARED_KEY
```

6.7.7.2.3.2 Passing Parameters for Self-signed Certificates Authentication Method

1. Run the script on the receiver's DPU:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh --side=r --
initiator_ip_addr=INITIATOR_IP_ADDRESS --receiver_ip_addr=RECEIVER_IP_ADDRESS --port_num=PORT_NUM \
--auth_method=ssc --initiator_cert_path=INITIATOR_CERT_PATH --receiver_cert_path=RECEIVER_CERT_PATH --
receiver_key_path=RECEIVER_KEY_PATH
```

2. Run the script on the initiator's DPU:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh --side=i --
initiator_ip_addr=INITIATOR_IP_ADDRESS --receiver_ip_addr=RECEIVER_IP_ADDRESS --port_num=PORT_NUM \
--auth_method=ssc --initiator_cert_path=INITIATOR_CERT_PATH --receiver_cert_path=RECEIVER_CERT_PATH --
initiator_key_path=INITIATOR_KEY_PATH
```

6.7.7.2.3.3 Passing Parameters for CA Certificates Authentication Method

1. Run the script on the receiver's DPU:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh --side=r --
initiator_ip_addr=INITIATOR_IP_ADDRESS --receiver_ip_addr=RECEIVER_IP_ADDRESS --port_num=PORT_NUM \
--auth_method=ca --initiator_cert_path=INITIATOR_CERT_PATH --receiver_cert_path=RECEIVER_CERT_PATH --
receiver_key_path=RECEIVER_KEY_PATH --receiver_cacert_path=RECEIVER_CACERT_PATH --initiator_cn=INITIATOR_CN
```

2. Run the script on the initiator's DPU:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh --side=i --
initiator_ip_addr=INITIATOR_IP_ADDRESS --receiver_ip_addr=RECEIVER_IP_ADDRESS --port_num=PORT_NUM \
--auth_method=ssc --initiator_cert_path=INITIATOR_CERT_PATH --receiver_cert_path=RECEIVER_CERT_PATH --
initiator_key_path=INITIATOR_KEY_PATH --initiator_cacert_path=INITIATOR_CACERT_PATH --
receiver_cn=RECEIVER_CN
```

For help and usage, run the script with `--help` / `-h` flag:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh -h
```

6.7.7.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.7.7.4 Reverting IPsec Configuration

To destroy IPsec configuration, run the following on both machines:

```
/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh -d
```

⚠ Make sure to run this command only after at least two minutes have passed from running the application on either machines. Otherwise, this may lead to errors.

⚠ If you run this command without initializing the connection first (in Running strongSwan Example), you may receive errors. These errors have no functional impact and may be safely ignored.

6.7.8 References

- `/opt/mellanox/doca/applications/east_west_overlay_encryption/east_west_overlay_encryption.sh`

6.8 DOCA Eth L2 Forwarding Application Guide

This document provides an Ethernet L2 Forwarding implementation on top of the NVIDIA® BlueField® DPU.

6.8.1 Introduction

The Ethernet L2 Forwarding application is a DOCA Ethernet based application that forwards traffic from a single RX port to a single TX port and vice versa, leveraging DOCA's task/event batching feature for enhanced performance.

The application can run both on the host and the BlueField, and has two main modes:

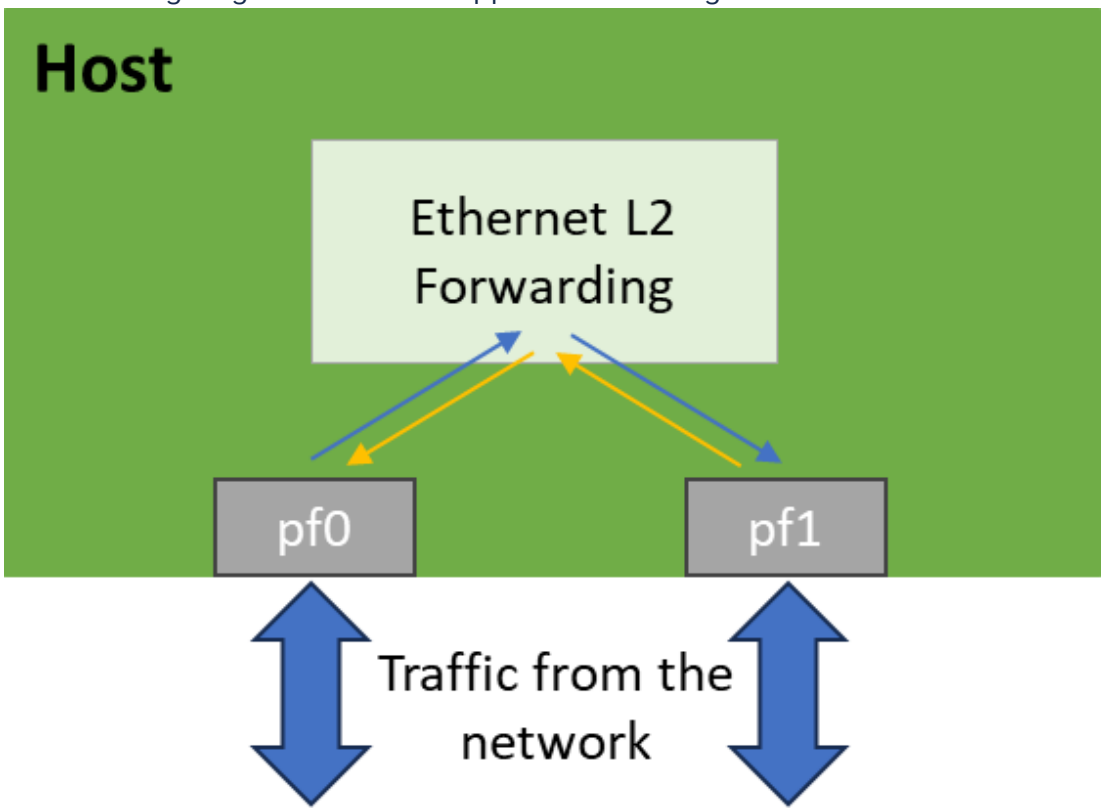
- Two-sided forwarding – device 1 → device 2 *and* device 2 → device 1
- One-sided forwarding – device 1 → device 2 *or* device 2 → device 1

The one-sided mode offers better performance, enlarging the packets forwarding rate.

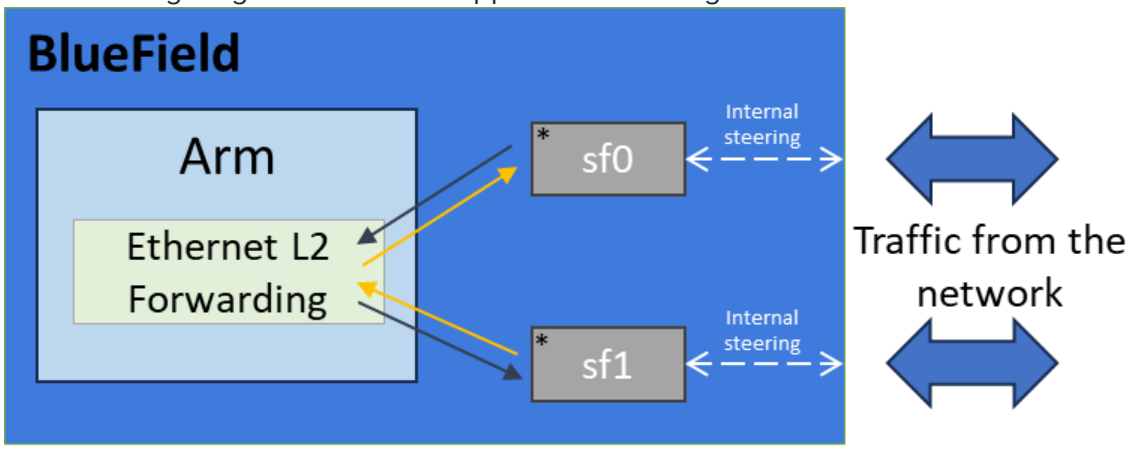
6.8.2 System Design

The Ethernet L2 Forwarding application runs on the host or the BlueField.

- The following diagram shows the application running on the host.



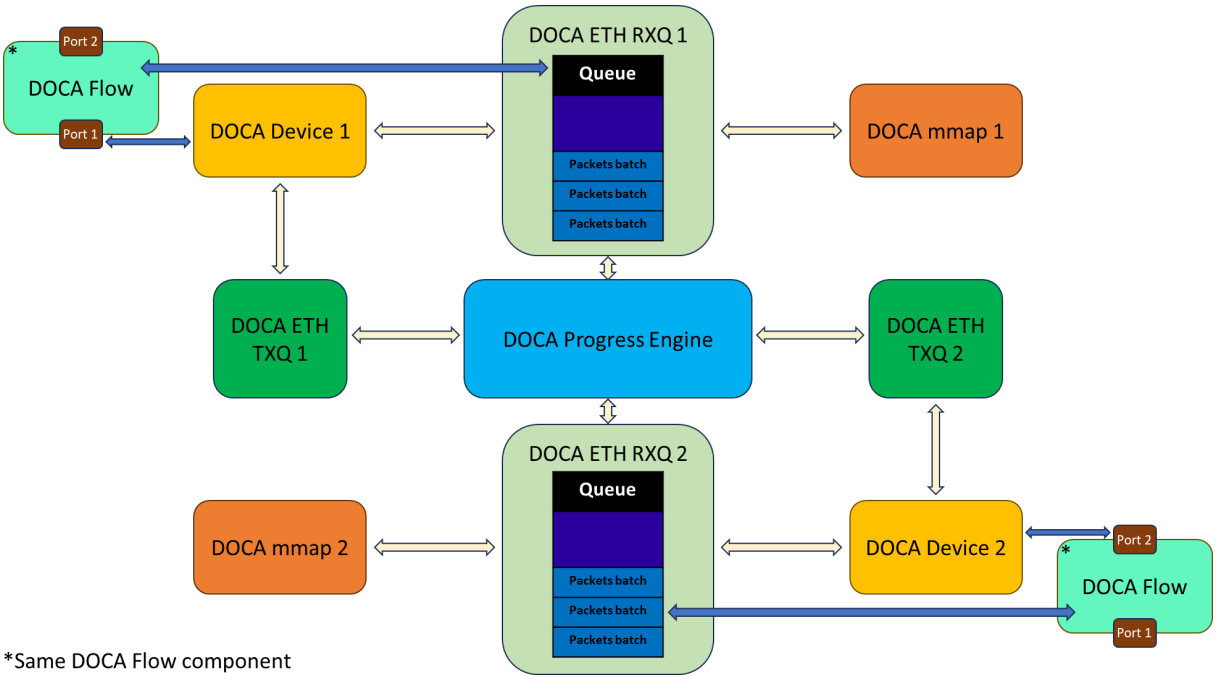
- The following diagram shows the application running on the BlueField:



*DOCA Ethernet library only handles SFs

6.8.3 Application Architecture

The Ethernet L2 Forwarding application runs on top of the DOCA Ethernet API to form an (two/one-sided) L2 forwarding between two ports.



*Same DOCA Flow component

1. Two DOCA devices are opened.
2. Two DOCA mmaps are created.
3. Two DOCA Flow ports are configured and started, each with a different opened DOCA device.
4. Two DOCA Ethernet TXQ and RXQ contexts are initialized, each TXQ-RXQ pair with a different opened DOCA device such that traffic is steered from the device to the corresponding RXQ, and from the corresponding TXQ to the device.
5. Forwarding - Packets received by device x are steered to RXQ x, then allocated to TXQ y and sent by device y (and vice versa).

6.8.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Ethernet
- DOCA Flow

For additional information about the used DOCA libraries, please refer to the respective programming guides.

6.8.5 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/eth_l2_fwd/
```

6.8.5.1 Compiling All Applications

The applications are all defined under a single meson project, meaning that the default compilation will compile all the DOCA applications.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_eth_l2_fwd` will be created under `/tmp/build/eth_l2_fwd/`.

6.8.5.2 Compiling Only the Current Application

1. To directly build only the Ethernet L2 Forwarding application:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build -Denable_all_applications=false -Denable_eth_l2_fwd=true
   ninja -C /tmp/build
   ```

   `doca_eth_l2_fwd` will be created under `/tmp/build/eth_l2_fwd/`.

2. Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:
   a. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
      - Set `enable_all_applications` to `false`
      - Set `enable_eth_l2_fwd` to `true`
   b. The same compilation commands should be used, as were shown in the previous section:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_eth_l2_fwd` will be created under `/tmp/build/eth_l2_fwd/`.

6.8.6 Running the Application

6.8.6.1 Application Execution

The Ethernet L2 Forwarding application is provided in source form, hence a compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_eth_l2_fwd [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --devs-names <name1,name2>    Set two IB devices names separated by a comma, without spaces.
  -r, --rate <rate>                 Set packets receive rate (in [MB/s]), default is 12500.
  -ps, --pkt-size <size>            Set max packet size (in [B]), default is 1600.
  -t, --time <time>                 Set packet max process time (in [µs]), default is 1.
  -nt, --num-tasks <num>            Set number of tasks per batch, default is 128.
  -nb, --num-batches <num>          Set number of task batches, default is 32.
  -o, --one-sided-forwarding <num>  Set one-sided forwarding: 0 - two-sided forwarding, 1 - device 1 ->
device 2, 2 - device 2 -> device 1. default is 0.
  -f, --max-forwardings <num>       Set max forwardings after which the application run will end, default
 is 0, meaning no limit.
```

For additional information, please refer to the Command Line Flags section below.

The above usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_eth_l2_fwd -h
```

- CLI example for running the application either on the BlueField or on the host:

```
./doca_eth_l2_fwd -d mlx5_0,mlx5_1
```

Both IB devices identifiers (`mlx5_0, mlx5_1`) should match the identifiers of the desired IB devices.

6.8.6.2 Command Line Flags

6.8.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.8.6.2.2 Program Flags

Short Flag	Long Flag	Description
`d`	`devs-names`	Two IB devices names, separated by a comma, without spaces. ⚠ This is a mandatory flag.
`r`	`rate`	The rate (in [MB/s]) in which the RX port is expected to receive traffic.
`ps`	`pkt-size`	The maximum size (in [B]) of a received packet.
`t`	`time`	The maximum time taking to process a single packet.

Short Flag	Long Flag	Description
`nt`	`num-tasks`	The number of tasks to set per a single task batch.
`nb`	`num-batches`	The number of task batches to set for the TX side.
`o`	`one-sided-forwarding`	Flag to set one of 3 options: • 0 – Two-sided forwarding. • 1 – One-sided forwarding from device 1 to device 2. • 2 – One-sided forwarding from device 2 to device 1.
`f`	`max-forwardings`	The maximum number of forwarding

6.8.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.8.7 Application Code Flow

1. Parse application argument.
    a. Initialize Arg parser resources and register DOCA general parameters.

    ```
    doca_argp_init();
    ```

    b. Register Ethernet L2 Forwarding application parameters.

    ```
    register_eth_l2_forwarding_params();
    ```

    c. Parse the arguments.

    ```
    doca_argp_start();
    ```

        i. Parse DOCA flags.
        ii. Parse application parameters.
2. Execute Ethernet L2 Forwarding application main logic.

    ```
    eth_l2_fwd_execute();
    ```

    a. Open the two chosen DOCA devices.
    b. Initialize necessary DOCA Core objects.
    c. Initialize ETH RXQ/TXQ contexts for the devices.
    d. Forward packets.
3. Clean up application resources.

    ```
    eth_l2_fwd_cleanup();
    ```

    a. Stop all contexts and drain tasks.

b. Free all application resources.

4. Arg parser destroy.

```
doca_argp_destroy()
```

6.8.8 References

- `/opt/mellanox/doca/applications/eth_l2_fwd/`

6.9 DOCA File Compression Application Guide

This document provides a file compression implementation on top of the NVIDIA® BlueField® DPU.

6.9.1 Introduction

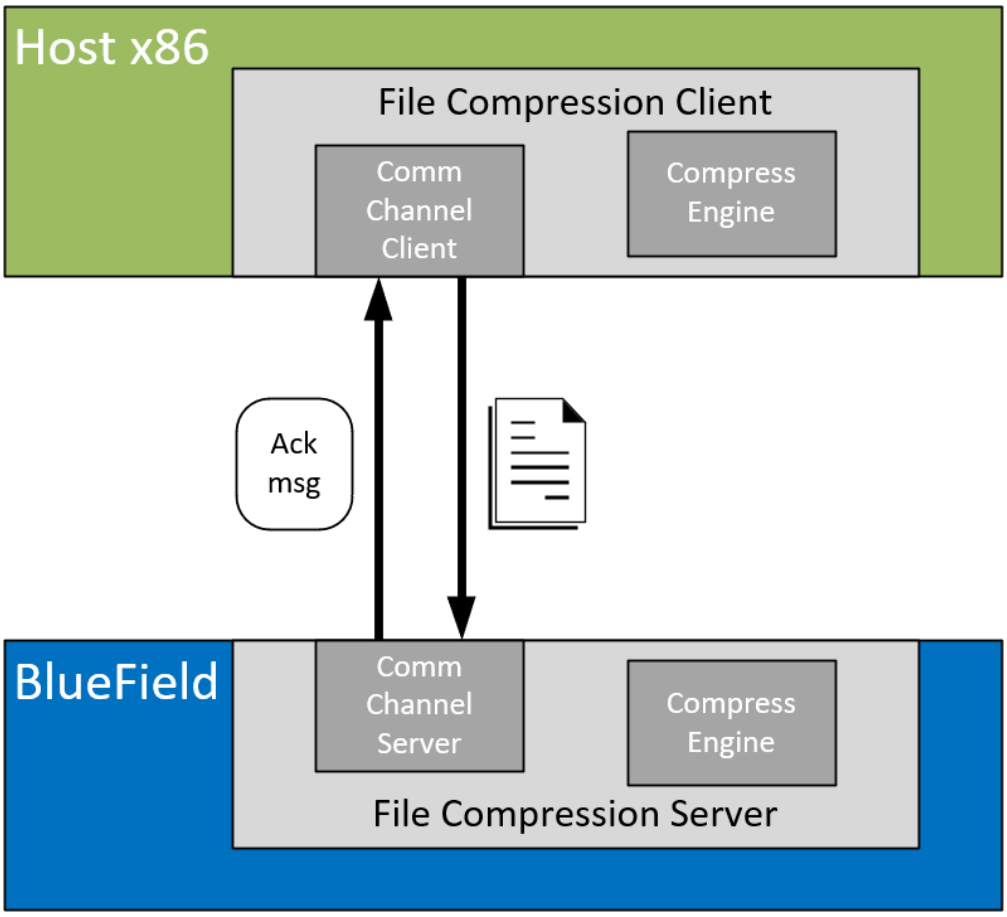
The file compression application exhibits how to use the DOCA Compress API to compress and decompress data using hardware acceleration as well as sending and receiving it using the DOCA Comch API.

The application's logic includes both a client and a server:

- Client side – the application opens a file, compresses it, and sends the checksum of the source file with the compressed data to the server
- Server side – the application saves the received file in a buffer, decompresses it, and compares the received checksum with the calculated one

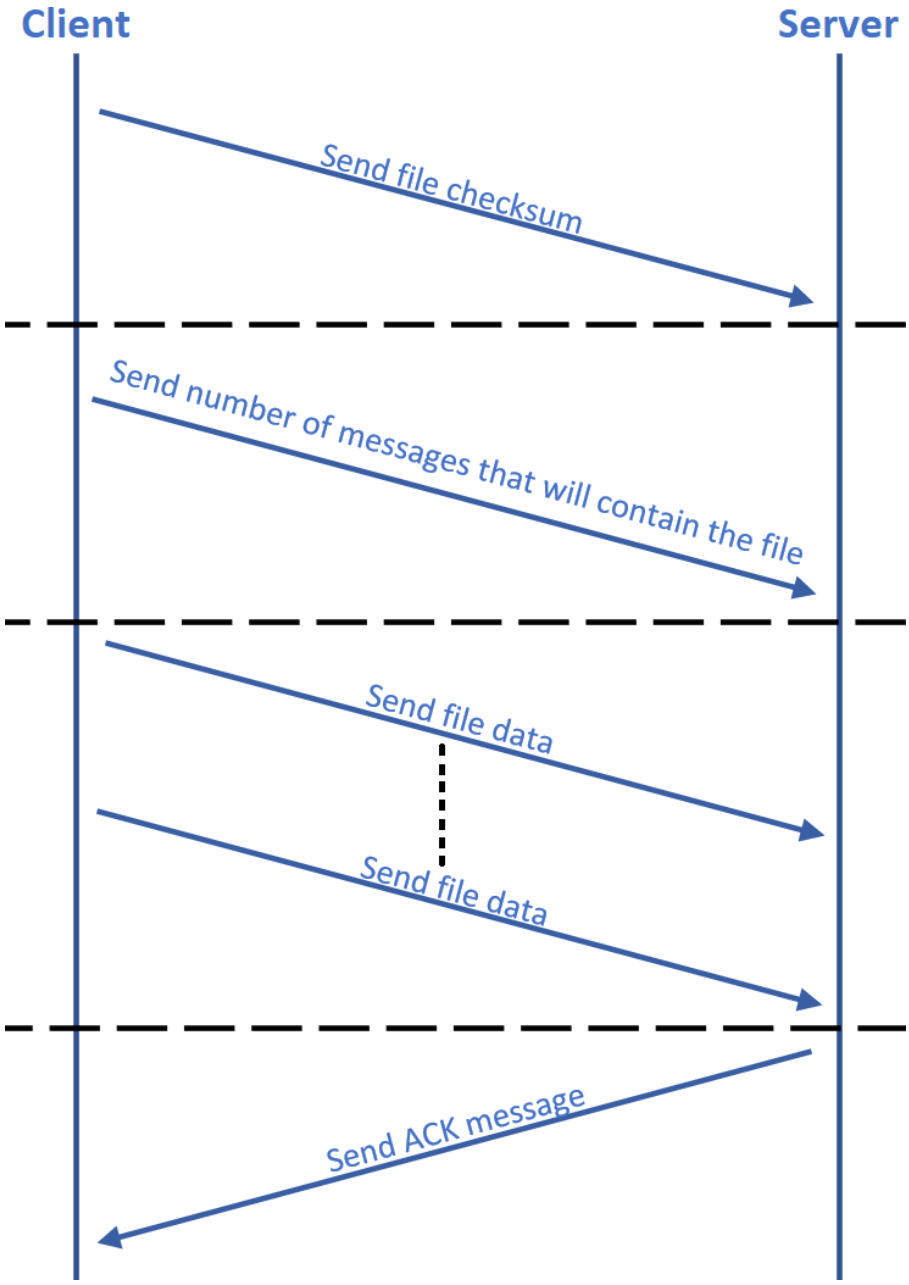
6.9.2 System Design

The file compression application client runs on the host and the server runs on the DPU.



6.9.3 Application Architecture

The file compression application runs on top of the DOCA Comm Channel API to send and receive the file from the host and to the DPU.



1. Connection is established on both sides by DOCA Comm Channel API.
2. Client compresses the data:
    - When compress engine is available – submits compress job with DOCA Compress API and sends the result to the server
    - When compress engine is unavailable – compresses the data in software
3. Client sends the number of messages needed to send the compressed content of the file.
4. Client sends data segments in size of up to 4080 bytes.
5. Server saves the received data in a buffer and submits a decompress job.
6. Server sends an ACK message to the client when all parts of the file are received successfully.

7. Server compares the received checksum to the calculated checksum.
8. Server writes the decompressed data to an output file.

6.9.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Compress
- DOCA Comch

Refer to their respective programming guide for more information.

6.9.5 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/file_compression/
```

6.9.5.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> `doca_file_compression` is created under `/tmp/build/file_compression/`.

6.9.5.2 Compiling File Compression Application Only

To directly build only the file compression application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_file_compression=true
ninja -C /tmp/build
```

> `doca_file_compression` is created under `/tmp/build/file_compression/`.

Alternatively, the user may set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_file_compression` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> `doca_file_compression` is created under `/tmp/build/file_compression/`.

6.9.6 Running the Application

6.9.6.1 Application Execution

The file compression application is provided in source form. Therefore, a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_file_compression [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA Comm Channel device PCI address
  -r, --rep-pci                     DOCA Comm Channel device representor PCI address
```

```
  -f, --file                      File to send by the client / File to write by the server
  -t, --timeout                   Application timeout for receiving file content messages, default is 5
sec
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_file_compression -h
```

For additional information, refer to section "Command Line Flags".

2. CLI example for running the application on BlueField:

```
./doca_file_compression -p 03:00.0 -r 3b:00.0 -f received.txt
```

Both the DOCA Comm Channel device PCIe address (`03:00.0`) and the DOCA Comm Channel device representor PCIe address (`3b:00.0`) should match the addresses of the desired PCIe devices.

3. CLI example for running the application on the host:

```
./doca_file_compression -p 3b:00.0 -f send.txt
```

The DOCA Comm Channel device PCIe address (`3b:00.0`) should match the address of the desired PCIe device.

6.9.6.2 Command Line Flags

6.9.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information

Short Flag	Long Flag	Description
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.9.6.2.2 Program Flags

Short Flag	Long Flag	Description
`f`	`file`	• For client – path to the file to be sent • For server – path to write the file into ⚠ This is a mandatory flag.
`p`	`pci-addr`	Comm Channel DOCA device PCIe address ⚠ This is a mandatory flag.
`r`	`rep-pci`	Comm Channel DOCA device representor PCIe address ⚠ This flag is mandatory only on the DPU.

6.9.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.9.7 Application Code Flow

1. Parse application argument.
    a. Initialize arg parser resources and register DOCA general parameters.

    ```
    doca_argp_init();
    ```

    b. Register file compression application parameters.

    ```
    register_file_compression_params();
    ```

    c. Parse the arguments.

    ```
    doca_argp_start();
    ```

        i. Parse app parameters.
2. Set endpoint attributes.

    ```
    set_endpoint_properties();
    ```

    a. Set maximum message size of 4080 bytes.
    b. Set maximum number of messages allowed.
3. Create comm channel endpoint.

    ```
    doca_comm_channel_ep_create();
    ```

    a. Create endpoint for client/server.
4. Run client/server main logic.

    ```
    file_compression_client/server();
    ```

5. Clean up the file compression application.

    ```
    file_compression_cleanup();
    ```

    a. Free all application resources.
6. Arg parser destroy.

    ```
    doca_argp_destroy()
    ```

6.10 DOCA File Integrity Application Guide

This guide provides a file integrity implementation on top of NVIDIA® BlueField® DPU.

6.10.1 Introduction

The file integrity application exhibits how to use the DOCA Comch and DOCA SHA libraries to send and receive a file securely.

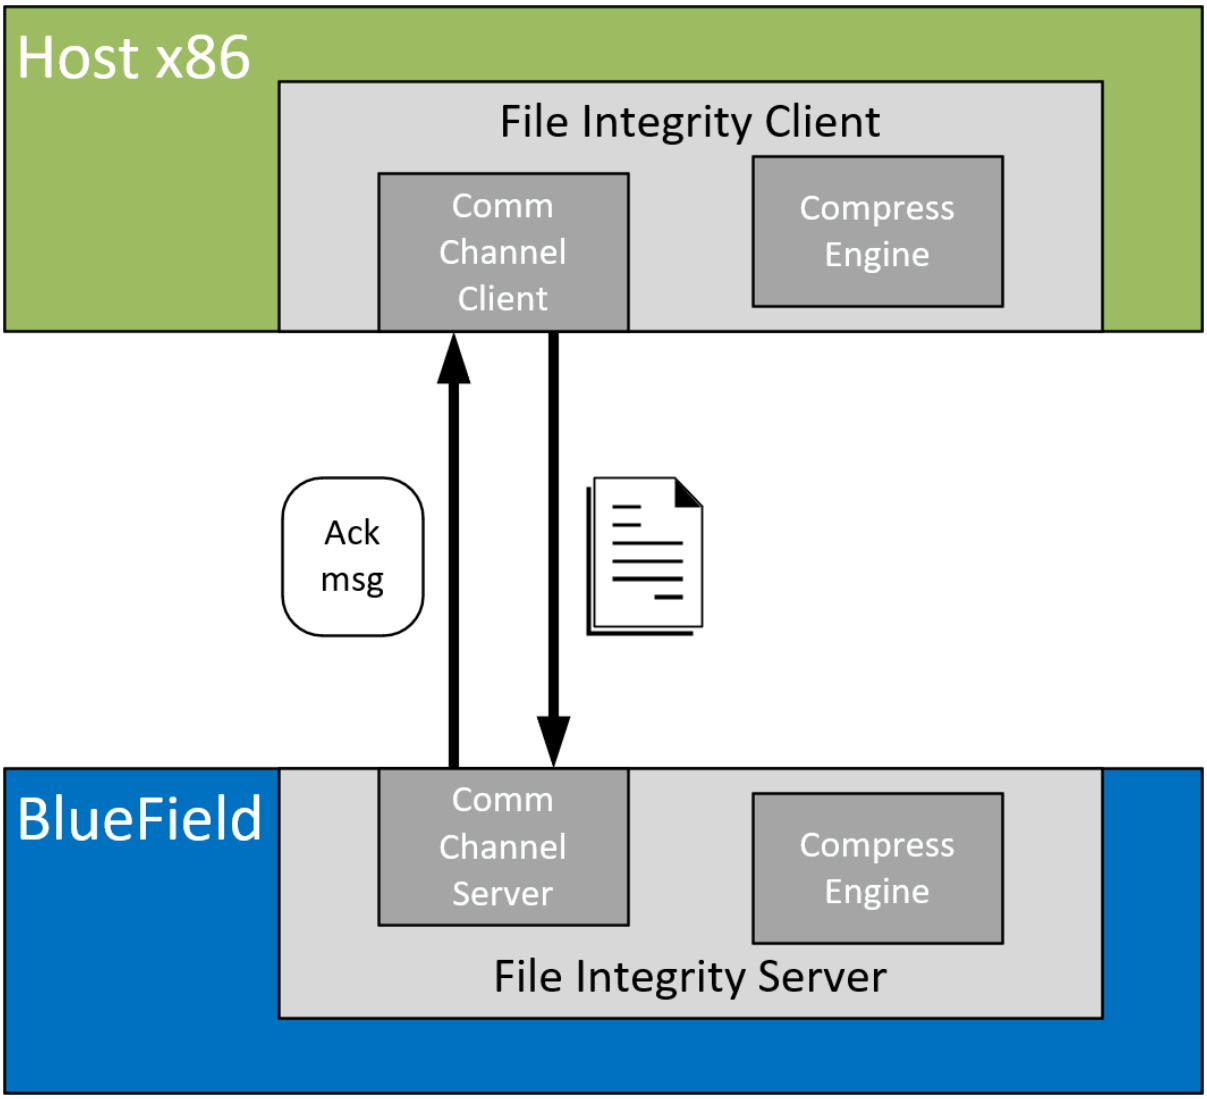
The application's logic includes both a client and a server:

- Client side – the application opens a file, calculates the SHA (secure hash algorithm) digest on it, and sends the digest of the source file alongside the file itself to the server
- Server side – the application calculates the SHA on the received file and compares the received digest to the calculated one to check if the file has been compromised

> ⚠ SHA hardware acceleration is only available on the BlueField-2 DPU. This application is not supported on BlueField-3.

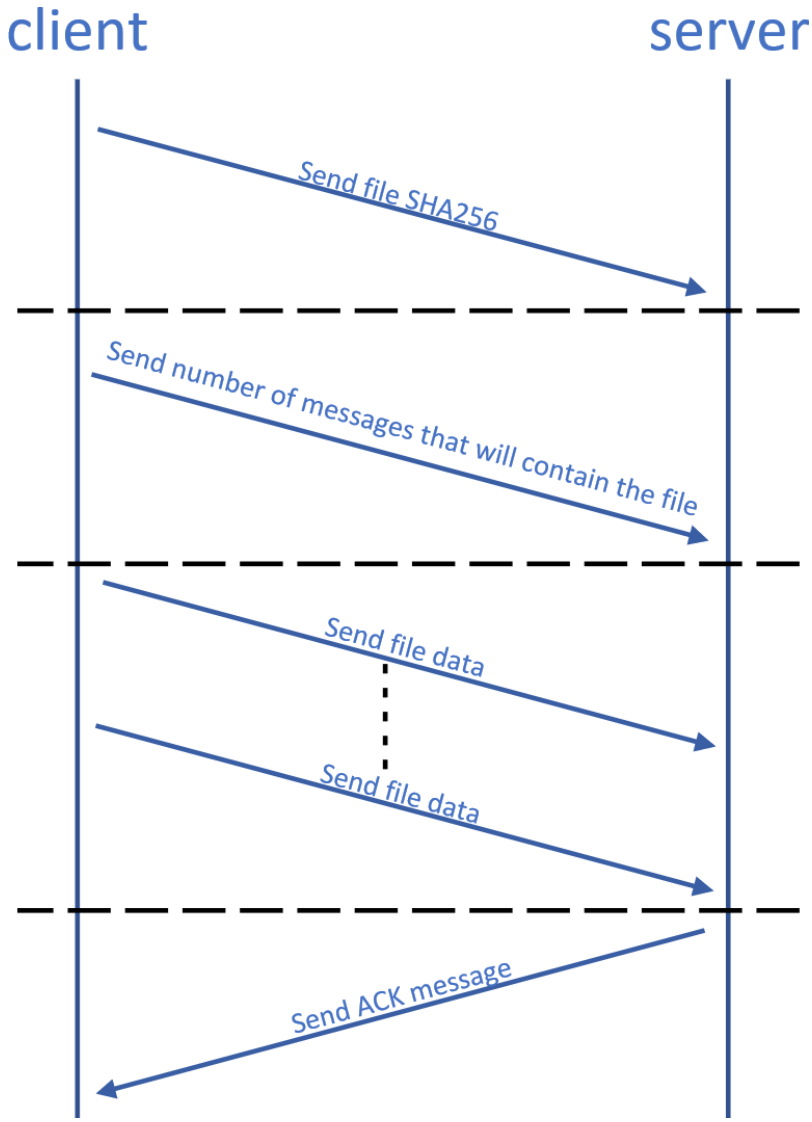
6.10.2 System Design

The file integrity application runs in client mode (host) and server mode (DPU).



6.10.3 Application Architecture

The file integrity application runs on top of the DOCA Comm Channel API to send and receive files from the host and DPU.



1. Connection is established on both sides by the Comm Channel API.
2. Client submits SHA job with the DOCA SHA library and sends the result to the server.
3. Client sends the number of messages required to send the content of the file.
4. Client sends data segments in size of up to 4032 bytes.
5. Server submits a partial SHA job on each received segment.
6. Server sends an ACK message to the client when all parts of the file are received successfully.
7. Server compares the received SHA to the calculated SHA.

6.10.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA SHA

- DOCA Comch

Refer to their respective programming guide for more information.

6.10.5 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/file_integrity/
```

6.10.5.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> `doca_file_integrity` is created under `/tmp/build/file_integrity/`.

6.10.5.2 Compiling Only the Current Application

To directly build only the file integrity application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_file_integrity=true
ninja -C /tmp/build
```

`doca_file_integrity` is created under `/tmp/build/file_integrity/`.

Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_file_integrity` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_file_integrity` is created under `/tmp/build/file_integrity/`.

6.10.6 Running the Application

6.10.6.1 Application Execution

The file integrity application is provided in source form. Therefore, a compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_file_integrity [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA Comm Channel device PCI address
  -r, --rep-pci                     DOCA Comm Channel device representor PCI address
  -f, --file                        File to send by the client / File to write by the server
  -t, --timeout                     Application timeout for receiving file content messages, default is 5
 sec
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_file_integrity -h
```

For additional information, refer to section "Command Line Flags".

- CLI example for running the application on BlueField:

```
./doca_file_integrity -p 03:00.0 -r 3b:00.0 -f received.txt
```

Both the DOCA Comm Channel device PCIe address (`03:00.0`) and the DOCA Comm Channel device representor PCIe address (`3b:00.0`) should match the addresses of the desired PCIe devices.

- CLI example for running the application on the host:

```
./doca_file_integrity -p 3b:00.0 -f send.txt
```

The DOCA Comm Channel device PCIe address (`3b:00.0`) should match the address of the desired PCIe device.

6.10.6.2 Command Line Flags

6.10.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70

Short Flag	Long Flag	Description
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.10.6.2.2 Host Program Flags

Short Flag	Long Flag	Description
`f`	`file`	• For client – path to the file to be sent • For server – path to write the file into This is a mandatory flag.
`p`	`pci-addr`	Comm Channel DOCA device PCIe address This is a mandatory flag.
`r`	`rep-pci`	Comm Channel DOCA device representor PCIe address This flag is mandatory only on the DPU.

6.10.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.10.7 Application Code Flow

1. Parse application argument.
   a. Initialize the arg parser resources and register DOCA general parameters.

```
doca_arg_init();
```

   b. Register file integrity application parameters.

```
register_file_integrity_params();
```

c. Parse application parameters.

```
doca_argp_start();
```

2. Set endpoint attributes.

```
set_endpoint_properties();
```

a. Set maximum message size of 4032 bytes.
b. Set number of maximum messages allowed per connection.

3. Create Comm Channel endpoint.

```
doca_comm_channel_ep_create();
```

a. Create endpoint for client/server.

4. Create SHA context.

```
doca_sha_create();
```

a. Create SHA context for submitting SHA jobs for client/server.

5. Run client/server main logic.

```
file_integrity_client/server();
```

6. Clean up the File Integrity app.

```
file_integrity_cleanup();
```

a. Free all application resources.

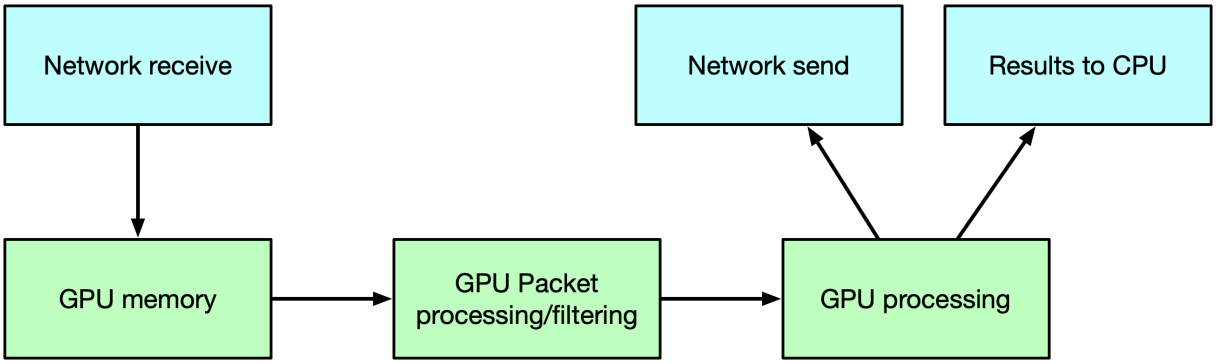
6.11 DOCA GPU Packet Processing Application Guide

This guide provides a description of the GPU packet processing application to demonstrate the use of DOCA GPUNetIO, DOCA Ethernet, and DOCA Flow libraries to implement a GPU traffic analyzer.

6.11.1 Introduction

Real-time GPU processing of network packets is a useful technique to several different application domains, including signal processing, network security, information gathering, and input reconstruction. The goal of these applications is to realize an inline packet processing pipeline to receive packets in GPU memory (without staging copies through CPU memory), process them in parallel with one or more CUDA kernels, and then run inference, evaluate, or send the result of the calculation over the network.

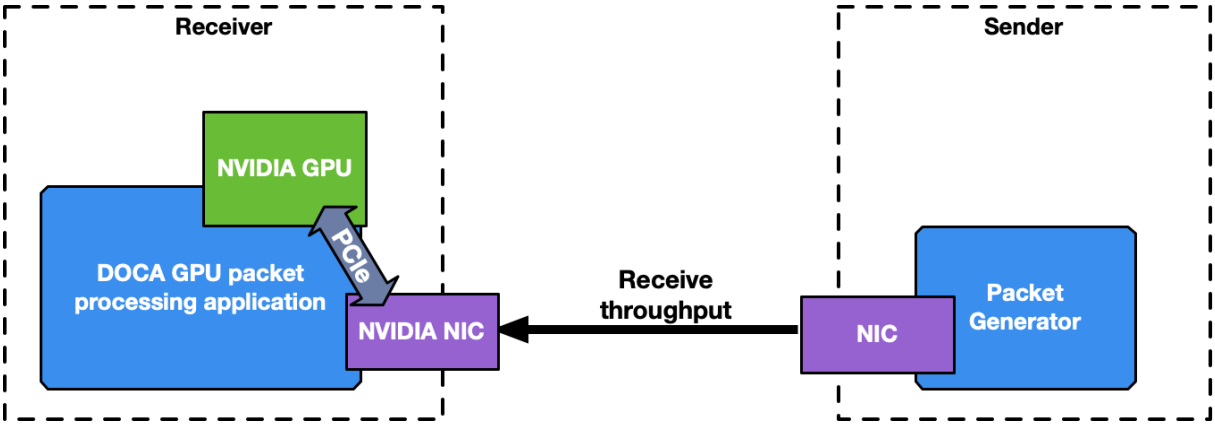


The type of data processing heavily depends on the use case. The goal of this application is to provide a basic layout to reuse in the most common use cases of being able to receive, differentiate and manage the following types of network traffic in multiple queues: UDP, TCP and ICMP.

This application is an enhancement of the use cases presented in this NVIDIA blog post about DOCA GPUNetIO.

6.11.2 System Design

This is a receive-and-process DOCA application, so a packet generator sending packets is required to test the application.



To launch the application, the PCIe address of the GPU and NIC are required.

6.11.3 Application Architecture

The application manages different types of traffic differently, dedicating up to 4 receive queues to each one using DOCA Flow with RSS mode to assign each packet to the right queue. The more queues the application uses, the higher is the degree of parallelism in how receive data is processed and how long it takes.

It is highly recommended to use more than one receive queue for 100Gb/s or higher network traffic throughput.

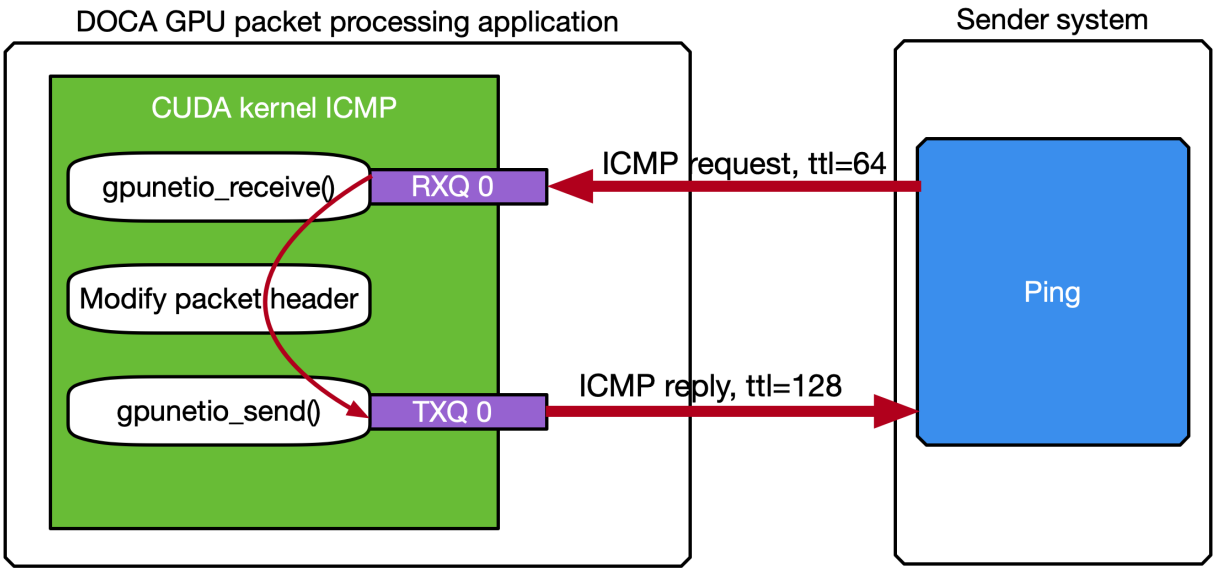
6.11.3.1 ICMP Network Traffic

If the network interface used for the application has an IP address, it is possible to ping that interface. ICMP packets are received by a dedicated CUDA kernel (file `gpu_kernels/receive_icmp.cu`) which:

1. Receives packets using the DOCA GPUNetIO CUDA warp-level function `doca_gpu_dev_eth_rxq_receive_warp`.
2. Checks if the packet is an ICMP echo request.
3. Forwards the same packet, modifying some header info (e.g., swapping MAC and IP addresses, changing ICMP packet type).
4. Pushes the modified packet into the send queue using the DOCA GPUNetIO thread-level function `doca_gpu_dev_eth_txq_send_enqueue_strong`.
5. Sends the packet using the DOCA GPUNetIO thread-level functions `doca_gpu_dev_eth_txq_commit_strong` and `doca_gpu_dev_eth_txq_push`.

This is not a compute intensive use case, so a single CUDA warp with only one receive queue and one send queue is enough to keep up with a decent latency.

By default, the OS CPU ping TTL is set to 64. Therefore, to be sure the GPU is actually replying to ICMP ping requests, TTL is set to 128 in this application.



The following are motivations for this use case:

- Providing an easy tool to check connectivity between packet the generator machine and the DOCA application machine
- Having a sense of network latency between the two machines using a well-known tool like ping
- Showing an easy way to receive and forward modified packets
- Providing a warp-level implementation of a CUDA kernel receiving and forwarding traffic

Assuming the IP address of the network interface to ping is `192.168.1.1`, this is the expected output:

```
$ ping 192.168.1.1
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
64 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=0.324 ms
64 bytes from 192.168.1.1: icmp_seq=2 ttl=64 time=0.332 ms
64 bytes from 192.168.1.1: icmp_seq=3 ttl=64 time=0.299 ms
64 bytes from 192.168.1.1: icmp_seq=4 ttl=64 time=0.309 ms
64 bytes from 192.168.1.1: icmp_seq=5 ttl=64 time=0.323 ms
64 bytes from 192.168.1.1: icmp_seq=6 ttl=64 time=0.300 ms
64 bytes from 192.168.1.1: icmp_seq=7 ttl=64 time=0.274 ms
64 bytes from 192.168.1.1: icmp_seq=8 ttl=64 time=0.314 ms
64 bytes from 192.168.1.1: icmp_seq=9 ttl=64 time=0.327 ms
64 bytes from 192.168.1.1: icmp_seq=10 ttl=64 time=0.384 ms
# At this point, the DOCA application has been started on the 192.168.1.1 interface
# TTL becomes 128 as it's the GPU replying to ICMP requests now instead of the OS
64 bytes from 192.168.1.1: icmp_seq=11 ttl=128 time=0.346 ms
64 bytes from 192.168.1.1: icmp_seq=12 ttl=128 time=0.274 ms
64 bytes from 192.168.1.1: icmp_seq=13 ttl=128 time=0.294 ms
64 bytes from 192.168.1.1: icmp_seq=14 ttl=128 time=0.240 ms
64 bytes from 192.168.1.1: icmp_seq=15 ttl=128 time=0.273 ms
64 bytes from 192.168.1.1: icmp_seq=16 ttl=128 time=0.238 ms
64 bytes from 192.168.1.1: icmp_seq=17 ttl=128 time=0.252 ms
64 bytes from 192.168.1.1: icmp_seq=18 ttl=128 time=0.232 ms
64 bytes from 192.168.1.1: icmp_seq=19 ttl=128 time=0.278 ms
.......
```

A DOCA Progress Engine is attached to the DOCA Ethernet Txq context used to forward ICMP packets. Those packets are sent from the GPU with the `DOCA_GPU_SEND_FLAG_NOTIFY` flag, which result in creating a notification after every packet is sent by the NIC.

All the notifications are then analyzed by the CPU through the `doca_pe_progress` function. The final effect is the output of the application which returns the distance, in seconds, between two pings. The following is an example with a ping every 0.5 seconds:

```
$ ping -i 0.5 192.168.1.1
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
64 bytes from 192.168.1.1: icmp_seq=1 ttl=128 time=0.202 ms
64 bytes from 192.168.1.1: icmp_seq=2 ttl=128 time=0.179 ms
64 bytes from 192.168.1.1: icmp_seq=3 ttl=128 time=0.199 ms
64 bytes from 192.168.1.1: icmp_seq=4 ttl=128 time=0.180 ms
64 bytes from 192.168.1.1: icmp_seq=5 ttl=128 time=0.200 ms
64 bytes from 192.168.1.1: icmp_seq=6 ttl=128 time=0.189 ms
......
```

On the DOCA side, the application should print a log for all the ICMP packets received and retransmitted:

```
Seconds 5
[UDP] QUEUE: 0 DNS: 0 OTHER: 0 TOTAL: 0
[TCP] QUEUE: 0 HTTP: 0 HTTP HEAD: 0 HTTP GET: 0 HTTP POST: 0 TCP [SYN: 0 FIN: 0 ACK: 0] OTHER: 0 TOTAL: 0

```

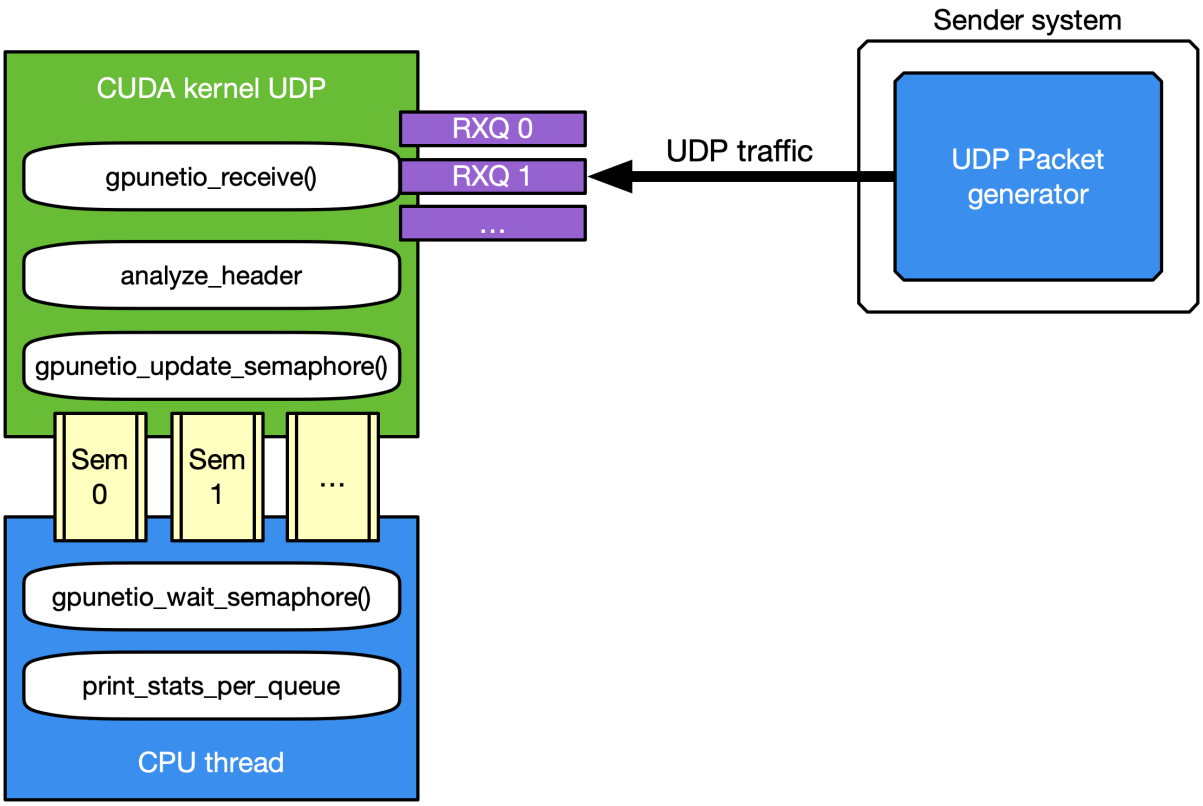
6.11.3.2 UDP Network Traffic

This is the most generic use case of receive-and-analyze packet headers. Designed to keep up with 100Gb/s of incoming network traffic, the CUDA kernel responsible for the UDP traffic dedicates one CUDA block of 512 CUDA threads (file `gpu_kernels/receive_udp.cu`) to a different Ethernet UDP receive queue.

The data path loop is:

1. Receive packets using the DOCA GPUNetIO CUDA block-level function `doca_gpu_dev_eth_rxq_receive_block`.
2. Each CUDA thread works on a subset of received packets.
3. DOCA buffer containing the packet is retrieved.

4. Packet payload is analyzed to differentiate between DNS packets from other UDP generic packets.
5. Packet payload is wiped-out to ensure that old stale packets are not analyzed again.
6. Each CUDA block reports to the CPU thread statistics about types of received packets through a DOCA GPUNetIO semaphore.
7. CPU thread polls on semaphores to retrieve and print the statistics to the console.



The motivation for this use case is mostly to provide an application template to:

- Receive and analyze packet headers to differentiate across different UDP protocols
- Report statistics to the CPU through the DOCA GPUNetIO semaphore
- Report UDP ingress data rate the application can keep up per receive queue

Several packet generators can be used to test this mode like T-Rex or DPDK testpmd.

The application measures the incoming data rate based on the amount of received bytes since the start of the application. To have a meaningful data rate report, the packet generator should start to send packets before starting the GPU packet processing application.

6.11.3.2.1 T-Rex Packet Generator

This is a valuable packet generator that can send or receive Ethernet packets and analyze network traffic metrics and performance.

The recipe to build and run is:

T-Rex

```
wget https://trex-tgn.cisco.com/trex/release/v3.08.tar.gz --no-check-certificate
tar -xvf v3.08.tar.gz
cd v3.08
# Only first time
sudo ./dpdk_setup_ports.py -i
```

This creates a configuration file named `trex_cfg.yaml`. It may be necessary to manually adjust the interface MTU in the config file setting it explicitly. For example:

T-Rex MTU

```
### Config file generated by dpdk_setup_ports.py ###
- version: 2
  interfaces: ['e5:00.0', 'e5:00.1']
  port_mtu: 9000
  port_info:...
```

To launch T-Rex:

T-Rex MTU

```
# On one window/session
sudo ./t-rex-64 -i -c 8 --cfg /etc/trex_cfg.yaml --no-scapy-server
# On second window/session
./trex-console
tui
```

Once the console is started, T-Rex can send or receive packets.

For example:

T-Rex command line

```
# Send 1kB packets at 100Gbps
start -f stl/bench.py -p 0 -m 100gbps --force -t size=1024,vm=var1
# Send 128B packets at 90Gbps
start -f stl/bench.py -p 0 -m 90gbps --force -t size=128,vm=var1
...
```

6.11.3.2.2 DPDK testpmd Packet Generator

Already included in the DPDK shipped with DOCA, an example command line to run `dpdk-testpmd` packet generator.

dpdk-testpmd

```
sudo sh -c 'echo 8192 > /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages'
sudo /opt/mellanox/dpdk/bin/dpdk-testpmd \
    -a <NIC PCIe address> \
    -l 0-3 \
    --socket-mem=4096 \
    -- \
    --forward-mode=txonly \
    --txpkts=1024 \
    --txq=4 --rxq=4 \
    --nb-cores=3 \
    --eth-peer=0,<DEST MAC ADDRESS> \
    --total-num-mbufs=131072 \
    --txonly-multi-flow \
    -i
```

6.11.3.3 TCP Network Traffic and HTTP Echo Server

By default, the TCP flow management is the same as UDP: Receive TCP packets and analyze their headers to report to the CPU statistics about the types of received packets. This is good for passive traffic analyzers or sniffers but sometimes a packet processing application requires receiving packets directly from TCP peers which implies the establishment of a TCP-reliable connection through the 3-way handshake method. Therefore, it is possible to enable TCP "server" mode through the `-s` command-line flag which enables an "HTTP echo server" mode where the CPU and GPU cooperate to establish a TCP connection and process TCP data packets.

Specifically, in this case there are two different sets of receive queues:

- CPU DPDK receive queues which receive TCP "control" packets (e.g. SYN, FIN or RST)
- DOCA GPUNetIO receive queues to receive TCP "data" packets

This distinction is possible thanks to DOCA Flow capabilities.

The application's flow requires CPU and GPU collaboration as described in the following subsections.

6.11.3.3.1 Step 1: TCP Connection Establishment

A CPU thread through DPDK queues receives a TCP SYN packet from a remote TCP peer. The CPU thread establishes a TCP reliable connection (replies with a TCP SYN-ACK packet) with the peer and uses DOCA Flow to create a new steering rule to redirect TCP data packets to one of the DOCA GPUNetIO receive queues. The new steering rule excludes control packets (e.g., SYN, FIN or RST).

6.11.3.3.2 Step 2: TCP Data Processing

The CUDA kernel responsible for TCP processing receives TCP data packets and performs TCP packet header analysis. If it receives an HTTP GET request, it stores the

relevant packet's info in the next item of a DOCA GPUNetIO semaphore, setting it to `READY`.

6.11.3.3.3 Step 3: HTTP Echo Server

A second CUDA kernel responsible for HTTP processing polls the DOCA GPUNetIO semaphore. Once it detects the update of the next item to `READY`, it reads the HTTP GET packet info and crafts an HTTP response packet with an HTML page.

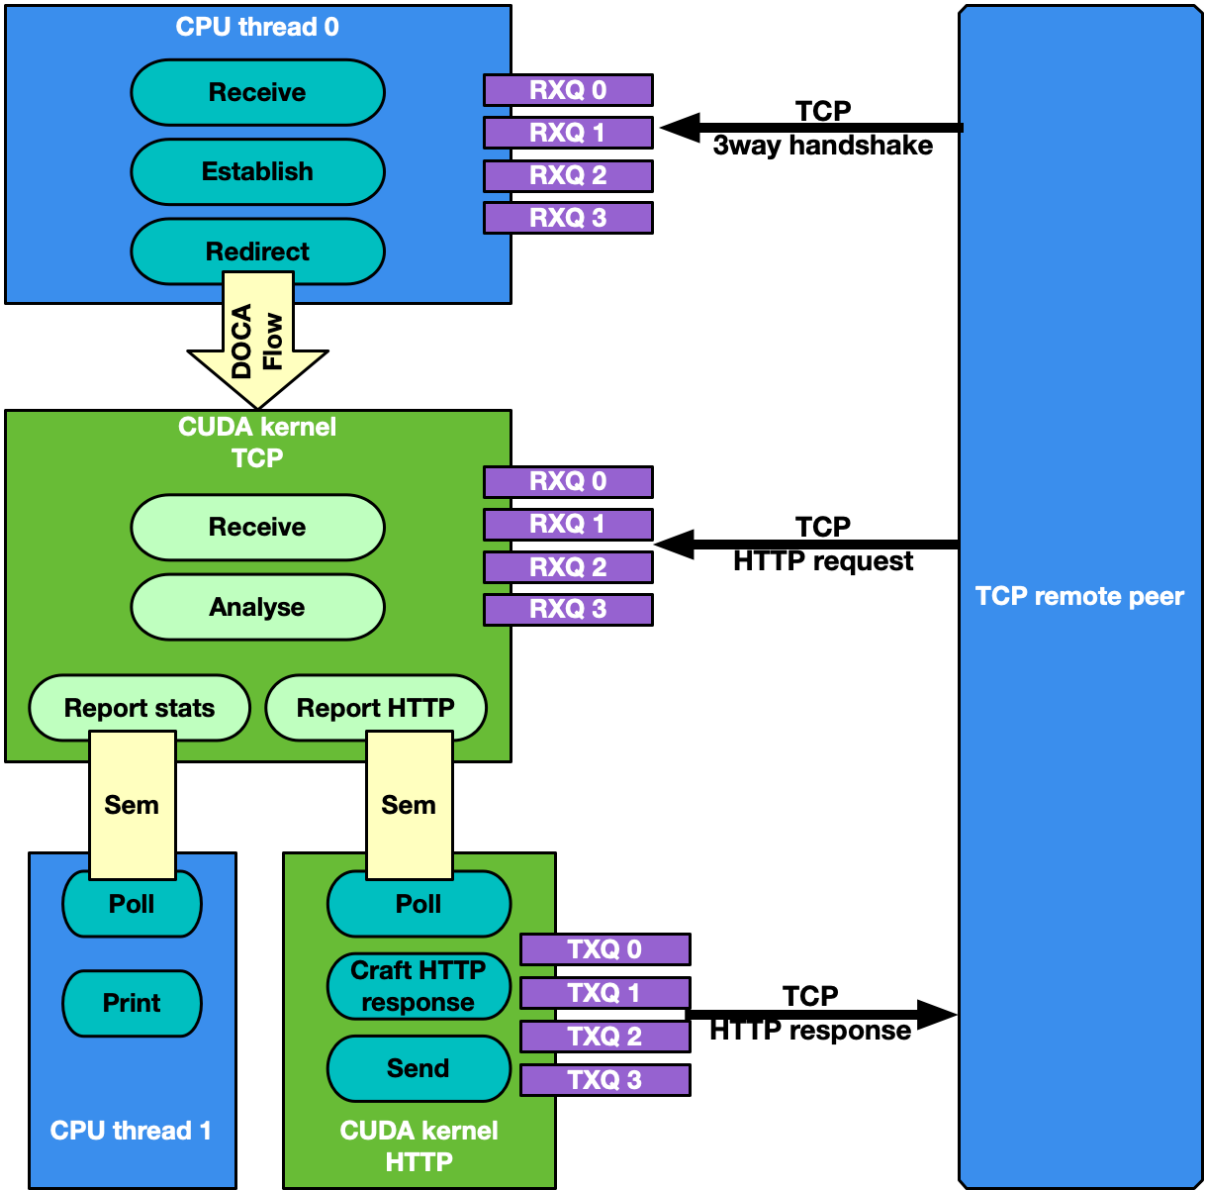
If the request is about `index.html` or `contacts.html`, the CUDA kernel replies with the appropriate HTML page using a `200 OK` code. For all other requests, the it returns a "Page not found" and `404 Error` code.

HTTP response packets are sent by this second HTTP CUDA kernel using DOCA GPUNetIO.

> ⚠ Care must be taken to maintain TCP sequence/ack numbers in the packet headers.

6.11.3.3.4 Step 4: TCP Connection Closure

If the CPU receives a TCP FIN packet through the DPDK queues, it closes the connection with the remote TCP peer and removes the DOCA Flow rule from the DOCA GPUNetIO queues so the CUDA kernel cannot receive anymore packets from that TCP peer.



Motivations for this use case:

- Receiving and analyzing packet headers to differentiate across different TCP protocols
- Processing TCP packets on GPU in passive mode (sniffing) and active mode (reliable connection)
- Having a DOCA-DPDK application able to establish a TCP reliable connection without using any OS socket and bypassing kernel routines
- Having CUDA-kernel-to-CUDA-kernel communication through a DOCA GPUNetIO semaphore
- Showing how to create and send a packet from scratch with DOCA GPUNetIO

Assuming the network interface used to run the application has the IP address `192.168.1.1`, it is possible to test this HTTP echo server mode using simple tools like `curl` or `wget`.

Example with `curl`:

```
$ curl http://192.168.1.1/index.html -ivvv

*   Trying 192.168.1.1:80...
* Connected to 192.168.1.1 (192.168.1.1) port 80 (#0)
> GET /index.html HTTP/1.1
> Host: 192.168.1.1
> User-Agent: curl/7.81.0
> Accept: */*

```

6.11.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA GPUNetIO
- DOCA Ethernet
- DOCA Flow

Refer to their respective programming guide for more information on system configuration and requirements.

Refer to the DOCA Installation Guide for Linux for details on how to install DOCA package software.

6.11.5 Dependencies

Before running the application make sure to have the following:

- `gdrdrv` kernel module – active and running on the system

- `dmabuf or nvidia-peermem`
- Network card interface you want to use is up

6.11.6 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/gpu_packet_processing/
```

6.11.6.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_gpu_packet_processing` is created under `/tmp/build/gpu_packet_processing/`.

6.11.6.2 Compiling Only the Current Application

To directly build only the GPU packet processing application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_gpu_packet_processing=true
ninja -C /tmp/build
```

`doca_gpu_packet_processing` is created under `/tmp/build/gpu_packet_processing/`.

Alternatively, users can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_gpu_packet_processing` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_gpu_packet_processing` is created under `/tmp/build/gpu_packet_processing/`.

6.11.7 Running the Application

The GPU packet processing application is provided in source form. Therefore, a compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_gpu_packet_processing [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                      Print a help synopsis
  -v, --version                   Print program version information
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                    Filter logs from specific modules, separated by comma
  -j, --json <path>               Parse command line flags from an input json file

Program Flags:
  -g, --gpu <GPU PCIe address>      GPU PCIe address to be used by the app
  -n, --nic <NIC PCIe address>      DOCA device PCIe address used by the app
  -q, --queue <GPU receive queues>  DOCA GPUNetIO receive queue per flow
  -s, --httpserver <Enable GPU HTTP server> Enable GPU HTTP server mode
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_gpu_packet_processing -h
```

For additional information, refer to section "Command Line Flags".

- CLI example for running the application on the host:
  a. Assuming a GPU PCIe address `ca:00.0` and NIC PCIe address `17:00.0` with 2 GPUNetIO receive queues:

```
./doca_gpu_packet_processing -n 17:00.0 -g ca:00.0 -q 2
```

Refer to section "Running DOCA Application on Host" in the DOCA Virtual Functions User Guide.

6.11.7.1 Command Line Flags

6.11.7.1.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.11.7.1.2 Program Flags

Short Flag	Long Flag	Description
`g`	`gpu`	GPU PCIe address in `<bus>:<device>.<function>` format. This can be obtained using the `nvidia-smi` or `lspci` commands.
`n`	`nic`	Network card port PCIe address in `<bus>:<device>.<function>` format. This can be obtained using the `lspci` command.
`q`	`queue`	Number of receive queues to use in the example. Default is 1, maximum allowed is 4.
`s`	`httpserver`	Enable the TCP HTTP server mode. With this flag, TCP packets are not received by GPUNetIO as regular sniffer as it requires a TCP 3-way handshake to establish a reliable connection first.

6.11.7.2 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.11.8 Application Code Flow

The following explains the application's flow, highlighting main code blocks and functions:

1. Parse application argument.

```
doca_argp_init();
register_application_params();
doca_argp_start();
```

2. Initialize network device as DOCA device, initialize DPDK, and get device DPDK port ID.

```
init_doca_device();
```

   Calls `rte_eal_init()` with empty flags to initialize EAL resources.

3. Initialize a GPU device, creating a DOCA GPUNetIO handle for it.

```
doca_gpu_create();
```

4. Initialize DOCA Flow, starting the DPDK port.

```
init_doca_flow();
```

   Flags to initialize DOCA Flow are VNF, HW steering, and isolated mode (to prevent the default RSS flows from interfering with the GPUNetIO queues).
5. Create RX and TX queue related objects (i.e., Ethernet handlers, GPUNetIO handlers, flow rules, semaphores) to manage UDP, TCP and ICMP flows.

```
create_udp_queues();
create_tcp_queues();
create_icmp_queues();
/* Depending on TCP mode (HTTP server or not) properly connect different DOCA Flow pipes */
create_root_pipe();
```

6. Allocate generic exit flag. All CUDA kernels periodically poll on this flag. If the CPU set it to 1, CUDA kernels exit from their main loop and return.

```
doca_gpu_mem_alloc(gpu_dev, sizeof(uint32_t), alignment, DOCA_GPU_MEM_GPU_CPU, (void
 **)&gpu_exit_condition, (void **)&cpu_exit_condition);
```

7. Launch CUDA kernels, each on a different stream.

```
kernel_receive_udp(rx_udp_stream, gpu_exit_condition, &udp_queues);
kernel_receive_tcp(rx_tcp_stream, gpu_exit_condition, &tcp_queues, app_cfg.http_server);
kernel_receive_icmp(rx_icmp_stream, gpu_exit_condition, &icmp_queues);
if (app_cfg.http_server)
    kernel_http_server(tx_http_server, gpu_exit_condition, &tcp_queues, &http_queues);
```

8. Launch the CPU thread responsible to poll on DOCA GPUNetIO semaphores and print UDP and TCP stats on the console.

```
rte_eal_remote_launch((void *)stats_core, NULL, current_lcore);
```

9. Launch CPU thread responsible for managing TCP 3-way handshake connections.

```
if (app_cfg.http_server) {
    ...
    rte_eal_remote_launch(tcp_cpu_rss_func, &tcp_queues, current_lcore);
}
```

10. Wait for the user to send a signal to quit the application. When this happens, the signal handler function sets the `force_quit` flag to true which causes the main thread to move forward and set the exit condition to 1.

```
while (DOCA_GPUNETIO_VOLATILE(force_quit) == false);
DOCA_GPUNETIO_VOLATILE(*cpu_exit_condition) = 1;
```

11. Wait for CUDA kernels to exit and finalize all DOCA Flow and GPUNetIO resources.

```
cudaStreamSynchronize(rx_udp_stream);
cudaStreamSynchronize(rx_tcp_stream);
cudaStreamSynchronize(rx_icmp_stream);
if (app_cfg.http_server)
    cudaStreamSynchronize(tx_http_server);
destroy_flow_queue();
doca_gpu_destroy();
```

6.12 NVIDIA DOCA IP Fragmentation Application Guide

This guide provides an implementation of IP fragmentation application on top of NVIDIA® BlueField®-3 DPU.

6.12.1 Introduction

This IP Fragmentation application is designed to handle IP fragmentation and reassembly efficiently, ensuring minimal processing overhead for non-fragmented packets while maintaining high performance for fragmented packets.

The application operates on a multi-core architecture, uses Receive Side Scaling (RSS) to distribute traffic, and supports configurable modes for flexible port configurations.

Key Features:

- IP Reassembly:
  - Functionality: The application assembles fragmented packets received on input ports based on their fragmentation headers.
  - Workflow: Upon successful reassembly, the complete packets are forwarded to their destination port.
- IP Fragmentation:
  - Functionality: Packets exceeding a configurable Maximum Transmission Unit (MTU) are fragmented into smaller packets.
  - Workflow: Fragments are generated with correct headers and forwarded while maintaining efficient resource utilization.
- Transparent Forwarding: Packets that are neither fragmented nor require reassembly are forwarded directly without additional processing overhead.
- Inner and Outer Fragmentation Handling: The application supports handling fragmentation at both inner (e.g., encapsulated traffic like GRE, VXLAN) and outer IP layers.
- Performance Optimization:
  - Designed for high throughput using multi-core processing.
  - Utilizes RSS to distribute traffic across multiple cores, ensuring efficient CPU utilization and scalability.

- Debuggability with Counters.
- Dual Operating Modes:
    - Dual Port Mode (Bidirectional): Traffic flows bidirectionally between two ports A ↔ B.
    - Quad Port Mode (Multiport): Independent unidirectional forwarding from Port A ↔ Port B and Port C ↔ Port D. In this mode, the direction of the traffic is isolated to go through two ports each time.
    - In both modes, non-fragmented or valid-sized packets follow the same path without additional actions.

6.12.2 System Design

The IP Fragmentation application can either run as a SW on BlueField-3's cores serving as an underlying service for host applications or on the host.

6.12.3 Application Architecture

6.12.3.1 Operational Workflow

- Packet Reception and Classification:
    - Traffic is received on the input ports, with RSS distributing flows to the cores the applications runs on.
    - Packets are classified into three categories:
        - Fragmented (Needs Reassembly)
        - Too Large (Needs Fragmentation)
        - Standard Packets (Direct Forwarding)
- Reassembly:
    - Fragments are buffered and reassembled using a configurable timeout.
    - Once reassembled, the full packet is validated and forwarded to the dedicated port (depending on the mode).
- Fragmentation:
    - Large packets exceeding the MTU are fragmented.
    - Fragments are prepared with correct headers, sequence numbers, and size.
- Direct Forwarding:
    - Standard packets are forwarded with minimal processing

6.12.3.2 Performance and Scalability

- Multi-Core Processing: The application scales horizontally with the number of CPU cores, with each core handling a subset of traffic flows.
- RSS Traffic Distribution: Receive Side Scaling ensures optimal load balancing across cores.
- Minimal Overhead: Processing logic is optimized for low-latency handling of standard packets while ensuring efficient fragmentation and reassembly operations.

6.12.3.3 Debugging and Monitoring

Application provides real-time counters for insights for:

- Packets processed.
- Fragments reassembled or fragmented.
- Errors such as timeout on incomplete fragments.

6.12.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Flow

For additional information about the used DOCA libraries, please refer to the respective programming guides.

6.12.5 Dependencies

- NVIDIA BlueField-3 DPU is required.
- Ubuntu 22.04 host (x86)

6.12.6 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/ip_frag/
```

6.12.6.1 Compiling All Applications

All DOCA applications are defined under a single Meson project. By default, the build process compiles all of them.

To build all applications:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

6.12.6.2 Compiling Only the Current Application

To build the IP fragmentation application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_ip_frag=true
ninja -C /tmp/build
```

`doca_ip_frag` is created under `/tmp/build/ip_frag/`.

Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
    a. Set `enable_all_applications` to `false`
    b. Set `enable_ip_frag` to `true`
2. Execute:

    ```
    cd /opt/mellanox/doca/applications/
    meson /tmp/build
    ninja -C /tmp/build
    ```

    `doca_ip_frag` is created under `/tmp/build/ip_frag/`.

6.12.7 Running the Application

6.12.7.1 Prerequisites

- The Fragmentation application is based on DOCA Flow. Therefore, the user is required to allocate huge pages.

```
$ echo '4096' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

- The Flex Parser Profile is a setting that enables flexible protocol parsing on NVIDIA NICs/DPUs. To enable GTP protocol support, set the Flex Parser Profile to 3. This configuration is mandatory and must be done manually in the system:

```
$ sudo mlxconfig -d <pcie_address> s FLEX_PARSER_PROFILE_ENABLE=3
```

6.12.7.2 Application Execution

The IP Fragmentation application is provided in source form, hence a compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_ip_frag [DPDK Flags] -- [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -a, --device                      device
  -r, --rep                         device representor
  -m, --mode                        Ip_frag application mode. Bidirectional mode forwards packets between a
single reassembly port and a single fragmentation port (two ports in total). Multiport mode forwards
packets between two pairs of reassembly and fragmentation ports (four ports in total). For more information
consult DOCA IP Fragmentation Application Guide. Format: bidir, multiport
  -u, --mtu                         MTU size
  -t, --frag-aging-timeout          Aging timeout of fragments pending packet reassembly in the
fragmentation table (in ms)
  -s, --frag-tbl-size               Frag table size, i.e. maximum amount of concurrent defragmentation
contexts per worker thread
  -c, --mbuf-chain                  Enable mbuf chaining (required for IPv6 fragmentation support)
  -w, --cksum-accel-disable         Disable hardware-accelerated checksum calculation
```

  For additional information, please refer to the Command Line Flags section below. The above usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
/tmp/build/ip_frag/doca_ip_frag -- -h
```

- CLI example for running the application on BlueField-3:

```
/tmp/build/ip_frag/doca_ip_frag -l 3-15 -- -a aux/2,dv_flow_en=2,sft_en=1 -a aux/3,dv_flow_en=2,sft_en=1 -a
aux/4,dv_flow_en=2,sft_en=1 -a aux/5,dv_flow_en=2,sft_en=1 -l 50 -m multiport
```

- CLI example for running the application on the host:

```
/tmp/build/ip_frag/doca_ip_frag -l 0-7 -- -a pci/0000:08:00.0,dv_flow_en=2 -a pci/0000:08:00.1,dv_flow_en=2
 -l 60 -m bidir -t 1000
```

For additional information regarding the command line syntax of the device and device representor identifiers, please referr to the matching section in the DOCA Arg Parser Guide.

6.12.7.3 Command Line Flags

6.12.7.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.12.7.3.2 Program Flags

Short Flag	Long Flag	Description
`a`	`device`	Device identifier
`r`	`rep`	Device representor identifier
`m`	`mode`	Execution mode: bidir, multiport This is a mandatory flag.
`u`	`mtu`	MTU for fragmentation
`t`	`frag-aging-timeout`	Fragmentation table aging timeout (in milliseconds)
`s`	`frag-tbl-size`	Fragmentation table size
`c`	`mbuf-chain`	Enable mbuf chaining support on packet reassembly

6.12.7.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the installation or execution of the DOCA applications.

6.12.8 References

- `/opt/mellanox/doca/applications/ip_frag/`

6.13 DOCA IPsec Security Gateway Application Guide

This document provides an IPsec security gateway implementation on top of NVIDIA® BlueField® DPU.

> **Important note for NVIDIA® BlueField®-2 DPUs**
>
> If your target application utilizes 100Gb/s or higher bandwidth, where a substantial part of the bandwidth is allocated for IPsec traffic, please refer to the *NVIDIA BlueField-2 DPUs Product Release Notes* to learn about a potential bandwidth limitation. To access the relevant product release notes, please contact your NVIDIA sales representative.

6.13.1 Introduction

DOCA IPsec Security Gateway leverages the DPU's hardware capability for secure network communication. The application demonstrates how to insert rules related to IPsec encryption and decryption based on the DOCA Flow library.

The application demonstrates how to insert rules to create an IPsec tunnel.

> ⚠ An example for configuring the Internet Key Exchange (IKE) can be found under section "Keying Daemon Integration (StrongSwan)" but is not considered part of the application.

The application can be configured to receive IPsec rules in one of the following ways:

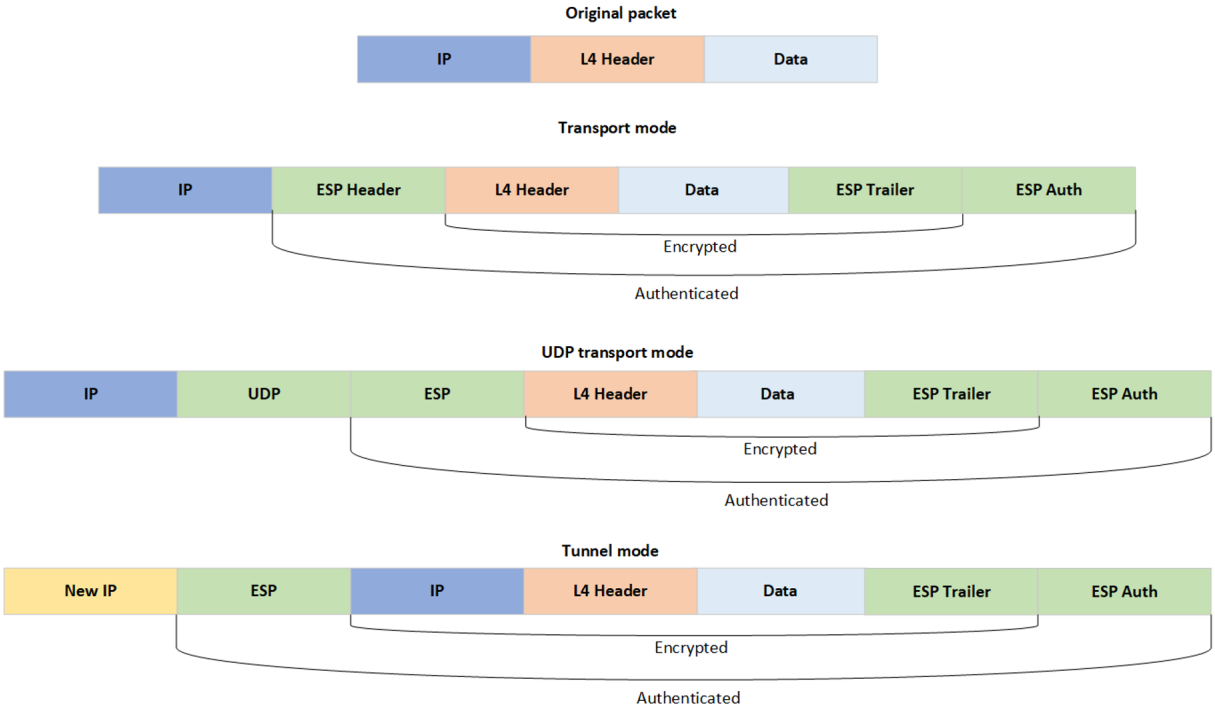
- Static configuration – (default) receives a fixed list of rules for IPsec encryption and decryption

  > ⚠ When creating the security association (SA) object, the application gets the key, salt, and other SA attributes from the JSON input file.

- Dynamic configuration – receives IPsec encryption and decryption rules during runtime through a Unix domain socket (UDS) which is enabled when providing a socket path to the application

  > ⚠ You may find an example of integrating a rules generator with the application under strongSwan project (DOCA plugin).

The application supports the following IPsec modes: Tunnel, transport, UDP transport.

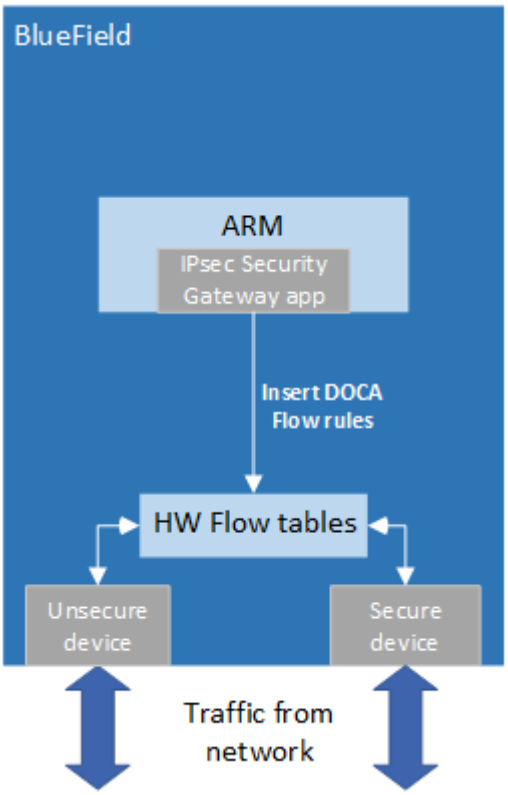


6.13.2 System Design

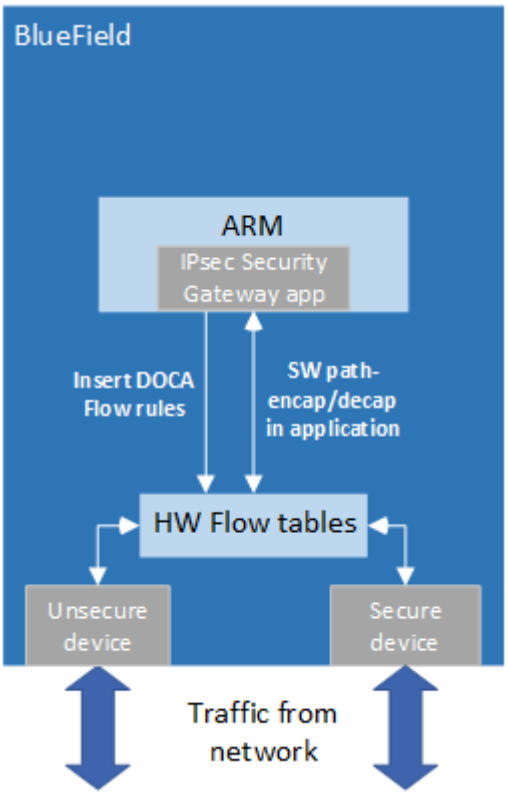
DOCA IPsec Security Gateway is designed to run with 2 ports, secured and unsecured:

- Secured port – BlueField receives IPsec encrypted packets and, after decryption, they are sent through the unsecured port
- Unsecured port – BlueField receives regular (plain text) packets and, after encryption, they are sent through the secured port

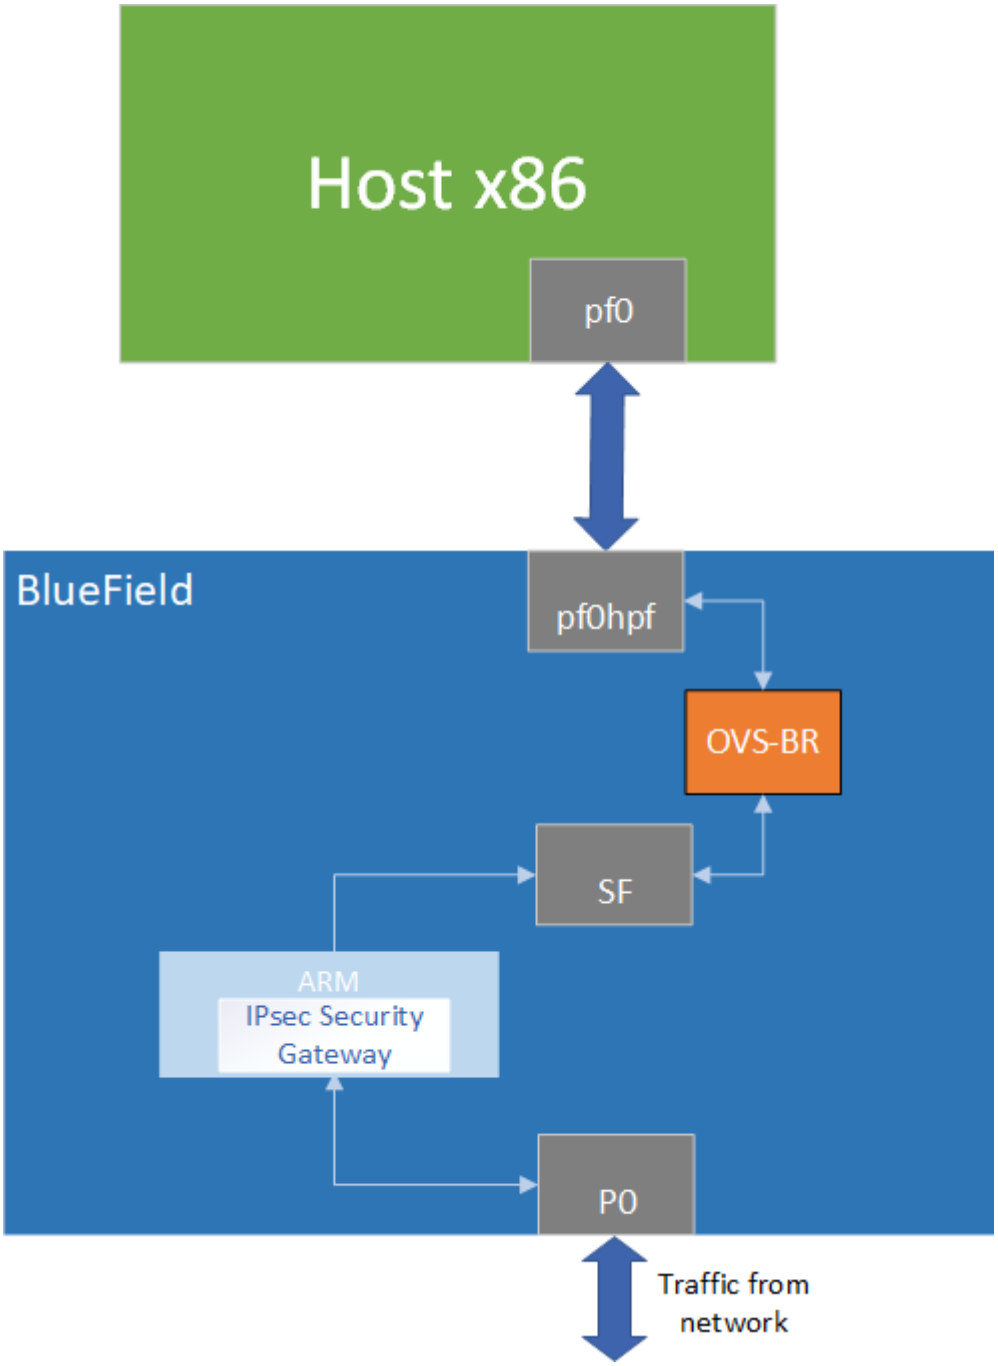
Example packet path for hardware (HW) offloading:



Example packet path for partial software processing (handling encap/decap in software):



Using the application with SF:

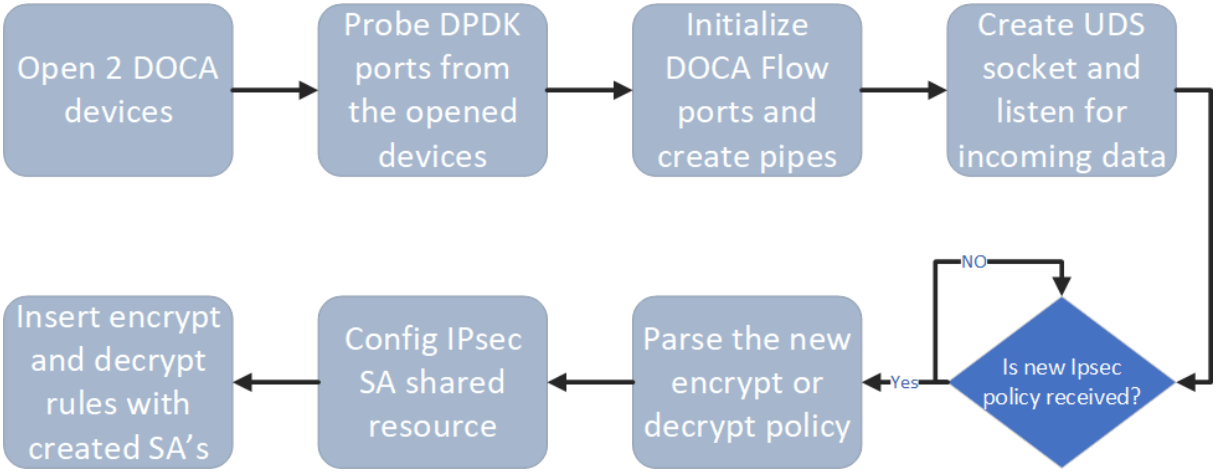


6.13.3 Application Architecture

6.13.3.1 Static Configuration

1. Open two DOCA devices, one for the secured port and another for the unsecured port.
2. With the open DOCA devices, the application probes DPDK ports and initializes DOCA Flow and DOCA Flow ports accordingly.
3. On the created ports, build DOCA Flow pipes.
4. In a loop according to the JSON rules:
    a. Create IPSec SA shared resource for the new rule.
    b. Insert encrypt or decrypt rule to DOCA Flow pipes.

6.13.3.2 Dynamic Configuration



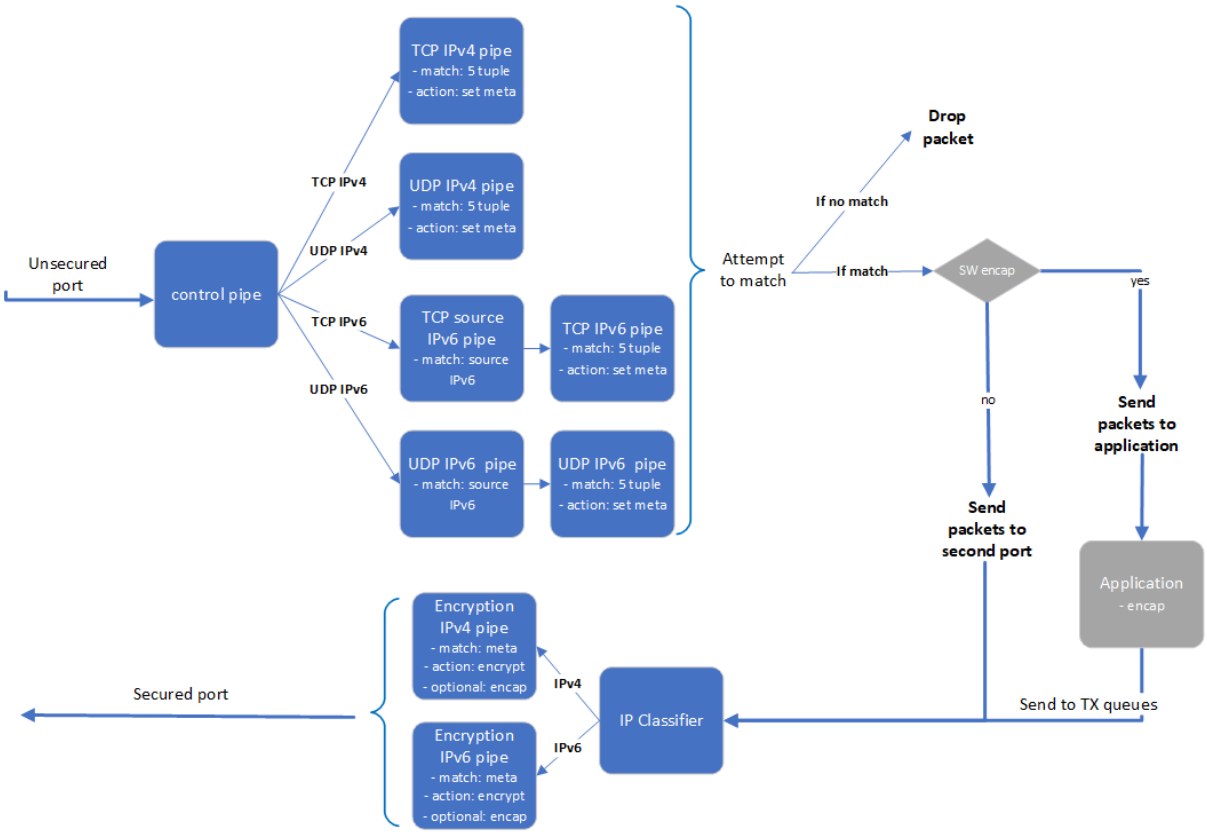
1. Open two DOCA devices, one for the secured port and another for the unsecured port.
2. With the open DOCA devices, the application probes DPDK ports and initializes DOCA Flow and DOCA Flow ports accordingly.
3. On the created ports, build DOCA Flow pipes.
4. Create UDS socket and listen for incoming data.
5. While waiting for new IPsec policies to be received in a loop, if a new IPsec policy is received:
    a. Parse the policy whether it is an encryption or decryption rule.
    b. Create IPSec SA shared resource for the new rule.
    c. Insert encrypt or decrypt rule to DOCA Flow pipes.

6.13.3.3 DOCA Flow Modes

The application can run in two modes, `vnf` and `switch`. For more information about the modes, please refer to "Pipe Mode" in the DOCA Flow.

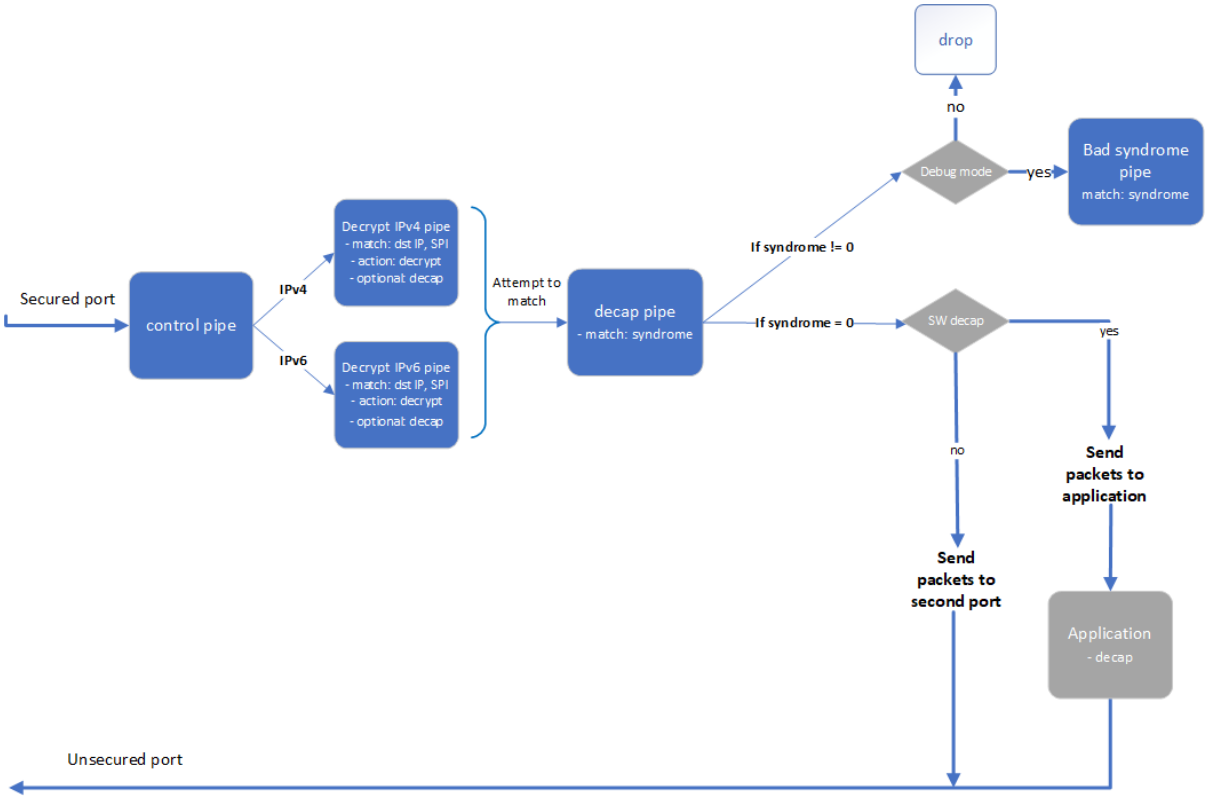
6.13.3.3.1 VNF Mode

6.13.3.3.1.1 Encryption



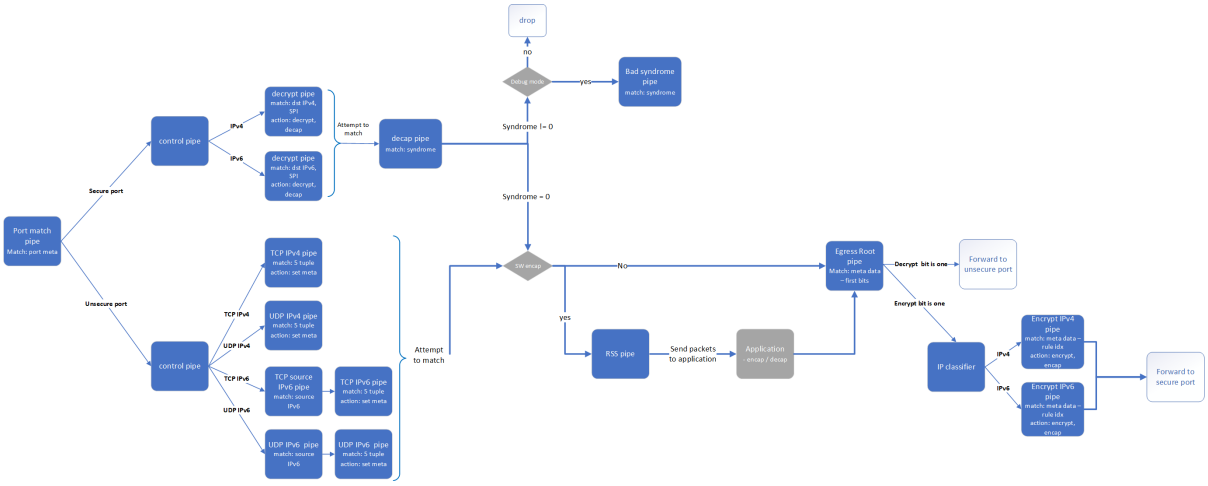
1. The application builds pipes for encryption. Control pipe as root with four entries that match L3 and L4 types and forward the traffic to the relevant pipes.
    a. IPv6 pipes – match the source IP address and forward the traffic to a pipe that matches 5-tuple excluding the source IP.
    b. In the 5-tuple match pipes set action of "set meta data", the metadata would be the rule's index in the JSON file.
    c. The matched packet is forwarded to the second port.
2. In the secured egress domain, the IP classifier pipe sends the packets to the correct encryption pipe (IPv4 or IPv6) which has a shared IPsec encrypt action. According to the metadata match, the packet is encrypted with the encap destination IP and SPI as defined in the user's rules.

6.13.3.3.1.2 Decryption



1. The application builds pipes for decryption. Control pipe as root with two entries that match L3 type and forward the traffic to the relevant decrypt pipe.
2. The decrypt pipe matches the destination IP and SPI according to the rule files and has a shared IPsec action for decryption.
3. After decryption, the matched packets are forwarded to the decap pipe and, if the syndrome is non-zero, the packets are dropped. Otherwise, the packets decap the ESP header and forward to the second port.
    a. In debug mode, if syndrome is non-zero, then it sends to bad syndrome pipe to match on the syndrome, count and drop/send to application.

6.13.3.3.2 Switch Mode



In switch mode, an ingress root pipe matches the source port to decide what the next pipe is:

- Based on the port, the packet passes through almost the same path as VNF mode and the metadata is set. Afterwards, the packet moves to egress root pipe.

In egress root pipe, the match is on encrypt and decrypt bits that were set in the packet meta:

- Decrypt bit is 1 – packet finishes the decrypt path and must be sent to the unsecure port
- Encrypt bit is 1 – packet almost finishes the encrypt path and must be sent to the encrypt pipe on the secure egress domain and to the secure port from there

Additional information about the application's pipeline can be found in the detailed layered view as shown by the DOCA Flow Tune tool.

6.13.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Flow

Refer to their respective programming guide for more information.

6.13.5 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/ipsec_security_gw/
```

6.13.5.1 Prerequisites

The application relies on the `json-c` open source, hence, requires the following installation:

- Ubuntu/Debian:

```
$ sudo apt install libjson-c-dev
```

- CentOS/RHEL:

```
$ sudo yum install json-c-devel
```

6.13.5.2 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_ipsec_security_gw` is created under `/tmp/build/ipsec_security_gw/`.

6.13.5.3 Compiling Only the Current Application

To directly build only the IPsec Security Gateway application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_ipsec_security_gw=true
ninja -C /tmp/build
```

> `doca_ipsec_security_gw` is created under `/tmp/build/ipsec_security_gw/`.

Alternatively, users can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_ipsec_security_gw` to `true`
2. Run the following compilation commands:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build
   ninja -C /tmp/build
   ```

   > `doca_ipsec_security_gw` is created under `/tmp/build/ipsec_security_gw/`.

6.13.6 Running the Application

6.13.6.1 Prerequisites

1. The IPsec security gateway application is based on DOCA Flow. Therefore, the user is required to allocate huge pages.

   ```
   $ echo '2048' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
   $ sudo mkdir /mnt/huge
   $ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
   ```

2. VNF mode – the IPsec security gateway application requires disabling some of the hardware tables:

   ```
   /opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode legacy
   /opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode legacy

   echo none > /sys/class/net/p0/compat/devlink/encap
   echo none > /sys/class/net/p1/compat/devlink/encap
   ```

```
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode switchdev
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode switchdev
```

To restore the old configuration:

```
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode legacy
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode legacy

echo basic > /sys/class/net/p0/compat/devlink/encap
echo basic > /sys/class/net/p1/compat/devlink/encap

/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode switchdev
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode switchdev
```

3. Switch mode – the IPsec security gateway application requires configuring the ports to run in switch mode:

```
sudo mlxconfig -d /dev/mst/mt41686(mt41692)_pciconf0 s LAG_RESOURCE_ALLOCATION=1
# power cycle the host to apply this setting

/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode legacy
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode legacy

sudo devlink dev param set pci/0000:03:00.0 name esw_pet_insert value false cmode runtime
sudo devlink dev param set pci/0000:03:00.1 name esw_pet_insert value false cmode runtime

/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode switchdev
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode switchdev

sudo devlink dev param set pci/0000:03:00.0 name esw_multiport value true cmode runtime
sudo devlink dev param set pci/0000:03:00.1 name esw_multiport value true cmode runtime
```

Make sure to perform BlueField system reboot prior to power cycling the host.

To restore the old configuration:

```
sudo devlink dev param set pci/0000:03:00.0 name esw_multiport value false cmode runtime
sudo devlink dev param set pci/0000:03:00.1 name esw_multiport value false cmode runtime
```

6.13.6.2 Application Execution

The IPsec Security Gateway application is provided in source form. Therefore, a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_ipsec_security_gw [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -s, --secured                     secured port device identifier
  -u, --unsecured                   unsecured port device identifier
  -c, --config                      Path to the JSON file with application configuration
  -m, --mode                        ipsec mode - {tunnel/transport/udp_transport}
  -i, --ipc                         IPC socket file path
  -ur, --unsecured-rep              unsecured port representor device identifier
  -n, --nb-cores                    number of cores
  --debug                           Enable debug counters
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_ipsec_security_gw -h
```

For additional information, refer to section "Command Line Flags".

2. CLI example for running the application on the BlueField or host:
   - Static Configuration:

```
./doca_ipsec_security_gw -s pci/03:00.0 -u pci/03:00.1 -c ./ipsec_security_gw_config.json -m
transport
```

Both the PCIe address identifiers (`-s` and `-u` flags) should match the addresses of the desired PCIe devices.

   - Dynamic Configuration:

```
./doca_ipsec_security_gw -s pci/03:00.0 -u pci/03:00.1 -c ./ipsec_security_gw_config.json -m
transport -i /tmp/rules_socket
```

Both the PCIe address identifiers (`-s` and `-u` flags) should match the addresses of the desired PCIe devices.

For additional information regarding the command line syntax of the device and device representor identifiers, please referr to the matching section in the DOCA Arg Parser Guide.

6.13.6.3 Command Line Flags

6.13.6.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information

Short Flag	Long Flag	Description
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.13.6.3.2 Program Flags

Short Flag	Long Flag	Description
`c`	`config`	Path to JSON file with configurations
`s`	`secured`	Device identifier for the secured port
`u`	`unsecured`	Device identifier for the unsecured port
`ur`	`unsecured-rep`	Device representor identifier for the unsecured port (switch mode)
`m`	`mode`	IPsec mode. Possible values: `tunnel`, `transport`, `udp_transport`
`i`	`ipc`	IPC socket file path for receiving IPsec rules during runtime
`n`	`nb-cores`	Number of cores
N/A	`debug`	Add counters to all the entries

6.13.6.4 Static Configuration IPsec Rules

IPsec rules and other configuration can be added with a JSON config file which is passed using the `--config` parameter.

Section	Field	Type	Description	Example
`config`	`switch`	bool	Configures whether DOCA Flow runs in VNF (`false`) or switch (`true`) mode	`"switch": true`
	`esp-header-offload`	string	Decap and encap offloading: `both` , `encap` , `decap` , or `none` . Default is `both` (offloading both encap and decap).	`"esp-header-offload": "none"`
	`sw-sn-inc-enable`	bool	Increments sequence number of ESP in software if set to `true` . Default is false. ⚠ Available only if `esp_header_offload` is `decap` or `none` .	`"sw-sn-inc-enable": true`
	`sw-antireplay-enable`	bool	Enables anti-replay mechanism in software if set to `true` . Default is false. ⚠ Available only if `esp_header_offload` is `encap` or `none` . ⚠ Window size is 64. Not ESN. Supports non-zero `sn_initial` .	`"sw-antireplay-enable": true`
	`sn-initial`	uint	Initial sequence number for ESP header. Used also when `sw_antireplay_enable` is true. Default is 0.	`"sn-initial": 0`
	`debug`	bool	Set debug counter for all entries when `true` . Default is `false` . This parameter is also used from CLI, will be taken as true if was sent in one of them.	`"debug": false`
	`fwd-bad-syndrome`	string	Forward packets that has bad syndrome: `drop` , `RSS` . Default is `drop` . ⚠ Only available in debug mode.	`"fwd-bad-syndrome": "drop"`
	`perf-measurements`	string	Possible values: `none` , `insertion-rate` , `bandwidth` , `both` . Default is `none` . • `insertion-rate` – print the total time it took to add the entries • `bandwidth` – optimize the pipe to improve pps for IPv6	`"perf-measurements": "both"`

Section	Field	Type	Description	Example
	`vxlan-encap`	bool	When `true`, preform `vxlan-encap` after encryption and decap before decryption. Default is `false`.	`"vxlan-encap": false`
	`vni`	uint	When `vxlan-encap` is true, use this `vni` value in the VXLAN tunnel.	`"vni": 5`
	`marker-encap`	bool	When `true`, add an extra non-ESP marker of 8 bytes. Default is `false`.	`"marker-encap": false`
	`icv-length`	int	ICV length value: `8`, `12`, or `16`. Default is `16`.	`"icv-length": 12`
`encrypt_rules`	`ip-version`	int	Source and destination IP version. Possible values: `4`, `6`. Optional; default is `4`.	`"ip-version": 6`
	`src-ip`	string	Source IP to match	`"src-ip": "1.2.3.4"`
	`dst-ip`	string	Destination IP to match	`"dst-ip": "101:101:101:101:101:101:101:101"`
	`protocol`	string	L4 protocol: TCP or UDP	`"protocol"`
	`src-port`	int	Source port to match	
	`dst-port`	int	Destination port to match	`"dst-port": 55`
	`encap-ip-version`	int	Encap IP version: `4` or `6`. Optional; default is `4`.	`"ip-version": 4`
	`encap-dst-ip`	string	Encap destination IP ⚠ Mandatory for tunnel mode only.	`"encap-dst-ip": "1.1.1.1"`
	`spi`	int	SPI integer to set in the ESP header	`"spi": 5`
	`key`	string	Key for creating the SA (in hex format)	`"key": "1122334455667788 99aabbccdd"`

Section	Field	Type	Description	Example
	`key-type`	int	Key size: `128` or `256`. Optional; default is `256`.	`"key-type": 128`
	`iv`	string	Initial vector (IV) for creating the SA (in hex format). Optional; default is an IV of zero bytes.	`"iv": "0102030405060708"`
	`salt`	int	Salt value for creating the SA. Default ICS `6`.	`"salt": 1212`
	`lifetime-threshold`	int	Set IPsec lifetime threshold. Ignored if `sw-sn-inc-enable` is true. Default is 0.	`"lifetime-threshold": 1000000`
	`esn_en`	bool	Enables extended sequence number. Default is `false`.	`"esn_en" : true`
`decrypt_rules`	`ip-version`	int	Destination IP version: `4` or `6`. Optional; default is `4`.	`"ip-version": 6`
	`dst-ip`	string	Destination IP to match	`"dst-ip": "1122:3344:5566:7788:99aa:bbcc:ddee:ff00"`
	`inner-ip-version`	int	Inner IP version: `4` or `6`. Optional; default is `4`. ⚠ Mandatory for tunnel mode only.	`"inner-ip-version": 4`
	`spi`	int	SPI to match in the ESP header	`"spi": 5`
	`key`	string	Key for creating the SA (in hex format)	`"key": "1122334455667788 99aabbccdd"`
	`key-type`	int	Key size: `128` or `256`. Optional; default is `256`.	`"key-type": 128`
	`iv`	string	Initial vector (IV) for creating the SA (in hex format). Optional; default is an IV of zero bytes.	`"iv": "0102030405060708"`
	`salt`	int	Salt value for creating the SA. Default is `6`.	`"salt": 1212`

Section	Field	Type	Description	Example
	`lifetime-threshold`	int	Set IPsec lifetime threshold. Ignored if `sw-antireplay-enable` is true. Default is 0.	`"lifetime-threshold": 1000000`
	`esn_en`	bool	Enables extended sequence number. Default is `false`.	`"esn_en" : true`

6.13.6.5 Dynamic Configuration IPsec Rules

The application listens on the UDS socket for receiving a predefined structure for the IPsec policy defined in the `policy.h` file.

The client program or keying daemon should connect to the socket with the same socket file path provided to the application by the `--ipc` / `-i` flags, and send the policy structure as packed to the application through the same socket.

> ⚠ In the dynamic configuration, the application uses the `config` section from the JSON config file and ignores the `encrypt_rules` and `decrypt_rules` sections.

The IPsec policy structure:

```
struct ipsec_security_gw_ipsec_policy {
    /* Protocols attributes */
    uint16_t src_port;                  /* Policy inner source port */
    uint16_t dst_port;                  /* Policy inner destination port */
    uint8_t l3_protocol;                /* Policy L3 proto {POLICY_L3_TYPE_IPV4, POLICY_L3_TYPE_IPV6} */
    uint8_t l4_protocol;                /* Policy L4 proto {POLICY_L4_TYPE_UDP, POLICY_L4_TYPE_TCP} */
    uint8_t outer_l3_protocol;          /* Policy outer L3 type {POLICY_L3_TYPE_IPV4, POLICY_L3_TYPE_IPV6} */

    /* Policy attributes */
    uint8_t policy_direction;           /* Policy direction {POLICY_DIR_IN, POLICY_DIR_OUT} */
    uint8_t policy_mode;                /* Policy IPSEC mode {POLICY_MODE_TRANSPORT, POLICY_MODE_TUNNEL} */

    /* Security Association attributes */
    uint8_t esn;                        /* Is ESN enabled? */
    uint8_t icv_length;                 /* ICV length in bytes {8, 12, 16} */
    uint8_t key_type;                   /* AES key type {POLICY_KEY_TYPE_128, POLICY_KEY_TYPE_256} */
    uint32_t spi;                       /* Security Parameter Index */
    uint32_t salt;                      /* Cryptographic salt */
    uint8_t enc_key_data[MAX_KEY_LEN];  /* Encryption key (binary) */

    /* Policy inner and outer addresses */
    char src_ip_addr[MAX_IP_ADDR_LEN + 1];      /* Policy inner IP source address in string format */
    char dst_ip_addr[MAX_IP_ADDR_LEN + 1];      /* Policy inner IP destination address in string format */
    char outer_src_ip[MAX_IP_ADDR_LEN + 1];     /* Policy outer IP source address in string format */
    char outer_dst_ip[MAX_IP_ADDR_LEN + 1];     /* Policy outer IP destination address in string format */
};
```

> ⚠ The policy type, whether it is encrypted or decrypted, is classified according to the `policy_direction` attribute:
>
> - `POLICY_DIR_IN` – decryption policy
> - `POLICY_DIR_OUT` – encryption policy

6.13.6.6 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.13.7 Application Code Flow

1. Parse application argument.
    a. Initialize arg parser resources and register DOCA general parameters.

    ```
    doca_argp_init();
    ```

    b. Register the application's parameters.

    ```
    register_ipsec_security_gw_params();
    ```

    c. Parse the arguments.

    ```
    doca_argp_start();
    ```

        i. Parse app parameters.
2. DPDK initialization.

    ```
    rte_eal_init();
    ```

    Call `rte_eal_init()` to initialize EAL resources with the provided EAL flags for not probing the ports.
3. Parse config file.

    ```
    ipsec_security_gw_parse_config();
    ```

4. Initialize devices and ports.

    ```
    ipsec_security_gw_init_devices();
    ```

    a. Open DOCA devices with input PCIe addresses / interface names.
    b. Probe DPDK port from each opened device.
5. Initialize and start DPDK ports.

    ```
    dpdk_queues_and_ports_init();
    ```

    a. Initialize DPDK ports, including mempool allocation.
    b. Initialize hairpin queues if needed.
    c. Binds hairpin queues of each port to its peer port.
6. Initialize DOCA Flow.

```
ipsec_security_gw_init_doca_flow();
```

a. Initialize DOCA Flow library.

b. Find the indices of the DPDK-probed ports and start DOCA Flow ports with them.

7. Insert rules.

a. Insert encryption rules.

```
ipsec_security_gw_insert_encrypt_rules();
```

b. Insert decryption rules.

```
ipsec_security_gw_insert_decrypt_rules();
```

8. Wait for traffic.

```
ipsec_security_gw_wait_for_traffic();
```

a. wait in a loop until the user terminates the program.

9. IPsec security gateway cleanup:

a. DOCA Flow cleanup; destroy initialized ports.

```
doca_flow_cleanup();
```

b. SA destruction.

```
ipsec_security_gw_destroy_sas();
```

c. IPsec objects destruction.

```
ipsec_security_gw_ipsec_ctx_destroy();
```

d. Destroy DPDK ports and queues.

```
dpdk_queues_and_ports_fini();
```

e. DPDK finish.

```
dpdk_fini();
```

Calls `rte_eal_destroy()` to destroy initialized EAL resources.

f. Arg parser destroy.

```
doca_argp_destroy()
```

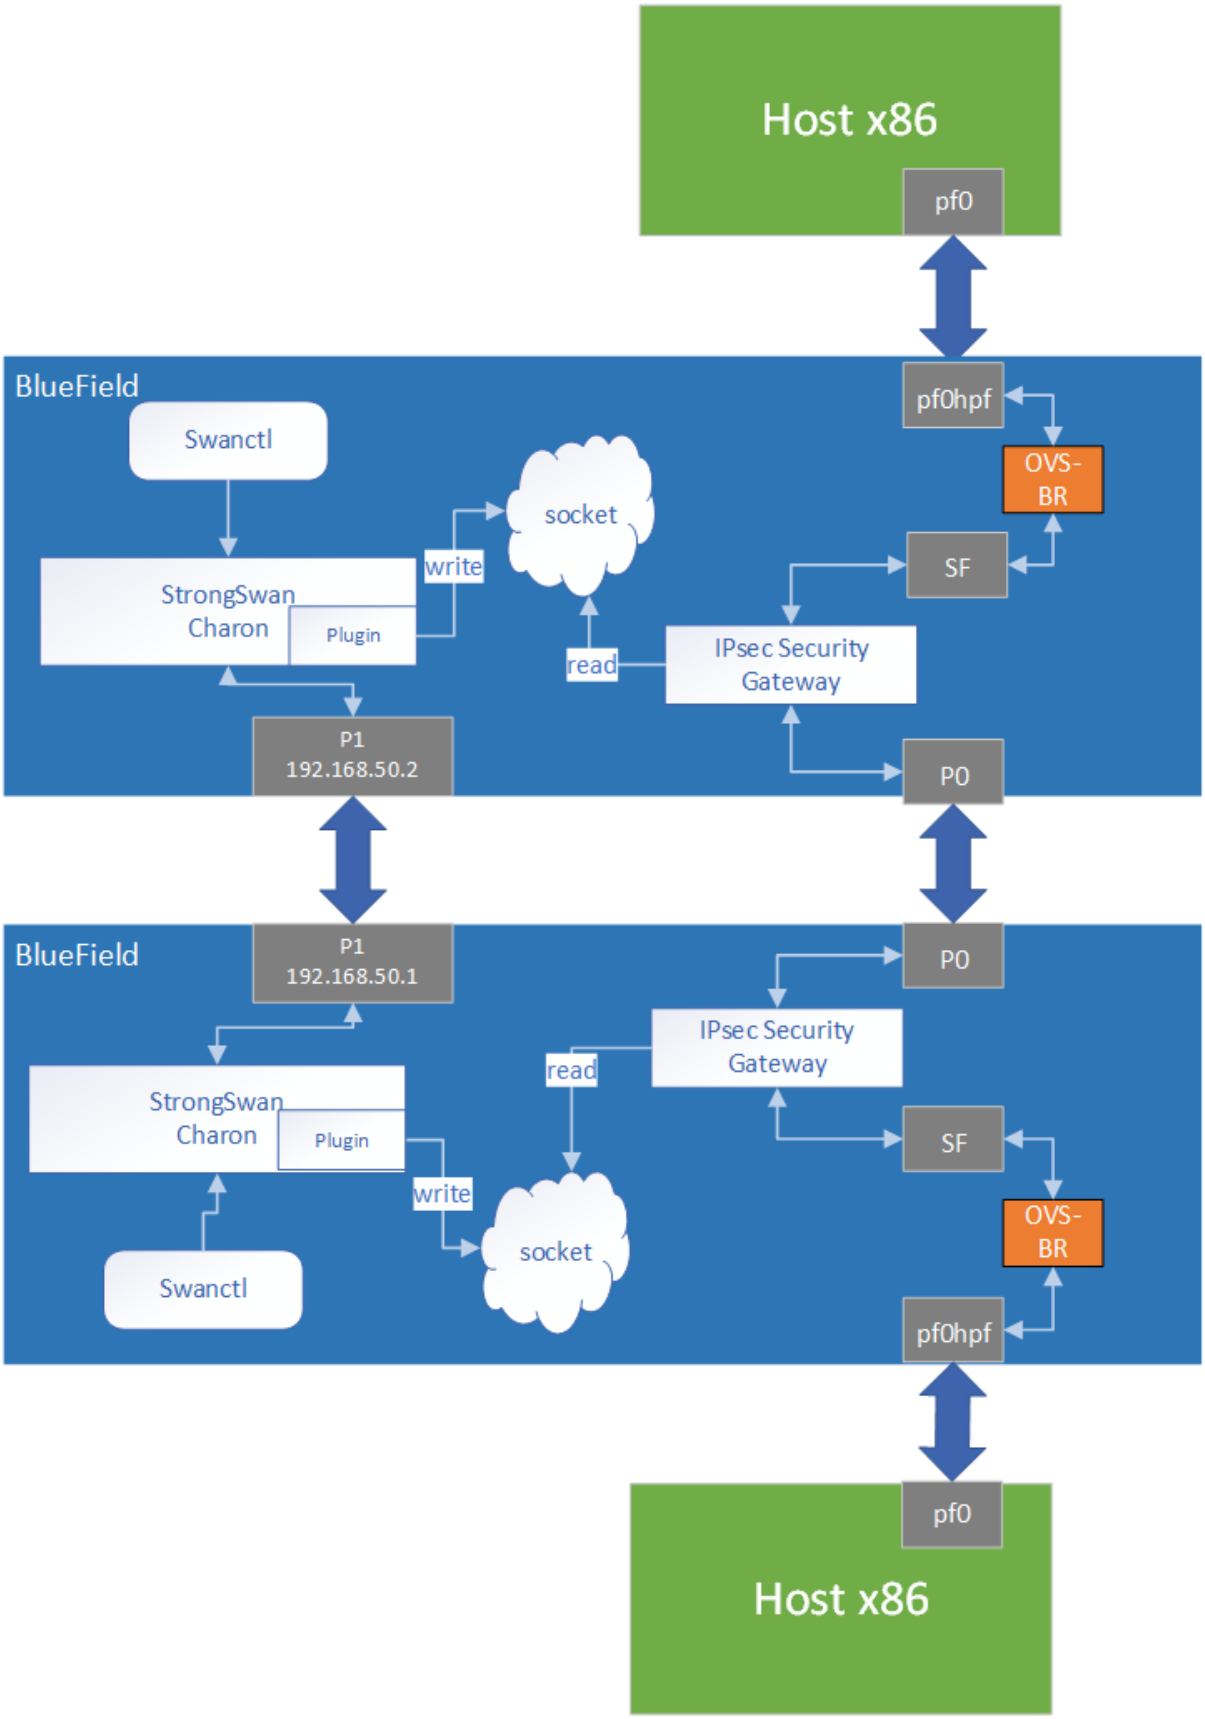
6.13.8 Keying Daemon Integration (StrongSwan)

strongSwan is a keying daemon that uses the Internet Key Exchange Version 2 (IKEv2) protocol to establish SAs between two peers. strongSwan includes a DOCA plugin that is part of the strongSwan package in BFB. The plugin is loaded only if the DOCA IPsec Security Gateway is triggered. The plugin connects to UDS socket and sends IPsec policies to the application after the key exchange completes.

For more information about the key daemon, refer to strongSwan documentation.

6.13.8.1 End-to-end Architecture

The following diagram presents an architecture where two BlueField DPUs are connected to each other with DOCA IPsec Security Gateway running on each.



Host x86
pf0
BlueField
pf0hpf
OVS-BR
SF
Swanctl
socket
write
StrongSwan Charon
Plugin
read
IPsec Security Gateway
P1 192.168.50.2
P0
BlueField
P1 192.168.50.1
P0
IPsec Security Gateway
read
StrongSwan Charon
Plugin
SF
write
socket
OVS-BR
Swanctl
pf0hpf
pf0
Host x86

`swanctl` is a command line tool used for strongSwan IPsec configuration:

1. Run DOCA IPsec Security Gateway on both sides in a dynamic configuration.
2. Start strongSwan service.
3. Configure strongSwan IPsec using the `swanctl.conf` configuration file on both sides.
4. Start key exchange between the two peers. At the end of the flow, the result arrives to the DOCA plugin, populates the policy-defined structure, and sends it to the socket.
5. DOCA IPsec Security Gateway on both sides reads new policies from the socket, performs the parsing, creates a DOCA SA object, and adds flow decrypt/encrypt entry.

This architecture uses P1 uplink on both BlueField DPUs to run the strongSwan key daemon. To configure the uplink:

1. Configure an IP addresses for the PFs of both DPUs:
   a. On BF1:

   ```
   ip addr add 192.168.50.1/24 dev p1
   ```

   b. On BF2:

   ```
   ip addr add 192.168.50.2/24 dev p1
   ```

   It is possible to configure multiple IP addresses to uplinks to run key exchanges with different policy attributes.

2. Verify the connection between two BlueField DPUs.

   ```
   BF1> ping 192.168.50.2
   ```

   Make sure that the uplink is not in OVS bridges.

3. Configure the `swanctl.conf` files for each machine. The file should be located under `/etc/swanctl/conf.d/`.
   Adding `swanctl.conf` file examples:
   - Transport mode
     - `swanctl.conf` example for BF1:

     ```
     connections {
        BF1-BF2 {
           local_addrs  = 192.168.50.1
           remote_addrs = 192.168.50.2
           rekey_time = 0

           local {
             auth = psk
             id = host1
           }
           remote {
             auth = psk
     ```

```
        id = host2
      }

      children {
         bf {
            local_ts = 192.168.50.1/32 [udp/60]
            remote_ts = 192.168.50.2/32 [udp/90]
            esp_proposals = aes128gcm128-x25519-esn
            mode = transport
            policies_fwd_out = yes
            life_time = 0
         }
      }
      version = 2
      mobike = no
      reauth_time = 0
      proposals = aes128-sha256-x25519
   }
}

secrets {
   ike-BF {
      id-host1 = host1
      id-host2 = host2
      secret = 0sv+NkxY9LLZvwj4qCC2o/gGrWDF2d21jL
   }
}
```

- `swanctl.conf` example for BF2:

```
connections {
   BF2-BF1 {
      local_addrs  = 192.168.50.2
      remote_addrs = 192.168.50.1
      rekey_time = 0

      local {
        auth = psk
        id = host2
      }
      remote {
        auth = psk
        id = host1
      }

      children {
         bf {
            local_ts = 192.168.50.2/32 [udp/90]
            remote_ts = 192.168.50.1/32 [udp/60]
            esp_proposals = aes128gcm128-x25519-esn
            mode = transport
            life_time = 0
         }
      }
      version = 2
      mobike = no
      reauth_time = 0
      proposals = aes128-sha256-x25519
   }
}

secrets {
   ike-BF {
      id-host1 = host1
      id-host2 = host2
      secret = 0sv+NkxY9LLZvwj4qCC2o/gGrWDF2d21jL
   }
}
```

- Tunnel mode

```
connections {
   BF1-BF2 {
      local_addrs  = 192.168.50.2
      remote_addrs = 192.168.50.1
      rekey_time = 0

      local {
        auth = psk
        id = host2
      }
      remote {
        auth = psk
        id = host1
      }

      children {
         bf {
            local_ts = 2001:db8:85a3::8a2e:370:7334/128 [udp/3030]
            remote_ts = 2001:db8:85a3::8a2e:370:7335/128 [udp/55]
            esp_proposals = aes128gcm128-x25519-esn
            life_time = 0
         }
      }
      version = 2
      mobike = no
      proposals = aes128-sha256-x25519
```

```
    }
}

secrets {
   ike-BF {
      id-host1 = host1
      id-host2 = host2
      secret = 0sv+NkxY9LLZvwj4qCC2o/gGrWDF2d21jL
   }
}
```

> ⚠ `local_ts` and `remote_ts` must have a netmask of /32 for IPv4 addresses and /128 for IPv6 addresses.

> ⚠ SA rekey is not supported in DOCA plugin. `connection.rekey_time` must be set to 0 and `connection.child.life_time` must be set to 0.

DOCA IPsec only supports ESP headers, AES-GCM encryption algorithm, and key sizes 128 or 256. Therefore, when setting ESP proposals in the `swanctl.conf`, please adhere to the values provided in the following table:

ESP Proposal	Algorithm Type Including ICV Length	Key Size
aes128gcm8	`ENCR_AES_GCM_ICV8`	128
aes128gcm64	`ENCR_AES_GCM_ICV8`	128
aes128gcm12	`ENCR_AES_GCM_ICV12`	128
aes128gcm96	`ENCR_AES_GCM_ICV12`	128
aes128gcm16	`ENCR_AES_GCM_ICV16`	128
aes128gcm128	`ENCR_AES_GCM_ICV16`	128
aes128gcm	`ENCR_AES_GCM_ICV16`	128
aes256gcm8	`ENCR_AES_GCM_ICV8`	256
aes256gcm64	`ENCR_AES_GCM_ICV8`	256
aes256gcm12	`ENCR_AES_GCM_ICV12`	256
aes256gcm96	`ENCR_AES_GCM_ICV12`	256
aes256gcm16	`ENCR_AES_GCM_ICV16`	256
aes256gcm128	`ENCR_AES_GCM_ICV16`	256
aes256gcm	`ENCR_AES_GCM_ICV16`	256

6.13.8.2 Building strongSwan

To enable the DOCA plugin in strongSwan:

1. Verify that the dependencies listed here are installed in your environment. `libgmp-dev` is missing from that list so make sure to install that as well.
2. Git clone https://github.com/Mellanox/strongswan.git.
3. Git checkout BF-5.9.10 branch.
4. Add your changes in the plugin located under `src/libcharon/plugins/doca`.
5. Run `autogen.sh` within the strongSwan repo.
6. Run the following:

```
./configure --enable-openssl --disable-random --prefix=/usr/local --sysconfdir=/etc --enable-systemd --
enable-doca
make
make install
systemctl daemon-reload
systemctl restart strongswan.service
```

6.13.8.3 Running the Solution

Run the following commands on both BlueField peers.

1. Run DOCA IPsec Security Gateway in dynamic configuration, assuming the socket location is `/tmp/rules_socket`.

```
doca_ipsec_security_gw -s 03:00.0 -u <sf_net_dev> -c ./ipsec_security_gw_config.json -m transport -i /tmp/
rules_socket
```

> ⚠ DOCA IPsec Security Gateway application should be run first.

2. Edit the `/etc/strongswan.d/charon/doca.conf` file and add the UDS socket path. If the `socket_path` is not set, the plugin uses the default path `/tmp/strongswan_doca_socket`.

```
doca {

# Whether to load the plugin
load = yes

# Path to DOCA socket
socket_path = /tmp/rules_socket
}
```

> ⚠ You must provide the application with this path as well.

3. Restart the strongSwan server:

```
systemctl restart strongswan.service
```

If the application has been run with log level debug, you can see that the connection has been done successfully, and the application is waiting for new IPsec policies.

4. Verify that the `swanctl.conf` file exists in `/etc/swanctl/conf.d/` . directory.

   It is recommended to remove any unused conf files under `/etc/swanctl/conf.d/` .

5. Load IPsec configuration:

```
swanctl --load-all
```

6. Start IKE protocol on either the initiator or the target side:

```
swanctl -i --child <child_name>
```

   In the example above, the child's name is `bf` .

6.14 DOCA NVMe Emulation Application Guide

This document provides an NVMe emulation implementation on top of the NVIDIA® BlueField® DPU.

6.14.1 Introduction

The NVMe emulation application exhibits how to use the DOCA DevEmu PCI Generic API along with SPDK to emulate an NVMe PCIe function using hardware acceleration to fully emulate the storage device.

6.14.2 Application Architecture

6.14.2.1 Brief Introduction to NVMe

NVMe (Non-Volatile Memory Express) is a high-performance storage protocol designed for accessing non-volatile storage media. NVMe operates over the PCI Express bus, which provides a direct and high-speed connection between the CPU and storage. It enables significantly lower latency and higher input/output operations per second compared to older storage protocols. NVMe achieves this through its scalable, multi queue architecture, allowing thousands of I/O commands to be processed in parallel.

NVMe emulation is a mechanism that allows NVMe device behavior to be simulated in a virtualized or development environment without the need for physical NVMe hardware.

6.14.2.1.1 Controller Registers

NVMe controllers feature several memory-mapped registers located within memory regions defined by the Base Address Registers (BARs). These registers convey the controller's status, enable the host to configure operational settings, and facilitate error reporting.

Key NVMe controller registers include:

- CC (Controller Configuration) – Configures the controller's operational parameters, including enabling or disabling it and specifying I/O command sets.
- CSTS (Controller Status) – Reports the controller's status, including its readiness and any fatal error.
- CAP (Capabilities) – Details the capabilities of the controller.
- VS (Version) – Indicates the supported NVMe version.
- AQA (Admin Queue Attributes) – Specifies the sizes of the admin queues.

6.14.2.1.1.1 Initialization

Initializing an NVMe controller involves configuring the controller registers and preparing the system to communicate with the NVMe device. The process typically follows these steps:

1. The host clears the enable bit in the CC register (sets it to 0) to reset the controller.
2. The host configures the controller by setting initial parameters in the CC register and enables it by setting the enable bit.
3. The host sets up the admin submission and completion queues for handling administrative commands.

4. Administrative commands are issued to retrieve namespace information and perform other setup tasks.
5. The host creates I/O submission and completion queues, preparing the controller for I/O operations.

6.14.2.1.1.2 Reset and Shutdown

Reset and shutdown operations ensure the controller is properly handled and data integrity is maintained.

- The reset process sets the enable bit in CC register to 0, stopping all I/O operations and clearing the controller's state to ensure it returns to a known state.
- Shutdown is initiated by setting the Shutdown Notification (SHN) field in the CC register. This allows the controller to halt operations, flush caches, and ensure data in flight is safely handled before powering off or resetting.

6.14.2.1.2 Completion Queue (CQ)

The Completion Queue in NVMe stores entries that the controller writes after processing commands. Each entry in the CQ corresponds to a command submitted through a Submission Queue, and the host checks the CQ to track the status of these commands.

CQs are implemented as circular buffers in host memory. The host can either poll the CQ or use interrupts to be notified when new entries are available.

6.14.2.1.2.1 Completion Queue Element (CQE)

Each completion queue element in an NVMe Completion Queue (CQ) is an individual entry that contains status information about a completed command, including:

- CID – Identifier of the completed command.
- SQID – ID of the Submission Queue from which the command was issued.
- SQHD – Marks the point in the Submission Queue up to which commands have been completed.
- SF – Indicates the status of the completed command.
- P – Flags whether the completion entry is new.

6.14.2.1.3 Submission Queue

The submission queue (SQ) is where the host places admin and I/O commands for the controller to execute. It operates as a circular buffer, and each SQ is paired with a Completion Queue (CQ). NVMe supports multiple SQs, with each one assigned to a specific CQ.

The controller is notified of new commands via the doorbell mechanism.

6.14.2.1.3.1 Submission Queue Element (SQE)

A Submission Queue Element (SQE) is an individual entry in a Submission Queue that represents a command for the NVMe controller to process. Each SQE contains:

- CID – A unique identifier for the command
- OPC – The opcode that specifies the operation to be performed
- PSDT – Specifies whether PRPs (Physical Region Pages) or SGLs (Scatter-Gather Lists) are used for data transfer associated with the command
- NSID – The identifier of the target namespace for the command

Additionally, the SQE includes fields for command-specific details, such as logical block addresses and transfer sizes.

6.14.2.1.4 Admin Queue Pair (Admin QP)

The Admin Queue Pair consists of an Admin Submission Queue (SQ) and an Admin Completion Queue (CQ), both assigned a command identifier (CID) of 0. There is only one Admin Queue Pair (QP) for each NVMe controller, and it is created asynchronously during the initialization phase. Unlike I/O queues, this QP is dedicated solely to controller management tasks, facilitating the processing of administrative commands.

6.14.2.1.4.1 Admin Commands

- **Identify Command (** `SPDK_NVME_OPC_IDENTIFY 0x06` **)**

  This command allows the host to query information from the NVMe controller, retrieving a data buffer that describes attributes of the NVMe subsystem, the controller, or the namespace. This information is essential for host software to properly configure and utilize the storage device effectively.

- **Create I/O Submission Queue (** `SPDK_NVME_OPC_CREATE_IO_SQ 0x01` **)**

  This command allows the host to instruct the NVMe controller to establish a new queue for submitting I/O commands.

  Key parameters:

  - SQID – Identifies the specific I/O Submission Queue being created.
  - Queue Depth – Specifies the number of entries the queue can hold.
  - CQID – The identifier of the associated Completion Queue.

  Once the host sends the command with the necessary parameters, the controller allocates the required resources and returns a status indicating success or failure.

- **Delete I/O Submission Queue (** `SPDK_NVME_OPC_DELETE_IO_SQ 0x00` **)**

This command is used to remove an I/O Submission Queue when it is no longer required.

Key parameters:

- SQID – The identifier of the I/O Submission Queue to be deleted.

Once the host issues the command, the controller releases all resources associated with the queue and returns a status confirming the deletion. After the queue is deleted, no additional I/O commands can be submitted to it.

- **Create I/O Completion Queue (`SPDK_NVME_OPC_CREATE_IO_CQ 0x05`)**

  This command is issued by the host to set up an I/O completion queue in the NVMe controller.

  Key parameters:

  - CQID – The identifier of the I/O Completion Queue to be created.
    - Queue Depth – The number of entries the completion queue can hold.
  - PRP1/PRP2 – Pointers to the memory location where the CQ entries are stored.
  - MSIX – The Interrupt vector associated with this CQ.

  Once the host issues the command, the controller allocates the necessary resources, links the CQ to the specified interrupt vector, and returns a status confirming the creation.

- **Delete I/O Completion Queue (`SPDK_NVME_OPC_DELETE_IO_CQ 0x04`)**

  This command is issued by the host to remove an existing I/O Completion Queue from the NVMe controller.

  Key parameters:

  - CQID – The identifier of the I/O Completion Queue to be deleted.

  Upcoming receiving this command, The NVMe controller removes the specified CQ and frees all associated resources. Before a CQ can be deleted, all SQs linked to it must be either deleted or reassigned to another CQ. The Controller returns a status code indicating whether the deletion was successful or if an error occurred. Once deleted, the CQ no longer processes completions entries from any linked SQ.

- **Get Feature (`SPDK_NVME_OPC_GET_FEATURES 0x0A`)**
  This command is issued by the host to query specific features supported by the NVMe controller.
  Key parameters:
  - FID (Feature ID) – Specifies which feature the host wants to retrieve. The controller returns information based on the requested feature. Common features include:
    - Arbitration (FID 0x01)

- Power Management (FID 0x02)
- Temperature Threshold (FID 0x04)
- Error Recovery (FID 0x05)
- Volatile Write Cache (FID 0x06)
- Number of Queues (FID 0x07)
- Interrupt Coalescing (FID 0x08)

Depending on the FID, the feature information may be returned in the Completion Queue Entry (CQE) or written to an output buffer in host memory. If an output buffer is used, the host provides a memory region that the controller accesses via PRP entries or SGL.

- Select – Determines which version of the feature value to return. There are four options:
  - Current (0x0) – Returns the active value of the feature
  - Default (0x1) – Returns the default value of the feature
  - Saved (0x2) – Returns the saved value from non-volatile memory
  - Supported Capabilities (0x3) – Returns the capabilities supported by the controller for the feature

After executing the command, the controller returns a status code in the CQE indicating whether the query was successful.

- **Set Feature (** `SPDK_NVME_OPC_SET_FEATURES 0x09` **)**
  This command is issued by the host to modify specific features on the NVMe controller.
  Key parameters:
  - FID (Feature ID): Specifies which feature the host intends to modify. Common features include:
    - Arbitration (FID 0x01)
    - Power Management (FID 0x02)
    - Temperature Threshold (FID 0x04)
    - Error Recovery (FID 0x05)
    - Volatile Write Cache (FID 0x06)
    - Number of Queues (FID 0x07)
    - Interrupt Coalescing (FID 0x08)
  - Data location: depending on the FID, the new value can be provided directly in the SQE or stored in an input buffer located in host memory and is accessible by the controller via PRP or SGL.
  - Save: this field allows the host to specify whether the modification should persist after a controller reset, if set the modified value is saved in the controller non-volatile memory.

After the command is issued and the controller modifies the feature as requested, it returns a status code in the CQE, indicating whether the modification was successful or if an error occurred.

- **Log Page (** `SPDK_NVME_OPC_GET_LOG_PAGE 0x02` **)**
  This command is issued by the host to retrieve various types of log pages from the NVMe controller for monitoring and diagnosing the state of an NVMe device. Key parameters:
  - LID: log page identifier that specifies the type of log page to retrieve. some common log pages include:
    - SMART / Health Information (LID 0x02): provides device health metrics, temperature, available spare, and more.
    - Error Information (LID 0x01): contains details about errors encountered by the controller.
    - Firmware Slot Information (LID 0x03): information on the firmware slots and active firmware.
    - Telemetry Host-Initiated (LID 0x07): contains telemetry data about device performance.
  - NUMD: the number of DWORDs of log data to return. this allows partial or full-page retrieval.
  - Log page data location: the retrieved log data is written into the output buffer provided by the host. The buffer is accessible by the controller via PRP or an SGL.

  When the host issues the get log command, the controller retrieves the requested log information and writes it to the host-provided memory. The controller then returns a status code in the CQE, indicating the success or failure of the operation.

6.14.2.1.5 Input/Output Queue Pair (I/O QP)

An I/O Queue Pair consists of one Submission Queue and its corresponding Completion Queue, which are used to perform data transfers (I/O operations). Multiple I/O Queue Pairs can be created to enable parallel I/O operations. Each queue pair functions independently, maximizing the use of multi-core processors.

- I/O Submission Queue: where the host places read/write/flush commands
- I/O Completion Queue: where the controller posts completion entries after processing the commands

6.14.2.1.5.1 NVM Commands

- **Flush (** `SPDK_NVME_OPC_FLUSH 0x00` **)**

  The NVMe Flush Command is issued by the host to ensure that any data residing in volatile memory is securely written to permanent storage. If no volatile write cache is present or enabled, the Flush command completes successfully without any effect. Once the Flush operation is finished, the controller updates the associated I/O Completion Queue with a completion entry.

- **Read** (`SPDK_NVME_OPC_READ 0x02`)

The NVMe read command is one of the core I/O operations in NVMe. This command is issued by the host to retrieve data from a specified namespace and transfer it to the host memory.
Key parameters:

- NSID – the identifier of the namespace from which the data is being read.
- LBA – the starting address of the data to be read within the namespace.
- NLB (Number of LBAs) – specifies the size of the read operation in terms of the number of logical blocks to be read.
- Destination buffer – The controller gets the read data from the namespace and sends it to the host memory, where the destination buffer is specified using PRP or SGL.

Upon completion, the controller posts a completion entry to the I/O Completion Queue which includes a status code indicating success or failure.

- **Write (** `SPDK_NVME_OPC_WRITE 0x01` **)**

The write command is also one of the core I/O operations in NVMe. this command is issued by the host to write data to a specific namespace at a given logical block address (LBA).
Key parameters:

- NSID – The identifier of the namespace where the data is being written
- LBA – The destination address within the namespace where data is written
- NLB – Specifies the size of the write operation in terms of the number of logical blocks to be written
- Source buffer – The data to be written is located in host memory, and the controller reads this data from the source buffer, which is provided using PRP or SGL.

Upon completion, the controller posts a completion entry to the I/O Completion Queue, which includes a status code indicating the success or failure of the write operation.

6.14.2.2 Brief Introduction To SPDK

The Storage Performance Development Kit (SPDK) is an open-source framework that offers tools and libraries for building high-performance, scalable storage solutions, particularly for NVMe devices. SPDK allows applications to implement transport protocols for NVMe over Fabrics (NVMe-oF) by bypassing the kernel and using user-space drivers, enabling direct interaction with storage hardware. This approach significantly reduces latency and overhead, making it ideal for demanding storage environments.

A key component of SPDK is its highly optimized NVMe driver, which operates entirely in user space. By allowing direct communication with NVMe devices without involving the kernel, this driver minimizes I/O latency and boosts performance, supporting both local NVMe storage and remote NVMe devices over NVMe-oF.

6.14.2.2.1 SPDK Threading Model

SPDK's threading model is designed for high concurrency, scalability, and low-latency I/O processing. It operates on a cooperative multitasking model where SPDK threads are assigned to pollers and tasks are executed entirely in user space without kernel involvement. Each SPDK thread runs on a dedicated CPU core, ensuring minimal context switching and enabling tight control over workloads in a non-preemptive environment.

6.14.2.2.1.1 Reactor Threads

At the core of this model are reactor threads, which are SPDK's main execution threads responsible for handling I/O processing and application logic. Each reactor thread is bound to a specific core and runs in polling mode, meaning it continuously polls for tasks and I/O requests rather than relying on interrupts.

Example:

```
struct spdk_thread *thread = spdk_get_thread();
```

This function retrieves the current SPDK thread, which is mapped to a specific core.

SPDK provides the ability to register pollers to reactor threads, which are periodic functions designed to complete asynchronous I/O operations, manage RPC servers, or perform custom operations. Once a poller completes an operation, it can trigger a user-defined callback to finalize the task.

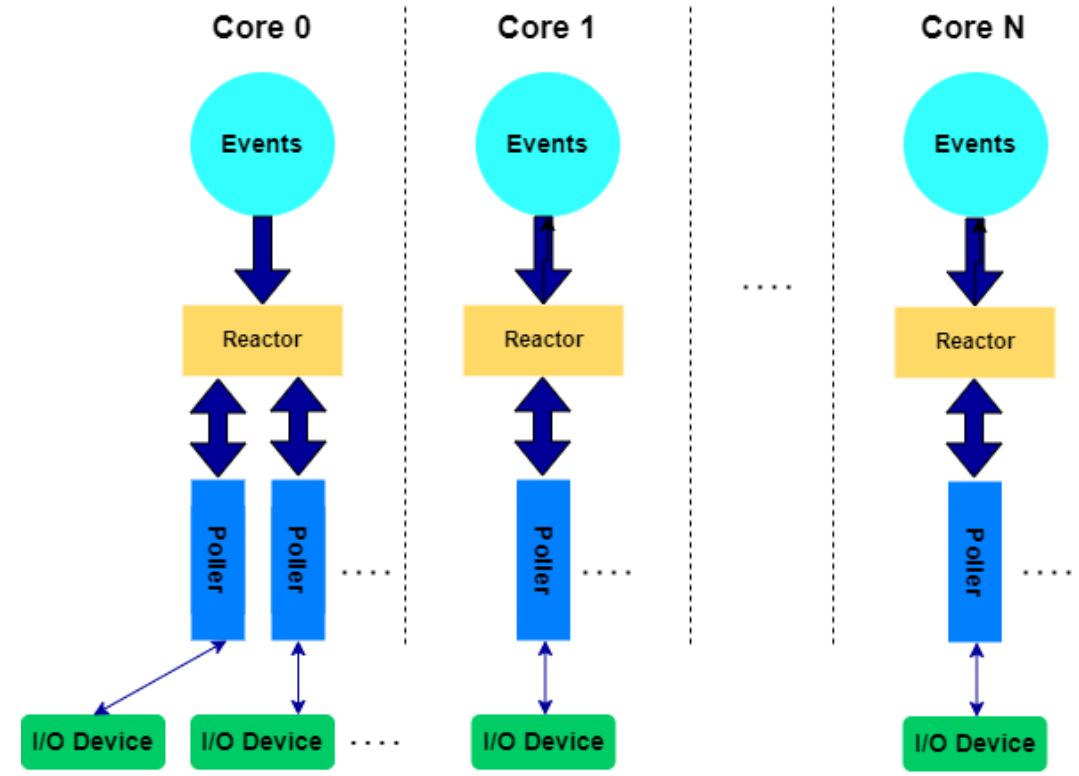
Example of registering a poller:

```
struct spdk_poller *my_poller = spdk_poller_register(my_poll_function, arg, poll_interval_us);
```

Here, `my_poll_function` is invoked repeatedly by the reactor thread.

6.14.2.2.1.2 Poll Groups

Poll Groups consist of multiple SPDK threads working together to manage I/O across multiple devices or connections. A poll group allows a set of threads to coordinate and handle shared workloads, ensuring efficient distribution of tasks across available cores with minimal latency.



6.14.2.2.1.3 Thread Synchronization

In SPDK's cooperative threading model, thread synchronization is designed to be efficient and minimal, as threads do not experience preemptive context switching like traditional kernel threads. This allows for fine-grained control over when tasks are executed. However, there are situations where coordination between threads becomes necessary, such as when handling shared resources or passing tasks between cores.

Instead of relying on traditional locking mechanisms, which can introduce performance bottlenecks due to contention, SPDK uses message passing as the primary method for thread communication. This involves sending events or tasks between threads through a lockless event ring, which allows for coordination without the overhead associated with locks.

Example of sending a message between threads:

```
void send_message(struct spdk_thread *target_thread, spdk_msg_fn fn, void *arg) {
    spdk_thread_send_msg(target_thread, fn, arg);
}
```

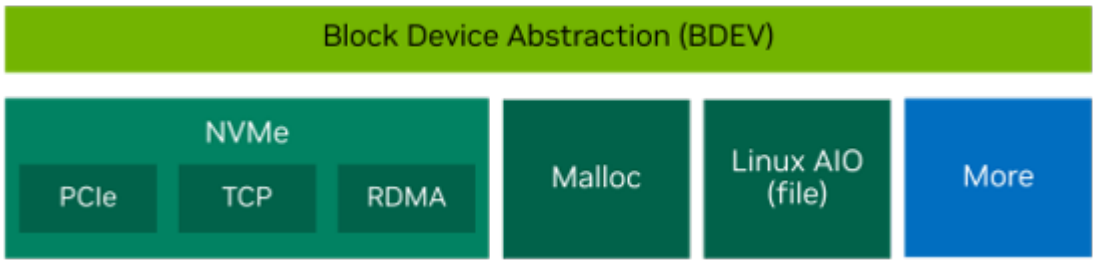
`target thread` is the SPDK we want to send a message to, `fn` is the function to be executed in the context of the target thread, and `arg` is the argument passed to the function.

6.14.2.2.2 Block Device

SPDK provides a flexible system for working with different types of storage devices, like NVMe SSDs, virtual block devices, AIO devices, and RAM disks. It uses high-performance, user-space APIs to let applications bypass the operating system's kernel, reducing delays and improving performance.

SPDK's block device (bdev) layer gives applications a unified way to perform read and write operations on these devices. It supports popular devices out of the box and allows users to create custom block devices. Advanced features like RAID and acceleration with technologies like DPDK are also supported.

Block devices can be easily created or destroyed using SPDK's RPC server. In NVMe-oF environments, a block device represents a namespace, which helps manage storage across different systems. This makes SPDK ideal for building fast, scalable storage solutions.



6.14.2.2.3 NVMe-oF Target

The NVMe-oF target is a user-space application within the SPDK framework that exposes block devices over network fabrics such as Ethernet, InfiniBand, or Fibre Channel. It typically uses transport protocols like TCP, RDMA, or vfio-user to enable clients to access remote storage.

To use the NVMe-oF target, it is required to configure it to work with one of these transport protocols:

- TCP
- RDMA (over InfiniBand or RoCE)
- vfio-user (mainly for virtual machines)
- FC-NVMe (Fibre Channel, less common in SPDK environments)

6.14.2.2.3.1 NVMe-oF Transport

Each NVMe-oF transport plays a crucial role in facilitating communication between the NVMe-oF initiator (the client) and the target. The transport handles how NVMe commands are transmitted over the network fabric. For example:

- TCP uses IP-based addressing over Ethernet.

- RDMA leverages the low-latency, high-throughput characteristics of InfiniBand or RoCE.
- vfio-user provides virtualization support, allowing virtual machines to access NVMe devices.
- FC-NVMe uses Fibre Channel, often found in enterprise SAN environments.

Additionally, SPDK is designed to be flexible, allowing developers to create custom transports and extend the functionality of the NVMFS target beyond the standard transports provided by SPDK.

The NVMe-oF transport is responsible for:

- Establishing the connection between the initiator and the target.
- Translating network-layer commands into SPDK NVMe commands.
- Managing data transfer across the network fabric.

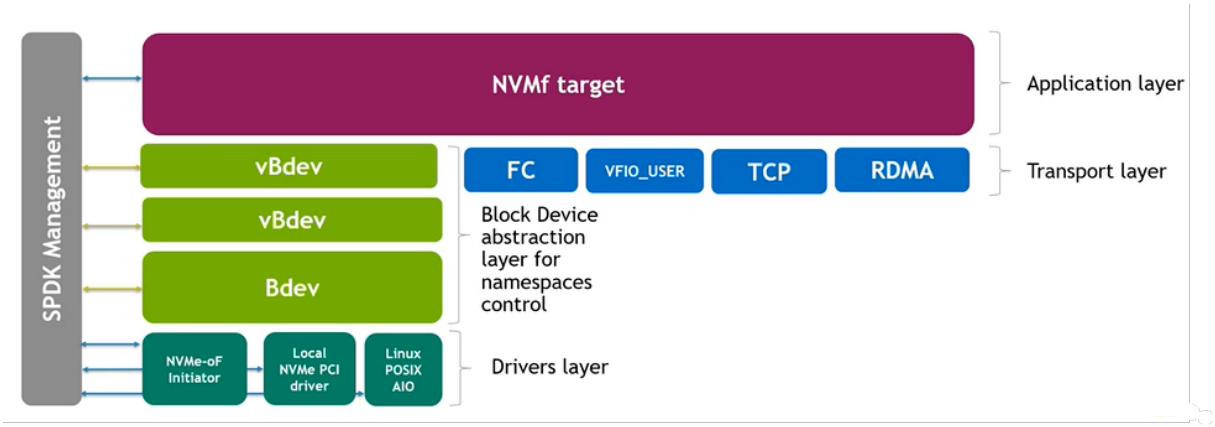
Once a connection is established through the transport, the NVMe-oF target processes the NVMe commands sent by the initiator.

6.14.2.2.3.2 Application Layer

Above the transport layer is the SPDK application layer, which is transport-agnostic. This means that regardless of the transport being used (TCP, RDMA, etc.), the application layer handles NVMe commands uniformly. It is responsible for:

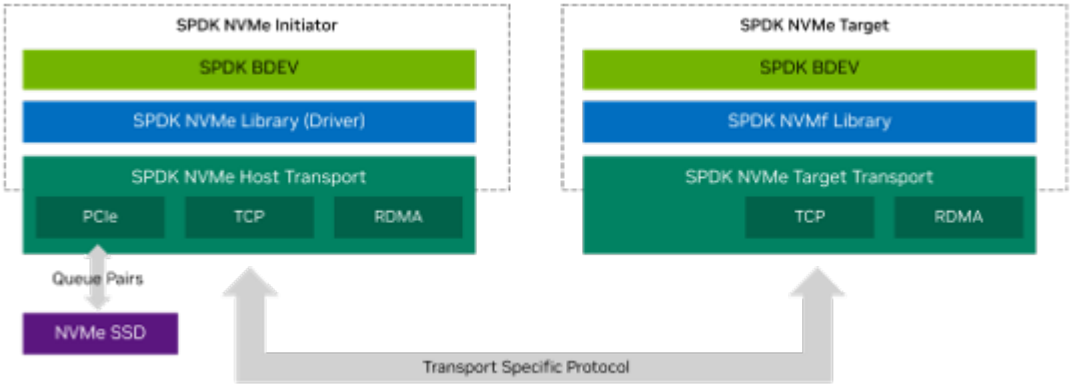
- Managing subsystems, namespaces, and controllers.
- Processing NVMe commands received over the network.
- Mapping these commands to the appropriate storage devices (such as NVMe SSDs or virtual devices like SPDK's `malloc` or `null` devices).

This uniform application layer ensures that the transport layer interacts with the same logic for processing and responding to NVMe commands, regardless of the underlying network fabric.



6.14.2.2.3.3 NVMe Driver in SPDK

In the context of NVMe storage, the initiator is the host system that needs to access an NVMe storage device to send data or retrieve data from an NVMe storage device, and the driver is responsible for generating and sending the appropriate commands such as read and write. the driver uses the transport to communicate with the NVMe target. the transport sends those commands either over a network in case of remote target or directly to a local NVMe device through the PCIe bus. The target receives these requests from the initiator, processes them and responds back with the data or completion status.



–

6.14.2.2.4 RPC Server

SPDK's Remote Procedure Call (RPC) server provides a flexible interface for clients to interact with various SPDK services, such as NVMe-oF, block devices (bdevs), and other storage subsystems. The server is based on JSON-RPC and runs within the SPDK application, allowing external clients to dynamically configure, control, and manage SPDK components without the need for application restarts. Through RPC requests, users can create, delete, or query subsystems, configure network storage layers, and manage NVMe-oF targets. The main functionality of RPC server is to process incoming RPC commands that are usually in JSON format, to execute the functions based on the RPC requests and to return the result back to the client.

The RPC server runs within the SPDK application.

6.14.2.2.5 RPC Client

The RPC client in SPDK interacts with the RPC server to issue commands for configuring and managing various SPDK subsystems. It sends a command, typically in JSON format, asking the server to perform a certain task or retrieve data. The main functionality of RPC client is to construct the request message that it wants the server to process sends the request to the RPC server and receives the response from the server,

The RPC client runs on the user or application side.

6.14.2.2.5.1 Transport RPCs

SPDK provides several transport RPCs are used to configure and manage the transport layer for NVMe-oF. Here are the primary transport RPCs:

- `nvmf_create_transport`
- `nvmf_get_transports`
- `nvmf_subsystem_add_listener`
- `nvmf_get_subsystems`
- `nvmf_delete_listener`
- `nvmf_get_stats`
- `nvmf_delete_transport`

6.14.2.2.5.2 Block Device RPCs

SPDK provides several transport RPCs are used to configure and manage the transport layer for NVMe-oF. Here are the primary transport RPCs:

- `nvmf_create_transport`
- `nvmf_get_transports`
- `nvmf_subsystem_add_listener`
- `nvmf_get_subsystems`
- `nvmf_delete_listener`
- `nvmf_get_stats`
- `nvmf_delete_transport`

6.14.2.2.5.3 Namespace RPCs

Namespace RPCs are used to manage NVMe namespaces within NVMe-oF subsystems or NVMe controllers, here is a list of Namespaces RPCs available:

- `nvmf_subsystem_add_ns`
- `nvmf_subsystem_remove_ns`
- `nvmf_subsystem_get_ns`
- `nvmf_subsystem_get_ns_stats`
- `nvmf_subsystem_get_namespaces`

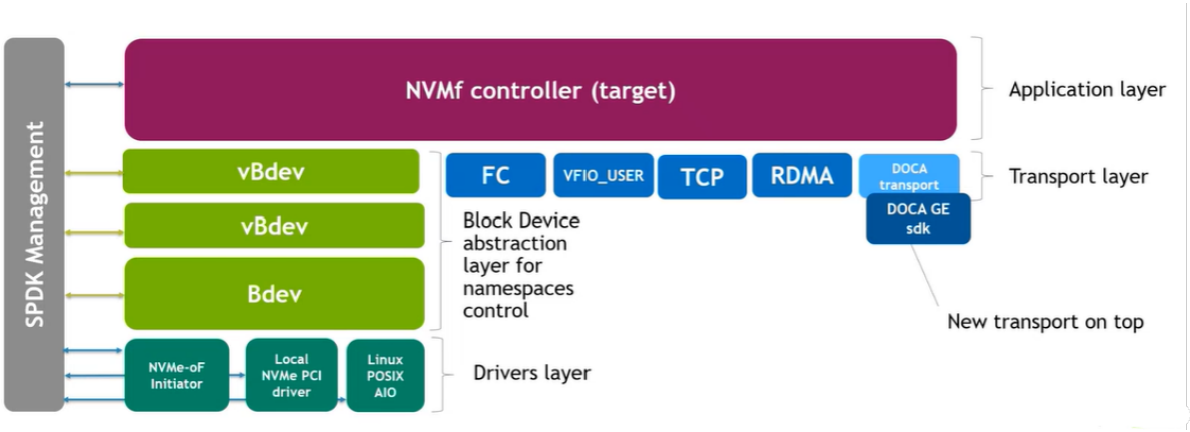
6.14.2.3 Solution Overview

6.14.2.3.1 Integration with SPDK

Using the DOCA Generic PCI Emulation SDK, the BlueField DPU can emulate NVMe devices through PCIe endpoints. This allows the DPU to appear as a physical NVMe device to the host system, enabling the host to send NVMe commands. While the DPU hardware can handle data movement and basic I/O tasks, managing the complete NVMe protocol, including admin commands, queue management, and register operations, requires additional software support. This is where SPDK comes in.

With SPDK, the DPU can offload the complex handling of NVMe commands, making it a fully functional and high-performance NVMe device without the need to develop custom firmware for each command.

6.14.2.3.1.1 DOCA Generic Device Emulation as NVMe-oF Transport



While NVMe-oF is designed for remote transports like TCP or RDMA, SPDK enables us to treat PCIe as another transport option by adding a memory-based transport. This allows the DPU to function as if it's communicating with a remote NVMe-oF target, even though it's local to the host system.

To implement this, we use a DOCA transport, a custom transport layer that acts as a connection tunnel and provides NVMe-oF with generic emulation capabilities. By leveraging SPDK's RPCs for NVMe-oF, we can create a DPU that effectively emulates an NVMe device. The DOCA transport ensures efficient routing and processing of NVMe commands, while SPDK takes care of the software-based emulation.

(The application utilizes the NVMe-oF application transport layer to implement an NVMe emulation solution, inspired by SPDK blogpost.)

6.14.2.3.1.2 Emulated Function as NVMe Controller

In the DOCA transport, the NVMe controller is mapped to a PCIe DOCA device known as the emulation manager. In this context, the emulation manager serves as the hardware interface that provides access to the NVMe controller, which exposes its capabilities through specific PCIe registers and memory-mapped regions.

When connecting a device to a controller, the transport is responsible for providing the controller's unique ID through the Connect command, as specified by the NVMe-oF protocol.

To make the core NVMe-oF target logic work with our DOCA transport, we need to implement specific operations in the `spdk_nvmf_transport_ops` structure. These operations handle tasks like managing connections, transferring data, and processing NVMe commands for DOCA. This structure provides a standard way to connect different transports to SPDK, so the core NVMe-oF logic can work with any transport without needing to know its specific details.

```
const struct spdk_nvmf_transport_ops spdk_nvmf_transport_doca = {
    .name = "DOCA",
    .type = SPDK_NVME_TRANSPORT_CUSTOM,
    .opts_init = nvmf_doca_opts_init,
    .create = nvmf_doca_create,
    .dump_opts = nvmf_doca_dump_opts,
    .destroy = nvmf_doca_destroy,

    .listen = nvmf_doca_listen,
    .stop_listen = nvmf_doca_stop_listen,
    .listen_associate = nvmf_doca_listen_associate,

    .poll_group_create = nvmf_doca_poll_group_create,
    .get_optimal_poll_group = nvmf_doca_get_optimal_poll_group,
    .poll_group_destroy = nvmf_doca_poll_group_destroy,
    .poll_group_add = nvmf_doca_poll_group_add,
    .poll_group_remove = nvmf_doca_poll_group_remove,
    .poll_group_poll = nvmf_doca_poll_group_poll,

    .req_free = nvmf_doca_req_free,
    .req_complete = nvmf_doca_req_complete,

    .qpair_fini = nvmf_doca_close_qpair,
    .qpair_get_listen_trid = nvmf_doca_qpair_get_listen_trid,
};
```

6.14.2.3.1.3 New SPDK RPCs

Since the DOCA transport requires specific configurations that are not covered by the existing SPDK RPCs and differ from other transports, such as managing emulation managers, we need to implement custom RPCs to expose these options to users:

RPC	Description	Details	Arguments	Output	Example

`nvmf_doca_get_managers`	Provides the ability to list all emulation managers, which are equivalent to DOCA devices	Returns the names of all available local DOCA devices with management capabilities.	None.	If successful, the RPC returns a list of device names for the emulation managers. If it fails, it returns an error code.	`/usr/bin/spdk_rpc.py --plugin rpc_nvmf_doca nvmf_doca_get_managers`
					`[`
					`  {`
					`  "name": "mlx5_0"`
					`  }`
					`]`

RPC	Description	Details	Arguments	Output	Example

`nvmf_doca_create_function`	Provides the ability to create an emulated function under a specified device name.	Creates a new representor device, retrieves its VUID, and then closes the device.	• `-d` – Device name (string)	If successful, the RPC returns the VUID of the newly created function. In case of failure, it returns an error code.	`/usr/bin/spdk_rpc.py --plugin rpc_nvmf_doca nvmf_doca_get_managers`
					`[`
					`  {`
					`  "name": "mlx5_0"`
					`  }`
					`]`

`nvmf_doca_destroy_function`	Provides the ability to destroy an emulated function.	Destroys a DOCA device representor.	• `-d` – The device name associated with the created function (string) • `-v` – The VUID of the function to be destroyed (string)	On success, the RPC returns nothing. On failure, it returns an error code.	`/usr/bin/spdk_rpc.py --plugin rpc_nvmf_doca nvmf_doca_destroy_function -d mlx5_0 -v MT2306XZ00AYGES2D0F0`

`nvmf_doca_list_functions`	Lists all the emulated functions under the specified device name.	Lists all the available representor devices.	• `-d` – Device name (string)	If successful, the RPC returns a list containing the VUID and PCIe address of all the emulated functions under the specified device name. In case of failure, it returns an error code.	`/usr/bin/spdk_rpc.py --plugin rpc_nvmf_doca nvmf_doca_list_functions -d mlx5_0`
					`[`
					`  {`
					`  "Function VUID: ": "MT2306XZ00AYGES1D0F0",`
					`  "PCI Address: ": "0000:00:00.0"`
					`  },`
					`  {`
					`  "Function VUID: ": "MT2306XZ00AYGES2D0F0",`
					`  "PCI Address: ": "0000:00:00.0"`
					`  }`
					`]`

⚠ `/usr/bin/spdk_rpc.py` is the Python script that sends RPC commands to SPDK. The `spdk_rpc.py` script is responsible for handling SPDK commands via the JSON-RPC interface.

6.14.2.3.1.4 Extended RPCs

Some existing SPDK RPCs need to be modified because certain configurations or capabilities of the DOCA transport are not supported by the default RPCs:

RPC	Description	Details	Arguments	Output	Example
`nvmf_create_transport`	Creates a new NVMe-oF transport by defining the transport type and configuration parameters, allowing the SPDK target to communicate with hosts using the specified transport.	Creates DOCA transport and its resources.	• `-t` – The transport type (string) • `-u` – The number of I/O queue pairs per system. (Optional) • `-i` – The maximum I/O size in bytes. (Optional) • `-c` – The maximum of inline data size in bytes. (Optional)	None	`/usr/bin/spdk_rpc.py nvmf_create_transport -t doca -u 8192 -i 131072 -c 819`
`nvmf_subsystem_add_listener`	Adds a listener to an NVMe-oF subsystem, enabling it to accept connections over a specified transport.	Hot-plugs the device, allowing the host to interact with it as an NVMe device.	• The subsystem NQN (NVMe qualified name) to which to add the listener. • `-t` – The transport type for this listener. • `-a` – The VUID of the function we want to use to create the emulated device.	None	`/usr/bin/spdk_rpc.py nvmf_subsystem_add_listener nqn.2016-06.io.spdk:cnode1 -t doca -a MT2306XZ00AYGES1D0F0`

`/usr/bin/spdk_rpc.py` is the Python script that sends RPC commands to SPDK. The `spdk_rpc.py` script is responsible for handling SPDK commands via the JSON-RPC interface.

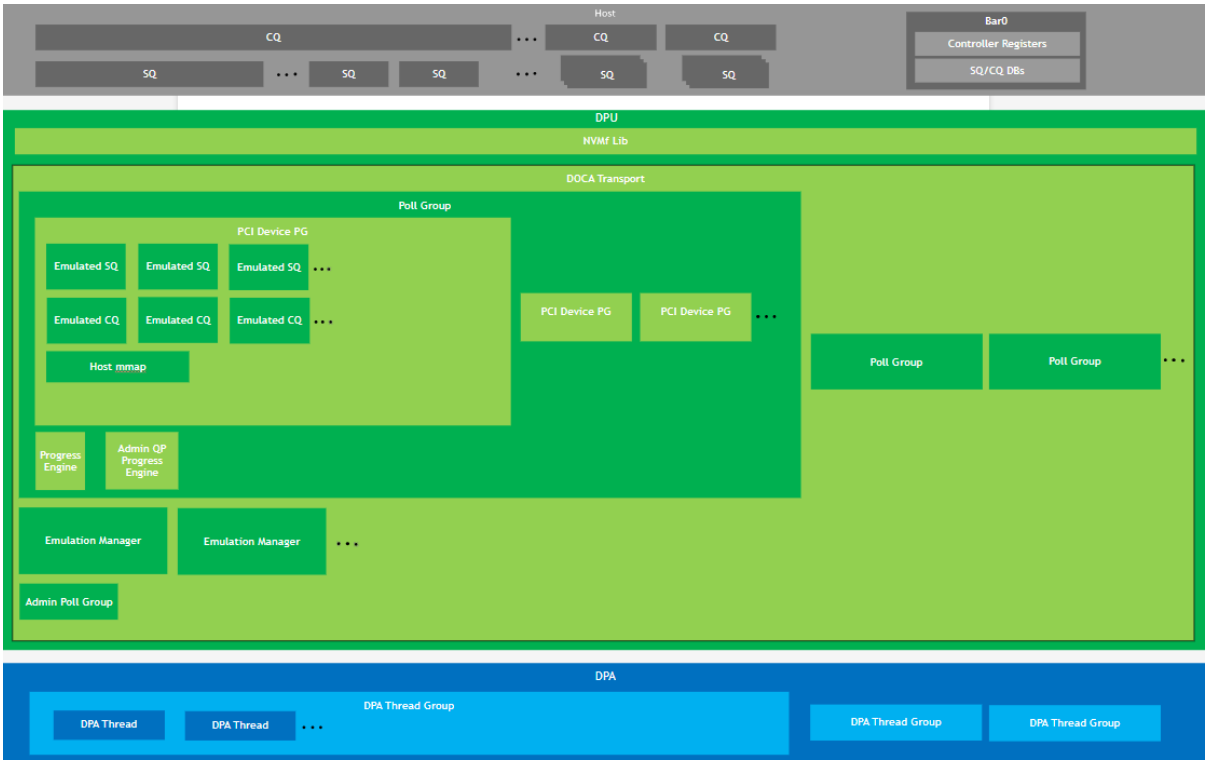
6.14.2.4 Data Structures

To implement the APIs for `spdk_transport_ops` mentioned above, we created transport-specific data structures that efficiently interact with these APIs. These structures are designed to manage the transport's state, connections, and operations.

The upper layer represents the host, followed by the DPU, and further down is the DPA, which is part of the DPU. Within the DPU, the NVMe-oF application is running, divided into two parts: the NVMe-oF library, which we use as a black box, and the DOCA transport, which we implement.

In the DOCA transport, there are several poll groups, each representing a thread. In addition to the poll group list, the transport maintains an emulation managers list, consisting of all devices managed by this transport. There is also a special poll group instance dedicated to polling PCIe events.

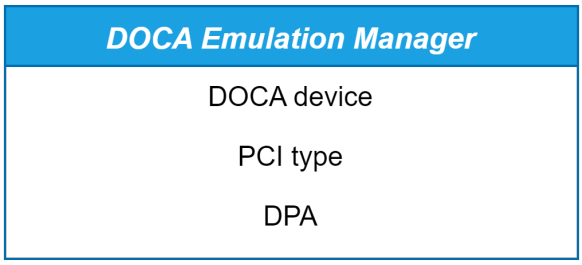
If we dive into the poll group, there are two progress engines: one that polls the I/O queues and another that handles the admin queues. Additionally, there is a list of PCIe device poll groups, each of which manages the completion queues, submission queues, and host memory mappings for a specific device.



The following sections provide more information on each of the main structures.

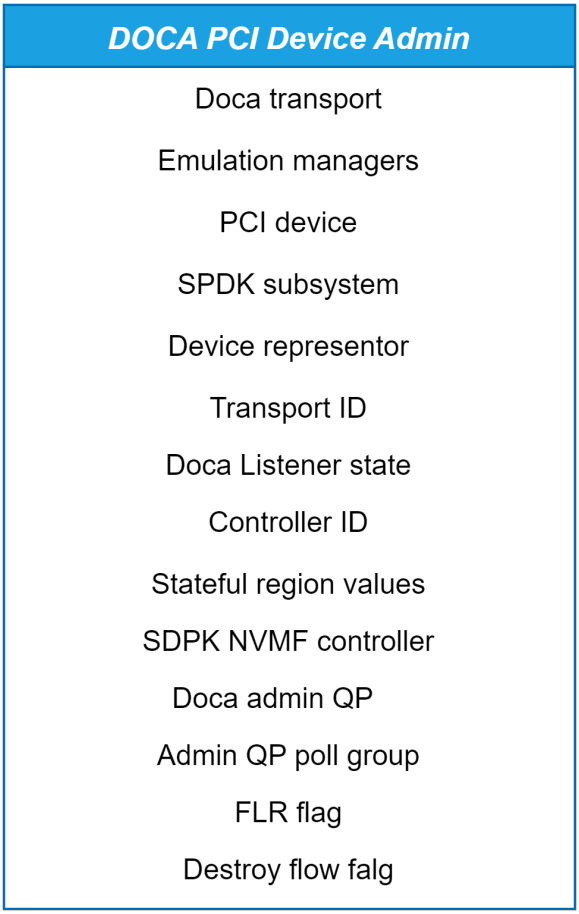
6.14.2.4.1 Emulation Manager

The first structure to address is the emulation manager context. During initialization, the DOCA transport scans for all available DOCA devices that can serve as emulation managers. For each of these devices, it creates a PCIe type, initializes a DPA instance, assigns a DPA application, and starts the DPA process. It also opens the DOCA device (emulation manager). All of these devices are stored within the emulation manager context, where they are tracked for as long as the transport is active.



6.14.2.4.2 PCIe Device Admin

This is the representor of the emulated device. and it contains the following:



- A pointer to the DOCA transport this device belongs to.
- The emulation manager described previously
- The emulated PCIe device
- A pointer to the SPDK subsystem this device belongs to
- The transport ID this device belongs to
- A pointer to SPDK NVMe-oF controller
- The stateful region values and are updated after each query
- Admin Queue Pair context
- Admin Queue Pair poll group that manages the admin QP, and it is selected from the system using the round-robin method
- The FLR flag Indicates if an FLR event has occurred
- Destroy flag that indicates if PCIe device should be destroyed

Once the user issues the add listener RPC, this context is established to facilitate the hot-plug of the emulated device to the host, enabling it to start listening for interactions from the host.

6.14.2.4.3 DOCA Poll Group

Each poll group in SPDK is associated with a thread running on a specific CPU core. For each core, a reactor thread is responsible for executing pollers, and the poll group is one of those pollers. When an NVMe-oF is created, it is assigned to each poll group so that the transport can handle I/O and connection management for the devices across multiple CPU cores, so each transport has a representative within each poll group.

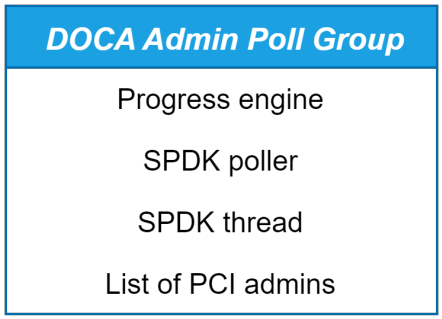
DOCA poll group Fields:

DOCA Poll Group
SPDK NVMF transport poll group
Progress engine
Admin QP progress engine
Admin QP poll rate
Admin QP rate limiter
List of PCI device poll group

- SPDK NVMe-oF transport poll group (`struct spdk_nvmf_transport_poll_group`): refers to a structure that is part of the NVMe-oF subsystem and is responsible for handling transport specific I/O operations at the poll group level.
- Progress engine (`struct doca_pe`): When each poll group runs its set of pollers, it also invokes the DOCA progress engine to manage transport operations. On the DOCA side, the doca_pe_progress function is called to drive the progress engine within each poll group. This is how DOCA's PE integrates into SPDK's poll group mechanism.
- Admin QP progress engine (`struct doca_pe`): Another progress engine (`struct doca_pe`) dedicated to handling admin queues while the previous one is dedicated to handling the I/O queues. this separation allows for more control over the polling rate of each queue type, which helps optimize performance.
- Admin QP poll rate and Admin QP rate limiter: They determine how often the system checks the admin queue for new commands.
- List of PCIe device poll group: List of devices that this poll group typically polls for their queues.

6.14.2.4.4 Admin Poll Group

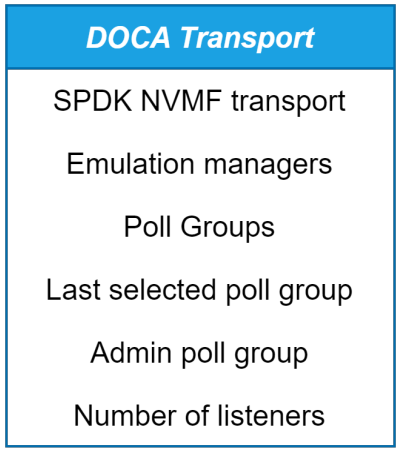
This object is a per-transport entity, functioning as a dedicated unit for polling PCIe events and managing Admin Queue activities.



- Progress engine – The DOCA used by the poller.
- SPDK Poller – This poller is used on SPDK application thread. It continuously monitors for PCIe events such as FLR, stateful region and hot plug events.
- SPDK thread – The application thread associated with the currently executing SPDK thread.
- PCIe admins – List of all the PCIe device admins.

6.14.2.4.5 DOCA Transport

This structure holds the overall state and configuration of the transport as it includes:

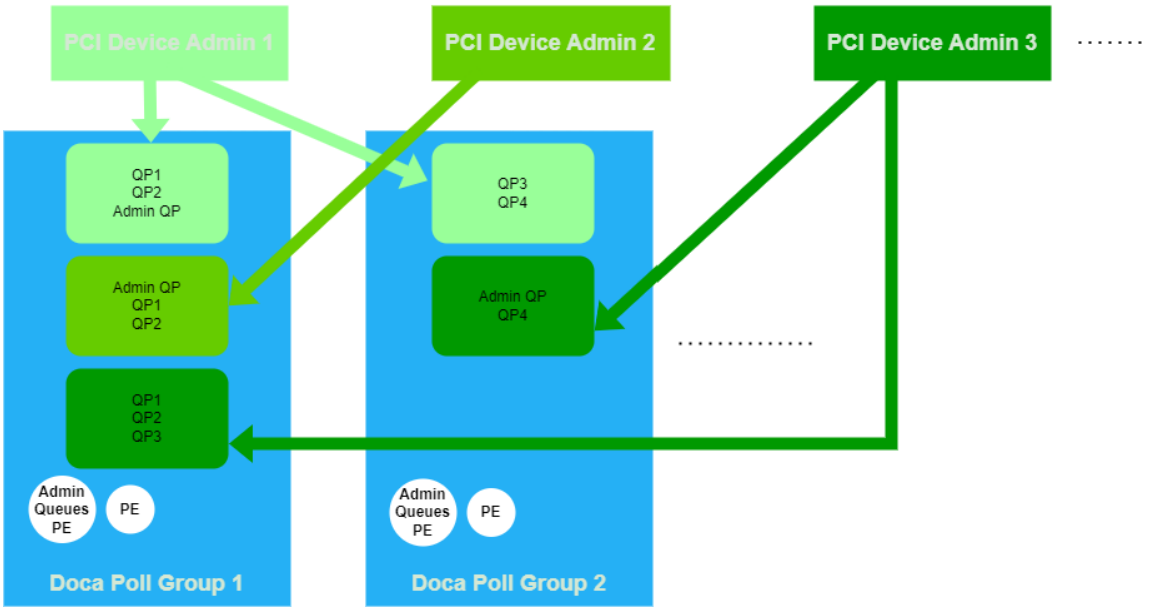


- SPDK NVMe-oF transport – Defines the transport layer within SPDK NVMe-oF framework. It holds essential data for managing the transport, such as configuration parameters, operational states, and connections.
- Emulation managers – Includes all the devices managed by this transport
- Poll groups – Contains all the poll groups actively polling for this transport

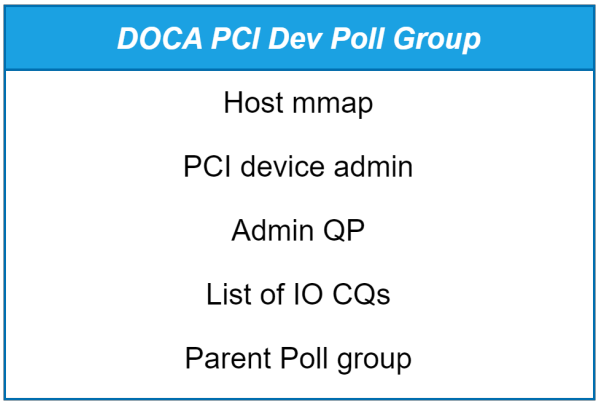
- Last selected poll group – Used to assist with round-robin selection of poll groups, ensuring even distribution of workload across poll groups during transport operations
- Admin poll group – described previously
- Number of listeners – Number of devices within this transport

6.14.2.4.6 PCIe Device Poll Group

Based on the previous descriptions of the transport structures, the following diagram illustrates the relationship between PCIe devices and the poll groups within a transport. Each PCIe device contains I/O and admin queues, which are distributed across the poll groups.



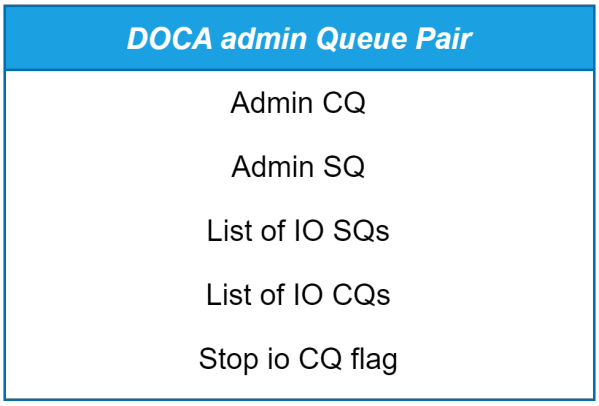
This relationship is managed by a structure called the PCIe dev poll group (`struct nvmf_doca_pci_dev_poll_group`), which holds the device's memory map (mmap), the PCIe device's admin details, admin QPs (if applicable), a list of I/O queues, and the poll group responsible for polling those queues.



When creating a new I/O or admin queue for a specific device and poll group, we first check if a PCIe dev poll group structure already exists that links the two. If not, we create a new `struct nvmf_doca_pci_dev_poll_group` to combine them.

6.14.2.4.7 Admin QP

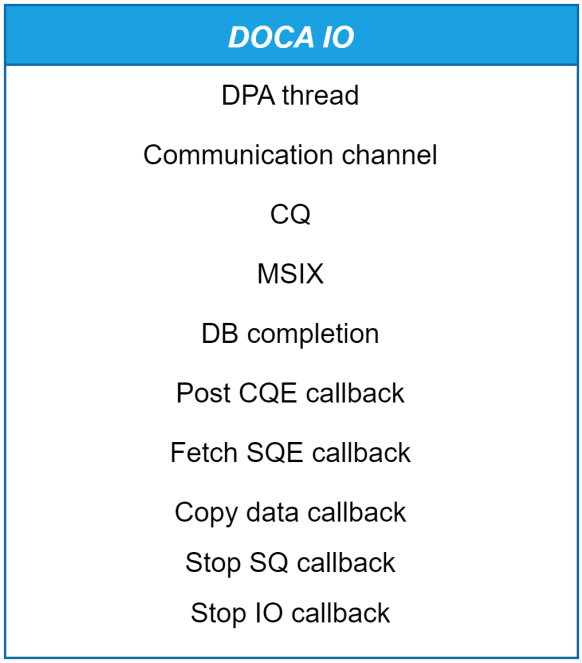
This structure manages the queues for a specific device. It holds an admin completion queue and admin submission queue to handle admin command operations. Additionally, it includes lists for I/O completion queues and I/O submission queues, which manage data-related operations. The structure also contains a flag `stopping_all_io_cqs` to indicate whether all completion queues should be stopped, used for gracefully halting the device's queue processing when needed.



6.14.2.4.8 DOCA IO

The I/O structure is responsible for managing I/O operations, including receiving doorbells on the completion queue (CQ) and its associated submission queues (SQs). It handles reading SQ entries (SQEs) from the host, writing SQEs back to the host, and raising MSI-X interrupts. This structure contains a single CQ, along with an MSI-X vector

index that is raised by the DPA, and a doorbell completion that is polled by the DPA thread.



It also holds several callbacks:

- Post CQE – Invoked once CQE is posted to the host CQ, freeing resources afterward
- Fetch CQE – Invoked when an SQE is fetched from the host, parsing and executing the request
- Copy data – Invoked after data is copied to the host, completing the request and freeing resources
- Stop SQ – Invoked when an admin or I/O SQ is stopped, to fully release resources
- Stop IO – Invoked when an admin or I/O CQ is stopped, to complete resource cleanup

The function `nvmf_doca_io_create` synchronously creates an emulated I/O.

6.14.2.4.8.1 DOCA CQ

The CQ's main task is to write cookies to host. The main fields are:

DOCA CQ
SQ ID
DOCA queue
Doorbell
Consumer index (CI)
Producer index (PI)

- In case it is an Admin CQ then the CQ ID is zero.
- The DOCA queue is a shared structure that acts as both the completion queue (admin and I/O CQ) and submission queue (admin and I/O SQ), mirroring the host's queues with the same size. It is responsible for fetching Submission Queue Entries (SQEs) from the host and posting Completion Queue Entries (CQEs) back to the host. The NVMe driver issues commands through its submission queues and receives their completions via the completion queues. To facilitate efficient processing by the DPU, the DOCA queue leverages DMA to handle data transfers between the host and DPU in both directions. Each queue is equipped with a pointer to a DMA structure that contains the necessary resources for these operations. During initialization, DMA resources and local buffers are allocated based on the queue's size. The DOCA queue also maintains an array of tasks, with each task at index idx corresponding to and synchronized with the task at the same index in the host's queue. When DMA operations are required, these resources are utilized for data transfer. The below outlines its main fields:

DOCA Queue
Buffer Inventory
DMA
Local queue MMAP
Local queue address
Elements (DMA tasks)
Number of elements

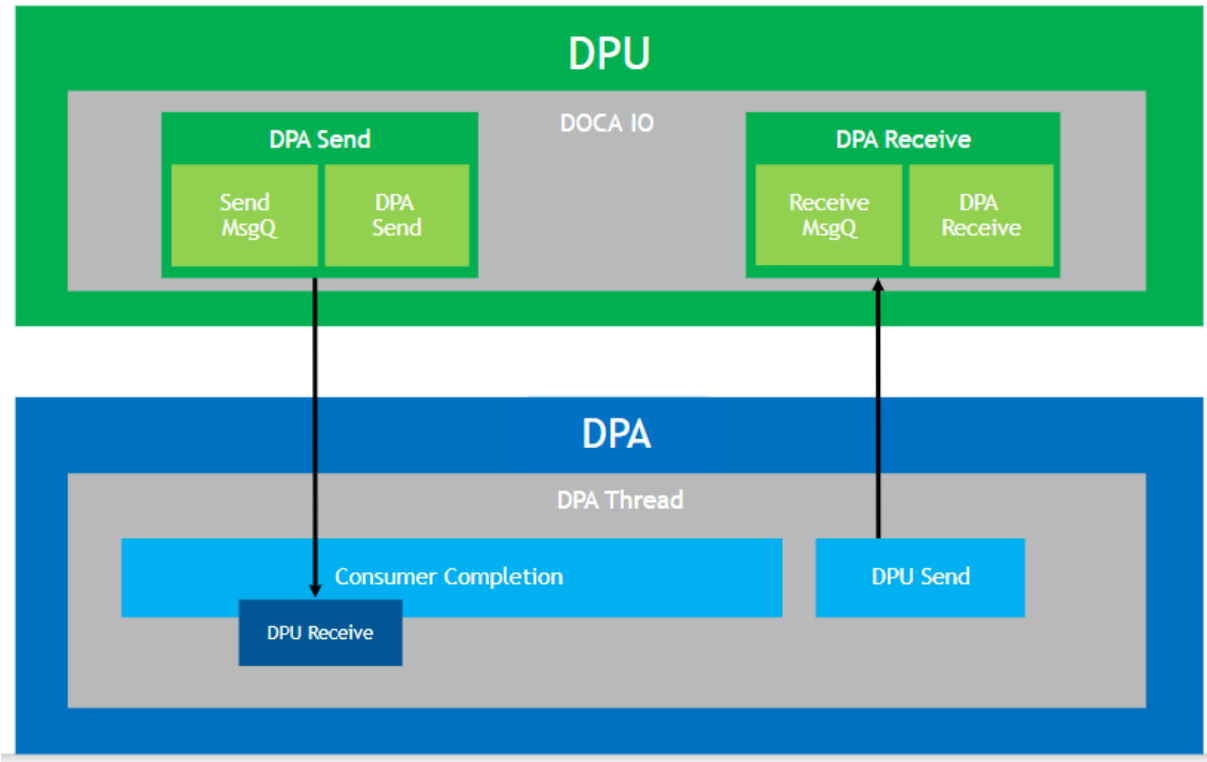
  - The buffer inventory is for allocating the queue elements
  - DMA context handles data transfer to and from the host
  - The queue MMAP represents the local memory where elements are stored for copying

- The local address for copying the elements to or from the host
- The elements themselves are DMA tasks for copy/write
- The maximum number of elements the queue can hold

6.14.2.4.8.2 DOCA Comch

A full-duplex communication channel is used to facilitate message passing between the DPA and DPU in both directions. This channel is contained within the DOCA IO and consists of two key components:

- A send message queue (`nvmf_doca_dpa_msgq`) with a producer completion (`doca_dpa_completion`) context.
- A receive message queue (`nvmf_doca_dpa_msgq`) with a consumer completion (`doca_comch_consumer_completion`) context.

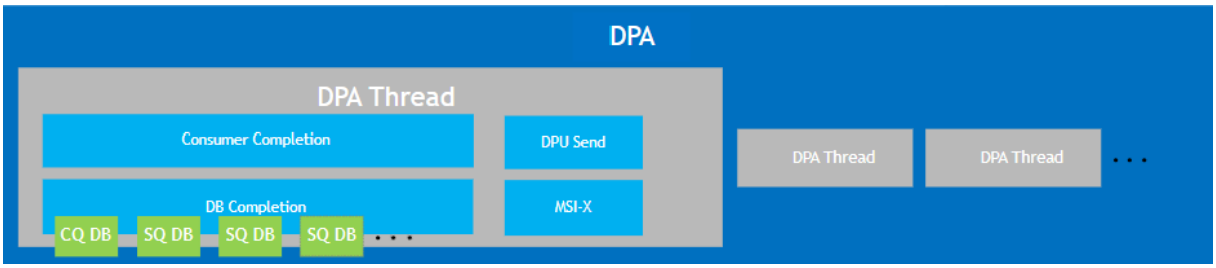


6.14.2.4.8.3 DOCA DPA Thread

In addition to the communication channel, the I/O structure also includes a DPA thread context, (with each thread dedicated to a single CQ). It consists of:

- A pointer to the DPA
- A pointer to the DPA thread
- The necessary arguments for the DPA thread, include:
  - Consumer Completion: Continuously polled by the DPA thread to detect new messages from the host.

- Producer Completion: Monitored to verify if messages have been successfully sent.
- DB Completion Context: Provides the doorbell values and connects to both CQ and SQ doorbells.
- MSIX: Allows the device to send interrupts to the host.

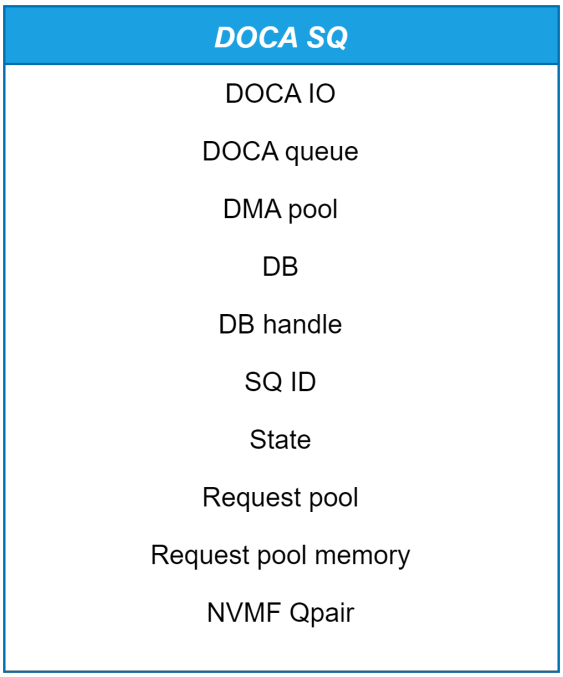


The DPA thread performs three main operations:

- `nvmf_doca_dpa_thread_create` – Creates a DPA thread by providing the DOCA DPA, the DPA handle, and the size of the arguments to be passed to the DPA. It also allocates memory on the device.
- `nvmf_doca_dpa_thread_run` – Copies the arguments to the DPA and runs the thread.
- `nvmf_doca_dpa_thread_destroy` – Deletes the thread and frees the allocated arguments."

6.14.2.4.9 DOCA SQ

The main fields that construct the DOCA submission queue (`nvmf_doca_sq`) include:

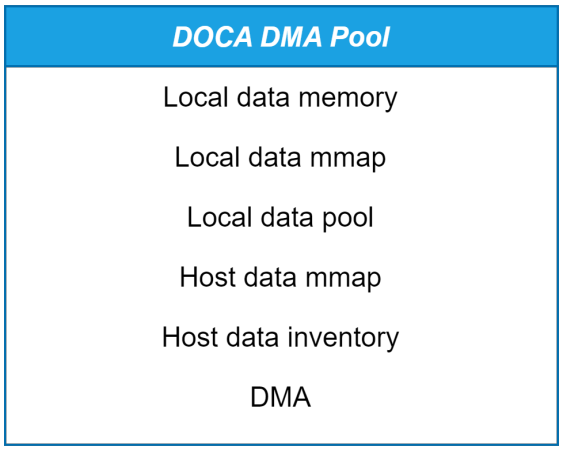


- A reference to the DOCA I/O to which this submission queue belongs, and where its completion is posted. Multiple SQs can belong to a single I/O.
- The DOCA queue, which was previously described, that handles copying Submission Queue Entries (SQEs) from the host.
- A pool of DMA (`nvmf_doca_dma_pool`) data copy operations (to be defined shortly).
- The doorbell associated with this submission queue.
- The DPA handle of the doorbell.
- The submission queue identifier (SQID).
- The state of the submission queue, used for monitoring purposes.
- NVMe-oF request pool memory (to be defined shortly).
- A list of NVMe-oF DOCA empty requests, used whenever a new SQE is received and a request needs to be prepared.
- The Queue Pair (QP) created for this submission queue by the NVMe-oF target, which is used to execute commands.

The submission queue creation is asynchronous because, when we create the completion queue (CQ), we also initialize the DPA. However, when creating the SQ, the DPA is already running, so we need to update the DPA about the newly added SQ. Directly modifying its state could lead to synchronization issues, which is why we use a communication channel, making the process asynchronous.

6.14.2.4.9.1 DOCA DMA Pool

As previously noted, a Submission Queue (SQ) includes the `nvmf_doca_dma_pool` structure, which manages data transfer operations between the host and the DPU, in both directions. It consists of the following elements:



- Memory allocated for local data buffers
- Memory-mapped region for the local data buffers
- A pool of local data buffers
- Memory mapping that provides access to host data buffers
- An inventory for allocating host data buffers
- A DMA context used for transferring data between the host and the DPU

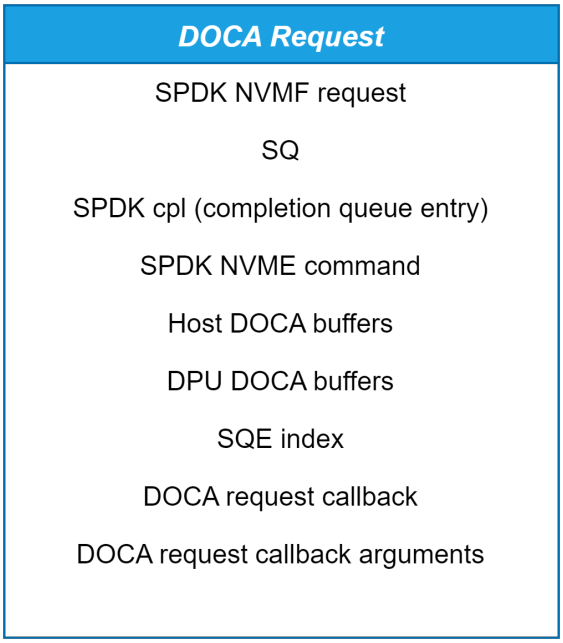
This structure is initialized whenever the SQ is created. The size of the local data memory is determined by multiplying the maximum number of DMA copy operations by the maximum size in bytes for each DMA copy operation. All these local buffers are allocated during the creation of the SQ. The key operations performed on the DMA are:

- `nvmf_doca_sq_get_dpu_buffer` – Retrieves a buffer in DPU memory, enabling data transfers between the host and the DPU.
- `nvmf_doca_sq_get_host_buffer` – Retrieves a buffer pointing to host memory, also used for data transfers between the host and the DPU.
- `nvmf_doca_sq_copy_data` – Copies data between the host and the DPU. This operation is asynchronous, and upon completion, it invokes the `nvmf_doca_io::copy_data_cb` callback function.

6.14.2.4.9.2 DOCA NVMe-oF Request

The NVMe-oF target utilizes requests to handle incoming commands. When a new command is received by any transport (not limited to the DOCA transport), it creates an instance of the struct `spdk_nvmsf_request`. This structure contains various elements, including the NVMe command, the Submission Queue (SQ) to which the command

belongs, the Queue Pair (qpair), the IO Vector (IOV), and other relevant data. In our design, we introduce a new wrapper structure called `nvmf_doca_request`, which encapsulates the NVMe-oF request structure along with additional fields specific to the DOCA transport. The main fields included in this structure:



Where:

- SPDK request is and instance of struct `spdk_nvmf_request`, which represents the command being processed.
- Host and DPU DOCA buffers are pointers to data buffers located at the host or DPU, containing data associated with this command.
- DOCA request callback is the function invoked upon request completion, receiving the appropriate DOCA request callback arguments.

The key operations performed on requests include:

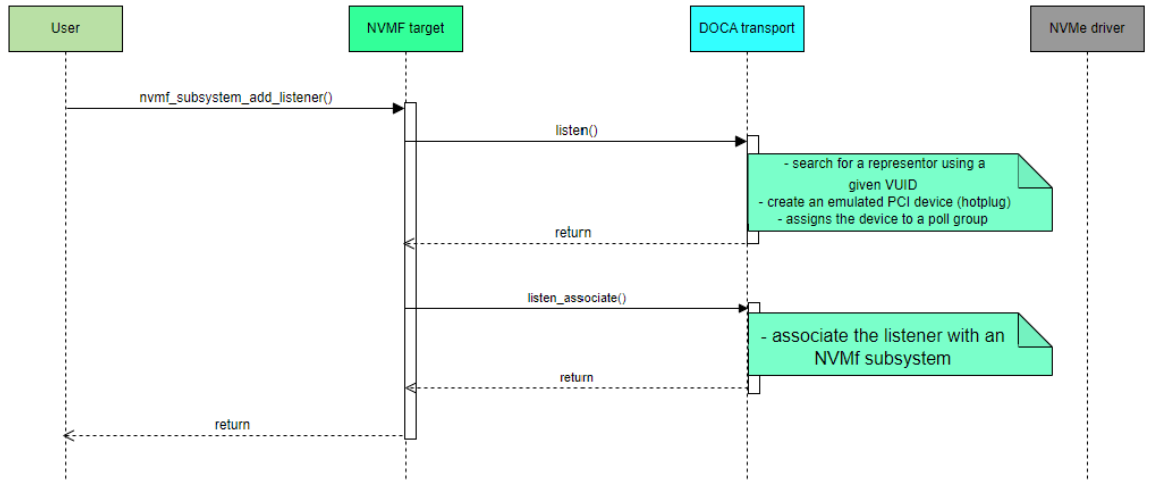
- `nvmf_doca_request_pool_create` – When the SQ is created, a request pool is allocated with a size matching the SQ depth.
- `nvmf_doca_request_pool_destroy` – This function destroys the request pool when the SQ is removed.
- `nvmf_doca_request_get` – Retrieves an NVMe-oF request object from the pool associated with a specific SQ, and is called after fetching an SQE from the host.
- `nvmf_doca_request_complete` – Completes an NVMe-oF request by invoking its callback and then releasing the request back to the pool.

6.14.2.5 Control Path Flows

6.14.2.5.1 DOCA Transport Listen

6.14.2.5.1.1 Hotplug and Hotunplug

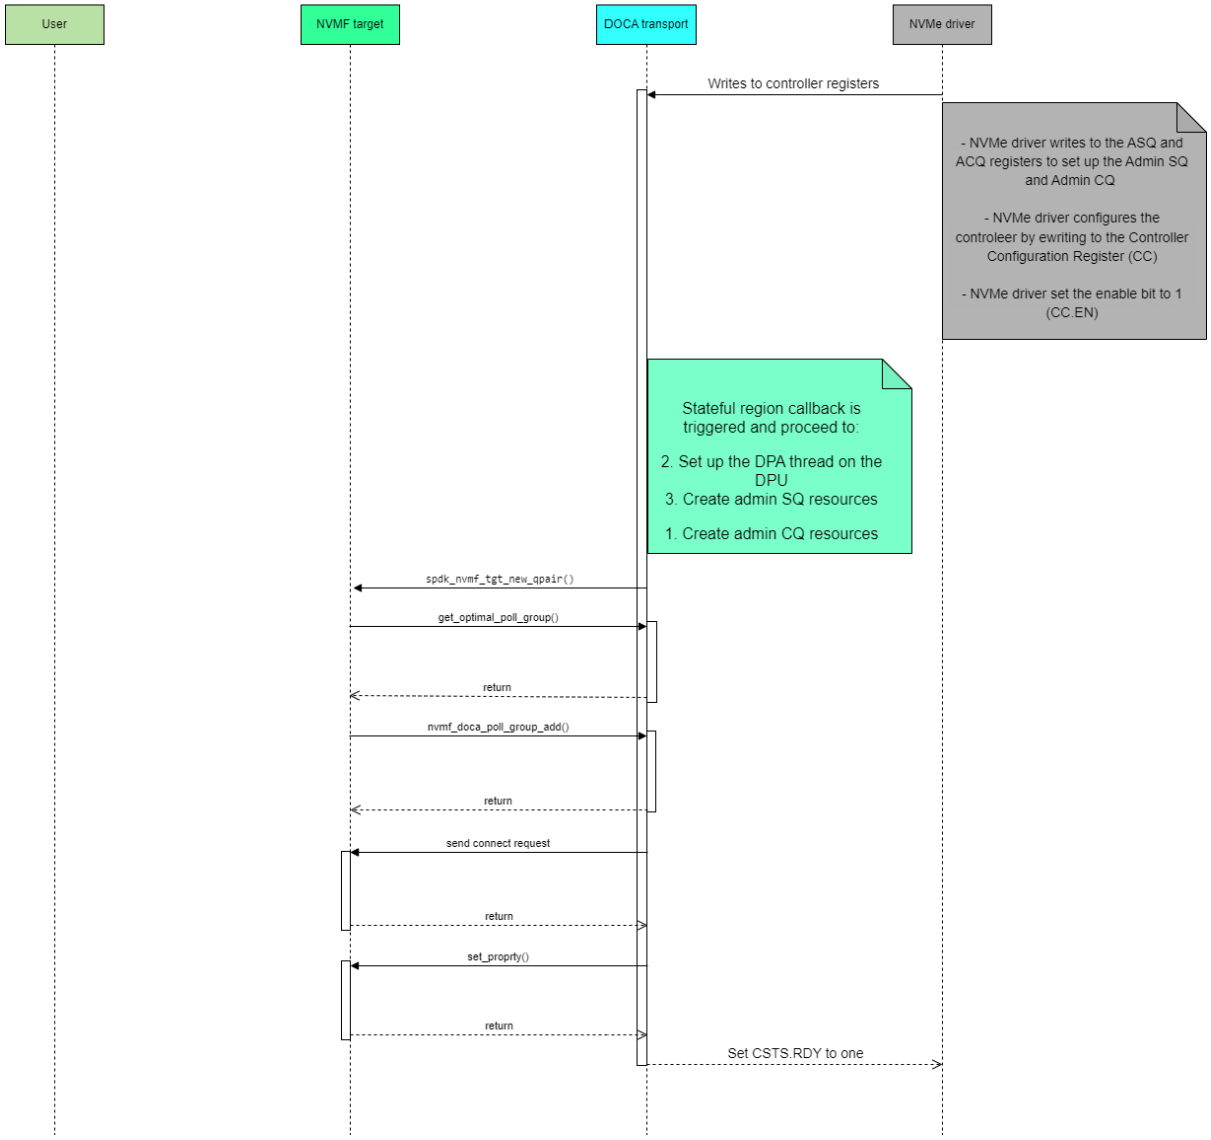
1. Start with `add_listener` RPC trigger – The flow begins when the `add_listener` RPC is called. SPDK then pauses all poll groups.
2. Lookup for representor by VUID – The transport searches for a representor using a given VUID.
3. Create emulated PCIe device – Once the representor is found, the transport creates an emulated PCIe device and assigns it to a poll group.
4. Initialize memory mapping (mmap) – For each poll group, the transport sets up a memory-mapped area representing the host memory.



At this stage, the NVMe driver detects the newly hot-plugged device.

6.14.2.5.2 Controller Register Events

6.14.2.5.2.1 Initialization



- Controller Initialization – The process begins by configuring the controller registers:
  - The NVMe driver writes to the ASQ and ACQ registers to set up the Admin Submission Queue and Admin Completion Queue.
  - The driver configures the controller by writing to the controller configuration (CC) register, setting parameters like memory page size, arbitration, and timeout values.
  - The driver sets the CC.EN bit in the CC register to 1, transitioning the controller from `Disabled` to `Enabled`.

    - The NVMe driver waits for the CC.RDY (Controller Status Register - Ready bit) to become 1. This indicates that the controller has successfully completed its initialization and is ready to process commands.
- Stateful Region Callback Trigger – At this point, the PCI-emulated device triggers a callback to the stateful region. This callback detects the host's initialization process by checking the changes in the enable bit. This callback may occur multiple times, but it only proceeds if the enable bit has been altered.
- CQ and DPU Setup – The callback proceeds to create the Completion Queue (CQ) resources and sets up the DPA thread on the DPU. The DPA thread is equipped with two message queues: one for sending and one for receiving.
- Binding CQ Doorbell to DB Completion – An RPC is sent to bind the CQ doorbell to the DB completion context. This is done while the DPA is not yet active, preventing synchronization issues.
- SQ Resource Creation – The Submission Queue (SQ) resources are created, including the SQE pools and the local buffer size needed for copying SQEs from the host to the DPU. The DOCA DMA is used for the data transfer operations.
- SQ Bind DB Message – The SQ sends a "bind DB" message to the DPA.
- DPA Receives Bind DB Message – The DPA processes the "bind DB" message and sends the SQ's doorbell information to the DB completion context.
- SQ Sends Bind Done Message – The SQ sends a "bind done" message to the DPU.
- Start SQ DB – The DPU receives the "bind done" message and starts the SQ DB.
- NVMe-oF QPair and Request Pool Creation – An NVMe-oF QPair and an NVMe-oF request pool are created.
- Asynchronous QPair Creation – The NVMe-oF library starts an asynchronous operation to create the QPair.
- NVMe-oF Library Calls –
    - The library creates the QPair and calls the transport to get the optimal poll group.
    - It then calls `poll_group_add` on the selected thread.
- NVMe-oF Connect Request – The transport sends an NVMe-oF connect request.
- Set Property Request – After the connect request is complete, a `set_property` request is sent to update the controller configuration as provided by the host during initialization.
- Callback Triggered – Once the `set_property` request is finished, the NVMe-oF triggers callbacks.
- Update Stateful Region – The transport updates the stateful region, setting the `CSTS.RDY` bit to 1.
- Host Polling Unblocked – With the CSTS.RDY set to 1, the host polling is now unblocked, completing the initialization process.

6.14.2.5.2.2 Reset and Shutdown Flow

The reset flow in NVMe using SPDK is crucial for maintaining the integrity and stability of the storage subsystem, to allow the system afterwards to recover gracefully.

The reset process can be initiated by:

- The Host: The host can initiate a shutdown or reset of the NVMe controller by configuring specific registers in the controller's register space. in this case the `handle_controller_register_events()` function is triggered.
  - Configuring Shutdown Notification (SHN): The host can write to the CC (Controller Configuration) register, specifically the SHN field, to specify how the controller should handle a shutdown:
    - Normal Shutdown – `SPDK_NVME_SHN_NORMAL` – Allows for a graceful shutdown where the controller can complete outstanding commands.
    - Abrupt Shutdown – `SPDK_NVME_SHN_ABRUPT` – Forces an immediate shutdown without completing outstanding commands.
  - Resetting the NVMe controller by setting the CC.enablebit to zero. Also `handle_controller_register_events()` function is triggered in this case.
  - The host can initiate a reset the NVMe controller by using Function-Level Reset (FLR). In this case the `flr_event_handler_cb()` is triggered.
- DOCA transport can initiate reset flow through `nvmf_doca_on_initialization_error()` when it detects an internal error condition during initialization flow.

Once a shutdown or reset is requested, the transport proceeds to destroy all resources associated with the controller. If it is a shutdown request, the shutdown status is updated accordingly. When the host performs a function-level reset (FLR) or a controller reset, the transport must take several actions: it destroys all submission and completion queues (SQs and CQs) across all poll groups for the specified device, destroys the admin SQ and CQ via the admin thread, stops the PCIe device, and then restart it.

Regardless of the reason for the reset flow, it all starts from `nvmf_doca_pci_dev_admin_reset()`. This function marks the beginning of the asynchronous process for resetting the PCIe device NVMe-oF context. The flow consists of callbacks that are triggered in sequence to track the completion of each process and to proceed to the next one. Let us now illustrate the rest of the flow:

- If the admin QP exists, the process first checks for any I/O submission queues (SQs).
- If I/O SQs are found, an asynchronous flow begins to stop all I/O SQs.
- For each I/O SQ associated with the admin queue, it retrieves the corresponding poll group responsible for destroying its specific SQ, as no other poll group can perform this action.
- Once all I/O SQs are stopped, if any I/O completion queues (CQs) remain, a message is sent to each poll group instructing them to delete their I/O CQs.

- After all I/O queues are destroyed, the flow proceeds to destroy the admin CQ and SQ.

After this flow is done, it moves to `nvmf_doca_pci_dev_admin_reset_continue()` to finalize the reset flow:

- If a reset is issued by configuring the NVMe controller registers, then set `CSTS.BITS.SHST` to `SPDK_NVME_SHST_COMPLETE` and `CSTS.BITS.RDY` to 0
- If the reset is triggered by a FLR, then stop the PCIe device context: `doca_ctx_stop(doca_devemu_pci_dev_as_ctx())`

6.14.2.5.3 I/O QP Create/Destroy

The process of creating and destroying I/O Queue Pairs (QPairs) begins with the initiator (host) sending an NVMe-oF connect command to the NVMe-oF target following the completion of transport initialization. The host sends an NVMe-oF connect command to the NVMe-oF target after the transport has completed its initialization. The NVMe-oF target receives an admin command and begins processing it through `nvmf_doca_on_fetch_sqe_complete()`. Based on the command opcode, the following steps are executed:

1. Creating an I/O Completion Queue – `SPDK_NVME_OPC_CREATE_IO_CQ` – `handle_create_io_cq()`:
    a. First, the system selects a poll group that is responsible for creating the CQ.
    b. The target searches for the `nvmf_doca_pci_dev_poll_group` entity within the selected poll group. If it is not found, it indicates that this is the first queue associated with the specific device managed by this poll group, necessitating the creation of a new entity.
    c. Next, the target allocates a DOCA IO (`nvmf_doca_io`) using the attributes and data provided in the command, such as CQ size, CQ ID, CQ address, and CQ MSI-X.
    d. Create the DMA context, the message queues, consumer and producer handle and the DPA thread.
    e. Once the asynchronous allocation and setup are complete, the target posts a Completion Queue Entry (CQE) to indicate that the operation has succeeded. it is done through static void `nvmf_doca_poll_group_create_io_cq_done()`.
2. Creating an I/O Submission Queue – `SPDK_NVME_OPC_CREATE_IO_SQ` – `handle_create_io_sq()`:
    a. Based on the CQ ID argument provided in the command, the system first identifies the I/O entity to which the new Submission Queue (SQ) should be added. From this entity, it retrieves the associated `nvmf_doca_pci_dev_poll_group`.

b. Next, a DOCA Submission Queue `nvmf_doca_sq` is allocated using the attributes and data specified in the command, including the SQ size, SQ ID, and SQ address. This allocation is handled within the `nvmf_doca_poll_group_create_io_sq()` function.
c. The DMA context and the DB completions are also created.
d. Once the asynchronous process of creating the SQ is complete, a Completion Queue Entry (CQE) is posted via the `nvmf_doca_poll_group_create_io_sq_done()` function.
e. Next, the target begins the QPair allocation, which creates a new Queue Pair comprising a submission queue (SQ) and a completion queue (CQ).
f. Then, it determines the optimal poll group for the new QPair by calling `get_optimall_poll()` group ensuring that both the CQ and SQ attached to it runs on the same poll group.
g. After identifying the appropriate poll group, the target adds the newly created QPair to it using `nvmf_doca_poll_group_add()`, enabling management of the QPair's events and I/O operations.
h. After the connection is established, the initiator can start sending I/O commands through the newly created QPair.

3. Destroying an I/O Completion Queue – `SPDK_NVME_OPC_DELETE_IO_CQ` – `handle_delete_io_cq()`:
a. The process starts by fetching the identifier of the queue that needs to be deleted from the NVMe request.
b. Once the identifier is retrieved, the corresponding `nvmf_doca_io` entity is located.
c. The associated poll group is then extracted from the I/O, as it is responsible for destroying the CQ associated with it. The thread retrieved schedules the execution of `nvmf_doca_pci_dev_poll_group_stop_io_cq()` using `spdk_thread_send_msg`.
d. The `nvmf_doca_io_stop()` function is called to initiate the stopping process. If there are CQs in this I/O that are not idle, it triggers `nvmf_doca_io_stop_continue()` to advance the sequence. This flow then executes a series of asynchronous callback functions in order, ensuring that each step completes fully before the next begins, performing the following actions:
i. Stop the DOCA devemu PCIe device doorbell to prevent triggering completions on the associated doorbell completion context
ii. Stop the NVMe-oF DOCA DMA pool
iii. Stop the DMA context associated with the Completion Queue and frees all elements of the NVMe-oF DOCA Completion Queue.
iv. Stop the NVMe-oF DOCA DPA communication channel, halting both the receive and send message queues.

v. Stop and destroy the PCIe device DB.
vi. Stop the MSI-X.
vii. Stop and destroy the DB completion.
viii. Destroy the communication channel.
ix. Destroy the DPA thread.

e. Finally, the target posts a Completion Queue Entry (CQE) to indicate that the operation has succeeded.

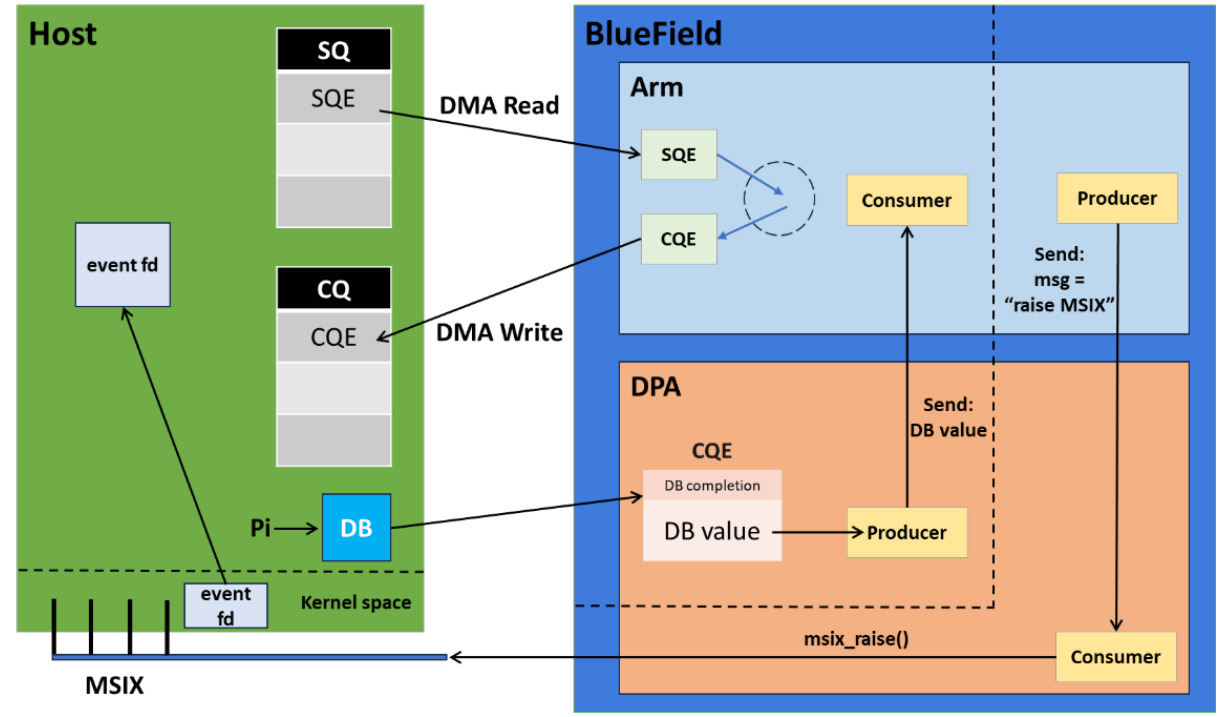
4. Destroying an I/O Submission Queue – `SPDK_NVME_OPC_DELETE_IO_SQ` – `handle_delete_io_sq()`:
   a. The process starts by fetching the identifier of the queue that needs to be deleted from the NVMe request.
   b. Once the identifier is retrieved, the corresponding `nvmf_doca_sq` entity is located.
   c. The associated poll group is then extracted from the I/O, as it is responsible for destroying the SQ associated with it. The thread retrieved schedules the execution of `nvmf_doca_pci_dev_poll_group_stop_io_sq()` using `spdk_thread_send_msg`.
   d. The `nvmf_doca_sq_stop()` function is called to initiate the stopping process.
   e. The stopping process begins by calling `spdk_nvmf_qpair_disconnect()` To disconnect an NVMe-oF queue pair (QP), clean up associated resources and terminate the connection.
   f. Once this step is complete, `nvmf_doca_sq_stop_continue()` is triggered to proceed with a sequence of asynchronous callback functions, ensuring that each step completes before moving to the next, performing the following actions:
      i. Disconnect an NVMe-oF queue pair (QP), cleaning up associated resources and terminate the connection.
      ii. Stop the DOCA devemu PCIe device doorbell to prevent triggering completions on the associated doorbell completion context.
      iii. Send unbind SQ doorbell message to DPA.
      iv. Stop the NVMe-oF DOCA DMA pool
      v. Stop the DMA context associated with the Submission Queue and frees all elements of the NVMe-oF DOCA Submission Queue.
      vi. Destroy the resources associated with the SQ: the DMA pool, the queue and the request pool.
      vii. Finally, the target posts a Submission Queue Entry (CQE) to indicate that the operation has succeeded.

6.14.2.6 Data Path Flows

From the host's perspective, it is communicating with a standard NVMe device. To create this experience, the DOCA transport uses the available NVMe-oF APIs to mimic the behavior of a real NVMe device effectively.

The data path flow involves a series of steps that handle the transfer and processing of commands between the host and the NVMe-oF target. It begins with the host writing commands to the Submission Queue (SQ) entries, specifying operations like read or write requests that the NVMe-oF target processes.

The diagram below provides a holistic view and data path steps:



1. The host writes the Submission Queue Entry (SQE).
2. The host rings the doorbell (DB), and the DB value is received by the DPA.
3. The producer forwards the DB value to the ARM processor.
4. The system reads the SQE from the host.
5. The SQE is processed.
6. A Completion Queue Entry (CQE) is written back.
7. If MSI-X is enabled, the producer triggers the MSI-X interrupt.
8. The DPU's consumer raises the MSI-X interrupt to the host.

Each step is described in depth below:

6.14.2.6.1 Retrieve Doorbell

The process starts by retrieving the doorbell values, which indicate new commands submitted by the host, allowing the system to identify and process pending commands:

The DPA wakes up and checks the reason for activation—it could either be that the DPU has posted something for the DPA consumer, or a new doorbell value needs to be passed to the DPU. In this case, the DPA detects a new doorbell value and sends it to the DPU via message queues. The DPU then calculates the number of Submission Queue Entries (SQEs) that need to be fetched from the host's submission queue and retrieves the commands using DMA via the `nvmf_doca_sq_update_pi()` function.

6.14.2.6.2 Fetch SQE From Host

After retrieving the Submission Queue Entry (SQE), the system must translate this command into a request object that the NVMe-oF target can understand and process. The SQE contains crucial command details that need to be executed, such as read or write operations. This process involves populating a `spdk_nvmf_request` structure, which includes:

- Command parameters extracted from the SQE.
- Associated data buffer locations (if any data is to be read from or written to).
- Metadata and additional information necessary for processing the command.

For admin commands, the SQEs are handled by the `nvmf_doca_on_fetch_sqe_complete()` function, while I/O NVMe-oF commands are managed by the `nvmf_doca_on_fetch_nvm_sqe_complete()` function. Both functions are responsible for filling the `nvmf_doca_request` structure.

A request is obtained from the SQ request pool, as described previously, and it is populated by setting various attributes based on the specific command being issued. These attributes may include the Namespace ID, the length of the request, and the queue to which the request belongs.

Next, there are three options for data direction handled in the command:

1. No data transfer:
    a. After preparing the request, the system sets the callback function to `post_cqe_from_response()`
    b. It then executes the request using `spdk_nvmf_request_exec()`
    c. Finally, the system posts the CQE to indicate completion
2. Data transfer from host to DPU:
    a. After preparing the request, the system retrieves buffers from the SQ pool and initializes them with the details of the data to be copied from the host

    b. It invokes `nvmf_doca_sq_copy_data()`, which performs a DMA copy from the host to the DPU
    c. Once the asynchronous copy completes, `spdk_nvmf_request_exec()` is called to continue processing
    d. Finally, the system posts the CQE to signal completion
3. Data transfer from DPU to host:
    a. After preparing the request, the system retrieves buffers from the SQ pool and initializes them with the data to be copied and the destination address on the host.
    b. It invokes `nvmf_doca_sq_copy_data()` to perform a DMA copy from the DPU to the host
    c. Once the asynchronous copy finishes, `spdk_nvmf_request_exec()` is called to complete processing
    d. The system then posts the CQE to indicate the operation's completion

While the overall flow for NVMe commands and admin commands is similar, there are subtle differences in the transport implementation to address the unique requirements of each command type. For I/O commands like read and write, the system may involve large data blocks transfer. Here the PRPs (Physical Region Pages) come into play, as they are used to describe the memory locations for the data to be read or written. The PRPs provide a list of physical addresses that the NVMe device uses to access the host's memory directly.

In this scenario, there could be multiple DMA operations required for copying the data. Therefore, after preparing the request, the function `nvme_cmd_map_prps()` is invoked to iterate over the entire PRP list, preparing the retrieved buffers from the pool and initializing them with the corresponding data and destination addresses. Once the buffers are properly set up, the function `buffer_ready_copy_data_host_to_dpu()` is called, which iterates through all the buffers and invokes `nvmf_doca_sq_copy_data()` for each one. Only after all asynchronous copy tasks for the buffers are completed does the function `nvmf_doca_request_complete()` get called to signal the end of the request processing.

6.14.2.6.3 Dispatch Command to NVMe-oF Target

Once the request is built, the function `spdk_nvmf_request_exec()` is called to execute it. `spdk_nvmf_request_exec()` initiates the processing of the request by determining the command type and dispatching it to the appropriate handler within the NVMe-oF target for processing. The NVMe-oF target interprets the command, allocates necessary resources, and performs the requested operation.

When a request is dispatched to the NVMe-oF target for execution via `spdk_nvmf_request_exec()`, a completion callback function is usually configured. This

callback is invoked once the request has been fully processed, indicating to the transport layer that the NVMe-oF target has completed handling the request.

6.14.2.6.4 Post CQE to Host

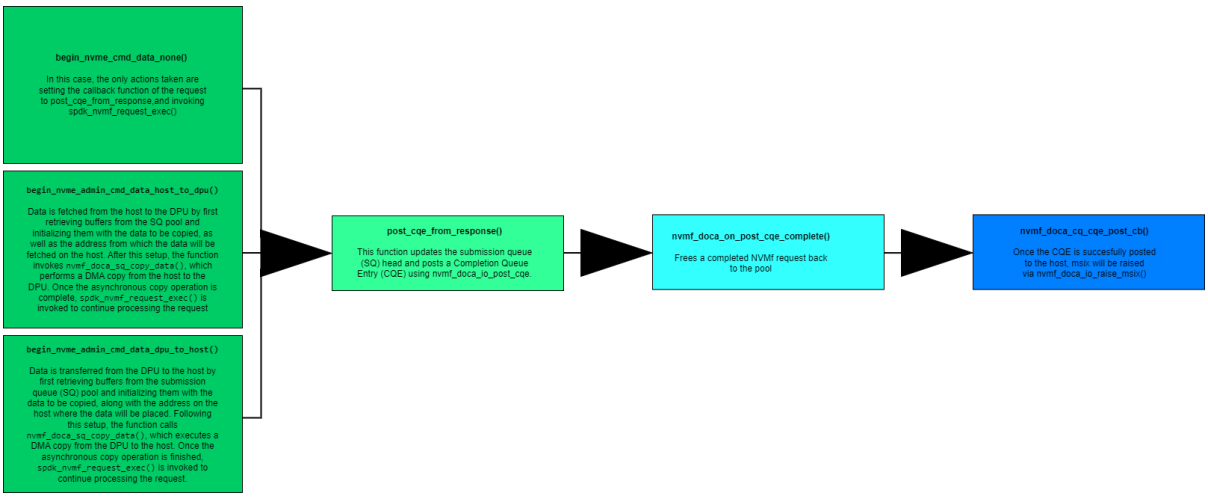
After the command has been processed, we create a Completion Queue Entry (CQE) and we posted back to the host to indicate the completion status of the command. This entry includes details about the operation's success or any errors encountered.

6.14.2.6.5 Raise RMSI-X

If the DMA for posting the CQE is completed successfully, MSIX is raised to the host, to inform the host that a completion event has occurred allowing to it read the CQE and process the result of the request.

In this scenario, the DPU calls `nvmf_doca_io_raise_msix()`, which in turn sends a message through `nvmf_doca_dpa_msgq_send()`. This action prompts the DPA to wake up and attempt to retrieve the consumer completion context. Then, DPA receives a message from the DPU instructing it to raise MSIX.

The flow diagram illustrates the steps from fetching SQEs and preparing the request to posting the CQE, highlighting the three possible data scenarios (case where PRP is not involved):



6.14.2.7 Limitations

6.14.2.7.1 Supported SPDK Versions

The supported SPDK version is 23.01.

6.14.2.7.2 Supported Admin Commands

Currently, not all admin commands are supported. The transport supports the following commands: `SPDK_NVME_OPC_CREATE_IO_CQ`, `SPDK_NVME_OPC_DELETE_IO_CQ`, `SPDK_NVME_OPC_CREATE_IO_SQ`, `SPDK_NVME_OPC_DELETE_IO_SQ`, `SPDK_NVME_OPC_ASYNC_EVENT_REQUEST`, `SPDK_NVME_OPC_IDENTIFY`, `SPDK_NVME_OPC_GET_LOG_PAGE`, `SPDK_NVME_OPC_GET_FEATURES`, `SPDK_NVME_OPC_SET_FEATURES`.

6.14.2.7.3 Supported NVM Commands

Currently, the transport supports only the following NVMe commands: `SPDK_NVME_OPC_FLUSH`, `SPDK_NVME_OPC_WRITE`, `SPDK_NVME_OPC_READ`.

6.14.2.7.4 SPDK Stop Listen Flow

The stop listener flow (`spdk_nvmf_stop_listen`) can be initiated through the `remove_listener` RPC. The current version of SPDK has limitations regarding the asynchronous handling of `remove_listener` requests. For this reason, it is recommended that the stop listener function be called only after freeing up resources like memory buffers and queue pairs. This can be accomplished on the host side by issuing the unbind script:

```
python3 samples/doca_devemu/devemu_pci_vfio_bind.py --unbind 0000:62:00.0
```

6.14.3 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Compress
- DOCA Comch

For additional information about the used DOCA libraries, please refer to the respective programming guides.

6.14.4 Dependencies

- BlueField-3 DPU is required
- SPDK version 23.0 is required

6.14.5 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/nvme_emulation/
```

6.14.5.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

1. To build all the applications together, run:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build
   ninja -C /tmp/build
   ```

   `doca_nvme_emulation` is created under `/tmp/build/applications/nvme_emulation/`

2. Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:
   a. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
      - Set `enable_all_applications` to `false`
      - Set `enable_nvme_emulation` to `true`
   b. The same compilation commands should be used, as were shown in the previous section:

      ```
      cd /opt/mellanox/doca/applications/
      meson /tmp/build
      ninja -C /tmp/build
      ```

6.14.5.2 Compiling With Custom SPDK

If you plan to use a custom or alternative SPDK version, update the paths in the following variables via Meson:

- `spdk_lib_path`
- `spdk_incl_path`
- `spdk_dpdk_lib_path`
- `spdk_isal_prefix`

6.14.6 Running the Application

6.14.6.1 Prerequisites

- From the server on the DPU – the user is required to allocate hugepages, and then run the application that runs continuously, remaining active and processing incoming RPC requests.

```
$ echo 1024 > /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages $ sudo mount -t hugetlbfs -o
pagesize=2M nodev /mnt/huge
$ sudo /tmp/build/applications/nvme_emulation/doca_nvme_emulation
```

- From the client on the DPU – the user can send various RPC requests to the application during its execution. For example, to remove a listener, the user could send the following command:

```
$ sudo PYTHONPATH=/doca/applications/nvme_emulation/ /usr/bin/spdk_rpc.py nvmf_subsystem_remove_listener
nqn.2016-06.io.spdk:cnode1 -t doca -a MT2306XZ00AYGES1D0F0
```

6.14.6.2 Application Execution

The NvMR emulation application is provided in source form, hence a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_nvme_application [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA Comm Channel device PCIe address
  -r, --rep-pci                     DOCA Comm Channel device representor PCIe address
```

```
 -f, --file                         File to send by the client / File to write by the server
 -t, --timeout                      Application timeout for receiving file content messages, default is 5
sec

-c, --config <config>     JSON config file (default none)
    --json <config>       JSON config file (default none)
    --json-ignore-init-errors
                          don't exit on invalid config entry
-d, --limit-coredump      do not set max coredump size to RLIM_INFINITY
-g, --single-file-segments
                          force creating just one hugetlbfs file
-h, --help                show this usage
-i, --shm-id <id>         shared memory ID (optional)
-m, --cpumask <mask or list>    core mask (like 0xF) or core list of '[]' embraced (like [0,1,10]) for
DPDK
-n, --mem-channels <num>  channel number of memory channels used for DPDK
-p, --main-core <id>      main (primary) core for DPDK
-r, --rpc-socket <path>   RPC listen address (default /var/tmp/spdk.sock)
-s, --mem-size <size>     memory size in MB for DPDK (default: 0MB)
    --disable-cpumask-locks    Disable CPU core lock files.
    --silence-noticelog   disable notice level logging to stderr
    --msg-mempool-size <size>  global message memory pool size in count (default: 262143)
-u, --no-pci              disable PCIe access
    --wait-for-rpc        wait for RPCs to initialize subsystems
    --max-delay <num>     maximum reactor delay (in microseconds)
-B, --pci-blocked <bdf>
                          PCIe addr to block (can be used more than once)
-R, --huge-unlink         unlink huge files after initialization
-v, --version             print SPDK version
-A, --pci-allowed <bdf>
                          PCIe addr to allow (-B and -A cannot be used at the same time)
    --huge-dir <path>     use a specific hugetlbfs mount to reserve memory from
    --iova-mode <pa/va>   set IOVA mode ('pa' for IOVA_PA and 'va' for IOVA_VA)
    --base-virtaddr <addr>      the base virtual address for DPDK (default: 0x200000000000)
    --num-trace-entries <num>   number of trace entries for each core, must be power of 2, setting 0 to
disable trace (default 32768)
    --rpcs-allowed    comma-separated list of permitted RPCS
    --env-context         Opaque context for use of the env implementation
    --vfio-vf-token       VF token (UUID) shared between SR-IOV PF and VFs for vfio_pci driver
-L, --logflag <flag>    enable log flag (all, accel, aio, app_config, app_rpc, bdev, bdev_concat,
bdev_ftl, bdev_group, bdev_malloc, bdev_null, bdev_nvme, bdev_raid, bdev_raid0, bdev_raid1, bdev_raid5f,
blob, blob_esnap, blob_rw, blobfs, blobfs_bdev, blobfs_bdev_rpc, blobfs_rw, ftl_core, ftl_init, gpt_parse,
json_util, log, log_rpc, lvol, lvol_rpc, notify_rpc, nvme, nvme_vfio, nvmf, nvmf_tcp, opal, rdma, reactor,
rpc, rpc_client, sock, sock_posix, thread, trace, uring, vbdev_delay, vbdev_gpt, vbdev_lvol, vbdev_opal,
vbdev_passthru, vbdev_split, vbdev_zone_block, vfio_pci, vfio_user, virtio, virtio_blk, virtio_dev,
virtio_pci, virtio_user, virtio_vfio_user, vmd)
-e, --tpoint-group <group-name>[:<tpoint_mask>]
                          group_name - tracepoint group name for spdk trace buffers (bdev, nvmf_rdma,
nvmf_tcp, blobfs, thread, nvme_pcie, nvme_tcp, bdev_nvme, nvme_nvda_tcp, all)
                          tpoint_mask - tracepoint mask for enabling individual tpoints inside a
tracepoint group. First tpoint inside a group can be enabled by setting tpoint_mask to 1 (e.g. bdev:0x1).
                           Groups and masks can be combined (e.g. thread,bdev:0x1).
                           All available tpoints can be found in /include/spdk_internal/trace_defs.h
```

The above usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
/tmp/build/applications/nvme_emulation/doca_nvme_emulation -h
```

6.14.6.3 Command Line Flags

The application uses the same command-line flags as SPDK, allowing for configuration and behavior control similar to standard SPDK applications.

For more details refer to SPDK's official Storage Performance Development Kit Documentation.

6.14.6.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.15 DOCA PCC Application Guide

This document provides a DOCA PCC implementation on top of NVIDIA® BlueField® networking platform.

6.15.1 Introduction

Programmable Congestion Control (PCC) allows users to design and implement their own congestion control (CC) algorithm, giving them the flexibility to work out an optimal solution to handle congestion in their clusters. On BlueField-3 networking platforms, PCC is provided as a component of DOCA.

The application leverages the DOCA PCC API to provide users the flexibility to manage allocation of DPA resources according to their requirements.

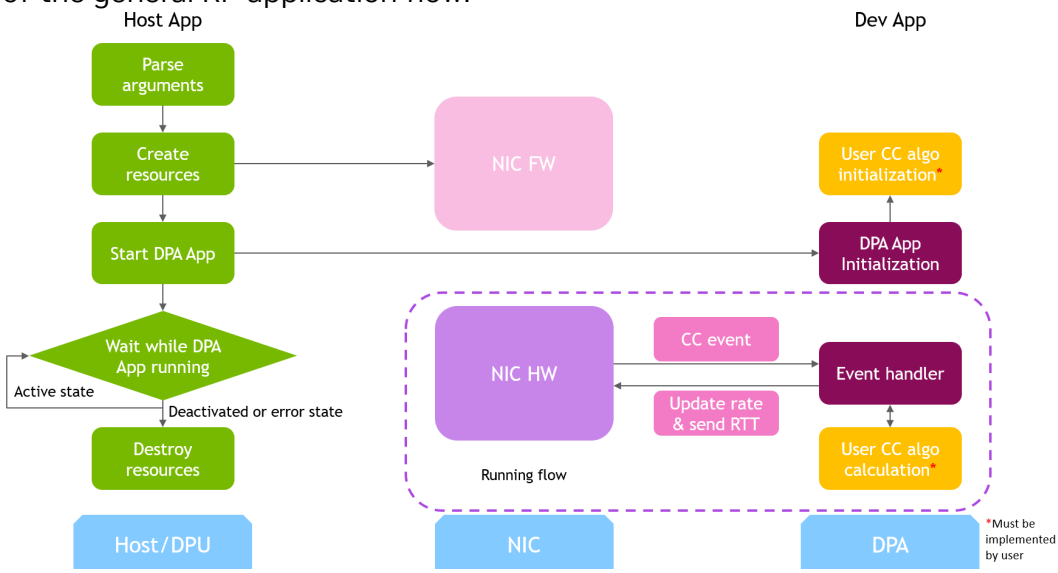
Typical DOCA application includes App running on host/Arm and App running on DPA. Developers are advised to use the host/Arm application with minimal changes and focus on developing their algorithm and integrating it into the DPA application.

6.15.2 System Design

DOCA PCC application consists of two parts:

- Host/Arm app is the control plane. It is responsible for allocating all resources and handover to the DPA app initially, then destroying everything when the DPA app finishes its operation. The host app must always be alive to stay in control while the device app is working.
- Device/DPA app is the data plane.

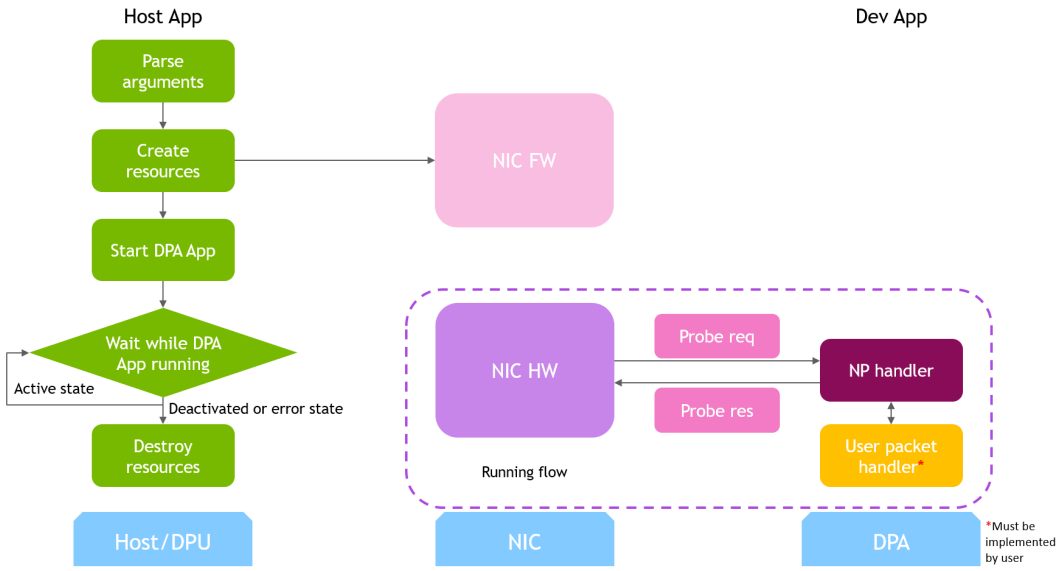
- The default mode of the data plane is running as a reaction point (RP). When the first thread is activated, DPA App initialization is done in the DOCA PCC library by calling the algorithm initialization function implemented by the user in the app. Moreover, the user algorithm execution function is called when a CC event arrives. The user algorithm takes event data as input and performs a calculation, using per-flow context, and replies with the updated rate value and a flag to send an RTT request. The following is an illustration of the general RP application flow:



The host/Arm application sends a command to the BlueField platform firmware when allocating or destroying resources. CC events are generated by the BlueField platform hardware automatically when sending data or receiving ACK/NACK/CNP/RTT packets, then the device application handles these events by calling the user algorithm. After the DPA application replies to hardware, handling of current event is done, and the next event can arrive.

> The device/DPA app can also run different algorithms for the RP program, which users can configure as a runtime option.

- The device/DPA app can function as a notification point (NP). When a new probe request packet arrives, the user handler can read and analyze the data and send a probe response back. The following is an illustration of the general NP application flow:



The device/DPA app is as well capable of functioning as a telemetry program for a NP switch operation, which users can configure as a runtime option.

6.15.3 Application Architecture

```
/opt/mellanox/doca/applications/pcc/
    host
        pcc.c
        pcc_core.c
        pcc_core.h
    device
        pcc_common_dev.h
        rp
            rtt_template
                algo
                    rtt_template.h
                    rtt_template_algo_params.h
                    rtt_template_ctxt.h
                    rtt_template.c
                rp_rtt_template_dev_main.c
            switch_telemetry
                algo
                    telem_template.h
                    telem_template_algo_params.h
                    telem_template_ctxt.h
                    telem_template.c
                rp_switch_telemetry_dev_main.c
        np
            switch_telemetry
                np_switch_telemetry_dev_main.c
```

The main content of the reference DOCA PCC application files are the following:

- `host/pcc.c` – entry point to entire application
- `host/pcc_core.c` – host functions to initialize and destroy the PCC application resources, parsers for PCC command line parameters
- `device/pcc_common_dev.h` – common util calls and definitions for device programs

- `device/rp/rtt_template/rp_rtt_template_dev_main.c` – callbacks for user CC algorithm initialization, user CC algorithm calculation and algorithm parameter change notification of the RTT template algorithm reference
- `device/rp/rtt_template/algo/*` – user CC algorithm reference for RTT template. Put user algorithm code here
- `device/rp/switch_telemetry/rp_switch_telemetry_dev_main.c` – callbacks for user CC algorithm initialization, user CC algorithm calculation, and algorithm parameter change notification of the switch telemetry algorithm reference
- `device/rp/switch_telemetry/algo/*` – user CC algorithm reference for switch telemetry. Put user algorithm code here.
- `device/np/switch_telemetry/np_switch_telemetry_dev_main.c` – callback for user NP handling, implemented as a switch telemetry program to observe last hop switch metadata

6.15.4 DOCA Libraries

This application leverages the following DOCA library:

- DOCA PCC

Refer to its respective programming guide for more information.

6.15.5 Dependencies

- NVIDIA BlueField-3 Platform is required
- Firmware 32.38.1000 and higher
- MFT 4.25 and higher

6.15.6 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/pcc/
```

6.15.6.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_pcc` is created under `/tmp/build/pcc/`.

6.15.6.2 Compiling Only the Current Application

To directly build only the PCC application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_pcc=true
ninja -C /tmp/build
```

`doca_pcc` is created under `/tmp/build/pcc/`.

Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_pcc` to `true`
2. Run the following compilation commands:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build
   ninja -C /tmp/build
   ```

`doca_pcc` is created under `/tmp/build/pcc/`.

6.15.6.3 Compilation Options

The application offers specific compilation flags which one can set for a desired behavior in the device/DPA program.

In the `meson_options.txt` file, one can find the following options:

- `enable_pcc_application_tx_counter_sampling`: set to `true` to use TX counters sampled at runtime in the RP CC handling algorithm.

6.15.7 Running the Application

6.15.7.1 Prerequisites

Enable `USER_PROGRAMMABLE_CC` in `mlxconfig`:

```
mlxconfig -y -d /dev/mst/mt41692_pciconf0 set USER_PROGRAMMABLE_CC=1
```

Perform a BlueField system reboot for the `mlxconfig` settings to take effect.

6.15.7.2 Application Execution

The PCC application is provided in source form. Therefore, a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_pcc [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device <RDMA device names> RDMA device name that supports PCC (mandatory).
  -rp-st, --rp-switch-telemetry <PCC Reaction Point Switch Telemetry> Flag to indicate running as a
Reaction Point Switch Telemetry (optional). The application will generate IFA2 probe packets. By default
 the flag is set to false.
  -np-st, --np-switch-telemetry <PCC Notification Point Switch Telemetry> Flag to indicate running as a
Notification Point Switch Telemetry (optional). The application will generate IFA2 probe packets. By
default the flag is set to false.
  -t, --threads <PCC threads list>  A list of the PCC threads numbers to be chosen for the DOCA PCC context
to run on (optional). Must be provided as a string, such that the number are separated by a space.
```

```
  -w, --wait-time <PCC wait time>   The duration of the DOCA PCC wait (optional), can provide negative
values which means infinity. If not provided then -1 will be chosen.
  -r-handler, --remote-sw-handler <CCMAD remote SW handler> CCMAD remote SW handler flag (optional). If not
provided then false will be chosen.
  -hl, --hop-limit <IFA2 hop limit> The IFA2 probe packet hop limit (optional). If not provided then 0XFE
 will be chosen.
  -gns, --global-namespace <IFA2 global namespace> The IFA2 probe packet global namespace (optional). If
not provided then 0XF will be chosen.
  -gns-ignore-mask, --global-namespace-ignore-mask <IFA2 global namespace ignore mask> The IFA2 probe
packet global namespace ignore mask (optional). If not provided then 0 will be chosen.
  -gns-ignore-val, --global-namespace-ignore-value <IFA2 global namespace ignore value> The IFA2 probe
packet global namespace ignore value (optional). If not provided then 0 will be chosen.
  -f, --coredump-file <PCC coredump file> A pathname to the file to write coredump data in case of
unrecoverable error on the device (optional). Must be provided as a string.
 --dpa-resources <DPA resources file> Path to a DPA resources .yaml file (optional). Must be provided
together with DPA application key.
 --dpa-app-key <DPA application key> Application key in specified DPA resources .yaml file (optional). Must
be provided together with DPA resources file.
  -tlm-ex, --enable-telemetry-export <Telemetry exporter enablement> Flag to enable exporting telemetry
data gathered by pcc algorithem (optional). By default the flag is set to false.
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_pcc -h
```

For additional information, refer to section "Command Line Flags".

2. CLI example for running the application on the BlueField Platform or the host:

```
./doca_pcc -d mlx5_0
```

The RDMA device identifier (`mlx5_0`) should match the identifier of the desired RDMA device.

6.15.7.3 Command Line Flags

6.15.7.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)

Short Flag	Long Flag	Description
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.15.7.3.2 Program Flags

Short Flag	Long Flag	Description
`d`	`device`	RDMA device name that supports PCC
`rp-st`	`rp-switch-telemetry`	(Optional) Flag to indicate running as a RP switch telemetry. The DOCA PCC application can run as a RP switch telemetry program. If this flag is used, the application loads a program to run on the DPA of a switch telemetry algorithm which receives metadata from the last hop switch congestion point from the NP node.
`np-st`	`np-switch-telemetry`	(Optional) Flag to indicate running as a NP switch telemetry. The DOCA PCC application can run as a NP switch telemetry program. If this flag is used, the application loads a program to run on the DPA to sample metadata from the last hop switch congestion point and send them in response packet.
`t`	`threads`	(Optional) A list of the PCC EU indexes to be chosen for the DOCA PCC event handler threads to run on. Must be provided as a string, such that the numbers are separated by a space. The placement of the PCC threads per core can be controlled using the EU indexes. Utilizing a large number of EUs, while limiting the number of threads per core, gives the best event handling rate and lowest event latency. The last EU is used for communication with the BlueField Platform while all others are for data path CC event handling.
`w`	`wait-time`	(Optional) In seconds, the duration of the DOCA PCC wait. Negative values mean infinity.

Short Flag	Long Flag	Description
`r-handler`	`remote-sw-handler`	(Optional) CCMAD remote SW handler flag. Relevant for RP contexts. This flag indicates whether the expected CCMAD probe packet responses are generated by a remote DOCA NP process or not. ⚠ If using other probe types than CCMAD, probe packet responses are always expected to be generated from a remote DOCA NP process.
`hl`	`hop-limit`	(Optional) The IFA2 probe packet hop limit ℹ Relevant for RP contexts.
`gns`	`global-namespace`	(Optional) The IFA2 probe packet global namespace ℹ Relevant for RP contexts.
`gns-ignore-mask`	`global-namespace-ignore-mask`	(Optional) The IFA2 probe packet global namespace ignore mask ℹ Relevant for NP contexts.
`gns-ignore-val`	`global-namespace-ignore-value`	(Optional) The IFA2 probe packet global namespace ignore value ℹ Relevant for NP contexts.
`f`	`coredump-file`	(Optional) A pathname to the file to write core dump data if an unrecoverable error occurs on the device
N/A	`dpa-resources`	(Optional) Path to a DPA resources `.yaml` file. Must be provided together with DPA application key.
N/A	`dpa-app-key`	(Optional) Application key in specified DPA resources `.yaml` file. Must be provided together with DPA resources file.

6.15.7.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.15.8 Application Code Flow

This section lists the application's configuration flow, explaining the different DOCA function calls and wrappers.

1. Parse application argument.
    a. Initialize arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

    b. Register PCC application parameters.

```
register_pcc_params();
```

    c. Parse the arguments.

```
doca_argp_start();
```

        i. Parse DOCA flags.
        ii. Parse DOCA PCC parameters.
2. PCC initialization.

```
pcc_init();
```

    a. Open DOCA device that supports PCC.
    b. Create DOCA PCC context.
    c. Configure affinity of threads handling CC events.
3. Start DOCA PCC.

```
doca_pcc_start();
```

    a. Create PCC process and other resources.
    b. Trigger initialization of PCC on device.
    c. Register the PCC in the BlueField Platform hardware so CC events can be generated and an event handler can be triggered.
4. Process state monitor loop.

```
doca_pcc_get_process_state();
doca_pcc_wait();
```

    a. Get the state of the process:

State	Description
`DOCA_PCC_PS_ACTIVE = 0`	The process handles CC events (only one process is active at a given time)
`DOCA_PCC_PS_STANDBY = 1`	The process is in standby mode (another process is already `ACTIVE`)
`DOCA_PCC_PS_DEACTIVATED = 2`	The process has been deactivated by the BlueField Platform firmware and should be destroyed
`DOCA_PCC_PS_ERROR = 3`	The process is in error state and should be destroyed

b. Wait on process events from the device.

5. PCC destroy.

```
doca_pcc_destroy();
```

a. Destroy PCC resources. The process stops handling PCC events.

b. Close DOCA device.

6. Arg parser destroy.

```
doca_argp_destroy()
```

6.15.9 Port Programmable Congestion Control Register

The Port Programmable Congestion Control (PPCC) register allows the user to configure and read PCC algorithms and their parameters/counters.

It supports the following functionalities:

- Enabling different algorithms on different ports
- Querying information of both algorithms and tunable parameters/counters
- Changing algorithm parameters without compiling and reburning user image
- Querying or clearing programmable counters

6.15.9.1 Usage

The PPCC register can be accessed using a string similar to the following:

```
sudo mlxreg -d /dev/mst/mt41692_pciconf0 -y --get --op "cmd_type=0" --reg_name PPCC --indexes
"local_port=1,pnat=0,lp_msb=0,algo_slot=0,algo_param_index=0,target_app=0"
sudo mlxreg -d /dev/mst/mt41692_pciconf0 -y --set "cmd_type=1" --reg_name PPCC --indexes
"local_port=1,pnat=0,lp_msb=0,algo_slot=0,algo_param_index=0,target_app=0"
```

Where you must:

- Set the `cmd_type` and the indexes
- Give values for `algo_slot`, `algo_param_index`
- Keep `local_port=1`, `pnat=0`, `lp_msb=0`
- Set `target_app = 0` for PCC
- Keep `doca_pcc` application running

cmd_type	Description	Method	Index	Input (in --set)	Output
`0x0`	Get algorithm info	Get	`algo_slot`	N/A	• Value – 32-bit `algo_num` or 0 if no algo is available at this index • Text – algorithm description • `sl_bitmask_support` – indicates whether the device supports `sl_bitmask` logic

`0x1`	Enable algorithm	Set		`sl_bitmask`
				`trace_en`
				`counter_en`
					N/A

`0x2`	Disable algorithm	Set		N/A	N/A

`0x3`	Get algorithm enabling status	Get		N/A	• Value:
					  • 0 – disabled
					  • 1 – enabled
					• `sl_bitmask` – this field allows to apply to specific SLs based on the bitmask
					• `sl_bitmask_support` – indicates whether the device supports `sl_bitmask` logic

`0x4`	Get number of parameters	Get		N/A	• Value – num of params of algo

`0x5`	Get parameter information	Get	`algo_slot`
			`algo_param_index`
				N/A	• `param_value1` – default value of param
					• `param_value2` – min value of param
					• `param_value3` – max value of param
					• prm –
					  • 0: read-only
					  • 1: read-write
					  • 2: read-only but may be cleared using the "get and clear" command

`0x6`	Get parameter value	Get		N/A	• Value – param value
`0x7`	Get and clear parameter	Get		N/A	• Value – param value
`0x8`	Set parameter value	Set		Parameter value	N/A
`0xA`	Bulk get parameters	Get	`algo_slot`	N/A	• `text_length` – param num x 4 bytes • `text[0]…text[n]` – param values
`0xB`	Bulk set parameters	Set		`text_length` - param num x 4 `text[0]…text[n]` - param values	N/A
`0xC`	Bulk get counters	Get		N/A	• `text_length` – counter num x 4 bytes • `text[0]…text[n]` – counter values

cmd_type	Description	Method	Index	Input (in --set)	Output
`0xD`	Bulk get and clear counters	Get		N/A	• `text_length` – counter num x 4 bytes • `text[0]…text[n]` – counter values
`0xE`	Get number of counters	Get		N/A	• Value – num of counters of algo

`0xF`	Get counter information	Get	`algo_slot` `algo_param_index`	N/A	• `param_value3` – max value of parameter
					• prm –
					  • 0: read-only
					  • 1: read-write
					  • 2: read-only but may be cleared via "get & clear" command

`0x10`	Get algorithm info array	Get	N/A	N/A	• `text_length` – algo slot initialized x 4 bytes • `text[0]…text[n]` – 32-bit `algo_num` or 0 if no algorithm is available at this slot index

6.15.9.2 Internal Default Algorithm

The internal default algorithm is used when enhanced connection establishment (ECE) negotiation fails. It is mainly used for backward compatibility and can be disabled using "force mode". Otherwise, users may change `doca_pcc_dev_user_algo()` in the device app to run a specific algorithm without considering the algorithm negotiation.

The force mode command is per port:

```
sudo mlxreg -d /dev/mst/mt41692_pciconf0 -y --get --op "cmd_type=2" --reg_name PPCC --indexes
"local_port=1,pnat=0,lp_msb=0,algo_slot=15,algo_param_index=0,target_app=0"
sudo mlxreg -d /dev/mst/mt41692_pciconf0.1 -y --get --op "cmd_type=2" --reg_name PPCC --indexes
"local_port=1,pnat=0,lp_msb=0,algo_slot=15,algo_param_index=0,target_app=0"
```

6.15.9.3 Counters

Counters are shared on the port and are only enabled on one `algo_slot` per port. The following command enables the counters while enabling the algorithm according to the `algo_slot`:

```
sudo mlxreg -d /dev/mst/mt41692_pciconf0 -y --set "cmd_type=1,counter_en=1" --reg_name PPCC --indexes
"local_port=1,pnat=0,lp_msb=0,algo_slot=0,algo_param_index=0,target_app=0"
```

After counters are enabled on the `algo_slot`, they can be queried using `cmd_type` 0xC or 0xD.

```
sudo mlxreg -d /dev/mst/mt41692_pciconf0 -y --get --op "cmd_type=12" --reg_name PPCC --indexes
"local_port=1,pnat=0,lp_msb=0,algo_slot=0,algo_param_index=0,target_app=0"
sudo mlxreg -d /dev/mst/mt41692_pciconf0 -y --get --op "cmd_type=13" --reg_name PPCC --indexes
"local_port=1,pnat=0,lp_msb=0,algo_slot=0,algo_param_index=0,target_app=0"
```

6.16 DOCA PSP Gateway Application Guide

This document describes the usage of the NVIDIA DOCA PSP Gateway sample application on top of an NVIDIA® BlueField® networking platform or NVIDIA® ConnectX® SmartNIC.

6.16.1 Introduction

DOCA PSP Gateway is supported only on BlueField-3 or ConnectX-7 and later.

The DOCA PSP Gateway application leverages the BlueField or ConnectX hardware capability for fully offloaded secure network communication using the PSP security protocol. The application demonstrates how to exchange keys between application instances and insert rules controlling PSP encryption and decryption using the DOCA Flow library.

The application exchanges keys using an unencrypted gRPC channel. If your environment requires the protection of encryption keys, you must modify the application to create the gRPC channel using the applicable certificates.

The PSP Gateway application supports only the PSP tunnel protocol. The PSP transport protocol is not supported by the application in this release, although it is supported by the underlying DOCA Flow library.

The PSP Gateway application supports only IPv4 inner and IPv6 outer headers. Other combinations are not supported by the application in the current release, although they are supported by the underlying DOCA Flow library.

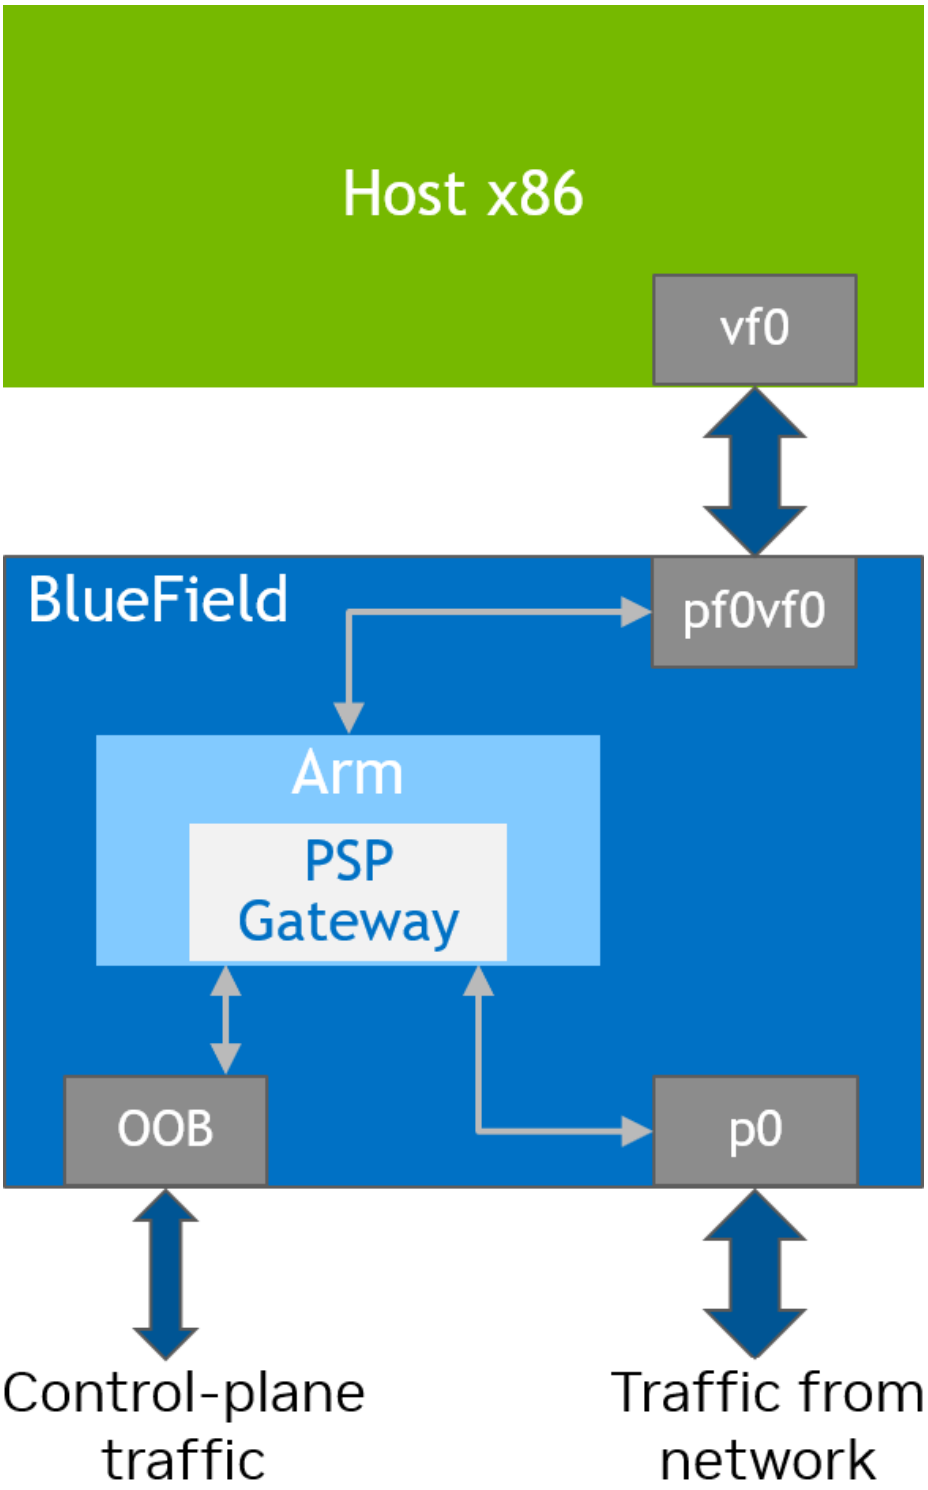
The application can be configured to establish out-bound PSP tunnel connections via individual command-line arguments, or via a text file configured via a command-line argument. The connections are established on-demand by default, but can also be configured to connect at startup.

6.16.2 System Design

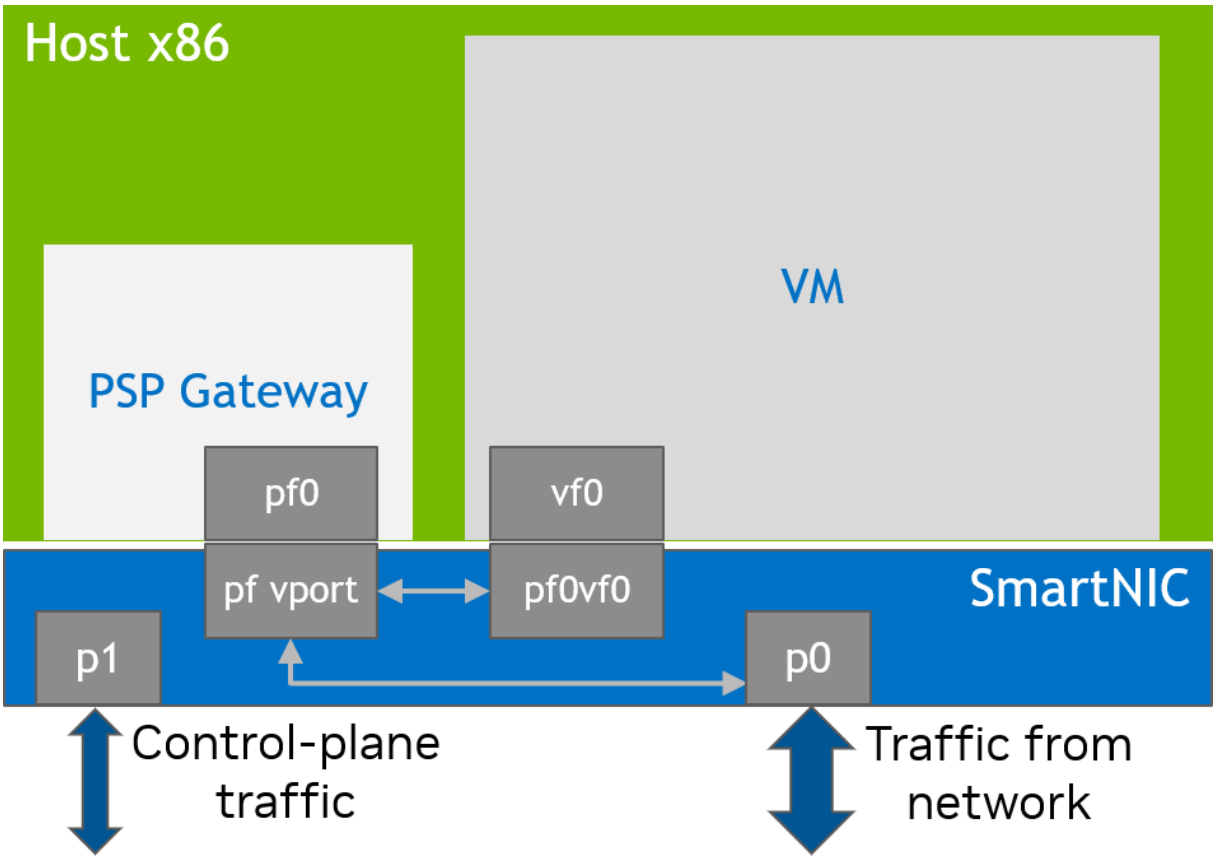
The DOCA PSP Gateway is designed to run with three ports:

- A secure (encrypted) uplink netdev (i.e., `p0`)
- An unsecured (plaintext) netdev representor (VF or SF)
- An out-of-bound (OOB) management port, used to communicate with peer instances using standard sockets

Whether the DOCA PSP Gateway is deployed to a BlueField or a ConnectX device, the functionality is the same. The Out of Bounds (OOB) network device carries PSP parameters between peers, the Uplink port carries secure (encrypted) traffic, and the VF carries the unencrypted traffic.



When the application is deployed to a DPU, the operation of the PSP encryption protocol is entirely transparent to the Host. All the resources required to manage the PSP connections are physically located on the DPU.



When the application is deployed to the host, the operation of the PSP encryption protocol is the responsibility of the host, and resources are allocated from the host. However, the operation of the PSP encryption protocol is entirely transparent to any virtual machines and containers attached to the VF network devices.

6.16.3 Application Architecture

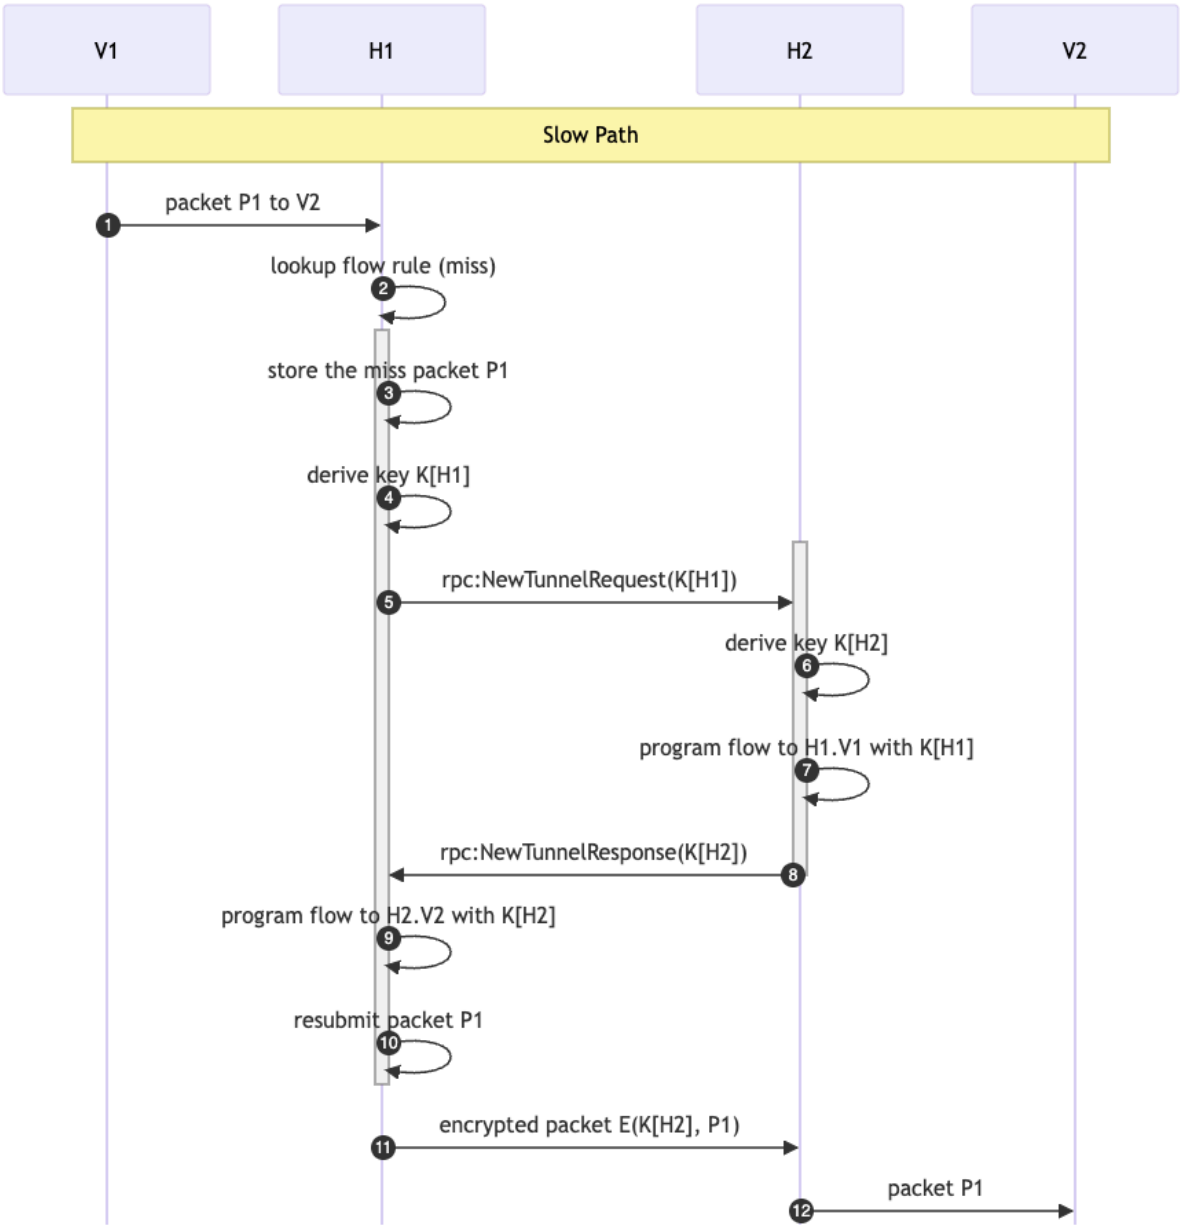
The creation of PSP tunnel connections requires two-way communication between peers. Each "sender" must request a unique security parameters index (SPI) and encryption key from the intended "receiver". The receiver derives sequential SPIs and encryption keys using the hardware resources inside the BlueField or ConnectX device, which manages a secret pair of master keys to produce the SPIs and encryption keys.

One key architectural benefit of PSP over similar protocols (e.g., IPsec) is that the receiver does not incur any additional resource utilization whenever it creates a new SPI and encryption key. This is because the decryption key associated with the SPI is computed on the fly, based on the SPI and master key, for each received packet. This lack of requirement for additional context memory for each additional decryption rule is partly responsible for the ability of the PSP protocol to scale to many thousands of peers.

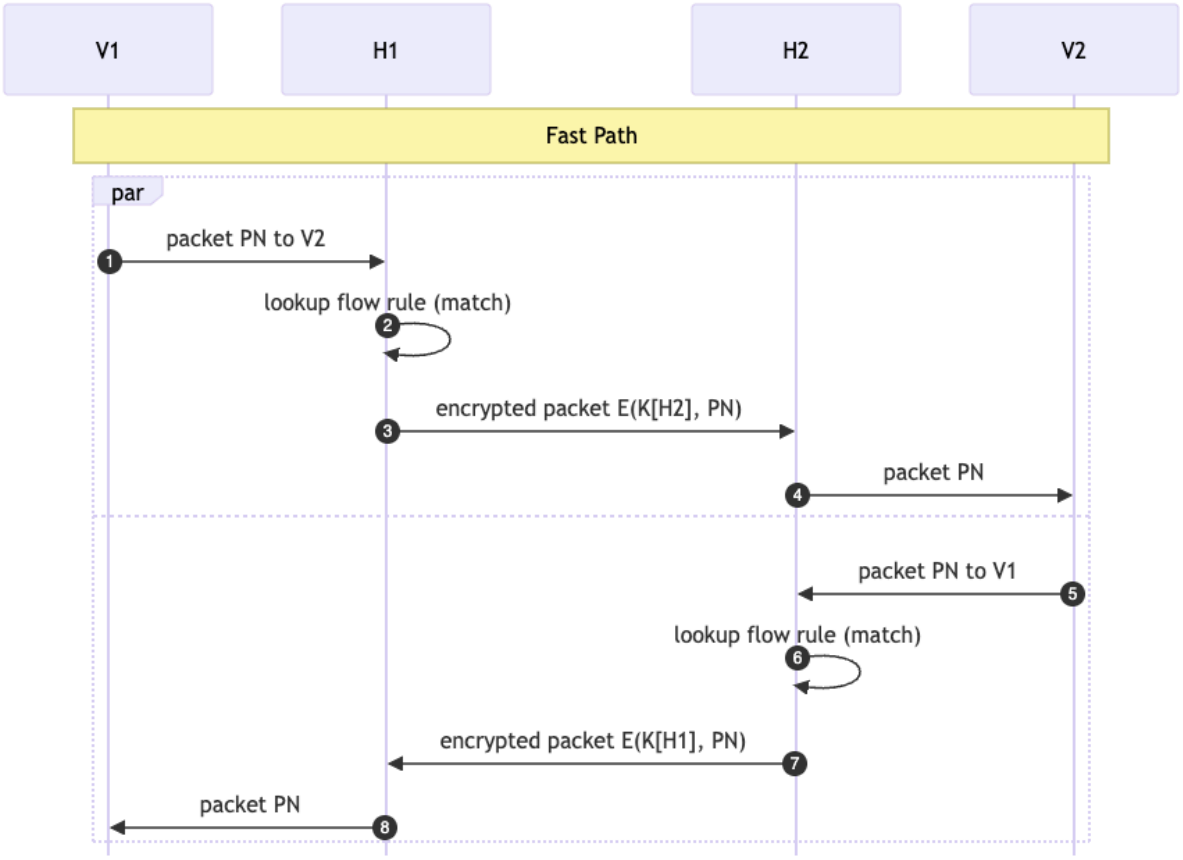
6.16.3.1 Startup vs. On-Demand Tunnel Creation

The default mode of operation is on-demand tunnel creation. That is, when a packet is received from the unsecured port for which the flow pipeline does not have an encryption rule, the packet misses to RSS, where the CPU must decide how to handle the packet. If the destination IP address in the packet belongs to a known peer's virtual network, the CPU uses gRPC on the OOB network connection to attempt a key exchange with the peer. If the key exchange is successful and a new encryption flow is created successfully, then the packet is then resubmitted to the pipeline, where it is encrypted and sent just as any of the following packets having the same destination IP address.

The following diagram illustrates this sequence (the "Slow Path"), for Virtual Machine V1 which intends to send a packet to Virtual Machine V2. In this case, V1 is hosted on physical host H1 and V2 on physical host H2. The first packet sent (1) results in a miss (2), so the packet is retained (3) while the keys are exchanged in both directions (4-8). Then the pipeline is updated (9) and the original packet is resubmitted (10). From there, the packet follows the same logic as the fast path, below.



Once the tunnel is established, and packets received from the VF (1) match a rule (2) and are encrypted and sent (3-4) without any intervention from the CPU ("Fast Path").



In the case of on-startup tunnel creation, the application's main thread repeatedly attempts to perform the key exchange for each of the peers specified on the command line until the list is completed. Each peer is connected only once and, if a connection to one peer fails, the loop continues onto the next peer and retries the failed connection after all the others have been attempted.

6.16.3.2 Sampling

The PSP gateway application supports the sample-at-receiver (S) bit in the PSP header. If sampling is enabled, then packets marked with the S bit are mirrored to the RSS queues and logged to the console. In addition, on transmit, the S bit of a random subset of packets (1 out of 2^N for command-line parameter N) is set to 1, and those packets are mirrored to RSS.

To avoid out-of-sequence indication in ROCE traffic, the `--maintain-order` flag can be used. When used, the application creates two mirror resources for egress sampling:

- One for when the sample bit is on – mirror is to RSS
- One for when the sample bit is off – mirror with fwd type drop

Sampling packets on transmit is currently supported only following encryption. Sampling of egress packets before encryption will be supported in a future release.

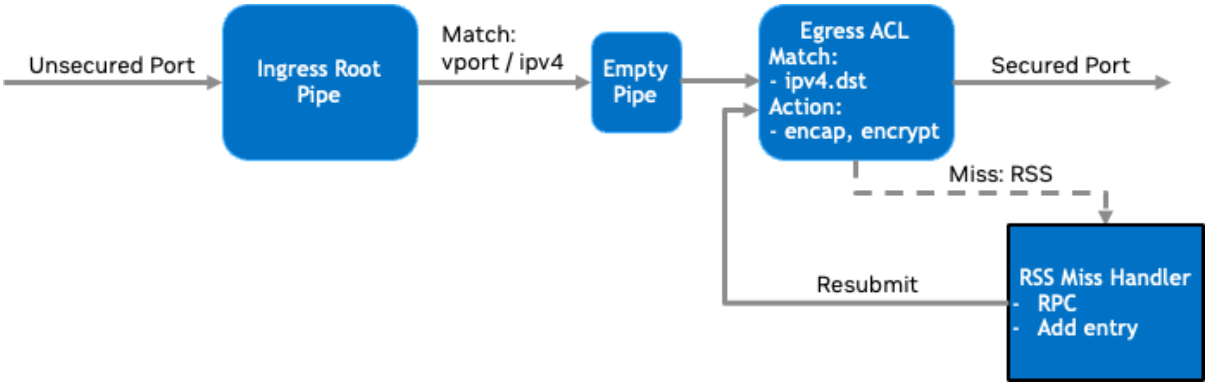
6.16.3.3 Pipelines

6.16.3.3.1 Host-to-Network Flows

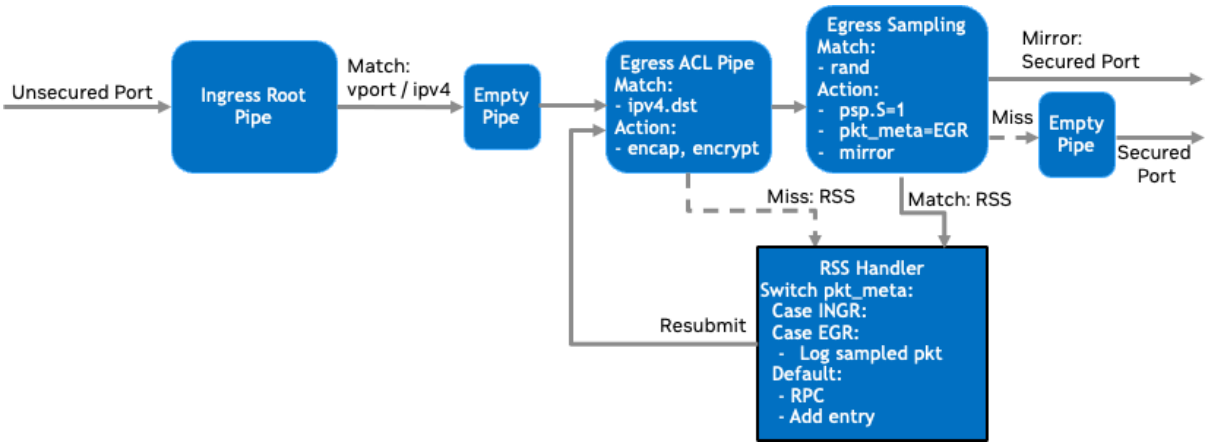
Traffic sent from the local, unsecured port (host-to-net) without sampling enabled travels through the pipeline as shown in the diagrams that follow. Note that the Ingress Root Pipe is the first destination for packets arriving from either the VF or the secured uplink port. However, the Egress ACL pipe is the first destination for packets sent via `tx_burst` on the PF (in the switch model's expert mode).

The Empty Pipe is a vestigial transition from the Default Domain, in which the Ingress Root Pipe is created, to the Secure Egress Domain, where the Egress ACL pipe performs encryption.

This pipe may be removed in a future release.



If sampling is enabled, the host-to-net pipeline is modified as shown in the following:



Here, an Egress Sampling Pipe is added between the Egress ACL Pipe and the Secured Port. It performs a match of the `random` metadata, masked according to command-line parameters, and then:

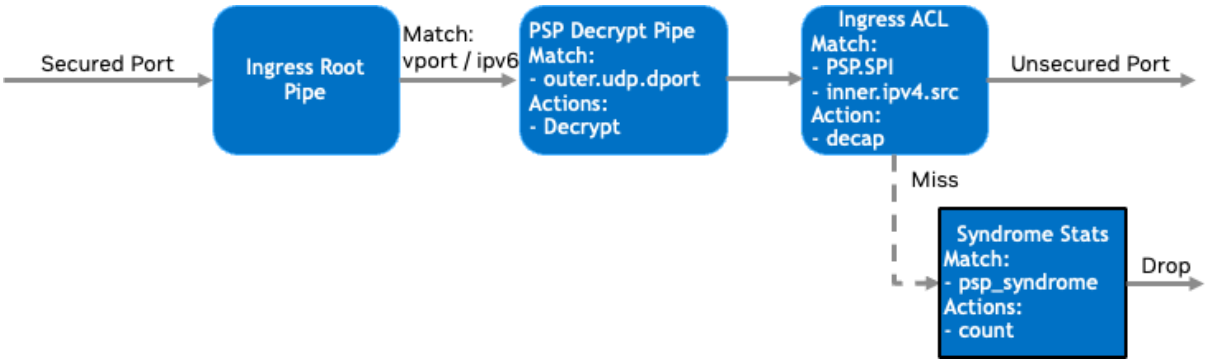
- On match, the following actions occur:
  a. Packet modifications:
    i. The S bit in the PSP header is set to `true`.
    ii. The `pkt_meta` field is set to a sentinel value to indicate to CPU software why the packet was sent to RSS.
  b. The original packet is forwarded to RSS.
  c. The mirror action forwards the packet to the secured port.
- On miss, the following actions occur:
  a. No packet modifications are made.
  b. The packet is forwarded to a vestigial pipe which can then forward the packet to the wire.

> A `fwd_miss` cannot target a port.

> This pipe may be removed in a future release.

6.16.3.3.2 Network-to-Host Flows

When a packet arrives from the secured port, the following flows are executed.

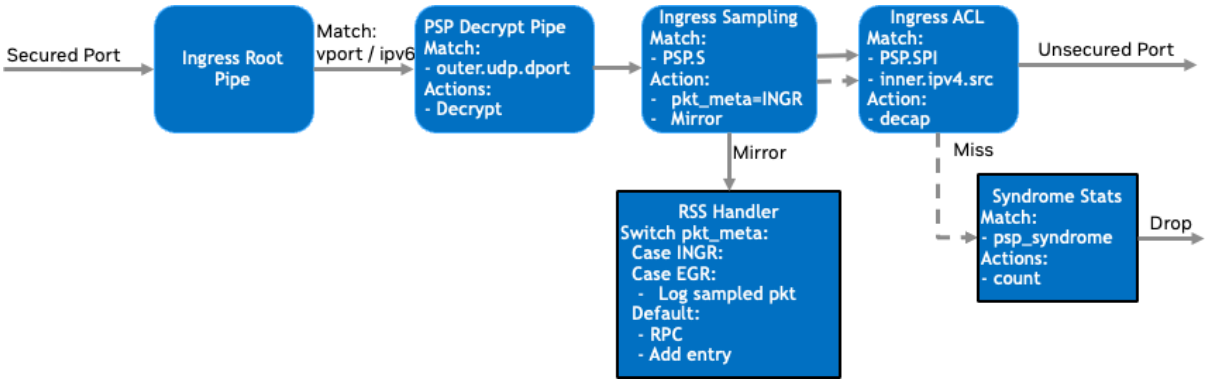


As before, the Ingress Root Pipe is the first destination and, here, the secured port ID as well as IPv6 outer L3 type are matched for. Matching packets flow to the decryption pipe, which matches the outer UDP port number against 1000, the constant specified in the PSP specification. On match, the packet is decrypted, but not yet de-capped. Then the Ingress ACL pipe checks the following:

- PSP_Syndrome – did the packet decrypt correctly and pass its ICV check?
- PSP SPI and inner IP src address – was this packet encrypted with the key associated with the given source?

If the packet passes the syndrome and ACL check, it is forwarded to the VF. Otherwise, the Syndrome Stats pipe counts the occurrences of the different bits in the PSP Syndrome word.

When sampling is enabled, the Ingress Sampling Pipe is inserted before the ACL. Unlike the Egress Sampling Pipe, no randomness is involved; the match criteria is the sample-on-receive flag in the PSP header. On a match, the incoming packet are mirrored to RSS with `pkt_meta` indicating the reason for forwarding the packet to RSS. On match or miss, the next pipe is the Ingress ACL Pipe.



6.16.3.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Flow

Refer to their respective programming guide for more information.

6.16.4 Compiling the Application

Please refer to the NVIDIA DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/psp_gateway/
```

6.16.4.1 Prerequisites

- The application relies on the `json-c` open source, requiring the following to be installed:
  - Ubuntu/Debian:

    ```
    $ sudo apt install libjson-c-dev
    ```

  - CentOS/RHEL:

    ```
    $ sudo yum install json-c-devel
    ```

- Installing the `gRPC` open source.

  `gRPC` can be installed either from upstream packages or by building it directly from source. Due to build changes on `gRPC`'s side, if building new versions directly from source, the following DOCA applications build flag will also be required:

  ```
  $ meson -Dupstream_grpc=false /tmp/build
  ```

6.16.4.2 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_psp_gateway` is created under `/tmp/build/psp_gateway/`.

6.16.4.3 Compiling Only the Current Application

To directly build only the PSP Gateway application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_psp_gateway=true
ninja -C /tmp/build
```

`doca_psp_gateway` is created under `/tmp/build/psp_gateway/`.

Alternatively, users can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_psp_gateway` to `true`
2. Run the following compilation commands:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build
   ninja -C /tmp/build
   ```

   `doca_psp_gateway` is created under `/tmp/build/psp_gateway/`.

6.16.5 Running the Application

6.16.5.1 Prerequisites

The PSP gateway application is based on DOCA Flow. Therefore, the user is required to allocate huge pages:

```
$ echo '2048' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

6.16.5.2 Application Execution

The PSP Gateway application is provided in source form. Therefore, a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_psp_gateway [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -s, --device                      Device identifier (required)
  -r, --repr                        Device representor (required)
  -m, --core-mask                   EAL Core Mask
  --decap-dmac                      mac_dst addr of the decapped packets
  -d, --vf-name                     Name of the virtual function device / unsecured port
  -n, --nexthop-dmac                next-hop mac_dst addr of the encapped packets
  --cookie                          Enable use of PSP virtualization cookies
  -a, --disable-ingress-acl         Allows any ingress packet that successfully decrypts
  --sample-rate                     Sets the log2 sample rate: 0: disabled, 1: 50%, ... 16: 1.5e-3%
  -x, --max-tunnels                 Specify the max number of PSP tunnels
  -o, --crypt-offset                Specify the PSP crypt offset
  --psp-version                     Specify the PSP version for outgoing connections (0 or 1)
  -z, --static-tunnels              Create tunnels at startup
  -k, --debug-keys                  Enable debug keys
  --stat-print                      Enable printing statistics
  --perf-print                      Enable printing performance metrics (key-gen, insertion, all)
  --show-rss-rx-packets             Show RSS rx packets
  --outer-ip-type                   outer IP type
  --inner-ip-type                   inner IP type
  -c, --config                      Path to the JSON file with application configuration
  --mode                            tunnel or transport mode
```

2. This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_psp_gateway -h
```

> For additional information, refer to section "Command Line Flags".

3. CLI example for running the application on the BlueField or host:

```
./doca_psp_gateway -s pci/03:00.0 -r pci/03:00.0,pf0vf0 -d ens2f0v0 -c /tmp/psp_gw_config.json
```

- The device identifier (`-s` flag) should match the addresses of the desired PCIe device
- The `-d` flag indicates the vf that is used to extract MAC address and local IP. It should match the MAC address of the virtual function specified by the `-r` argument.
- The `-c` flag is the path to json configuration file that includes all info about tunnels.

For additional information regarding the command line syntax of the device and device representor identifiers, please referr to the matching section in the DOCA Arg Parser Guide.

6.16.5.3 Command Line Flags

6.16.5.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.16.5.3.2 Program Flags

Short Flag	Long Flag	Description
`s`	`device`	Device identifier of the desired device
`r`	`repr`	Device representor identifier of the desired representor
`m`	`core-mask`	EAL core mask
N/A	`decap-dmac`	`mac_dst` address of the decapped packets (cannot be used with `vf-name`)
N/A	`vf-name`	Name of the VF device/unsecured port (Host only. Automatically detects MAC/VIP. Requires IP address bound to VF.)
`n`	`nexthop-dmac`	Next-hop `mac_dst` address of the encapped packets
N/A	`cookie`	Enable use of PSP virtualization cookies
`a`	`disable-ingress-acl`	Allows any ingress packet that successfully decrypts
N/A	`sample-rate`	Sets the log2 sample rate: • 0 – disabled, • 1 – 50%, ... • 16 – 1.5e-3%
`x`	`max-tunnels`	Specify the max number of PSP tunnels
`o`	`crypt-offset`	Specify the PSP crypt offset
N/A	`psp-version`	Specify the PSP version for outgoing connections (`0` or `1`)
`z`	`static-tunnels`	Create tunnels at startup using the given local IP address
`k`	`debug-keys`	Enable debug keys
N/A	`stat-print`	Print statistics regarding active sessions
N/A	`perf-print`	Print performance metrics of key generation of key-SPI pairs (`key-gen`) or insertion rate (`insertion`) or both (`all`)
N/A	`show-rss-rx-packets`	Print RX packets that got to RSS queues (i.e., to software)
N/A	`outer-ip-type`	Outer IP tunnel type (`ipv4` or `ipv6`). When not specified, default is `ipv6`.

Short Flag	Long Flag	Description
N/A	`inner-ip-type`	Inner IP tunnel type (`ipv4` or `ipv6`). When not specified, the default is `ipv4` .
`c`	`config`	Path to JSON file that includes tunnel information See section "Config File JSON Format" for specifics on the JSON file format.
N/A	`maintain-order`	Force maintaining original packet ordering

6.16.5.4 Config File JSON Format

The JSON configuration file maps an OOB network address (gRPC server) to a list of virtual IP addresses behind that physical address. Each "peer" in the list contains information about a remote gRPC server to which the pairs of `local-vip` and `remote-vip` are mapped to.

The following is a template of the JSON file structure:

Json config

```
{
    "config": {
        "local-grpc-address": <local gRPC server ip address to listen for connections on, possible with port>
    },
    "peers": [ /* list of peers (differentiated by remote gRPC server) */
        {
            "remote-grpc-address": <remote gRPC server address to connect to for connections of given sessions> ,
            "sessions": [ /* list of sessions allowed with peer (differentiated by local vip) */
                {
                    "local-vip": <local virtual ip>, /* if not present, take the value from vf interface's IP ("--
vf-name" flag) */
                    "remote-vips": [
                        <ip address, possible with prefix mask>,
                        /* [<more ip addresses>...] */
                    ]
                },
                /* [<more sessions>... ] */
            ]
        },
        /* [<more peers>...] */
    ]
}
```

When a packet from the VF does not match any existing flows, this table defines the physical peer which should provide the tunnel to the given (virtual) src-ip, dst-ip 2-tuple.

Example JSON:

Json config

```
{
    "config": {
        "local-grpc-address": "10.237.113.143:3000"
    },
    "peers": [
        {
            "remote-grpc-address": "10.237.113.144",
```

```
            "sessions": [
                {
                    "local-vip": "6.6.6.5",
                    "remote-vips": [
                        "8.8.8.0/24",
                        "7.7.7.7"
                    ]
                },
                {
                    "local-vip": "6.6.6.4",
                    "remote-vips": [
                        "9.9.9.9"
                    ]
                }
            ]
        },
        {
            "remote-grpc-address": "10.237.1.1",
            "sessions": [
                {
                    // "local vip" not present - default value from vf interface's IP (Must run application with
"--vf-name" param)
                    "remote-vips": [
                        "11.11.11.11/24"
                    ]
                }
            ]
        }
    ]
}
```

6.16.5.5 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.16.6 Application Code Flow

1. Main loop code flow
    a. Initialize the logger facility.
        i. The standard logger and the SDK logger are created, and the SDK logger default log level is selected.

```
doca_log_backend_create_standard();
doca_log_backend_create_with_file_sdk(stdout, &sdk_log);
doca_log_backend_set_sdk_level(sdk_log, DOCA_LOG_LEVEL_WARNING);
```

        ii. The signal handler is connected to enable a clean shutdown.

```
signal(SIGINT, signal_handler);
signal(SIGTERM, signal_handler);
```

    b. Parse application arguments. The main function invokes `psp_gw_argp_exec()`, which initializes the arg parser resources and registers DOCA general parameters, and then registers the PSP application-specific parameters. Then the parser is invoked.

```
doca_argp_init();
psp_gw_register_params();
doca_argp_start();
```

c. Parse input configuration JSON file. This will include all information about peers and their sessions.

```
psp_gw_parse_config_file();
```

d. DPDK initialization. Call `rte_eal_init()` to initialize EAL resources with the provided EAL flags for not probing the ports (`-a00:0.0`).

```
rte_eal_init(n_eal_args, (char **)eal_args);
```

e. Initialize devices and ports.
   i. Open DOCA devices with input PCIe addresses/interface names.
   ii. Probe DPDK port from each opened device.

```
open_doca_device_with_pci(...); // not part of doca_flow; see doca/samples/common.c
doca_dpdk_port_probe(...);
```

   iii. The MAC and IP addresses of the PF are queried and logged.

```
rte_eth_macaddr_get(...);
doca_devinfo_get_ipv6_addr(...);
DOCA_LOG_INFO("Port %d: Detected PF mac addr: %s, IPv6 addr: %s, total ports: %d", ...);
```

f. Initialize and start DPDK ports. Initialize DPDK ports, including mempool allocation. No hairpin queues are created.

```
dpdk_queues_and_ports_init(); // not part of doca_flow; see doca/applications/common/dpdk_utils.c
```

g. Initialize DOCA Flow objects used by the PSP Gateway application. The DOCA Flow library is initialized with the string `"switch,hws,isolated,expert"`, because it is desirable for the application to act as an intermediary between the uplink physical port and some number of VF representors (switch mode), and `hws` (hardware steering mode) and `isolated` mode are mandatory for switch mode. The optional `expert` flag prevents DOCA Flow from automating certain packet operations and gives more control to the application, as described in the DOCA Flow page.

```
PSP_GatewayFlows psp_flows(&pf_dev, vf_port_id, &app_config);
psp_flows.init();
```

   i. Initialize DOCA Flow library.
   ii. Start the ports.
   iii. Allocate shared resources (PSP crypto objects and Mirror actions).
   iv. Create the ingress and egress pipes.

h. Create the gRPC service.

```
PSP_GatewayImpl psp_svc(&app_config, &psp_flows);
```

i. Launch the L-Core threads to handle RSS packets.

```
rte_eal_remote_launch(lcore_pkt_proc_func, &lcore_params, lcore_id);
```

j. Launch the gRPC service.

i. This implementation uses `InsecureServerCredentials`. Update as needed.

```
grpc::ServerBuilder builder;
builder.AddListeningPort(server_address, grpc::InsecureServerCredentials());
builder.RegisterService(&psp_svc);
auto server_instance = builder.BuildAndStart();
```

k. Wait for traffic. If configured to connect at startup, process the list of remaining connections. Then display the flow pipe counters.

```
while (!force_quit) {
    psp_svc.try_connect(remotes_to_connect, local_vf_addr);
...
    psp_flows.show_static_flow_counts();
    psp_svc.show_flow_counts();
}
```

- Wait in a loop until the user terminates the program.

l. PSP Gateway cleanup:

i. Destroy DPDK ports and queues.

```
dpdk_queues_and_ports_fini();
```

ii. DPDK finish.

```
dpdk_fini();
```

Calls `rte_eal_destroy()` to destroy initialized EAL resources.

iii. Arg parser destroy.

```
doca_argp_destroy()
```

2. Miss-packet code flow.

a. The L-Core launch routine from the main loop pointed to the `lcore_pkt_proc_func` routine.

b. The `force_quit` flag is polled to respond to the signal handler.

```
while (!*params->force_quit) { ... }
```

c. The `rte_eth_rx_burst` function polls the PF queue for received packets.

```
nb_rx_packets = rte_eth_rx_burst(port_id, queue_id, rx_packets, MAX_RX_BURST_SIZE);
```

d. Inside `handle_packet()`, the packet metadata is inspected to detect whether this packet is sampled on ingress, sampled on egress, or a miss packet.

```
uint32_t pkt_meta = rte_flow_dynf_metadata_get(packet);
```

   i. Sampled packets are simply logged using the `rte_pktmbuf_dump` function.

e. Miss packets are passed to the `handle_miss_packet` method of the gRPC service. This method handles cases where an application attached to the VF wishes to send a packet to another virtual address, but a PSP tunnel must first be established by exchanging SPI and key information between hosts.

f. The service acts as a gRPC client, and the appropriate server is looked up from the `config->net_config.hosts` vector, which is comprised of hosts passed via the `-t` tunnels arguments or the `-f` tunnels file argument.

g. Once the client connection exists, the `request_tunnel_to_host` method takes care of invoking the the `RequestTunnelParams` operation defined in the schema.

   - Optionally, this function generates a corresponding set of tunnel parameters appropriate for the server host to send traffic back via `generate_tunnel_params()`.

```
doca_flow_crypto_psp_spi_key_bulk_generate(bulk_key_gen);
doca_flow_crypto_psp_spi_key_bulk_get(bulk_key_gen, 0, &spi, key);
doca_flow_crypto_psp_spi_key_wipe(bulk_key_gen, 0);
```

h. The RPC operation is invoked, and if successful, `create_tunnel_flow` is called to create the egress flow:

```
status = stub->RequestTunnelParams(&context, request, &response);
```

i. The `create_tunnel_flow` method translates the resulting Protobuf objects to application-specific data structures and passes them to the `add_encrypt_entry` method of the flows object. Here, the PSP SPI and key are programmed into an available `crypto_id` index as follows.

SPI and `crypto_id` are two independent concepts:

- The SPI value in the PSP packet header indicates to the receiver which key was used by the sender to encrypt the data. Each receiver computes an SPI and key to provide to a sender. Since each receiver is responsible for tracking its next SPI, multiple receivers may provide the same SPI to a sender, so one sender may send the same SPI to multiple different peers. This is allowed, as each of the receiving peers has its own decryption key to handle that SPI.

- The `crypto_id` acts as an index into the bucket of PSP keys allocated by DOCA Flow. The `doca_flow_shared_resource_cfg()` function writes a given PSP encryption key to a given slot in the bucket of keys in NIC memory. These slots can be overwritten as needed by the application.
- There is no explicit association between `crypto_id` and SPI. The `doca_flow_shared_resource_cfg()` function writes a key at the slot provided by the `crypto_id` argument, then the flow pipe entry `actions.crypto.crypto_id` references this key, and `actions.crypto_encap.encap_data` includes a PSP header with the desired SPI.

```
struct doca_flow_shared_resource_cfg res_cfg = {};
res_cfg.domain = DOCA_FLOW_PIPE_DOMAIN_SECURE_EGRESS;
res_cfg.psp_cfg.key_cfg.key_type = DOCA_FLOW_CRYPTO_KEY_256;
res_cfg.psp_cfg.key_cfg.key = (uint32_t *)encrypt_key;
doca_flow_shared_resource_cfg(DOCA_FLOW_SHARED_RESOURCE_PSP, session->crypto_id, &res_cfg);
```

j. A flow pipe entry which references the newly programmed PSP encryption key (via its index `crypto.crypto_id`) must be inserted. Additionally, this pipe entry must specify all the outer Ethernet, IP, UDP, and PSP header fields to insert.

```
format_encap_data(session, actions.crypto_encap.encap_data);
actions.crypto.action_type = DOCA_FLOW_CRYPTO_ACTION_ENCRYPT;
actions.crypto.resource_type = DOCA_FLOW_CRYPTO_RESOURCE_PSP;
actions.crypto.crypto_id = session->crypto_id;
...

doca_flow_pipe_add_entry(pipe_queue, pipe, match, actions, mon, fwd, flags, &status, entry);
...

doca_flow_entries_process(port, 0, DEFAULT_TIMEOUT_US, num_of_entries);
```

k. The original packet received via `rte_ethdev_rx_burst` is sent back through the newly updated pipelines via `rte_ethdev_tx_burst`. Since the `port_id` argument is that of the PF, and since DOCA Flow has been initialized in `expert` mode, the packet is transferred to the root of the egress domain (the "empty pipe" before `egress_acl_pipe`).

```
nsent = rte_eth_tx_burst(port_id, queue_id, &packet, 1);
```

3. Tunnel parameter request handling
   a. The gRPC service provided by the PSP Gateway implements the `RequestTunnelParams` operation referenced above. A client uses this operation to request an SPI and key to encrypt traffic to send to the server's NIC device. The request indicates the virtual remote address for which the tunnel will be created.

b. This operation begins by generating a new SPI and key inside `generate_tunnel_params()` as described previously.
c. The operation creates an ACL entry permitting the new SPI and the remote virtual address using the `add_ingress_acl_entry` method of the Flows object.

```
doca_flow_match match = {};
match.parser_meta.psp_syndrome = 0;
match.tun.type = DOCA_FLOW_TUN_PSP;
match.tun.psp.spi = RTE_BE32(session->spi_ingress);
match.inner.l3_type = DOCA_FLOW_L3_TYPE_IP4;
match.inner.ip4.src_ip = session->src_vip;
...

doca_flow_pipe_add_entry(pipe_queue, pipe, match, actions, mon, fwd, flags, &status, entry);
...

doca_flow_entries_process(port, 0, DEFAULT_TIMEOUT_US, num_of_entries);
```

d. If the request included parameters for traffic in the reverse direction (traffic to encrypt and send to the client), these parameters are translated and passed to the Flows object by calling `create_tunnel_flow` described above.

6.17 DOCA Secure Channel Application Guide

This guide provides a secure channel implementation on top of NVIDIA® BlueField® DPU.

6.17.1 Introduction

The DOCA Secure Channel reference application leverages the DOCA Comch API which creates a secure, network independent communication channel between the host and the NVIDIA BlueField DPU.

Comch allows the host to control services on the DPU, activate certain offloads, or exchange messages using client-server/producer-consumer framework.

The client (host) side can communicate only with one server at a time while the server side is able to communicate with multiple clients.

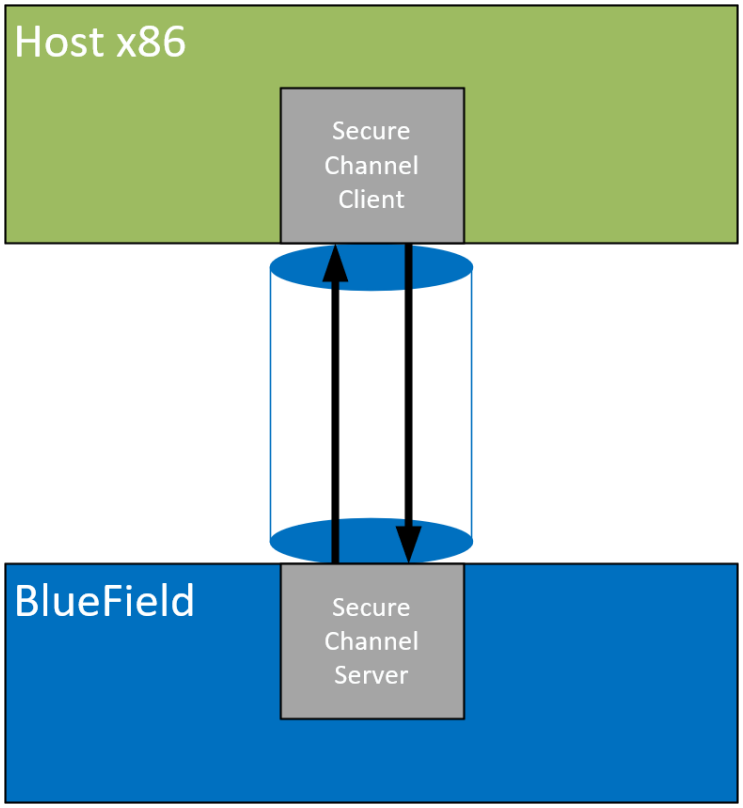
The API allows communication between any PF/VF/SF on the host to the server located on the DPU.

Once a client-server connection is established, multiple producer-consumer instances can be spawned to transfer large amount of data in a first-in-first-out (FIFO) style queue.

Secure channel allows the user to select the message size and amount to be exchanged between the client and the server to simulate heavy load on the channel.

6.17.2 System Design

A secure channel application runs on client mode (host) and server mode (DPU). Once a channel is open, messages can flow from both sides.



6.17.3 Application Architecture

The secure channel application runs on top of the DOCA Comch API.

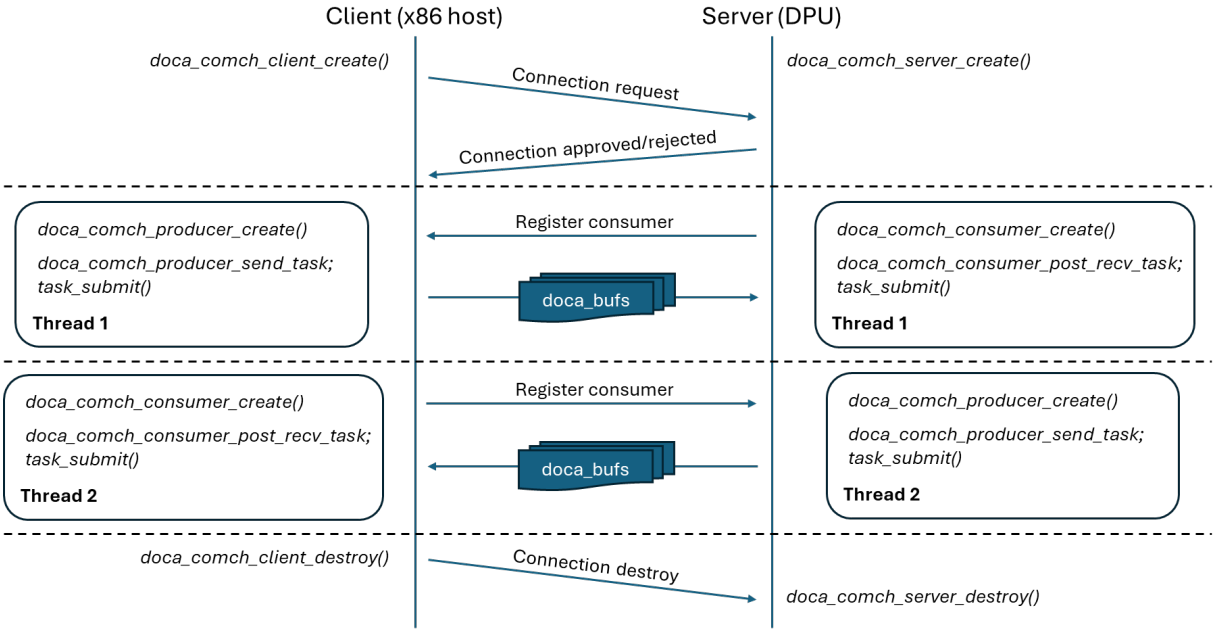
The application begins by establishing a client-server connection between host (client) and DPU (server). Once this connection is established, the application on both sides spawns two new threads:

- Consumer – The consumer thread registers a number of `post_recv` buffers with the opposite end of the connection
- Producer – The producer thread, after it detects the consumer, populates these `post_recv` buffers with data that can then be read by the consumer

Once the consumer has processed a received buffer, the buffer is reposted (via task submit) to again be populated by the opposite producer.

When the producer has sent the requested number of messages, and the consumer has received the same amount, both threads exit and the main client-server connection is destroyed.

The flow is described in the following diagram:



6.17.4 DOCA Libraries

This application leverages the following DOCA library:

- DOCA Comch

Refer to its respective programming guide for more information.

6.17.5 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/secure_channel/
```

6.17.5.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_secure_channel` is created under `/tmp/build/secure_channel/`.

6.17.5.2 Compiling Only the Current Application

To directly build only the secure channel application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_secure_channel=true
ninja -C /tmp/build
```

`doca_secure_channel` is created under `/tmp/build/secure_channel/`.

Alternatively, users can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_secure_channel` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_secure_channel` is created under `/tmp/build/secure_channel/`.

6.17.6 Running the Application

6.17.6.1 Application Execution

The secure channel application is provided in source form. Therefore, a compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_secure_channel [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -s, --msg-size                    Message size to be sent
  -n, --num-msgs                    Number of messages to be sent
  -p, --pci-addr                    DOCA Comm Channel device PCI address
  -r, --rep-pci                     DOCA Comm Channel device representor PCI address (needed only on DPU)
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_secure_channel -h
```

For additional information, refer to section "Command Line Flags".

- CLI example for running the application on the BlueField:

```
./doca_secure_channel -s 256 -n 10 -p 03:00.0 -r 3b:00.0
```

> Both the DOCA Comch device PCIe address (`03:00.0`) and the DOCA Comch device representor PCIe address (`3b:00.0`) should match the addresses of the desired PCIe devices. Users may use the DOCA Capabilities Print Tool to find out their device and device representor PCIe addresses.

- CLI example for running the application on the host:

```
./doca_secure_channel -s 256 -n 10 -p 3b:00.0
```

> The DOCA Comch device PCIe address (`3b:00.0`) should match the address of the desired PCIe device.

6.17.6.2 Command Line Flags

6.17.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.17.6.2.2 Program Flags

Short Flag	Long Flag	Description
`s`	`msg-size`	Message size in bytes ⚠ This is a mandatory flag.
`n`	`num-msgs`	Number of messages to send on both sides ⚠ This is a mandatory flag.
`p`	`pci-addr`	DOCA Comch device PCIe address ⚠ This is a mandatory flag.
`r`	`rep-pci`	DOCA Comch device representor PCIe address ⚠ This is a mandatory flag only on the DPU.

6.17.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.17.7 Application Code Flow

1. Parse application argument.
    a. Initialize the arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

    b. Register secure channel application parameters.

```
register_secure_channel_params();
```

    c. Parse application parameters:

```
doca_argp_start();
```

d. Establish the client-server control path connection:

```
comch_utils_fast_path_init();
```

i. Create a `doca_comch_client` or `doca_comch_server` depending on where the application is run (x86 host or DPU Arm cores).
ii. Register a callback which is triggered when new consumers are created on the opposite end.
iii. Progress the connection until it becomes established.

2. Run main logic.

```
sc_start();
```

a. Send a message on the control channel telling the opposite end how many fastpath messages it intends to send and their length.
b. Wait to receive a similar message from the opposite side.
c. Start a producer thread:
i. Create and starts a `doca_comch_producer`.
ii. Wait until a consumer has been registered from the opposite end of the control channel.
iii. Create a `doca_buf` of input message length to send repeatedly.
iv. Submit the max number of `doca_comch_producer_task_send` tasks each containing the `doca_buf`.
v. Resubmit each task from its completion callback until the requested number of tasks are sent.
vi. Destroy producer and ends thread.
d. Start a consumer thread
i. Create and starts a `doca_comch_consumer`.
ii. Progress until consumer has been fully registered with the control channel connection.
iii. Create `doca_buf`s of negotiated size to receive data on.
iv. Submit the max number of `doca_comch_consumer_task_post_recv` tasks with each of the allocated `doca_buf`s.
v. Resubmit each `post_recv` buffer from its callback when it has been populated by a producer.
vi. Destroy consumer and thread when it has received the communicated number of fastpath messages.
e. Sends (DPU) or waits (host) on a message to indicate that all fastpath messages have completed and the Comch control connection can be destroyed.

6.18 DOCA Simple Forward VNF Application Guide

This guide provides a Simple Forward implementation on top of NVIDIA® BlueField® DPU.

6.18.1 Introduction

Simple forward is a forwarding application that leverages the DOCA Flow API to take either VXLAN, GRE, or GTP traffic from a single RX port and transmits it on a single TX port.

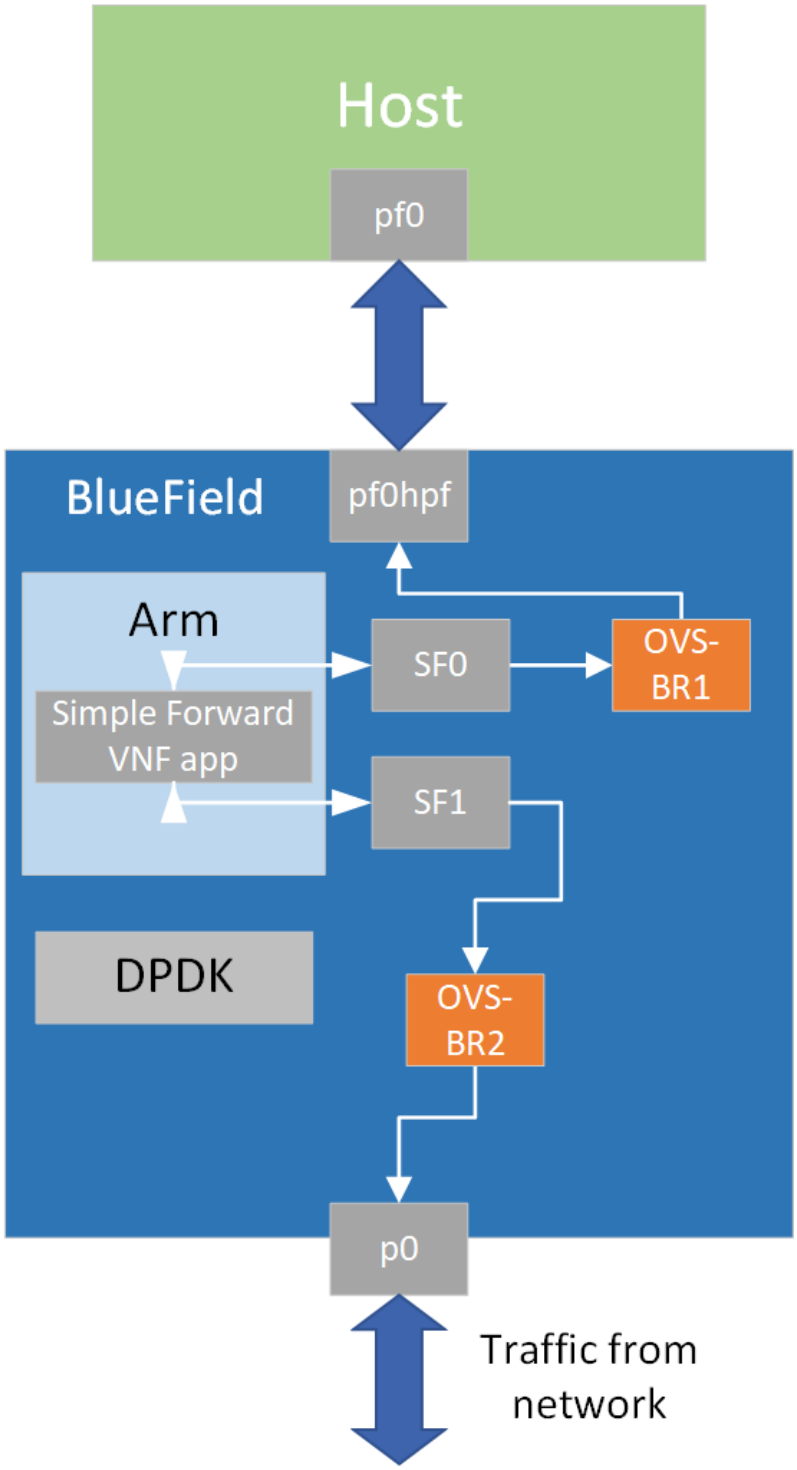
For every packet received on an RX queue on a given port, DOCA Simple Forward checks the packet's key, which consists of the inner 5-tuple. If it finds that the packet matches an existing flow, then it does not create a new one. Otherwise, a new flow is created with a FORWARDING component. Finally, the packet is forwarded to the TX queue of the egress port if the "rx-only" mode is not set.

The FORWARDING component type depends on the flags delivered when running the application. For example, if the `hairpinq` flag is provided, then the FORWARDING component would be hairpin. Otherwise, it would be RSS'd to software, and hence every VXLAN, GTP, or GRE packet would be received on RX queues.

Simple forward should be run with dual ports. By using a traffic generator, the RX port receives the VXLAN, GRE, or GTP packets and forwarding forwards them back to the traffic generator.

6.18.2 System Design

The following diagram illustrates simple forward's packet flows. It receives traffic coming from the wire and passes it to the other port.



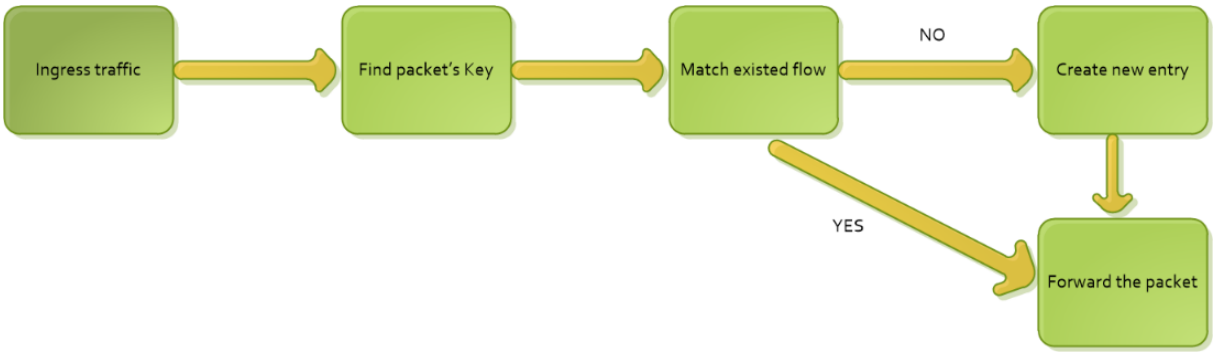
6.18.3 Application Architecture

Simple forward first initializes DPDK, after which the application handles the incoming packets.

The following diagram illustrates the initialization process.

1. `Init_DPDK` – EAL init, parse argument from command line and register signal.
2. Start port – `mbuf_create` , `dev_configure` , rx/tx/hairpin queue setup and start the port.
3. `Simple_fwd INIT` – create flow tables, build default forward pipes.

The following diagram illustrates how to process the packet.



1. Based on the packet's info, find the key values based on the **inner** headers (e.g. src/dst IP, src/dst port, etc).
2. Traverse the inner flow tables, check if the keys exist or not.
    - If yes, update inner counter
    - If no, a new flow table is added to the DPU
3. Forward the packet to the other port.

6.18.4 DOCA Libraries

This application leverages the following DOCA library:

- DOCA Flow

Refer to its respective programming guide for more information.

6.18.5 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/simple_fwd_vnf/
```

6.18.5.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_simple_fwd_vnf` is created under `/tmp/build/simple_fwd_vnf/`.

6.18.5.2 Compiling Simple Forward Application Only

To directly build only the simple forward application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_simple_fwd_vnf=true
ninja -C /tmp/build
```

`doca_simple_fwd_vnf` is created under `/tmp/build/simple_fwd_vnf/`.

Alternatively, users can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_simple_fwd_vnf` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_simple_fwd_vnf` is created under `/tmp/build/simple_fwd_vnf/`.

6.18.6 Running the Application

6.18.6.1 Prerequisites

1. A FLEX profile number should be manually set to 3 on the system for the application to build the GRE, standard VXLAN and GRE pipes.
   a. Set FLEX profile number to 3 from the DPU.

   ```
   sudo mlxconfig -d <pcie_address> s FLEX_PARSER_PROFILE_ENABLE=3
   ```

   b. Perform a BlueField system reboot for the `mlxconfig` settings to take effect.

   Resetting the firmware can be done from the BlueField as well. For more information, refer to step 3.b of the "Upgrading Firmware" section of the DOCA Installation Guide for Linux.

2. The Simple Forward application is based on DOCA Flow. Therefore, the user is required to allocate huge pages.

```
$ echo '2048' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

6.18.6.2 Application Execution

The simple forward application is provided in source form. Therefore, a compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_simple_fwd_vnf [DPDK Flags] -- [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                      Print a help synopsis
  -v, --version                   Print program version information
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                    Filter logs from specific modules, separated by comma
  -j, --json <path>               Parse command line flags from an input json file
```

```
Program Flags:
  -a, --device                    device
  -r, --rep                       device representor
  -t, --stats-timer <time>        Set interval to dump stats information
  -q, --nr-queues <num>           Set queues number
  -rx, --rx-only                  Set rx only
  -o, --hw-offload                Set PCI address of the RXP engine to use
  -hq, --hairping                 Set forwarding to hairpin queue
  -g, --age-thread                Start thread to do aging
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_simple_fwd_vnf -- -h
```

For additional information, refer to section "Command Line Flags".

- CLI example for running the application on the BlueField:

```
./doca_simple_fwd_vnf -- -a aux/4 -a aux/5 -l 60
```

SFs must be enabled according to the BlueField Scalable Function User Guide.

Before creating SFs on a specific physical port, it is important to verify the encap mode on the respective PF FDB. The default mode is `basic`. To check the encap mode, run:

```
cat /sys/class/net/p0/compat/devlink/encap
```

In this case, disable encap on the PF FDB before creating the SFs by running:

```
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode legacy
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode legacy
echo none > /sys/class/net/p0/compat/devlink/encap
echo none > /sys/class/net/p1/compat/devlink/encap
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.0 mode switchdev
/opt/mellanox/iproute2/sbin/devlink dev eswitch set pci/0000:03:00.1 mode switchdev
```

If the encap mode is set to `basic` then the application fails upon initialization.

The flag `-a aux/4 -a aux/5` is mandatory for proper usage of the application.

a. Modifying this flag will result in an unexpected behavior as only 2 ports are supported.
b. The SF number is arbitrary and configurable.

The SF numbers must match the desired SF devices.

- CLI example for running the application on the host:

```
./doca_simple_fwd_vnf -- -a pci/04:00.3 -a pci/04:00.4 -l 60
```

The device identifiers must match the desired network devices.

For additional information regarding the command line syntax of the device and device representor identifiers, please referr to the matching section in the DOCA Arg Parser Guide.

For more information, refer to section "Running DOCA Application on Host" in DOCA Virtual Functions User Guide.

6.18.6.3 Command Line Flags

6.18.6.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma

Short Flag	Long Flag	Description
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.18.6.3.2 Host Program Flags

Short Flag	Long Flag	Description
`a`	`device`	Device identifier
`r`	`rep`	Device representor identifiers
`t`	`stats-timer`	Set interval to dump stats information.
`q`	`nr-queues`	Set queues number.
`rx`	`rx-only`	Set RX only. When set, the packets will not be sent to the TX queues.
`o`	`hw-offload`	Set HW offload of the RXP engine to use.
`hq`	`hairpinq`	Set forwarding to hairpin queue.
`g`	`age-thread`	Start a dedicated thread that handles the aged flows.

6.18.6.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.18.7 Application Code Flow

1. Parse application argument.
   a. Initialize arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

   b. Register application parameters.

```
register_simple_fwd_params();
```

   c. Parse the arguments.

```
doca_argp_start();
```

   i. Parse DPDK flags and invoke handler for calling the `rte_eal_init()` function.
   ii. Parse app parameters.

2. DPDK initialization.

```
dpdk_init();
```

   Calls `rte_eal_init()` to initialize EAL resources with the provided EAL flags.

3. DPDK port initialization and start.

```
dpdk_queues_and_ports_init();
```

   a. Initialize DPDK ports.
   b. Create mbuf pool using `rte_pktmbuf_pool_create`.
   c. Driver initialization – use `rte_eth_dev_configure` to configure the number of queues.
   d. Rx/Tx queue initialization – use `rte_eth_rx_queue_setup` and `rte_eth_tx_queue_setup` to initialize the queues.
   e. Rx hairpin queue initialization – use `rte_eth_rx_hairpin_queue_setup` to initialize the queues.
   f. Start the port using `rte_eth_dev_start`.

4. Simple forward initialization.

```
simple_fwd_init();
```

   a. `simple_fwd_create_ins` – create flow tables using `simple_fwd_ft_create`.
   b. `simple_fwd_init_ports_and_pipes` – initialize DOCA port using `simple_fwd_init_doca_port` and build default pipes for each port.

5. Main loop.

```
simple_fwd_process_pkts();
```

   a. Receive packets using `rte_eth_rx_burst` in a loop.
   b. Process packets using `simple_fwd_process_offload`.
   c. Transmit the packets on the other port by calling `rte_eth_tx_burst`. Or free the packet mbuf if `rx_only` is set to `true`.

6. Process packets.

```
simple_fwd_process_offload();
```

   a. Parse the packet's `rte_mbuf` using `simple_fwd_pkt_info`.
   b. Handle the packet using `simple_fwd_handle_packet`. If the packet's key does not match the existed the flow entry, create a new flow entry and PIPE using `simple_fwd_handle_new_flow`. Otherwise, increase the total packet's counter.

7. Simple forward destroy.

```
simple_fwd_destroy();
```

   Simple forward close port and clean the flow resources.

8. DPDK ports and queues destruction.

```
dpdk_queues_and_ports_fini();
```

9. DPDK finish.

```
dpdk_fini();
```

   Calls `rte_eal_destroy()` to destroy initialized EAL resources.

10. Arg parser destroy.

```
doca_argp_destroy();
```

    - Free DPDK resources by call `rte_eal_cleanup()` function.

6.19 DOCA SNAP Virtio-fs Application Guide

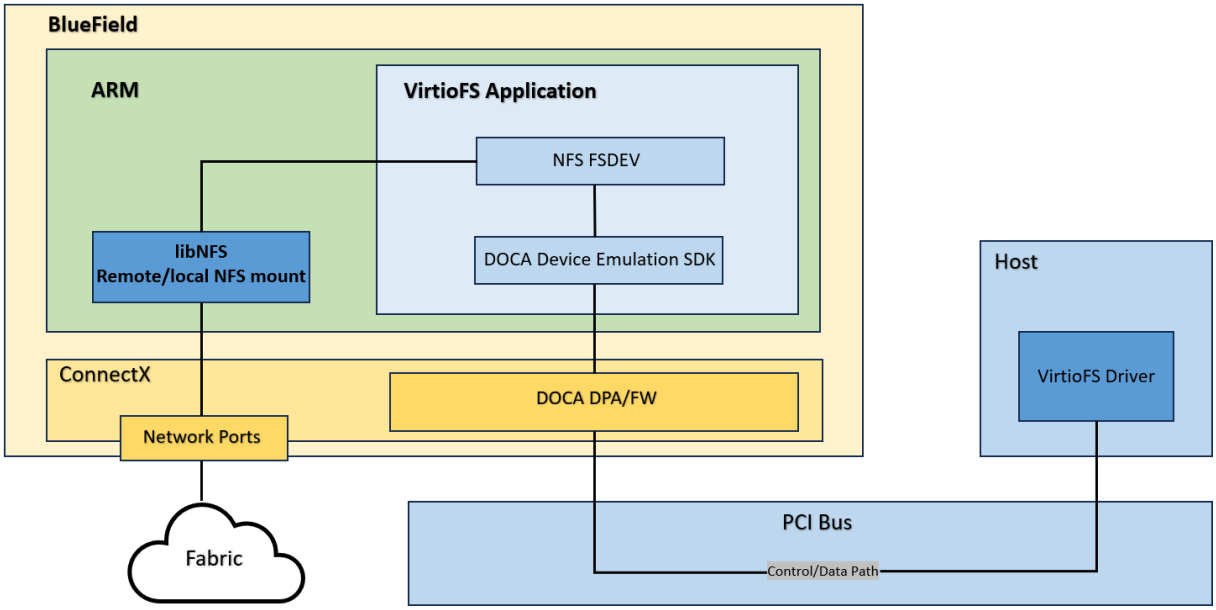
This guide describes the DOCA SNAP Virtio-fs Application which leverages DOCA DevEmu APIs and NFS backends via libnfs to provide high-performance, hardware-accelerated file system emulation.

> ⚠ This feature is currently supported at alpha level.

6.19.1 Introduction

The DOCA SNAP Virtio-fs Application demonstrates how to use the DOCA DevEmu PCI Generic API to emulate a virtio-fs PCIe function, enabling hardware-accelerated file system emulation on the BlueField DPU. This solution offloads virtio-fs handling from the host, facilitating seamless remote file access via NFS.

6.19.2 System Design



6.19.2.1 Host Side (Virtio-fs Client Driver)

- Runs a standard virtio-fs client driver in the host operating system.
- Host applications issue file system operations (e.g., open, read, write, mkdir).
- The virtio-fs driver translates these into virtio-fs protocol I/O requests.

6.19.2.2 BlueField DPU (DOCA SNAP Virtio-fs Application)

- Runs the DOCA SNAP Virtio-fs Application.
- Retrieves virtio-fs I/O requests from the host via Virtio queues.
- Decodes the requests into file operations (lookup, getattr, read, write, mkdir, etc.).
- Translates file operations into NFS requests using libnfs APIs (based on libnfs4).

6.19.2.3 Network Communication (libnfs)

- Communicates with a local or remote NFS server using libnfs over TCP.
- Executes file operations remotely on the NFS server.
- Receives responses from the NFS server and returns them to the host.

6.19.2.4 NFS Server

- Receives NFS requests (read, write, getattr, mkdir, etc.) sent by libnfs.
- Performs I/O operations on local storage.
- Sends responses back to the DPU, which forwards them to the host through virtio-fs.

6.19.2.5 End-to-End Flow

1. Host application initiates a file system operation.
2. Virtio-fs client driver sends a request to the DPU.
3. The DPU processes the request and forwards it to the NFS server via libnfs.
4. The NFS server executes the request and returns the result.
5. The DPU sends the result back to the host through virtio-fs.

This architecture offloads file system emulation from the host to the DPU, bridging virtio-fs requests to remote storage using the NFS protocol.

6.19.3 Application Architecture

Virtio-fs is a virtualization file system designed for efficient and secure file sharing between a host and guest VMs. It uses the Virtio framework to establish a high-performance communication channel, bypassing traditional network-based file system protocols to improve throughput and reduce latency.

Virtio-fs maps files and directories from a host or remote storage system into the guest's address space, achieving near-native file system performance over TCP protocol only.

Virtio-fs emulation allows this functionality to be simulated in virtualized or development environments without the need for dedicated hardware devices.

6.19.3.1 Virtio-fs Protocol Components

6.19.3.1.1 FUSE (Filesystem in Userspace)

Virtio-fs uses the FUSE protocol to forward file system operations from the guest VM to the host. Key FUSE operations include:

- LOOKUP – Resolves file names and retrieves attributes.
- GETATTR – Fetches file metadata.
- READ/WRITE – Performs I/O operations.
- MKDIR/MKNOD/UNLINK – Manages file and directory creation and deletion.

6.19.3.1.2 Virtio Queues

Virtio-fs employs request and response queues to communicate between guest and host:

- Request queue – The guest places file system operation requests.
- Response queue – The host returns operation results or error statuses.

6.19.3.2 Initialization Process

The virtio-fs initialization process involves:

1. Setting up virtio-fs request and response queues.
2. Establishing shared memory regions for efficient data transfer.
3. Negotiating feature capabilities between guest and host.
4. Mounting the shared filesystem into the guest environment.

6.19.3.3 libnfs Integration

While virtio-fs typically interfaces with local host storage, integrating libnfs enables seamless file sharing with remote NFS targets. libnfs provides a user-space NFS client implementation, allowing the DOCA SNAP Virtio-fs Application to translate virtio-fs requests into NFS protocol operations.

6.19.3.4 File Operations Workflow

1. Guest VM submits a file system request (e.g., open, read).
2. Virtio-fs forwards the request to the host via the Virtio request queue.

3. The DPU processes the request and uses libnfs to communicate with the NFS server.
4. The NFS server executes the file operation and returns the result to the DPU.
5. The DPU forwards the response to the guest VM via the Virtio response queue.

6.19.3.5 Reset and Shutdown

Proper reset and shutdown procedures ensure file system integrity and resource cleanup:

- Reset – Reinitializes Virtio queues and shared memory regions without affecting persistent data.
- Shutdown – Gracefully terminates file operations, ensuring all pending transactions are flushed and committed.

6.19.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Comch

For additional information about the used DOCA libraries, please refer to the respective programming guides.

6.19.5 Dependencies

The following software components are required to build and run the DOCA SNAP Virtio-fs Application:

- BlueField-3 DPU
- libnfs 4.0.0-1 for the FSDEV backend: https://packages.debian.org/bullseye/libnfs-dev. Install using the following command:

```
sudo apt update && sudo apt install -y libnfs-dev
```

In some setups, the following dependencies may be missing and must be installed before compiling the application:

- `libjson-c-dev`
- `libjsoncpp-dev`

6.19.5.1 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information on DOCA applications, development workflows, and build guidance, see the DOCA Reference Applications documentation page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/virtiofs/
```

6.19.5.2 Compiling All Applications

All DOCA reference applications are part of a unified meson project. By default, building the project compiles all available applications.

To build all applications:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_virtiofs` is created under `/tmp/build/virtiofs/`

6.19.5.3 Compiling Only the Current Application

To build only the virtio-fs application, use the following command to disable all other applications:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_virtiofs=true
ninja -C /tmp/build
```

`doca_virtiofs` is created under `/tmp/build/virtiofs/`.

Alternatively, you can configure build flags directly in the `meson_options.txt` file rather than passing them as command-line arguments:

1. Edit the following file `/opt/mellanox/doca/applications/meson_options.txt`.
2. Modify the flags:
    - Set `enable_all_applications` to `false`
    - Set `enable_virtiofs` to `true`
3. Run the standard build commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> `doca_virtiofs` is created under `/tmp/build/virtiofs/`

6.19.6 Running the Application

6.19.6.1 Prerequisites

- Enable the firmware configuration with virtio-fs emulation PF. A cold reboot is required after updating the firmware configuration:

```
[dpu] mlxconfig -d /dev/mst/mt41692_pciconf0 s VIRTIO_FS_EMULATION_ENABLE=1 VIRTIO_FS_EMULATION_NUM_PF=1
```

- This application is based on DOCA Flow and requires huge page allocation. Ensure huge pages are configured on the system.

> The application is not supported on OSs with huge page size greater than 2MB.

- To skip reads and writes to the backend file system, set the environment variable `DOCA_VIRTIOFS_USE_NULL_NFS_FSDEV=1`.
- The application supports a single static PF with hardcoded values for `num_request_queues` (32), `queue_size` (256), and `tag` (`docavirtiofs`). These values can be modified in the `virtiofs_device_create_static()` function before compiling the application.
- Configure a local or remote mounted NFS target over TCP.
    - Remote NFS server example:

```
sudo apt install nfs-kernel-server
echo "/export/data 10.245.16.0/24(rw,sync,no_subtree_check,insecure)" >> /etc/exports
sudo systemctl start nfs-kernel-server.service
```

- Local NFS server example:

```
apt-get install nfs-kernel-server
mkdir /VIRTUAL
echo "/VIRTUAL 127.0.0.1(rw,no_root_squash,insecure,no_subtree_check,sync)" >> /etc/exports
service nfs-kernel-server restart
```

6.19.6.2 Application Execution

This application is provided in source form; therefore, compilation is required before execution. Refer to the "Compiling the Application" section for build instructions.

6.19.6.2.1 Application Usage

```
Usage: doca_virtiofs [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -m, --core-mask <core_mask>       Set core mask.
  -s, --nfs-server <nfs_server>     Set NFS server.
  -e, --nfs-export <nfs_export>     Set NFS export.
  -q, --num_request_queues <num_request_queues> Set number of request queues to be used. (Range [1,254], Default:
32)
```

Use the `-h` or `--help` flag to print this usage information at runtime:

```
./doca_virtiofs -h
```

For additional information, refer to the "Command Line Flags" section.

6.19.6.2.2 Example Command Line Execution

- To run the application on BlueField with the default values presented in this table:

```
./doca_virtiofs
```

Long Flag	Description	Default content
`num-cores`	Application core mask	`"0x1"`
`nfs-server`	Local or remote NFS server IP.	`"localhost"`
`nfs-export`	`Local or remote NFS export folder.`	`"/VIRTUAL"`

- To run the application on BlueField with a specified core mask, NFS server, and export path:

```
./doca_virtiofs -m 0xff -s 1.1.1.11 -e /export/data
```

> There is a known issue with hugepage memory management on Ubuntu 24.04 when using 512 MB hugepages. In this configuration, the application supports up to 5 cores only.

6.19.6.2.3 JSON-Based Deployment Mode

The application also supports JSON-based configuration for deployment. All parameters can be provided via a JSON file:

```
./doca_virtiofs --json [json_file]
```

For example:

```
./doca_virtiofs --json ./virtiofs_params.json
```

> Ensure the JSON file includes the correct configuration parameters, particularly the NFS parameters required for deployment.

6.19.6.2.4 Mounting the Virtio-fs Device (Host/VM Side)

To mount the virtio-fs device from the host or guest VM:

1. Create a mount point and load the `virtiofs` module (if not already loaded):

```
mkdir /tmp/test
modprobe -v virtiofs
mount -t virtiofs docavirtiofs /tmp/test
```

2. To unmount and clean up:

```
umount /tmp/test
modprobe -rv virtiofs
```

6.19.6.3 Command Line Flags

6.19.6.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.19.6.3.2 Host Program Flags

Short Flag	Long Flag/JSON Key	Description	JSON Content
`m`	`num-cores`	Application core mask	`"num-cores": "0x1",`
`s`	`nfs-server`	Local or remote NFS server IP.	`"nfs-server": "localhost",`

Short Flag	Long Flag/JSON Key	Description	JSON Content
`e`	`nfs-export`	Local or remote NFS export folder.	`"nfs-export": "/VIRTUAL",`

6.19.6.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.19.7 Application Code Flow

This section provides a comprehensive guide to implementing a virtio-fs device emulation application using the DOCA library. The DOCA Virtio-fs Reference Application demonstrates how to leverage hardware acceleration on a Data Processing Unit (DPU) to emulate a fully functional file system storage device, appearing to the host as a standard virtio-fs PCIe device.

The implementation provides hardware-accelerated filesystem emulation, utilizing DPU resources for high-performance operation processing. The multi-threaded architecture, with explicit CPU core affinity, ensures optimal resource utilization and minimizes contention between worker threads. Asynchronous processing throughout the pipeline maintains high throughput by avoiding blocking operations that could degrade system performance.

The design supports basic filesystem functionality, including file and directory operations, metadata management, and data transfers. While the reference implementation uses default configuration values and supports a single device, the underlying architecture is designed for scalability and can be extended to support multiple devices with custom configurations in production environments.

This modular approach allows developers to understand each phase of the application flow independently while appreciating how they integrate into a complete virtio-fs emulation solution using DOCA libraries and hardware acceleration.

6.19.7.1 Framework Initialization

This section outlines the essential APIs and data structures required to initialize the DOCA virtio-fs emulation framework before creating and managing virtio-fs devices.

6.19.7.1.1 Initialization Flow

1. Parse application arguments

- Initialize the argument parser framework using `doca_argp_init()`.
- Register application-specific parameters via a custom function (e.g., `register_application_params()`).
- Store parsed values in a user-defined `struct application_config`.

2. Start argument parsing
   - Parse command-line arguments using `doca_argp_start()`.
   - Validate arguments and populate the configuration structure with parsed values.
3. Create logging backends
   - Configure application log backend using `doca_log_backend_create_standard()`.
   - Set up SDK internal message routing with `doca_log_backend_create_with_file_sdk()`.
   - Adjust SDK log verbosity using `doca_log_backend_set_sdk_level()`.
   - Logging configurations are maintained using `struct doca_log_backend`.
4. Create VFS configuration
   - Create a virtio-fs configuration object using `doca_devemu_vfs_cfg_create()`.
   - The returned `struct doca_devemu_vfs_cfg` will hold framework parameters and the device list.
5. Discover available devices
   - Enumerate DOCA-capable hardware devices using `doca_devinfo_create_list()`.
   - The function returns an array of `struct doca_devinfo` containing device properties and capabilities.
6. Filter supported devices
   - For each discovered device, verify virtio-fs emulation capability using `doca_devemu_vfs_is_default_vfs_type_supported()`.
7. Open supported devices
   - For devices supporting virtio-fs emulation, open device handles using `doca_dev_open()`.
   - This returns `struct doca_dev` handles necessary for subsequent operations.
8. Add devices to configuration
   - Register opened device handles into the virtio-fs configuration object using `doca_devemu_vfs_cfg_add_dev()`.
9. Set framework parameters
   - Configure per-request context size and other framework-specific parameters using `doca_devemu_vfs_cfg_set_vfs_fuse_req_user_data_size()`.
10. Initialize the virtio-fs framework

- Finalize the global framework setup with `doca_devemu_vfs_init()`.
- After this call, the framework assumes ownership of all registered devices.

11. Clean up temporary configuration objects
    - Release the temporary configuration object using `doca_devemu_vfs_cfg_destroy()`.
    - Free device information resources with `doca_devinfo_destroy_list()`, as the framework now owns the devices.

6.19.7.1.2 Key Points

- Resource Ownership – After initialization, the virtio-fs framework takes ownership of all registered device handles.
- Global Initialization – Framework initialization must be performed once per application instance.
- Thread Safety – All initialization procedures should be executed from the main thread before spawning worker threads.

6.19.7.2 Resource Management

This section describes the setup and initialization of core resources required for virtio-fs operation after the framework initialization is complete. These resources include device managers, worker threads, progress engines, memory pools, DMA contexts, and thread-local configurations necessary for high-performance virtio-fs emulation.

6.19.7.2.1 Resource Management Flow

1. Create device managers
    - Retrieve the default virtio-fs emulation type using `doca_devemu_vfs_type_create()`, which returns a `struct doca_devemu_vfs_type`.
    - For each opened device, create a device manager using `doca_devemu_vfs_manager_create()`. Each manager is represented by a `struct doca_devemu_vfs_manager`.
2. Initialize manager list
    - Organize all device managers into a list structure for efficient management.
    - Use application-defined linked list operations (e.g., `SLIST_INIT`, `SLIST_INSERT_HEAD`) to build and maintain the manager list.
    - The list is defined using an application-specific `struct manager_list`.
3. Determine thread configuration

- Calculate the number of worker threads based on the user-specified CPU core mask.
- Use CPU enumeration functions to identify available cores and select which cores to allocate for virtio-fs worker threads.

4. Create worker threads
   - For each designated CPU core, spawn a worker thread using `pthread_create()`.
   - Bind each thread to a specific CPU core using `pthread_setaffinity_np()` to ensure core affinity and minimize resource contention.
   - Thread handles are stored in `pthread_t`, with CPU affinity settings managed via `cpu_set_t`.
5. Initialize progress engines
   - For each worker thread, create a progress engine using `doca_pe_create()`.
   - Connect application contexts to the progress engines with `doca_pe_connect_ctx()` to enable asynchronous operation handling.
   - Progress engine handles are stored in `struct doca_pe`.
6. Set up memory pools
   - Create memory pools for efficient buffer allocation and management using `doca_mpool_create()`.
   - For DMA operations, create buffer inventories using `doca_buf_inventory_create()`.
   - Memory pools and inventories are represented by `struct doca_mpool` and `struct doca_buf_inventory`, respectively.
7. Create DMA contexts
   - Initialize DMA contexts for data transfer operations using `doca_dma_create()`.
   - Configure DMA task parameters, such as memcpy settings, using `doca_dma_task_memcpy_set_conf()`.
   - DMA context handles are maintained using `struct doca_dma`.
8. Configure thread contexts
   - Set up per-thread context structures using application-defined initialization routines.
   - Assign memory pools and DMA contexts to each thread.
   - Configure thread-local storage to maintain isolation and minimize cross-thread contention.
   - Thread-specific data is managed using an application-defined `struct thread_context`.
9. Start worker threads
   - Launch all worker threads using pthread-based startup mechanisms.
   - Each thread enters its main processing loop, where it continuously polls for incoming requests and performs I/O operations.

10. Verify resource readiness
    - Validate that all required resources have been properly initialized:
        - All device managers are created and registered.
        - Worker threads are running and bound to designated CPU cores.
        - Memory pools and DMA contexts are allocated and ready.
        - Progress engines are connected to their corresponding contexts.

6.19.7.2.2 Key Points

- Thread Affinity – Each worker thread must be bound to a dedicated CPU core to ensure optimal performance and minimize scheduling overhead.
- Admin Thread Role – The first worker thread (admin thread) is responsible for device lifecycle operations, such as polling control events, while other threads focus on I/O processing.
- Memory Pool Sizing – Memory pool sizes should be configured based on anticipated workload, queue depths, and expected concurrency levels to prevent allocation bottlenecks.
- Progress Engines – Each worker thread requires its own progress engine to independently handle asynchronous operations and maintain high throughput.
- Resource Isolation – Ensure that threads have isolated resources (e.g., memory pools, DMA contexts) to eliminate cross-thread contention and performance degradation.
- Error Recovery – If resource creation fails at any stage, the application must perform cleanup of already-initialized resources to avoid leaks and maintain system stability.
- Scalability – Resource allocation logic should scale with the number of configured CPU cores, allowing the application to adapt to various deployment environments.

6.19.7.3 Device Configuration

This section describes the process of creating and configuring virtio-fs device instances after the resource management infrastructure is in place. The reference application demonstrates how to emulate a virtio-fs PCIe function using hardware acceleration to fully emulate a file system storage device.

For simplicity, this implementation supports a single virtio-fs device created with default configuration values (number of queues, queue size, filesystem tag). However, the DOCA DevEmu PCI Generic API supports scalable deployments with multiple devices and fully customizable parameters.

6.19.7.3.1 Device Configuration Flow

- Create NFS backend filesystem
  - Initialize the NFS filesystem backend using an application-defined `nfs_fsdev_create()` function, which takes the NFS server address and export path (provided via command-line arguments).
  - The backend must be ready before creating the virtio-fs device, as it will be linked during device instantiation.

    > Backend creation details are provided in the "Backend Integration" section.

- Search for available virtio-fs functions
  - Discover available virtio-fs PCIe functions using `doca_devinfo_rep_create_list()` with the `DOCA_DEVINFO_REP_FILTER_EMULATED` filter.
  - Iterate through the list to find the first available virtio-fs function for device creation.
  - This reference implementation selects the first match for simplicity.
- Create device representors
  - Open the selected representor device using `doca_dev_rep_open()` to establish a communication channel between the DPU and the host.
  - Representor handles are managed via `struct doca_dev_rep`, while representor information is stored in `struct doca_devinfo_rep`.
- Match VUIDs to representors
  - Retrieve the Virtual Unique Identifier (VUID) for each representor using `doca_devinfo_rep_get_vuid()`.
  - Match the VUID against configured values to associate representors with specific virtio-fs virtual functions visible to the host.
- Create virtio-fs devices
  - Instantiate the virtio-fs device using `doca_devemu_vfs_dev_create()`, providing the selected representor, the admin thread's progress engine, and the initialized NFS backend.
  - The resulting device handle is maintained via `struct doca_devemu_vfs_dev`.
- Configure device attributes
  - Set device-specific parameters:
    - Filesystem tag using `doca_devemu_vfs_dev_set_tag()` (default tag in reference implementation).
    - Number of request queues using `doca_devemu_vfs_dev_set_num_request_queues()` (default value).

        - Queue size using `doca_devemu_virtio_dev_set_queue_size()` (default size).
    - In production, these parameters can be customized to meet performance and scaling requirements.
    - Configuration details are maintained in an application-defined `struct device_config`.
- Set up device callbacks
    - Register event handlers for device lifecycle management:
        - Device reset events via `doca_devemu_virtio_dev_event_reset_register()`.
        - PCIe Function Level Reset (FLR) events via `doca_devemu_pci_dev_event_flr_register()`.
        - State change notifications using `doca_ctx_set_state_changed_cb()`.
    - Application-defined callback functions handle these events appropriately.
- Configure virtio properties
    - Specify the number of I/O contexts using `doca_devemu_virtio_dev_set_num_required_running_virtio_io_ctxs()` (should match the number of worker threads).
    - Set the total number of virtqueues using `doca_devemu_virtio_dev_set_num_queues()`, including request queues and a high-priority queue for metadata operations.
- Initialize device contexts
    - Allocate per-device context structures using application-defined initialization functions.
    - Link the virtio-fs device with its assigned device manager and NFS backend.
    - These contexts maintain the association between virtio-fs emulation and underlying storage.
- Validate device configuration
    - Ensure all device parameters are correctly configured:
        - Queue sizes within hardware limits.
        - Filesystem tags properly formatted.
        - VUIDs correspond to valid virtual functions.
        - All required event callbacks are registered.
    - Validation prevents runtime misconfiguration and operational failures.
- Add devices to global list
    - Register the configured device into the application's global device list using linked list operations (`SLIST_INSERT_HEAD`).
    - Maintain counters for tracking active devices.
    - Although this reference supports a single device, the infrastructure allows scaling to multiple devices.
- Prepare for device startup
    - Set the initial device state to "stopped."

- Store startup callback information for later use when the host virtio-fs driver initiates device activation.
- Devices remain in the configuration state until explicitly started by host-side interactions.

6.19.7.3.2 Key Points

- Backend-first approach – The NFS backend must be created before virtio-fs device creation, as the device requires a functional storage backend during initialization.
- Function discovery – This reference uses the first available virtio-fs function. Production deployments can implement advanced selection logic based on performance or topology requirements.
- Reference implementation scope – Demonstrates single-device virtio-fs emulation with default configurations. DOCA APIs support large-scale, multi-device deployments with customizable parameters.
- Hardware acceleration – The virtio-fs PCIe function leverages hardware acceleration on the DPU for high-performance file system emulation.
- VUID association – Each virtio-fs device must be linked to a unique VUID that maps to a specific PCIe virtual function visible to the host OS.
- Admin thread execution – All device creation and configuration operations should be performed by the admin thread to ensure synchronization and thread safety.
- Queue configuration – The total number of queues includes request processing queues and a dedicated high-priority queue for handling filesystem metadata operations.
- Event handling – Correct registration of reset, FLR, and state change callbacks is essential for managing device lifecycle events triggered by the host.
- Resource validation – Comprehensive validation of device parameters ensures system stability and avoids runtime failures during activation.
- State management – Devices are initialized in a stopped state and require explicit commands to transition to an operational state when activated by the host.
- Scalability potential – Though this reference focuses on a single device, the architecture supports scalable deployments with multiple virtio-fs devices, each configurable for different use cases.

6.19.7.4 Backend Integration

This section details the setup and integration of the NFS filesystem backend, which provides the actual storage functionality behind the virtio-fs emulation. The backend

acts as a bridge between FUSE operations received from the host and the underlying NFS storage system.

6.19.7.4.1 Backend Integration Flow

1. Initialize NFS client library
    - Set up the NFS client infrastructure using libnfs initialization routines.
    - This includes initializing the RPC layer and NFS protocol handlers that facilitate communication with the remote NFS server.
    - NFS client state is managed through libnfs context structures.
2. Create NFS filesystem device
    - Instantiate the NFS backend using an application-defined `nfs_fsdev_create()` function, providing the configured NFS server address and export path.
    - This creates the main NFS filesystem device object (`struct nfs_fsdev`), which encapsulates the connection to the NFS server and provides the interface for file operations.
3. Configure NFS connection parameters
    - Set connection parameters such as:
        - NFS protocol version (typically NFSv3) using `nfs_set_version()`.
        - RPC timeout values using `nfs_set_timeout()`.
        - Connection-specific settings such as buffer sizes and retry counts.
    - These parameters should be tuned based on network conditions and server performance characteristics.
4. Establish NFS server connection
    - Connect to the NFS server using `nfs_mount()` to mount the specified export path.
    - This step involves mount protocol negotiations and, if required, authentication procedures.
    - The connection must be fully established before initiating any file operations.
5. Set up per-thread NFS contexts
    - For each worker thread, create a dedicated NFS client context using `nfs_fsdev_get()`.
    - Thread-local NFS contexts enable concurrent operations without requiring synchronization across threads.
    - Per-thread state is managed through `struct nfs_fsdev_thread_ctx`.
6. Initialize operation mapping
    - Define a translation layer that maps FUSE operations (e.g., LOOKUP, READ, WRITE, GETATTR) to corresponding NFS RPC calls (e.g., LOOKUP3, READ3, WRITE3, GETATTR3).

- Application-defined handler functions are used to perform this mapping for each supported FUSE operation.

7. Configure asynchronous operation support
    - Implement asynchronous NFS operations using callback mechanisms.
    - NFS requests are submitted asynchronously, with completion handled via registered callbacks to ensure non-blocking execution.
    - Application-defined callback structures are used for tracking in-flight operations and handling their completion.
8. Initialize request context pools
    - Allocate memory pools for NFS request contexts to efficiently manage allocation and reuse.
    - Each NFS operation requires a context structure to track its state and manage associated resources until completion.
9. Set up error handling and recovery
    - Implement error handling mechanisms to:
        - Translate NFS error codes to their corresponding FUSE error codes.
        - Retry transient failures where applicable.
        - Recover from NFS server disconnections by attempting reconnection or triggering failover logic.
10. Register progress polling
    - Integrate progress polling functions that are periodically invoked within each worker thread's main loop.
    - These functions check for completed NFS operations and trigger their associated completion callbacks.
    - Efficient polling ensures timely processing of operations without idle wait cycles.
11. Validate backend readiness
    - Perform backend readiness checks, such as:
        - Validating connectivity by performing a stat operation on the root directory of the NFS export.
        - Ensuring that all per-thread NFS contexts are properly initialized.
        - Confirming that the FUSE-to-NFS operation mapping is complete and functional.
12. Integrate with virtio-fs device
    - Link the prepared NFS backend to the virtio-fs device instance.
    - This integration ensures that FUSE requests received by the virtio-fs emulation layer are routed to the appropriate NFS backend handlers for processing.

6.19.7.4.2 Key Points

- NFS Protocol Support – The backend typically uses NFSv3 for broad compatibility, though NFSv4 can be employed for advanced features.
- Thread-Safe Operations – Each worker thread must operate with its own NFS client context to avoid synchronization overhead and maintain parallelism.
- Asynchronous Processing – All NFS operations are performed asynchronously, preventing blocking behavior and ensuring high throughput.
- Error Translation – Correct mapping between NFS and FUSE error codes is essential for consistent behavior on the host side.
- Connection Resilience – The backend must gracefully handle NFS server disconnections, implementing automatic reconnection or recovery procedures.
- Performance Tuning – NFS client parameters (e.g., timeouts, buffer sizes) should be tuned based on workload characteristics and network conditions.
- Memory Management – Efficient allocation and reuse of request context structures are critical for performance at scale.
- Progress Polling – Regular polling for completed NFS operations ensures timely request completion and system responsiveness.
- Operation Mapping – A comprehensive FUSE-to-NFS operation mapping ensures full filesystem functionality for the host.
- Backend Abstraction – The architecture supports backend abstraction, enabling future support for alternative storage backends (e.g., local POSIX FS, object storage) through the same interface.

6.19.7.5 Request Handler Registration

This section describes the process of registering FUSE operation handlers to process filesystem requests from the host, setting up DMA contexts for efficient data transfers, and configuring asynchronous callbacks for request completion and error handling.

6.19.7.5.1 Request Handler Registration Flow

1. Create VFS I/O contexts
    - Initialize I/O contexts for each worker thread using `doca_devemu_vfs_io_create()`.
    - Each worker thread receives its own `struct doca_devemu_vfs_io` handle to process FUSE requests independently, avoiding cross-thread contention.
2. Register FUSE operation handlers
    - For every supported FUSE operation, register corresponding handler functions:

        - Lookup: `doca_devemu_vfs_io_event_vfs_fuse_lookup_req_handler_register()`
        - Read: `doca_devemu_vfs_io_event_vfs_fuse_read_req_handler_register()`
        - Write: `doca_devemu_vfs_io_event_vfs_fuse_write_req_handler_register()`
        - Getattr, Setattr, Create, Mkdir, etc.
    - Each handler translates the incoming FUSE request into corresponding backend operations (e.g., NFS RPC calls) and manages the request lifecycle.
3. Set up DMA contexts for data transfers
    - Create DMA contexts for each I/O context using `doca_dma_create()`.
    - Configure DMA memcpy task parameters using `doca_dma_task_memcpy_set_conf()`, including completion and error callbacks.
    - DMA contexts are essential for enabling efficient zero-copy data transfers between host memory and DPU memory.
4. Configure DMA completion callbacks
    - Register completion and error handlers for DMA operations using `doca_dma_task_memcpy_set_conf()`.
    - Application-defined callback functions will handle the completion of data transfers and resume processing of the originating FUSE requests.
5. Connect I/O contexts to progress engines
    - Associate each I/O context with its corresponding thread's progress engine using `doca_pe_connect_ctx()`.
    - This ensures that I/O operations are executed within the correct thread context, maintaining thread affinity and balanced load distribution.
6. Initialize request context management
    - Set up request context pools using application-defined allocation mechanisms.
    - Each incoming FUSE request is assigned a context structure that tracks its state, associated DMA operations, and completion handlers.
7. Configure asynchronous operation handling
    - FUSE request handlers should submit backend operations (e.g., NFS RPC calls) asynchronously.
    - Completion callbacks are registered to be invoked when backend operations complete, enabling concurrent request processing without blocking worker threads.
8. Set up request queuing and scheduling

- Implement queuing mechanisms using application-defined structures to manage pending requests during high-load conditions.
- Queuing helps maintain fairness and prevents resource exhaustion by controlling the number of active in-flight operations.

9. Register error handling callbacks
    - Configure error handling routines to:
        - Translate backend error codes to corresponding FUSE error responses.
        - Handle DMA operation failures gracefully.
        - Ensure proper cleanup of request contexts in failure scenarios.
10. Initialize request statistics and monitoring
    - Set up performance monitoring structures to track:
        - Request counts.
        - Latency metrics.
        - Error rates.
        - Other relevant performance indicators.
    - This data aids in debugging, optimization, and capacity planning.
11. Configure request validation
    - Implement input validation routines to verify:
        - Request parameters.
        - Validity of file handles.
        - Access permissions.
        - Format and correctness of incoming requests.
    - Early validation helps prevent crashes, resource leaks, and security vulnerabilities.
12. Start I/O context processing
    - Activate each I/O context using `doca_ctx_start()`.
    - Once started, I/O contexts will begin accepting and processing FUSE requests from the host, dispatching them to the appropriate registered handlers.

6.19.7.5.2 Key Points

- Complete Operation Coverage – All relevant FUSE operations must have registered handlers to ensure full filesystem functionality on the host.
- Thread-Specific Contexts – Each worker thread must have its own VFS I/O context to avoid contention and maintain scalability.
- DMA Integration – Proper setup of DMA contexts and completion callbacks is essential for efficient data movement during read/write operations.
- Asynchronous Processing – Handlers should submit backend operations asynchronously to maximize throughput and avoid blocking threads.
- Robust Error Handling – Comprehensive error translation, recovery, and cleanup routines ensure stable and predictable application behavior.

- Request Lifecycle Management – Every request must be tracked from reception to completion, ensuring proper resource allocation and cleanup.
- Efficient Resource Management – Request contexts and DMA buffers should be managed via efficient allocation and reuse strategies to support high workloads.
- Performance Monitoring – Request statistics provide visibility into system performance, aiding in bottleneck identification and optimization efforts.
- Input Validation – Validating incoming requests early prevents invalid operations and mitigates security risks.
- Progress Engine Integration – All I/O contexts must be connected to progress engines to ensure correct and efficient operation processing.
- Callback Management – Completion and error callbacks for all operations must be correctly registered and invoked to maintain request flow and ensure system integrity.

6.19.7.6 Device Lifecycle Management

This section describes the procedures for starting device emulation, handling device state transitions, managing reset events, and implementing error recovery mechanisms to ensure robust and continuous virtio-fs device operation throughout its lifecycle.

6.19.7.6.1 Device Lifecycle Management Flow

1. Start VFS device context
    - Begin device emulation by starting the main virtio-fs device context using `doca_ctx_start()`.
    - This transitions the device from IDLE to STARTING state and initiates the device initialization sequence.
    - The operation is asynchronous, with completion signaled through state change callbacks.
2. Start I/O contexts
    - Activate all worker thread I/O contexts using `doca_ctx_start()` for each `struct doca_devemu_vfs_io` created during request handler registration.
    - All I/O contexts must be started to begin processing FUSE requests from the host.
    - Contexts are started in parallel across all worker threads.
3. Monitor device state transitions
    - Use registered state change callbacks (`doca_ctx_set_state_changed_cb()`) to track device state transitions:
        - IDLE → STARTING → RUNNING
    - These callbacks update application-level state tracking and trigger actions appropriate to each transition.

4. Handle device startup completion
    - When the device reaches RUNNING state:
        - Update device status.
        - Log successful startup.
        - Invoke any registered startup completion callbacks.
    - At this point, the device is fully operational and visible to the host system.
5. Manage device visibility to host
    - Upon entering RUNNING state, the virtio-fs device is exposed to the host as a PCIe device.
    - The host OS can now mount the filesystem and start sending FUSE requests for processing.
6. Handle device reset events
    - Process device reset requests from the host using the registered reset event callback (`doca_devemu_virtio_dev_event_reset_register()`).
    - Reset handling includes:
        - Stopping the device.
        - Clearing internal state.
        - Re-initializing and restarting the device to resume normal operation.
7. Handle function-level reset (FLR)
    - Process PCIe Function Level Reset (FLR) events using the registered FLR callback (`doca_devemu_pci_dev_event_flr_register()`).
    - FLR handling requires stopping all device activity and reinitializing the device to a clean state to maintain PCIe protocol compliance.
8. Implement graceful device stop
    - Use `doca_ctx_stop()` to gracefully shut down device operation.
    - The shutdown sequence involves:
        - Stopping all I/O contexts first.
        - Then stopping the main device context.
        - Ensuring all pending operations are either completed or safely aborted.
9. Manage device state during stop
    - Track device shutdown transitions using state change callbacks:
        - RUNNING → STOPPING → IDLE
    - Each transition requires specific cleanup actions and resource deallocation to ensure a clean shutdown.
10. Handle error recovery
    - Implement error recovery mechanisms to detect device failures and perform recovery actions:
        - Attempt soft recovery where possible.
        - Escalate to a full device restart if necessary.
    - These procedures ensure device availability during transient failures.

> ⚠ The application checks files under `/tmp/nfs_map/` to determine whether recovery is needed. If recovery is not required, the user should delete the `/tmp/nfs_map/` directory.

11. Coordinate multi-context lifecycle
    - Synchronize lifecycle operations across the main device context and all associated I/O contexts.
    - Application-defined coordination mechanisms should be used to ensure proper sequencing of start/stop operations and avoid race conditions.
12. Cleanup on device removal
    - On device removal or application shutdown:
      - Ensure all contexts are properly stopped.
      - Free all allocated resources.
      - Close backend connections.
      - Cleanly remove the device from the host system to prevent resource leaks or dangling devices.

6.19.7.6.2 Key Points

- Asynchronous Operations – Device start and stop procedures are asynchronous; completion is monitored via state change callbacks.
- State Synchronization – Synchronizing the state between the main device context and multiple I/O contexts is essential for correct and reliable operation.
- Host Visibility – The device becomes visible to the host only after successfully transitioning to `RUNNING` state.
- Reset Handling – Proper handling of both VirtIO resets and PCIe FLR events is required to maintain compatibility with standard host drivers.
- Graceful Shutdown – A structured stop sequence ensures all in-flight operations are safely completed or canceled, preventing data loss or corruption.
- Error Resilience – Robust error detection and recovery procedures help maintain device availability in the event of transient or recoverable errors.
- Resource Cleanup – All resources (contexts, memory pools, DMA buffers) must be freed upon shutdown to prevent memory leaks and resource exhaustion.
- Thread Coordination – Lifecycle operations (start/stop) must be carefully coordinated across multiple worker threads to ensure ordered and race-free execution.
- Callback Management – State change, reset, and FLR callbacks are critical for tracking device status and triggering necessary actions throughout the lifecycle.
- Host Driver Compatibility – Proper lifecycle management is essential to maintaining compatibility with standard virtio-fs drivers on the host side.

- Startup Sequencing – Device and I/O contexts must be started in the correct order to ensure proper initialization and readiness.
- Recovery Procedures – Failed startup or runtime errors should trigger cleanup routines and proper error reporting to maintain system stability.

6.19.7.7 Runtime Operations

This section describes the core operational phase where the application processes incoming FUSE requests from the host, executes corresponding filesystem operations via the NFS backend, and manages data transfers between the host and storage with hardware-accelerated efficiency.

6.19.7.7.1 Runtime Operations Flow

1. Receive FUSE requests from host
    - Incoming filesystem requests from the host are received through the virtio-fs device.
    - The appropriate FUSE operation handler is invoked based on the request's operation code (e.g., LOOKUP, READ, WRITE, GETATTR).
    - Requests are dispatched to their corresponding handler functions for further processing.
2. Parse and validate FUSE requests
    - Extract request parameters using:
        - `struct fuse_in_header` for common fields.
        - Operation-specific structures (e.g., `struct fuse_read_in`, `struct fuse_write_in`) for request-specific parameters.
    - Validate fields such as file handles, offsets, sizes, and permissions to ensure requests are well-formed before processing.
3. Allocate request context
    - Allocate a request context structure from a pre-allocated pool to manage the request's lifecycle.
    - The context tracks request state, intermediate results, associated DMA operations, and completion callbacks.
4. Translate FUSE operations to NFS calls
    - Map FUSE operations to corresponding NFS RPC calls:
        - FUSE_LOOKUP → NFS LOOKUP3
        - FUSE_READ → NFS READ3
        - FUSE_WRITE → NFS WRITE3
        - Parameter translation ensures compatibility between FUSE and NFS semantics.
5. Submit operations to NFS backend

- Submit NFS operations asynchronously using thread-specific NFS contexts.
- Asynchronous submission allows multiple operations to be in-flight concurrently without blocking worker threads.

6. Handle data transfers for read/write operations
    - For read operations:
        - DMA is used to transfer data from NFS buffers to host memory.
    - For write operations:
        - DMA transfers data from host memory to NFS buffers before sending it to the NFS server.
    - DMA enables zero-copy data movement, reducing CPU overhead and improving performance.
7. Process NFS operation completion
    - Upon NFS operation completion, registered callbacks are invoked.
    - Callbacks process NFS responses, extract result data, and prepare corresponding FUSE responses for the host.
8. Manage concurrent operations
    - Per-thread request queues and asynchronous processing allow worker threads to handle multiple requests concurrently.
    - Non-blocking operations ensure high throughput even under heavy load.
9. Handle operation errors
    - Failed operations are processed by translating NFS error codes to appropriate FUSE error responses.
    - Common errors include:
        - ENOENT (file not found)
        - EACCES (permission denied)
        - EIO (I/O errors)
    - Errors are propagated back to the host to ensure correct application behavior.
10. Complete FUSE responses
    - Responses are sent back to the host using `doca_virtiofs_req_complete()` or similar APIs.
    - Operation results are packaged into FUSE response structures and delivered through the virtio-fs interface to the host driver.
11. Update request statistics
    - Application-defined statistics collection tracks:
        - Request counts.
        - Latency metrics.
        - Error rates.
        - Throughput measurements.
    - Continuous monitoring helps identify bottlenecks and optimize system performance.
12. Manage memory and resource cleanup
    - After request completion:

- Release DMA buffers.
- Free or recycle request contexts.
- Ensure all resources are properly cleaned up to prevent memory leaks during prolonged operation.

6.19.7.7.2 Key Points

- High Concurrency – Multiple requests are processed simultaneously across worker threads, ensuring maximum throughput and low latency.
- Zero-Copy Transfers – DMA operations enable efficient data transfers between host and DPU memory without involving the CPU.
- Asynchronous Processing – All filesystem and data operations are handled asynchronously to prevent thread blocking and maintain system responsiveness.
- Error Propagation – Accurate translation of NFS errors to FUSE responses is essential for correct host-side application behavior.
- Resource Efficiency – Request contexts and DMA buffers are pooled and reused to minimize allocation overhead and support high workloads.
- Thread Isolation – Each worker thread processes requests independently, avoiding shared resource contention and synchronization bottlenecks.
- Performance Monitoring – Real-time statistics collection provides visibility into system health, enabling proactive performance tuning.
- Memory Management – Proper allocation and cleanup of resources are critical to prevent memory leaks during long-running operations.
- Protocol Compliance – All FUSE responses must conform to the virtio-fs specification to ensure compatibility with standard host drivers.
- Load Balancing – Request distribution across worker threads balances workload and optimizes hardware utilization.
- Data Consistency – Proper ordering and synchronization of requests ensure data consistency between the host and the NFS backend.
- Scalability – The architecture supports scaling to handle high request rates and large numbers of concurrent operations across multiple worker threads.

6.19.7.8 Cleanup and Shutdown

This section describes the procedures for gracefully shutting down the application, freeing allocated resources, closing active connections and contexts, and ensuring a clean termination without leaving resource leaks or dangling system components.

6.19.7.8.1 Cleanup and Shutdown Flow

1. Initiate graceful shutdown –
    - On receiving termination signals (SIGINT, SIGTERM), signal handlers set shutdown flags to begin the termination process.
    - The shutdown sequence ensures that all in-flight operations are allowed to complete before services are stopped.
2. Stop accepting new requests
    - Disable the acceptance of new FUSE requests.
    - Request handlers will reject incoming operations with appropriate error responses while allowing ongoing operations to complete.
3. Drain pending operations
    - Wait for all in-flight operations to complete:
        - NFS operations.
        - DMA transfers.
        - Outstanding FUSE requests.
    - Ensure all request contexts are returned to their respective pools before proceeding.
4. Stop VFS I/O contexts
    - Invoke `doca_ctx_stop()` on each VFS I/O context associated with worker threads.
    - These operations are asynchronous; completion is monitored through state change callbacks.
    - Stopping I/O contexts halts request processing and triggers per-thread resource cleanup.
5. Stop main VFS device context
    - Stop the primary device context using `doca_ctx_stop()`.
    - The device transitions from RUNNING → STOPPING → IDLE, becoming invisible to the host.
    - Device-level operations are halted.
6. Cleanup DMA resources
    - Free DMA contexts using `doca_dma_destroy()` for each allocated DMA context.
    - Ensure any pending DMA operations are properly finalized and associated memory allocations are released.
7. Destroy VFS I/O contexts
    - Free I/O contexts for each worker thread using `doca_devemu_vfs_io_destroy()`.
    - This step ensures cleanup of per-thread processing resources.
8. Close NFS backend connections
    - Unmount NFS exports and destroy NFS client contexts:
        - Use `nfs_umount()` to unmount NFS paths.

        - Use `nfs_destroy_context()` to release NFS client-side resources.
    - Clean up per-thread NFS contexts and connection pools to ensure backend disconnection.
9. Stop worker threads
    - Terminate worker threads gracefully:
        - Use `pthread_join()` to wait for threads to exit cleanly.
        - Use `pthread_cancel()` for unresponsive threads if necessary.
    - Ensure no threads remain active before continuing with shared resource deallocation.
10. Destroy progress engines
    - Free progress engines using `doca_pe_destroy()` for each progress engine created during initialization.
    - This ensures proper cleanup of asynchronous operation handling infrastructure.
11. Free memory pools and inventories
    - Destroy memory pools using `doca_mpool_destroy()` and buffer inventories using `doca_buf_inventory_destroy()`.
    - This step returns all allocated buffers and memory resources to the system.
12. Close devices and cleanup framework
    - Close all opened devices and representors:
        - Use `doca_dev_close()` for device handles.
        - Use `doca_dev_rep_close()` for representor handles.
    - Finalize VFS framework cleanup to ensure hardware resources are fully released.
13. Destroy device and manager resources
    - Free application-specific resources:
        - Device lists.
        - Manager structures.
        - Configuration objects.
    - Clean up linked lists, hash tables, and other dynamic data structures used in the application.
14. Cleanup argument parser and logging infrastructure
    - Destroy the argument parser with `doca_argp_destroy()`.
    - Tear down logging backends to clean up logging resources and ensure a clean exit.
15. Verify resource cleanup
    - Perform a final validation step to confirm:
        - All memory allocations are freed.
        - All contexts are destroyed.
        - No background threads or pending operations remain active.
    - Check for potential memory leaks or orphaned resources.

6.19.7.8.2 Key Points

- Graceful Shutdown – Ensure in-flight operations are completed before shutting down to avoid data corruption or loss.
- Ordered Cleanup – Resources must be released in the reverse order of their creation, respecting dependencies between components.
- Signal Handling – Proper handling of external termination signals ensures orderly shutdown procedures are triggered.
- Thread Synchronization – Worker threads must be fully stopped and joined before deallocating shared resources.
- Resource Tracking – A systematic cleanup approach is critical to prevent resource leaks and ensure system stability after termination.
- Error Handling During Cleanup – Cleanup operations should proceed even if individual cleanup steps encounter errors, ensuring best-effort resource release.
- State Verification – Confirm that all contexts and resources have been freed and no residual state remains.
- Backend Cleanup – NFS backend connections and contexts must be properly closed to prevent lingering open connections.
- Device Visibility – Devices should be made invisible to the host before initiating cleanup to avoid host-side errors.
- Timeout Handling – Ensure that cleanup operations have timeouts to prevent the application from hanging during shutdown.
- Dependency Management – Cleanup operations must respect dependencies, ensuring no premature deallocation of dependent resources.
- Memory Leak Prevention – All dynamically allocated memory (DMA buffers, request contexts, etc.) must be freed.
- Hardware Resource Release – All device handles, representors, and associated contexts must be properly closed to return hardware resources to the system.
- Framework Cleanup – DOCA framework resources must be de-initialized to restore the system to a clean state.
- Logging and Monitoring – Shutdown progress and any errors during cleanup should be logged to aid in debugging and post-mortem analysis.

6.19.8 FUSE Operations Support Summary

The following table summarizes the FUSE operations supported by the virtio-fs reference application, along with their implementation status and brief descriptions:

FUSE Operation	Status	Description
LOOKUP	✅ Supported	Look up a directory entry by name and return file attributes.
FORGET	✅ Supported	Forget an inode (decrease reference count).

FUSE Operation	Status	Description
GETATTR	✅ Supported	Get file attributes (similar to `stat` syscall).
SETATTR	✅ Supported	Set file attributes (`chmod` , `chown` , `truncate` , etc.).
READLINK	❌ Not Implemented	Read the target of a symbolic link.
SYMLINK	❌ Not Implemented	Create a symbolic link.
MKNOD	✅ Supported	Create a file node (regular file, device file, etc.).
MKDIR	✅ Supported	Create a directory.
UNLINK	✅ Supported	Remove a file.
RMDIR	❌ Not Implemented	Remove a directory.
RENAME	❌ Not Implemented	Rename or move a file or directory.
LINK	❌ Not Implemented	Create a hard link to a file.
OPEN	✅ Supported	Open a file and return a file handle.
READ	✅ Supported	Read data from a file.
WRITE	✅ Supported	Write data to a file.
STATFS	❌ Not Implemented	Retrieve filesystem statistics (disk space, etc.).
RELEASE	✅ Supported	Close a file handle.
FSYNC	❌ Not Implemented	Synchronize file contents to storage.
SETXATTR	❌ Not Implemented	Set extended file attributes.
GETXATTR	❌ Not Implemented	Get extended file attributes.
LISTXATTR	❌ Not Implemented	List extended file attributes.
REMOVEXATTR	❌ Not Implemented	Remove extended file attributes.
FLUSH	❌ Not Implemented	Flush cached data (called on file close).
INIT	✅ Supported	Initialize filesystem connection.
OPENDIR	✅ Supported	Open a directory for reading.
READDIR	✅ Supported	Read directory entries.
RELEASEDIR	✅ Supported	Close a directory handle.
FSYNCDIR	❌ Not Implemented	Synchronize directory contents.
GETLK	❌ Not Implemented	Test for file locks.
SETLK	❌ Not Implemented	Set non-blocking file locks.
SETLKW	❌ Not Implemented	Set blocking file locks.
ACCESS	❌ Not Implemented	Check file access permissions.
CREATE	❌ Not Implemented	Atomically create and open a file.
INTERRUPT	❌ Not Implemented	Interrupt a pending operation.
BMAP	❌ Not Implemented	Map file block to device block.
IOCTL	❌ Not Implemented	Device-specific input/output control.
POLL	❌ Not Implemented	Poll for I/O readiness.
FALLOCATE	❌ Not Implemented	Preallocate space for a file.

FUSE Operation	Status	Description
DESTROY	❌ Not Implemented	Cleanup filesystem connection.
NOTIFY_REPLY	❌ Not Implemented	Reply to kernel notification.
BATCH_FORGET	❌ Not Implemented	Batch version of FORGET.
READDIRPLUS	✅ Supported	Read directory entries with attributes.
RENAME2	❌ Not Implemented	Extended rename with flags.
COPY_FILE_RANGE	❌ Not Implemented	Copy data between files efficiently.
SETUPMAPPING	❌ Not Implemented	Set up DAX (Direct Access) memory mapping.
REMOVEMAPPING	❌ Not Implemented	Remove DAX memory mapping.
SYNCFS	❌ Not Implemented	Synchronize entire filesystem.
LSEEK	❌ Not Implemented	Seek to a position within a file.
TMPFILE	❌ Not Implemented	Create an unnamed temporary file.
STATX	❌ Not Implemented	Extended file status query.

6.20 DOCA Storage Applications

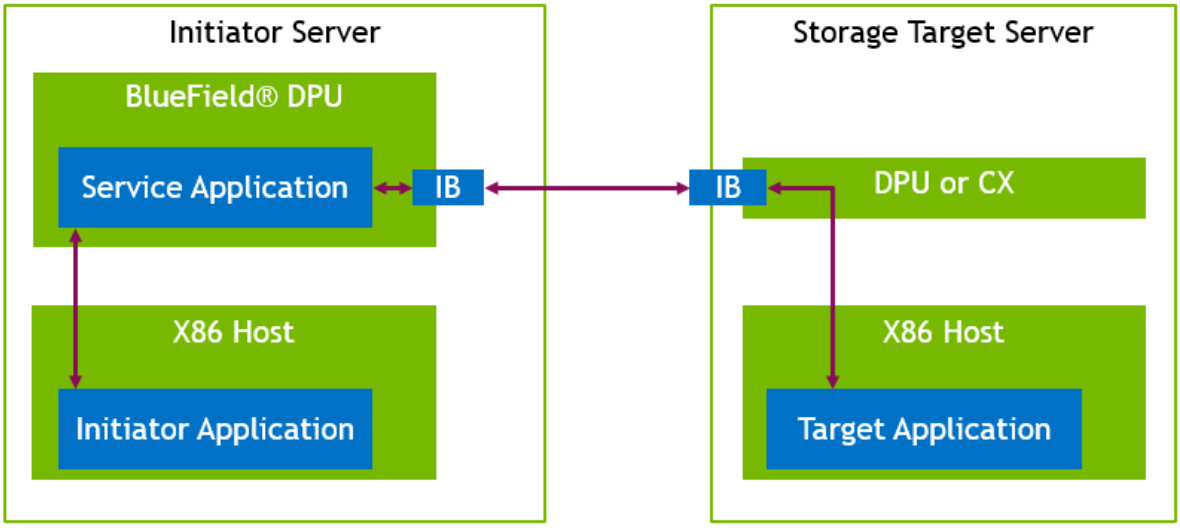
This page outlines NVIDIA DOCA storage applications that demonstrate how to develop data storage implementations on the NVIDIA® BlueField® platform.

6.20.1 Introduction

The DOCA storage applications serve as a reference to demonstrate how a block storage solution can be developed using the DOCA framework on the NVIDIA BlueField platform.

These applications are simplified to make the flow and overall process easy to understand. A real-world storage solution involves significantly more complexity, and solutions must be tailored to specific use cases, which is not attempted in this reference design.

The general architecture involves an initiator host application sending storage requests to a local DPU application. The DPU then interfaces with a remote storage target using RDMA, orchestrating the storage and retrieval of data directly to or from the initiator application's memory.



6.20.2 Applications

The storage reference consists of several applications that can be orchestrated in different combinations to support varying storage approaches and implementations. Each application is described at a high level below, followed by detailed use case examples highlighting how these applications can be combined.

6.20.2.1 doca_storage_initiator_comch

The doca_storage_initiator_comch application serves two purposes. First, it acts as the user/client of the storage reference application that controls the execution flow. Second, it includes benchmarking capabilities to demonstrate the achievable performance of the storage solution. The application supports the following tests:

- Read throughput performance test
- Write throughput performance test
- Read-only data validation test
- Write-then-read data validation test

6.20.2.2 doca_storage_target_rdma

The doca_storage_target_rdma application provides a simple storage backend by utilizing a block of memory instead of interfacing with physical non-volatile storage. It includes the following features:

- Configurable block count
- Configurable block size
- Import of initial data from a text file

- Import of initial data from a binary format (.sbc)

6.20.2.3 doca_storage_comch_to_rdma_zero_copy

The doca_storage_comch_to_rdma_zero_copy application serves as a bridge between the initiator and a single storage target. It facilitates the exchange of the control path messages and data path messages between the initiator and the target. The data being exchanged between the initiator and the target is never visible in this application as is exchanged directly between the initiator and the target via RDMA which is it is referred to as zero copy. It offers the following features:

- Facilitates the zero copy transfer of data from initiator to target

6.20.2.4 doca_storage_comch_to_rdma_gga_offload

The doca_storage_comch_to_rdma_gga_offload application serves as a bridge between the initiator and three storage targets. It is active in the transfer of data and uses `doca_libs` to accelerate some data operations transparently to the initiator and targets. It offers the following features:

- Transparent data redundancy and error correction
- Inline compression and decompression of stored data
- Inline creation of redundancy data
- Inline recovery of lost data blocks
- Configuration of how frequently a simulated data loss occurs

6.20.2.5 doca_storage_gga_offload_sbc_generator

The doca_storage_gga_offload_sbc_generator application is used to generate Storage Binary Content (.sbc) files. These files are consumed by the `doca_storage_target_rdma` application when it is used with the `doca_storage_comch_to_rdma_gga_offload` application.

Using a user-supplied data file, the generator:

1. Splits the input data into chunks.
2. Compresses each chunk.
3. Creates error correction blocks for each compressed block.

The output is stored in three files (named by the user), which can be used to initialize the storage with valid data upon startup:

- Data1 file (`data_1`)
- Data2 file (`data_2`)
- Data-parity file (`data_p`)

6.20.3 Use Case 1: Zero Copy

This use case demonstrates a simple, hardware-accelerated storage solution that avoids unnecessary data copying by using the DOCA Comch, DOCA Core, and DOCA RDMA libraries. Data is transferred directly between the initiator's memory and the storage target's memory via DOCA RDMA. The initiator has no awareness of the target; it only communicates with the service.

6.20.3.1 Application Components

This use case involves three distinct applications:

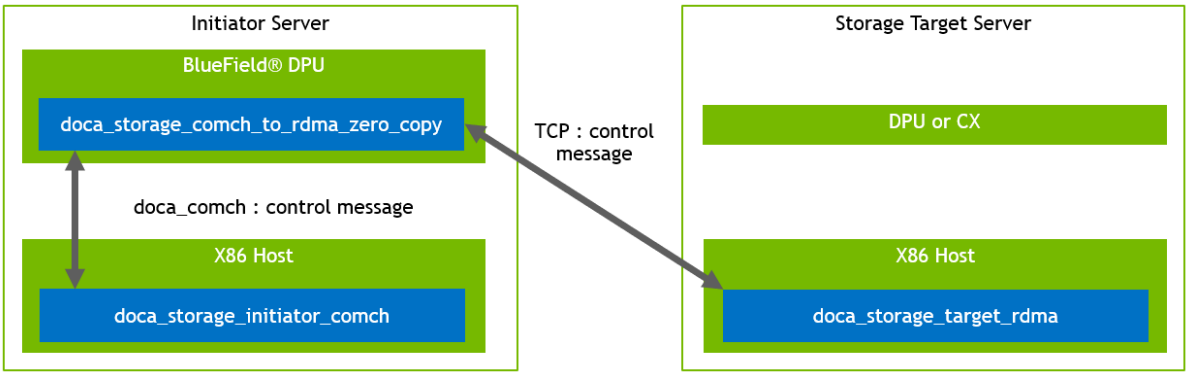
- Initiator (`doca_storage_initiator_comch`): A client/benchmark application that sends read and write requests to the storage backend.
- Service (`doca_storage_comch_to_rdma_zero_copy`): A bridge that abstracts the target's details from the initiator. It relays IO messages between the two.
- Target (`doca_storage_target_rdma`): A memory-based storage application that executes RDMA operations to fulfill the initiator's requests.

6.20.3.2 Operational Flow

The use case operates in two main phases.

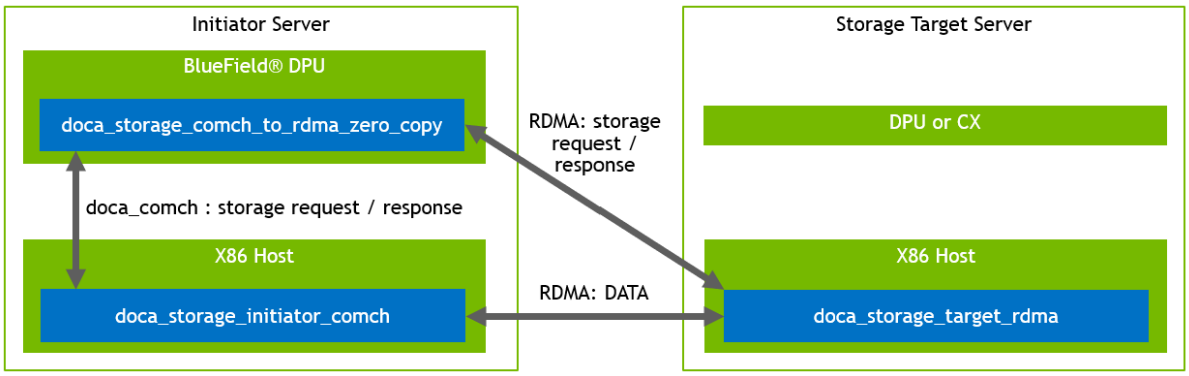
6.20.3.2.1 Setup Phase

The applications first use DOCA Comch and a TCP socket to register with each other, share configuration, and prepare the data path operations.



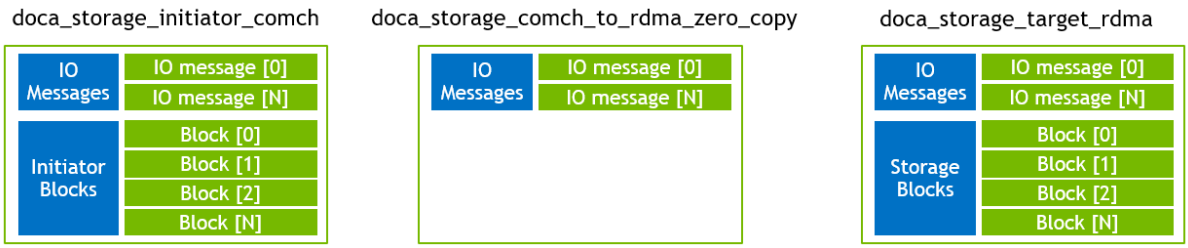
6.20.3.2.2 Data Path Phase

Once configured, the data path contexts (`doca_comch_producer` , `doca_comch_consumer` , and `doca_rdma`) are used to perform the actual storage requests and send completion responses.



6.20.3.3 Memory Layout

The memory layout is simple: both the initiator and the target allocate memory regions partitioned into blocks. All RDMA read/write operations transfer data directly between these memory regions.



The number of blocks on the initiator and target does not need to match, but their block size must be identical.

6.20.3.4 Data Flow

The data flow for a storage operation is as follows:

1. The Initiator sends a read/write IO request to the Service (via `doca_comch_producer`).
2. The Service receives the request (via `doca_comch_consumer`).
3. The Service forwards the request to the Target (via `doca_rdma`).
4. The Target performs the RDMA read or write operation, transferring data directly between its memory and the Initiator's memory.
5. The Target sends an IO response (completion) to the Service (via `doca_rdma`).
6. The Service receives the IO response.
7. The Service forwards the response to the Initiator (via `doca_comch_producer`).
8. The Initiator receives the final response (via `doca_comch_consumer`).

6.20.3.5 Running the Zero Copy Use Case

Assumptions:

- The service and storage applications can communicate via TCP
- The service is deployed on a BlueField-3 DPU
- Full line-rate RDMA data transfer is possible between service and storage

The examples below use CPU 0. Users should ensure that this CPU is suitable, considering NUMA configuration, pinned cores, kernel interrupts, etc.

Run the applications in the following order:

1. `doca_storage_target_rdma`
2. `doca_storage_comch_to_rdma_zero_copy`
3. `doca_storage_initiator_comch`

Replace the following placeholders with actual values:

- `{{INITIATOR_DEV_PCI_ADDR}}`
- `{{STORAGE_DEV_PCI_ADDR}}`
- `{{STORAGE_IP_ADDR}}`

- `{{STORAGE_TCP_PORT}}`

6.20.3.5.1 Run Write Data Validity Test

1. Run the storage target:

```
doca_storage_target_rdma \
    -d {{STORAGE_DEV_PCI_ADDR}} \
    --listen-port {{STORAGE_TCP_PORT}} \
    --block-size 4096 \
    --block-count 1024 \
    --cpu 0
```

2. Run the zero copy service:

```
doca_storage_comch_to_rdma_zero_copy \
    -d 03:00.0 \
    -r {{INITIATOR_DEV_PCI_ADDR}} \
    --storage-server {{STORAGE_IP_ADDR}}:{{STORAGE_TCP_PORT}} \
    --cpu 0
```

3. Run the initiator:

```
doca_storage_initiator_comch \
    -d {{INITIATOR_DEV_PCI_ADDR}} \
    --execution-strategy read_write_data_validity_test \
    --run-limit-operation-count 10000 \
    --cpu 0
```

6.20.3.5.2 Run Write Throughput Test

1. Repeat step 1 from the previous section.
2. Repeat step 2 from the previous section.
3. Run the initiator:

```
doca_storage_initiator_comch \
    -d {{INITIATOR_DEV_PCI_ADDR}} \
    --execution-strategy write_throughput_test \
    --run-limit-operation-count 1000000 \
    --cpu 0
```

6.20.3.5.3 Run Read Data Validity Test

The file provided to the storage and initiator should have the same content, and a size that matches `the storage block-size * the storage block-count`.

1. Run the storage target:

```
doca_storage_target_rdma \
    -d {{STORAGE_DEV_PCI_ADDR}} \
    --listen-port {{STORAGE_TCP_PORT}} \
    --block-size 4096 \
    --block-count 1024 \
```

```
    --binary-content storage_content.txt \
    --cpu 0
```

2. Run the zero copy service:

```
doca_storage_comch_to_rdma_zero_copy \
    -d 03:00.0 \
    -r {{INITIATOR_DEV_PCI_ADDR}} \
    --storage-server {{STORAGE_IP_ADDR}}:{{STORAGE_TCP_PORT}} \
    --cpu 0
```

3. Run the initiator:

```
doca_storage_initiator_comch \
    -d {{INITIATOR_DEV_PCI_ADDR}} \
    --execution-strategy read_only_data_validity_test \
    --storage-plain-content storage_content.txt \
    --run-limit-operation-count 10000 \
    --cpu 0
```

6.20.3.5.4 Run Read Throughput Test

1. Repeat step 1 from the previous section.
2. Repeat step 2 from the previous section.
3. Run the initiator:

```
doca_storage_initiator_comch \
    -d {{INITIATOR_DEV_PCI_ADDR}} \
    --execution-strategy read_throughput_test \
    --run-limit-operation-count 1000000 \
    --cpu 0
```

6.20.4 Use Case 2: GGA Offload

This use case demonstrates how to leverage hardware acceleration for a storage solution that provides transparent compression, recovery, and data mirroring. It uses a combination of the DOCA Comch, DOCA Core, DOCA RDMA, DOCA Erasure Coding and DOCA Compress libraries.

6.20.4.1 Architecture and Components

The GGA offload use case involves three applications running as five distinct instances:

- 1x Initiator (`doca_storage_initiator_comch`): A client/benchmark application that sends read and write requests.
- 1x Service (`doca_storage_comch_to_rdma_gga_offload`): A bridge that abstracts the storage details and orchestrates the offload operations (compression, erasure coding).
- 3x Targets (`doca_storage_target_rdma`): Three instances of a memory-based storage application, one for each data "shard":

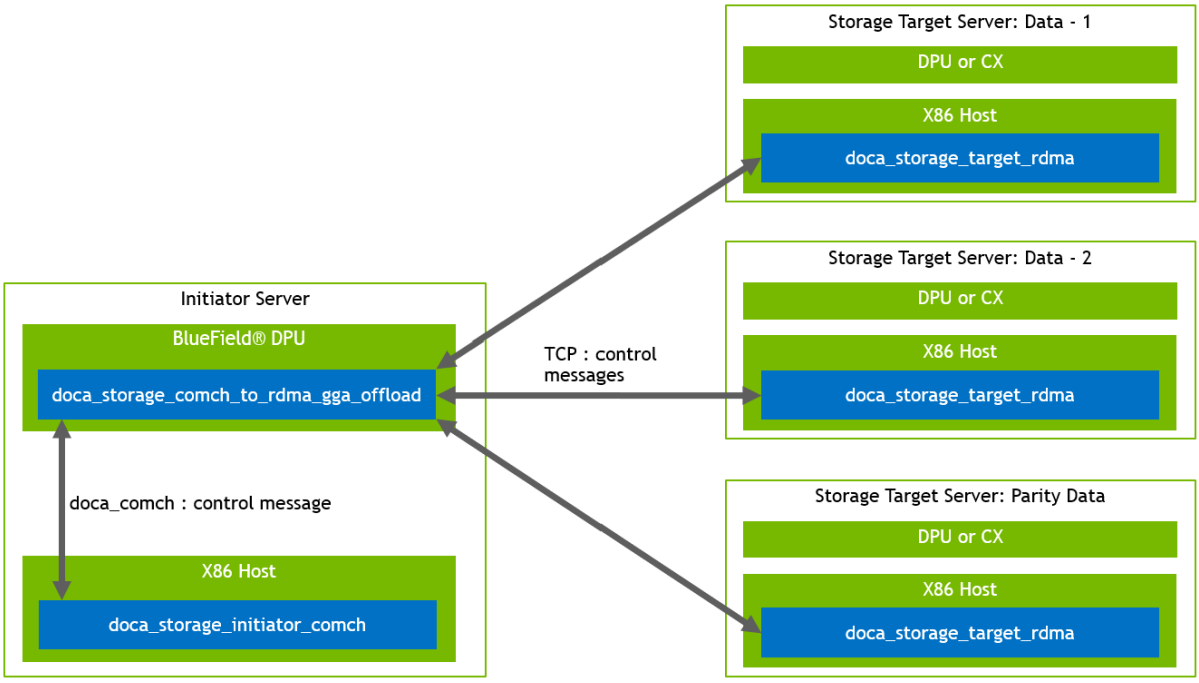
- Target 1 (`data1`): Stores 50% of the logical data.
- Target 2 (`data2`): Stores the other 50% of the logical data.
- Target 3 (`data_p`): Stores parity information for redundancy, allowing recovery if `data1` or `data2` is lost.

6.20.4.2 Operational Flow

The use case operates in two main phases.

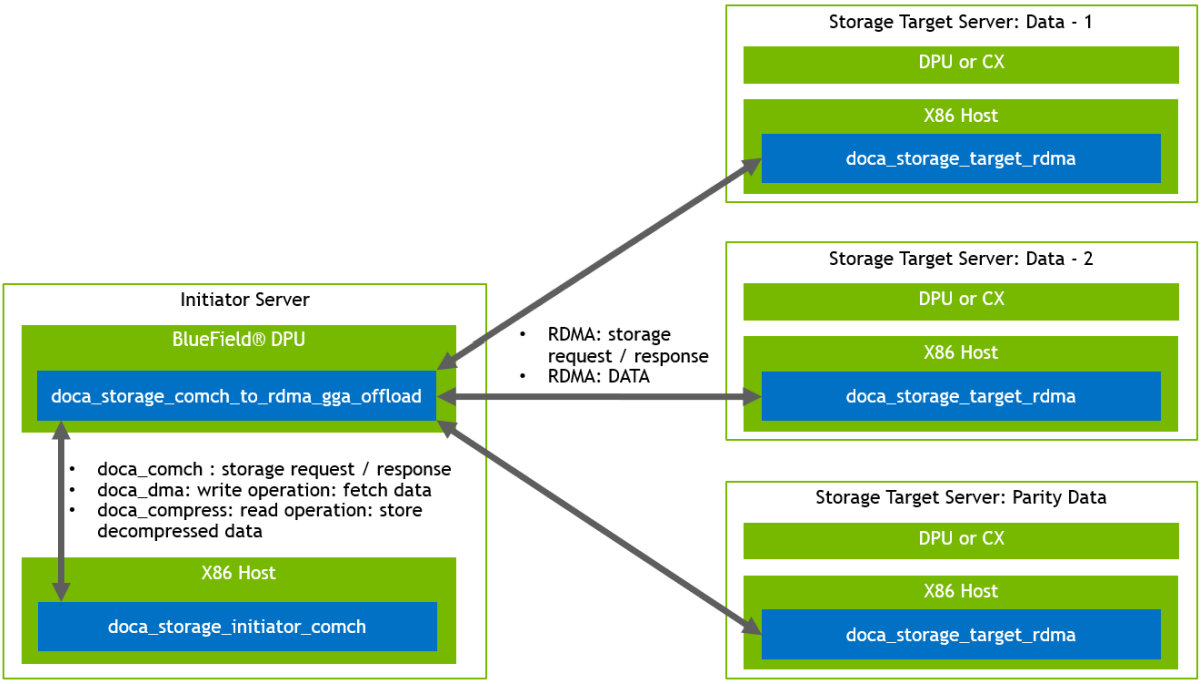
6.20.4.2.1 Setup Phase

The applications use DOCA Comch and three TCP sockets (one for each target) to register with each other, share configuration, and prepare the data path contexts.



6.20.4.2.2 Data Path Phase

Once configured, the contexts are used to perform storage requests and signal completions using `doca_comch_producer` , `doca_comch_consumer` , `doca_rdma` , `doca_dma` , `doca_ec` , and `doca_compress` .



6.20.4.3 Memory Layout

The memory layout for this use case is more complex:

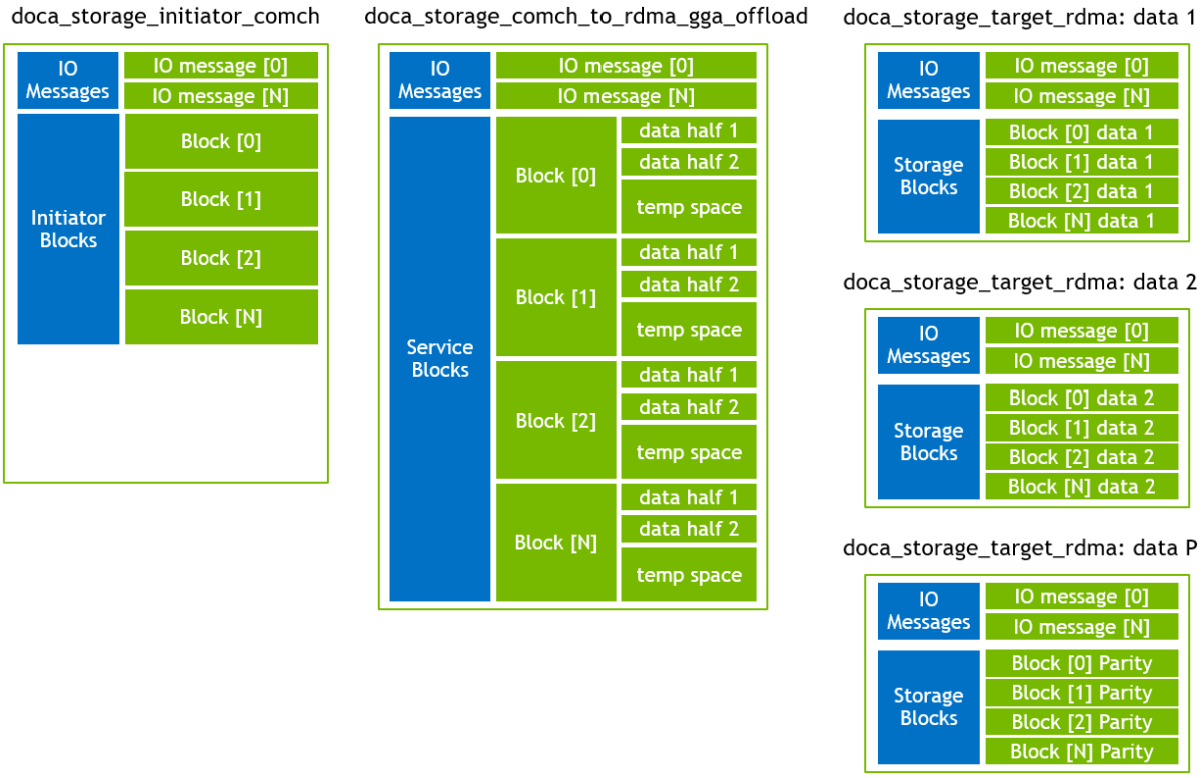
- Initiator: Allocates a memory region partitioned into data blocks.
- Service: Allocates a larger region where each block is twice the size of the initiator's blocks. This provides space to perform compression, decompression, and parity calculations.
- Storage Targets: Each of the three targets allocates blocks that are 50% of the *initiator's* block size. All targets must use the same block size and count.

Data is transferred between the targets and the service via RDMA. Cross-PCIe memory access via DOCA mmap (mmap from Export) is used for data transfers between the service (on the DPU) and the initiator (on the host).

The flow of data through this layout is as follows:

- During Write Operations: DOCA DMA is used to transfer initiator blocks into the service's larger storage blocks (using the cross-PCIe `DOCA mmap`). The block's content is then compressed, parity data is calculated, and the resulting data (`data_1`, `data_2`, `data_p`) is transferred to the storage targets via RDMA.
- During Normal Read Operations: Data is transferred from the targets to the service blocks via RDMA. The DOCA mmap is then used to decompress the data from the service blocks directly into the initiator's blocks.
- During Recovery Read Operations: The service uses RDMA to fetch the valid data half and the parity data into its temporary block space. It combines them to

reconstruct the missing data, and the resulting restored data is then decompressed into the initiator's block as normal.



6.20.4.4 Normal Read Flow

The standard read flow, when all targets are available, is as follows:

1. The Initiator sends a read request to the Service (via `doca_comch_producer`).
2. The Service receives the request (via `doca_comch_consumer`).
3. The Service sends two IO requests (via `doca_rdma`) to the `data_1` and `data_2` Targets.
4. Both Targets perform RDMA transfers, sending their storage blocks to the Service's blocks.
5. Both Targets send an IO response to the Service (via `doca_rdma`).
6. The Service, upon receiving both responses, examines the block metadata to determine the compressed data size.
7. The Service decompresses the data (via `doca_compress` using LZ4), using the cross-PCIe `DOCA mmap` feature to write the decompressed data *directly* into the Initiator's memory.
8. The Service forwards an IO response to the Initiator (via `doca_comch_producer`).
9. The Initiator receives the final response (via `doca_comch_consumer`).

6.20.4.5 Recovery Read Flow

If a data target is unavailable, the service performs a recovery read:

1. The Initiator sends a read request to the Service (via `doca_comch_producer`).
2. The Service receives the request (via `doca_comch_consumer`).
3. The Service sends two IO requests (via `doca_rdma`) to the *available* data target and the *parity* target.
    - To recover `data_1`: Send requests to `data_2` and `data_p`.
    - To recover `data_2`: Send requests to `data_1` and `data_p`.
4. Both Targets perform RDMA transfers to the Service's blocks.
5. Both Targets send an IO response to the Service (via `doca_rdma`).
6. The Service uses `doca_ec` to reconstruct the missing data block from the available data and parity blocks.
7. The Service examines the *recovered* block's metadata to determine the compressed data size.
8. The Service decompresses the recovered data (via `doca_compress`), using the cross-PCIe `DOCA mmap` to write the data directly into the Initiator's memory.
9. The Service forwards an IO response to the Initiator (via `doca_comch_producer`).
10. The Initiator receives the final response (via `doca_comch_consumer`).

6.20.4.6 Write Flow

> ⚠ The write path is only available if the `doca_storage_comch_to_rdma_gga_offload` service is compiled with the `liblz4` dev libraries.

1. The Initiator sends a write request to the Service (via `doca_comch_producer`).
2. The Service receives the request (via `doca_comch_consumer`).
3. The Service fetches the data block from the Initiator using `doca_dma` via the cross-PCIe `DOCA mmap`.
4. The Service compresses the data and packages it into a block with metadata.
    a. If the data is not compressible enough, an error is returned to the Initiator (via `doca_comch_producer`).
    b. The Initiator receives the error response (via `doca_comch_consumer`).
    c. The flow ends.
5. The Service sends three IO requests (via `doca_rdma`) to the Targets to write `data_1`, `data_2`, and `data_p`.
6. The Service waits for all three IO responses.

7. The Service forwards a final IO response to the Initiator (via `doca_comch_producer`).
8. The Initiator receives the response (via `doca_comch_consumer`).

6.20.4.7 Running the GGA Offload Use Case

It is assumed that:

- The service and storage applications can communicate via TCP
- The service (`doca_storage_comch_to_rdma_gga_offload`) is deployed on a BlueField-3 DPU
- Full line-rate RDMA data transfer is possible between the service and the storage targets

All examples use CPU 0. Users should verify if this is optimal by considering NUMA affinity, core pinning, and kernel interrupt distribution.

6.20.4.7.1 Execution Order

Running this use case involves running the applications in this specific order:

1. `doca_storage_target_rdma` (for `data_1`)
2. `doca_storage_target_rdma` (for `data_2`)
3. `doca_storage_target_rdma` (for `data_p`)
4. `doca_storage_comch_to_rdma_gga_offload` (the service)
5. `doca_storage_initiator_comch` (the initiator)

6.20.4.7.2 Placeholders

Replace the following placeholders in the commands with actual values:

- `{{INITIATOR_DEV_PCI_ADDR}}`
- `{{STORAGE_DEV_PCI_ADDR}}`
- `{{STORAGE_IP_ADDR_DATA_1}}`
- `{{STORAGE_IP_ADDR_DATA_2}}`
- `{{STORAGE_IP_ADDR_DATA_P}}`
- `{{STORAGE_TCP_PORT_DATA_1}}`
- `{{STORAGE_TCP_PORT_DATA_2}}`

- `{{STORAGE_TCP_PORT_DATA_P}}`

6.20.4.7.3 Generate SBC File

> ⚠ `doca_storage_gga_offload_sbc_generator` is not compiled if the `liblz4` dev libraries are not present.

```
doca_storage_gga_offload_sbc_generator \
    -d 3b:00.0 \
    --original-input-data storage_content.txt \
    --block-size 4096 \
    --data-1 data_1.sbc \
    --data-2 data_2.sbc \
    --data-p data_p.sbc
```

6.20.4.7.4 Run Read Data Validity Test

1. Run three storage targets:

   ```
   doca_storage_target_rdma -d {{STORAGE_DEV_PCI_ADDR}} --listen-port {{STORAGE_TCP_PORT_DATA_1}} --binary-
   content data_1.sbc --cpu 0
   doca_storage_target_rdma -d {{STORAGE_DEV_PCI_ADDR}} --listen-port {{STORAGE_TCP_PORT_DATA_2}} --binary-
   content data_2.sbc --cpu 1
   doca_storage_target_rdma -d {{STORAGE_DEV_PCI_ADDR}} --listen-port {{STORAGE_TCP_PORT_DATA_P}} --binary-
   content data_p.sbc --cpu 2
   ```

2. Run the offload service:

   ```
   doca_storage_comch_to_rdma_gga_offload \
       -d 03:00.0 \
       -r {{INITIATOR_DEV_PCI_ADDR}} \
       --data-1-storage {{STORAGE_IP_ADDR_DATA_1}}:{{STORAGE_TCP_PORT_DATA_1}} \
       --data-2-storage {{STORAGE_IP_ADDR_DATA_2}}:{{STORAGE_TCP_PORT_DATA_2}} \
       --data-p-storage {{STORAGE_IP_ADDR_DATA_P}}:{{STORAGE_TCP_PORT_DATA_P}} \
       --trigger-recovery-read-every-n 0 \
       --cpu 0
   ```

3. Run the initiator:

   ```
   doca_storage_initiator_comch \
       -d {{INITIATOR_DEV_PCI_ADDR}} \
       --execution-strategy read_only_data_validity_test \
       --storage-plain-content storage_content.txt \
       --run-limit-operation-count 20000 \
       --cpu 0
   ```

6.20.4.7.5 Run Read Throughput Test

1. Repeat step 1 from the "Read Data Validity Test".
2. Repeat step 2 from the "Read Data Validity Test".
3. Run the initiator:

   ```
   doca_storage_initiator_comch \
       -d {{INITIATOR_DEV_PCI_ADDR}} \
       --execution-strategy read_throughput_test\
   ```

```
    --storage-plain-content storage_content.txt \
    --run-limit-operation-count 1000000 \
    --cpu 0
```

6.20.4.7.6 Run Write Data Validity Test

1. Run three storage targets:

```
doca_storage_target_rdma -d {{STORAGE_DEV_PCI_ADDR}} --listen-port {{STORAGE_TCP_PORT_DATA_1}} --binary-
content data_1.sbc --cpu 0
doca_storage_target_rdma -d {{STORAGE_DEV_PCI_ADDR}} --listen-port {{STORAGE_TCP_PORT_DATA_2}} --binary-
content data_2.sbc --cpu 1
doca_storage_target_rdma -d {{STORAGE_DEV_PCI_ADDR}} --listen-port {{STORAGE_TCP_PORT_DATA_P}} --binary-
content data_p.sbc --cpu 2
```

2. Run the offload service:

```
doca_storage_comch_to_rdma_gga_offload \
    -d 03:00.0 \
    -r {{INITIATOR_DEV_PCI_ADDR}} \
    --data-1-storage {{STORAGE_IP_ADDR_DATA_1}}:{{STORAGE_TCP_PORT_DATA_1}} \
    --data-2-storage {{STORAGE_IP_ADDR_DATA_2}}:{{STORAGE_TCP_PORT_DATA_2}} \
    --data-p-storage {{STORAGE_IP_ADDR_DATA_P}}:{{STORAGE_TCP_PORT_DATA_P}} \
    --cpu 0
```

3. Run the initiator:

```
doca_storage_initiator_comch \
    -d {{INITIATOR_DEV_PCI_ADDR}} \
    --execution-strategy read_write_data_validity_test \
    --storage-plain-content storage_content.txt \
    --run-limit-operation-count 20000 \
    --cpu 0
```

6.20.4.7.7 Run Write Throughput Test

1. Repeat step 1 from the "Run Write Data Validity Test".
2. Repeat step 2 from the "Run Write Data Validity Test".
3. Run the initiator:

```
doca_storage_initiator_comch \
    -d {{INITIATOR_DEV_PCI_ADDR}} \
    --execution-strategy write_throughput_test \
    --run-limit-operation-count  50000 \
    --cpu 0
```

6.20.5 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Core
- DOCA Comch
- DOCA Compress
- DOCA DMA

- DOCA Erasure Coding
- DOCA RDMA

Refer to their respective programming guide for more information.

6.20.6 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/storage/
```

`doca_storage_gga_offload_sbc_generator` is not compiled when `liblz4` dev libraries are not present.

The write path is only available if the `doca_storage_comch_to_rdma_gga_offload` service is compiled with the `liblz4` dev libraries.

6.20.6.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

The storage zero copy applications are:

- `doca_storage_comch_to_rdma_gga_offload`

- `doca_storage_comch_to_rdma_zero_copy`
- `doca_storage_gga_offload_sbc_generator`
- `doca_storage_initiator_comch`
- `doca_storage_target_rdma`

The applications are built under `/tmp/build/storage/`.

6.20.6.2 Compiling Storage Applications Only

To directly build only the storage applications:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_storage=true
ninja -C /tmp/build
```

The storage applications are built under `/tmp/build/storage/`.

Alternatively, you can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_storage` to `true`
2. Run the following compilation commands:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build
   ninja -C /tmp/build
   ```

   The storage applications are created under `/tmp/build/storage/`.

6.20.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.20.7 Running the Applications

Refer to each use case for details on how to run the applications:

- Use case 1 examples
- Use case 2 examples

6.20.8 DOCA Storage Comch to RDMA GGA Offload Application Guide

6.20.8.1 Introduction

The `doca_storage_comch_to_rdma_gga_offload` application acts as a bridge between the initiator and three storage targets. It actively participates in data transfer and leverages `doca_libs` to accelerate certain data operations transparently to both the initiator and the targets.

6.20.8.2 System Design

The `doca_storage_comch_to_rdma_gga_offload` application performs the following key functions:

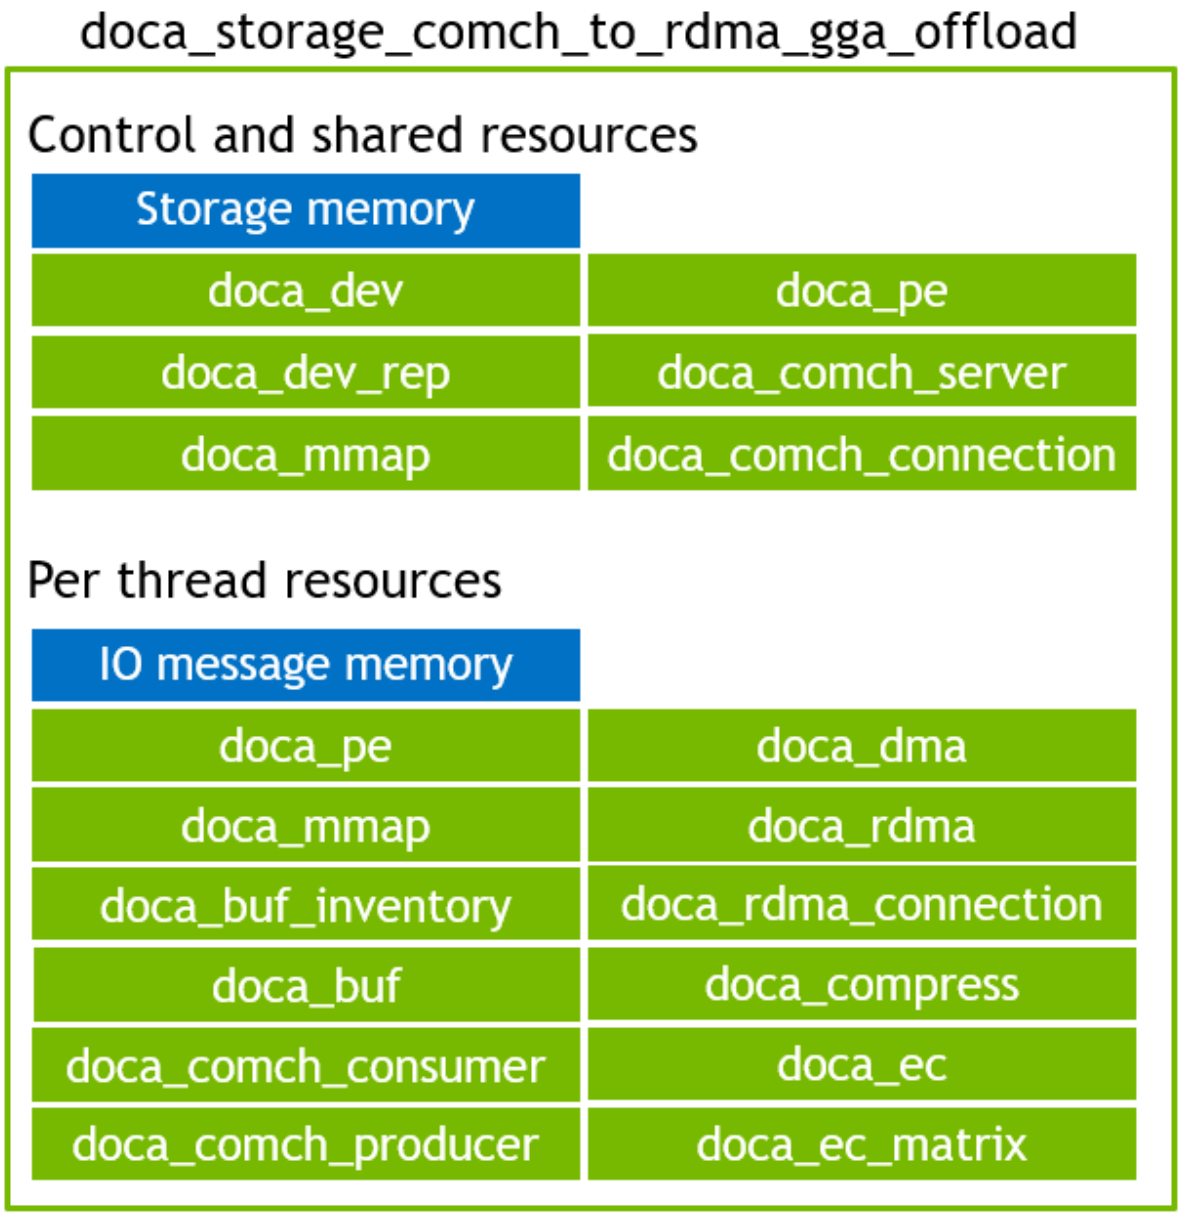
- Orchestrates communication between the initiator and the three storage instances
- Periodically triggers data recovery flows to simulate data loss
- Performs data recovery using erasure coding
- Performs inline data (de)compression
- Performs creation of erasure coding redundancy data

To accomplish these tasks, the application establishes TCP connections to three storage targets and listens for an incoming connection from a single initiator using `doca_comch_server`.

6.20.8.3 Architecture

The `doca_storage_comch_to_rdma_gga_offload` application is divided into two main functional areas:

- Control-time and shared resources
- Per-thread data path resources



The application execution follows two primary phases:

- Control phase
- Data path phase

6.20.8.3.1 Control Phase

This phase begins with establishing connections to the required storage targets, followed by awaiting a client connection. Once all connections are in place, the application waits for specific control commands:

- Query storage
- Init storage

- Start storage

Each control command is processed using the following sequence:

1. Relay the command to each connected storage target.
2. Wait for responses from all storage targets.
3. Perform required post-processing and consistency checks on the responses.
4. Send a response back to the client.

Issuing the start storage command initiates the data path phase. While the data threads begin execution, the main thread continues to wait for final control commands to complete the application's lifecycle:

- Stop storage
- Shutdown

6.20.8.3.2 Data Path Phase

This phase is executed per thread and involves each thread performing I/O operations requested by the client. For a read I/O operation, one of two flows is used:

- Regular read (no recovery)
- Recovery read

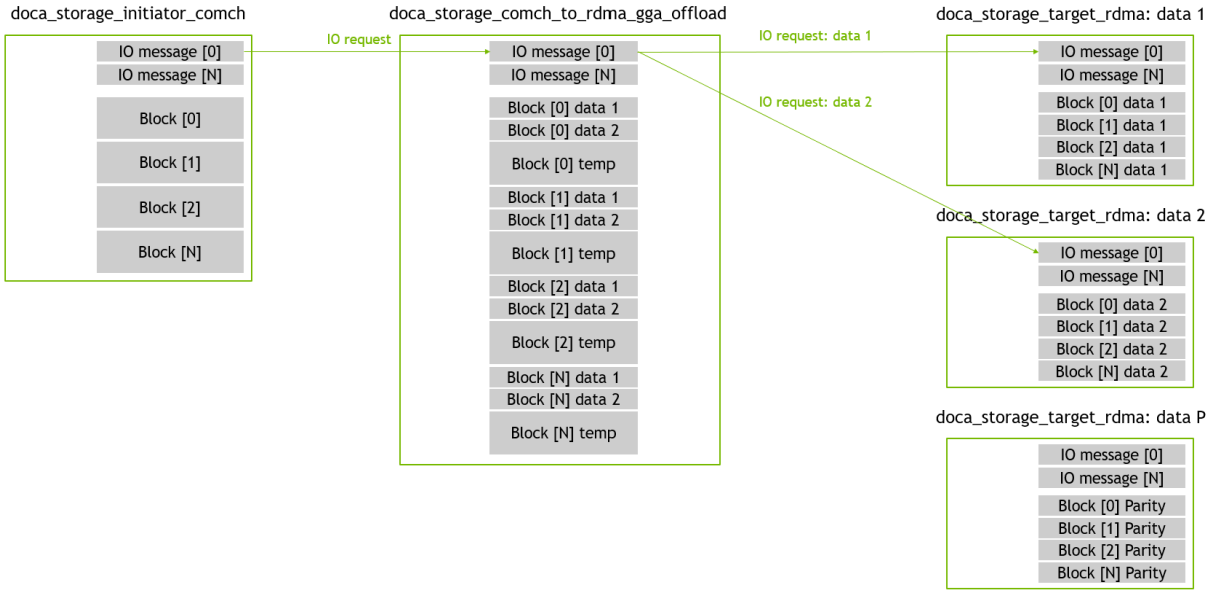
By default, only the regular read flow is executed. However, periodic recovery operations can be enabled by the user—see the "Command Line Flags" section for details.

6.20.8.3.2.1 Regular Read Data Flow

The regular read flow consists of the stages detailed in the following subsections.

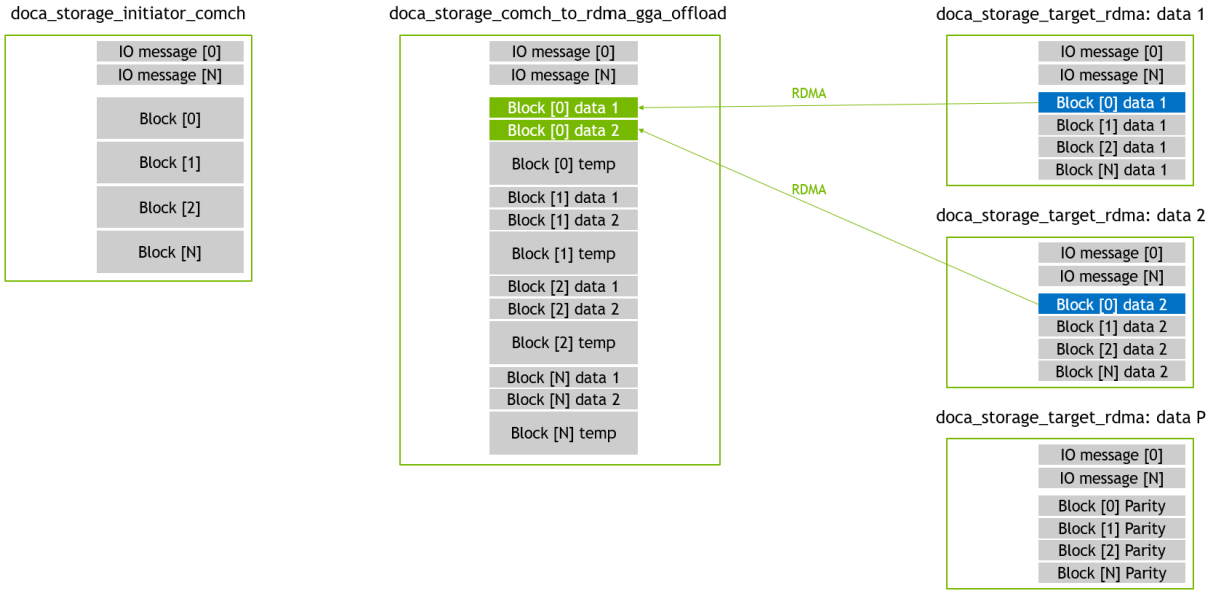
Initiator Request

1. The initiator sends an I/O request to the GGA offload application.
2. The GGA offload application generates two read requests: one for `data_1` and one for `data_2`. Since each storage target only stores a half block, these requests are resized to be half of the initiator's original block size. The output address for each request is set to place the resulting half-block of data into the correct slot (the `data_1` or `data_2` location) inside the service's larger temporary storage block.



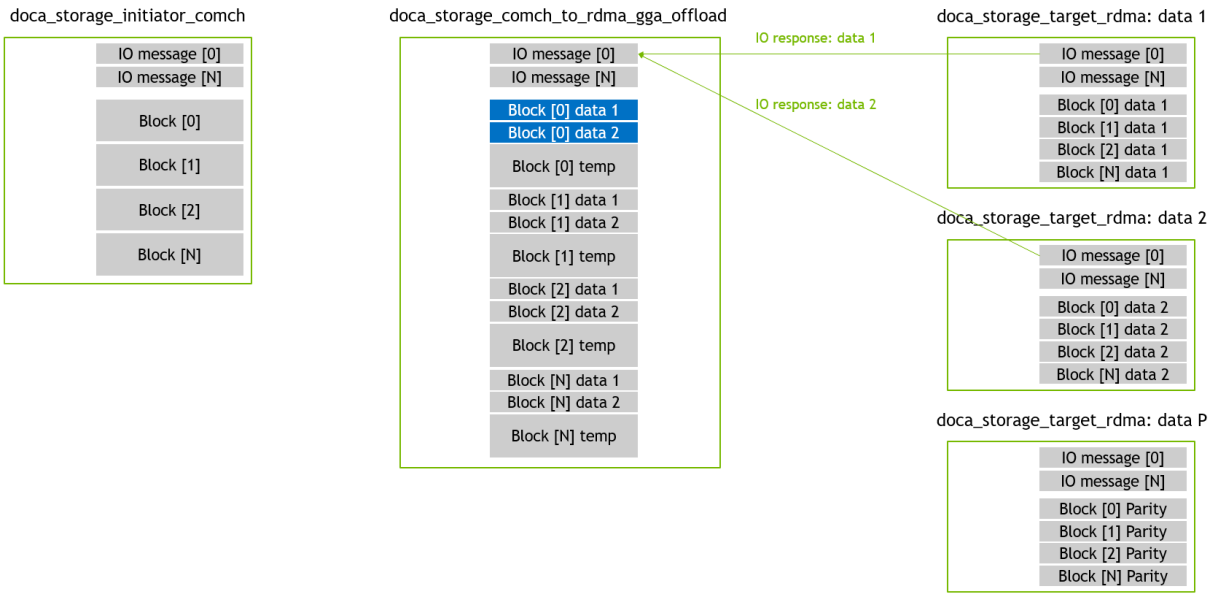
RDMA Transfers

Each storage target performs an RDMA write into the GGA offload memory block at the designated offsets.



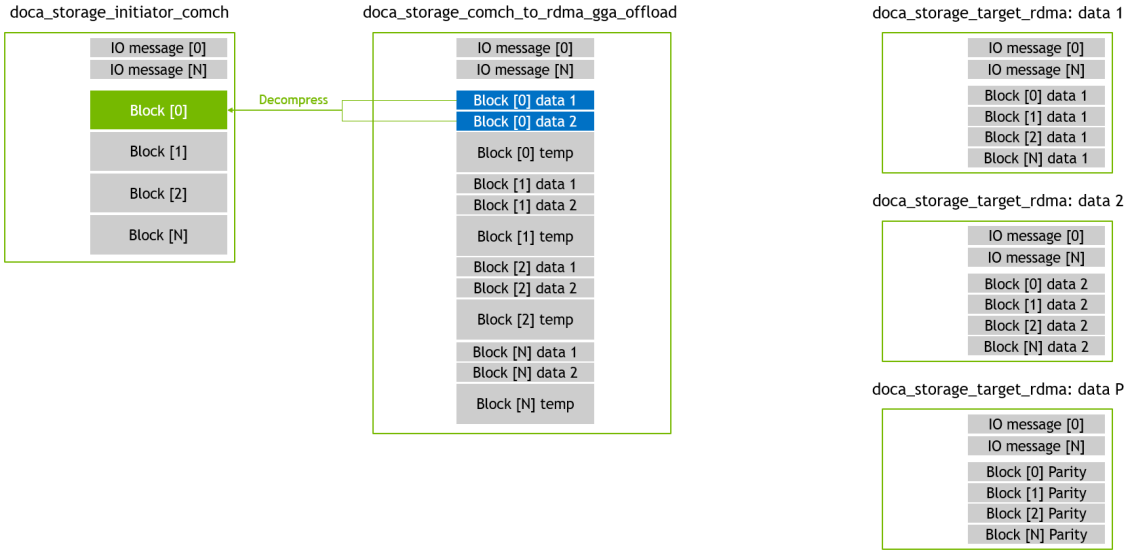
Target Responses

1. Both storage targets send I/O responses upon completing the RDMA transfers.
2. The GGA offload application waits until both responses are received.

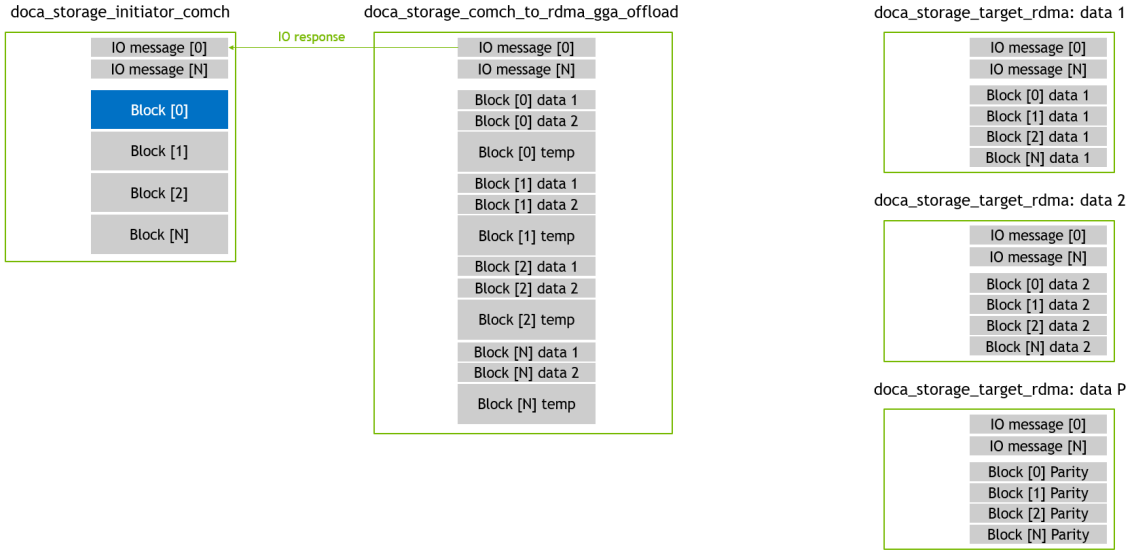


Decompression and Final Response

1. The application performs decompression using the received data blocks. Decompression output is written directly to the initiator memory using the `doca_decompress` task.



2. The application sends an I/O response to the initiator, completing the operation.

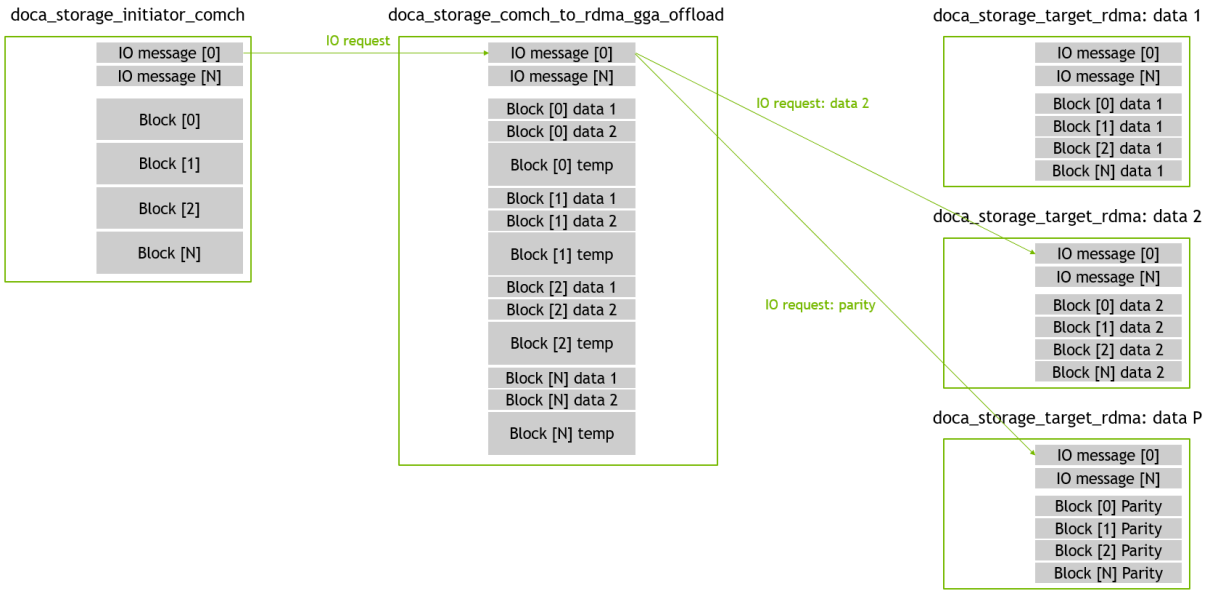


6.20.8.3.2.2 Recovery Read Data Flow

This flow is similar to the regular read, but with added steps for error correction using erasure coding. The process involves the stages detailed in the following subsections.

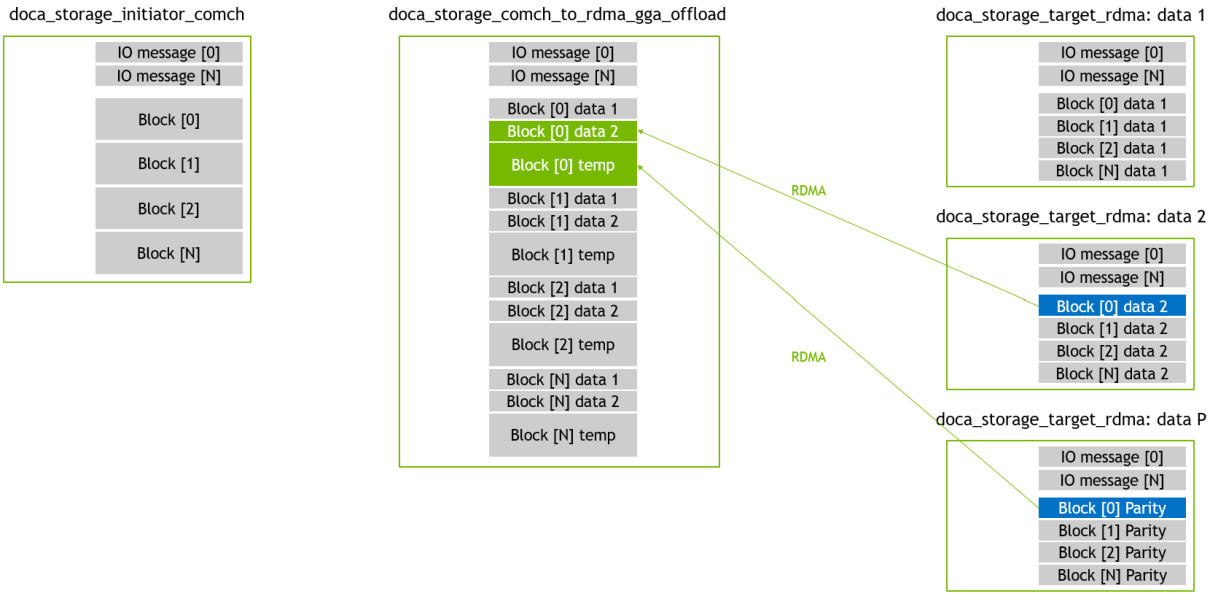
Initiator Request

1. The initiator sends an I/O request to the GGA offload application.
2. Given that recovery is required, the application:
    a. Translates the I/O address normally.
    b. Modifies one of the two storage requests to target the parity partition instead of a standard data partition.
    c. Adds an output offset field to redirect the parity data into a reserved region of GGA offload memory.



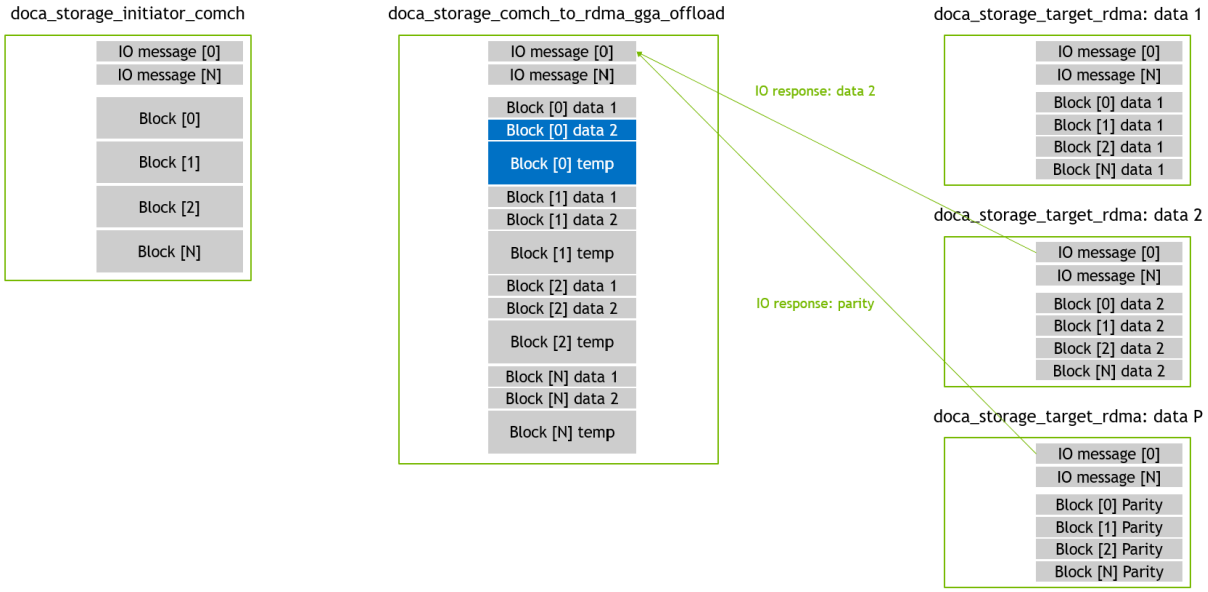
RDMA Transfers

1. Two RDMA transfers are issued:
   - One to the surviving data partition.
   - One to the parity partition.
2. The transferred blocks are written into the GGA offload memory with appropriate alignment.



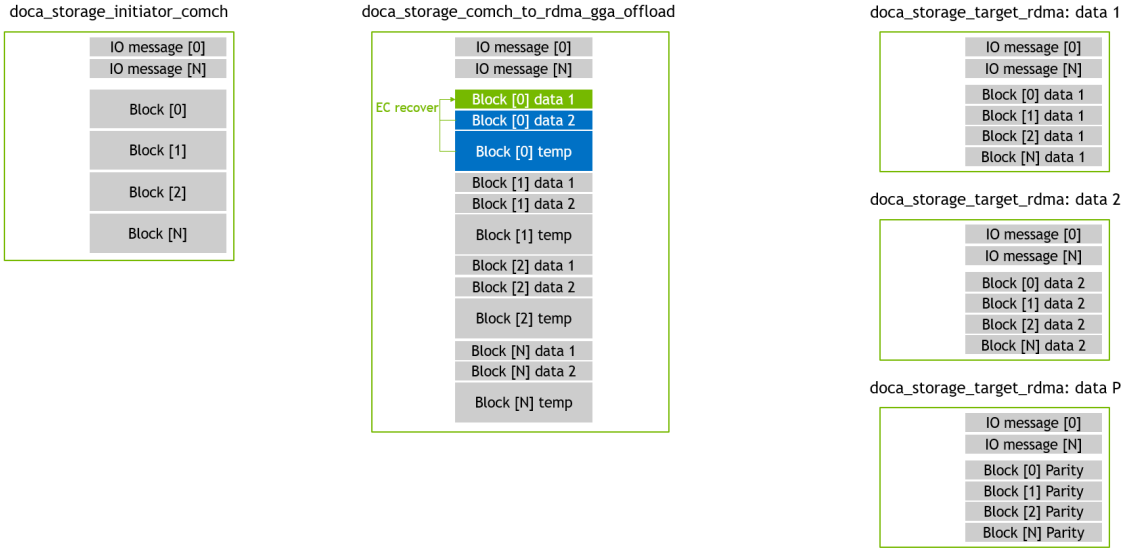
Target Responses

1. Both storage targets reply with I/O responses.
2. The GGA offload application waits for both to complete before proceeding.



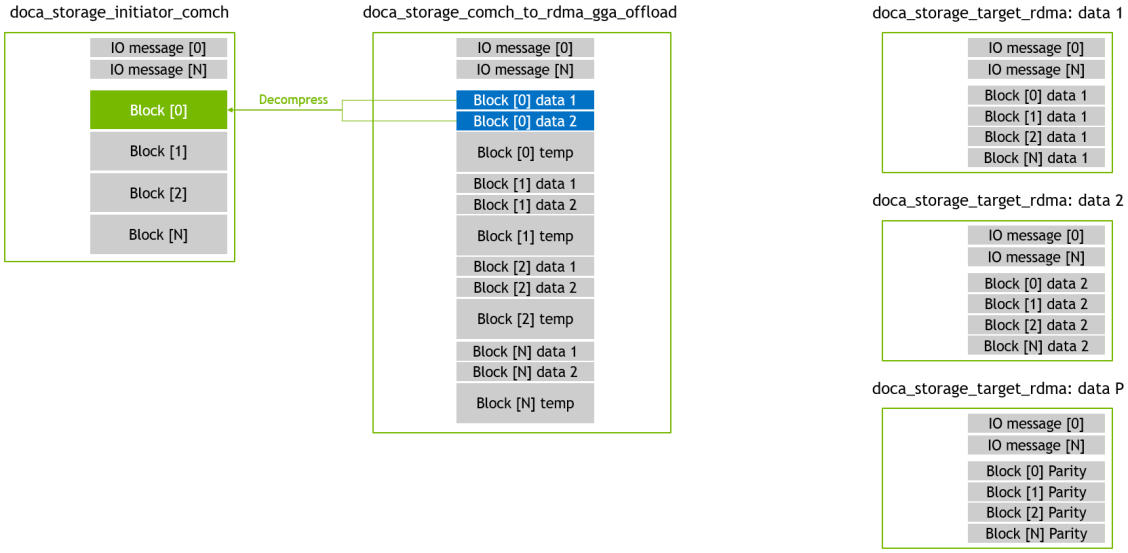
Data Recovery

1. The application performs recovery using the available half block and parity data to reconstruct the missing block.

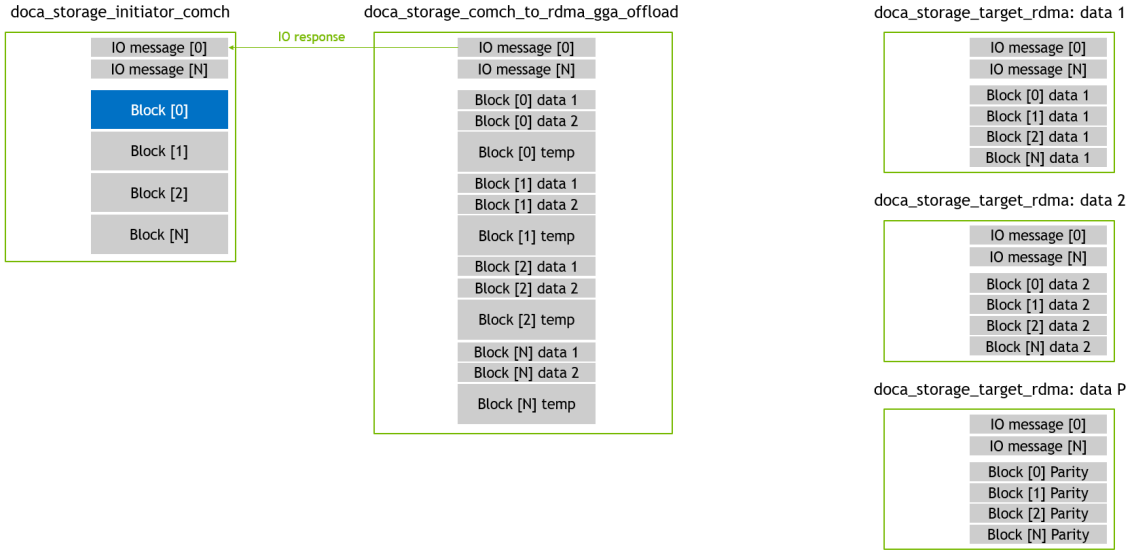


Decompression and Final Response

1. The recovered data is then decompressed. As with the regular read, decompression output is written directly to initiator memory.



- An I/O response is sent to the initiator, completing the operation.



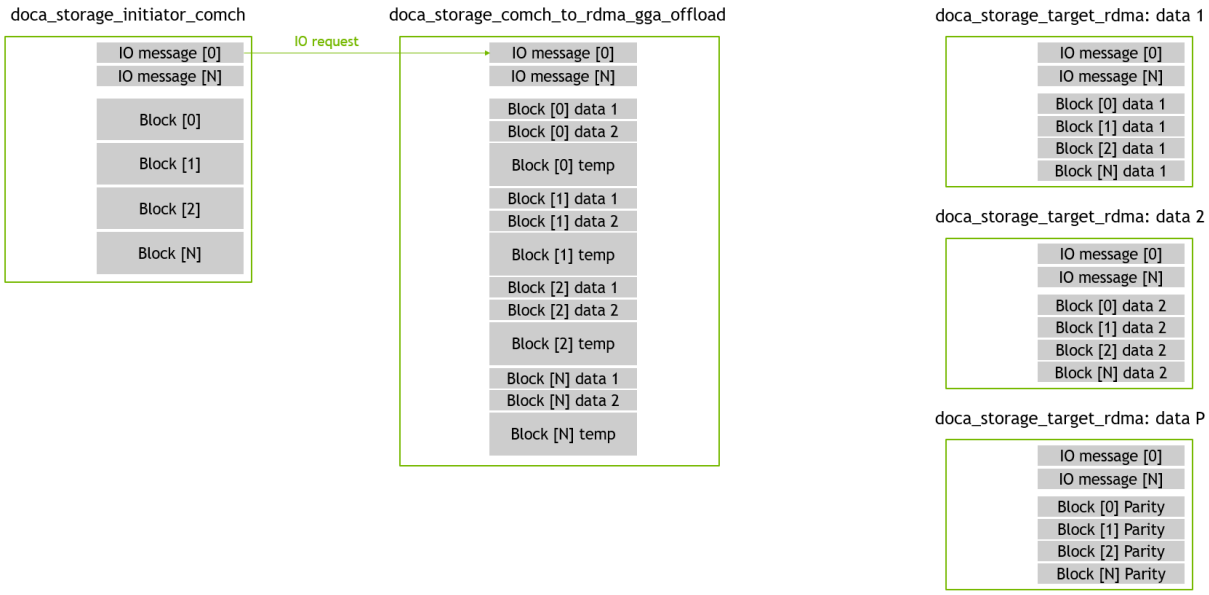
6.20.8.3.2.3 Write Data Flow

> ⚠ The write path is only available when the service is compiled with the `liblz4` dev libraries.

The write data flow consists of the stages detailed in the following subsections.

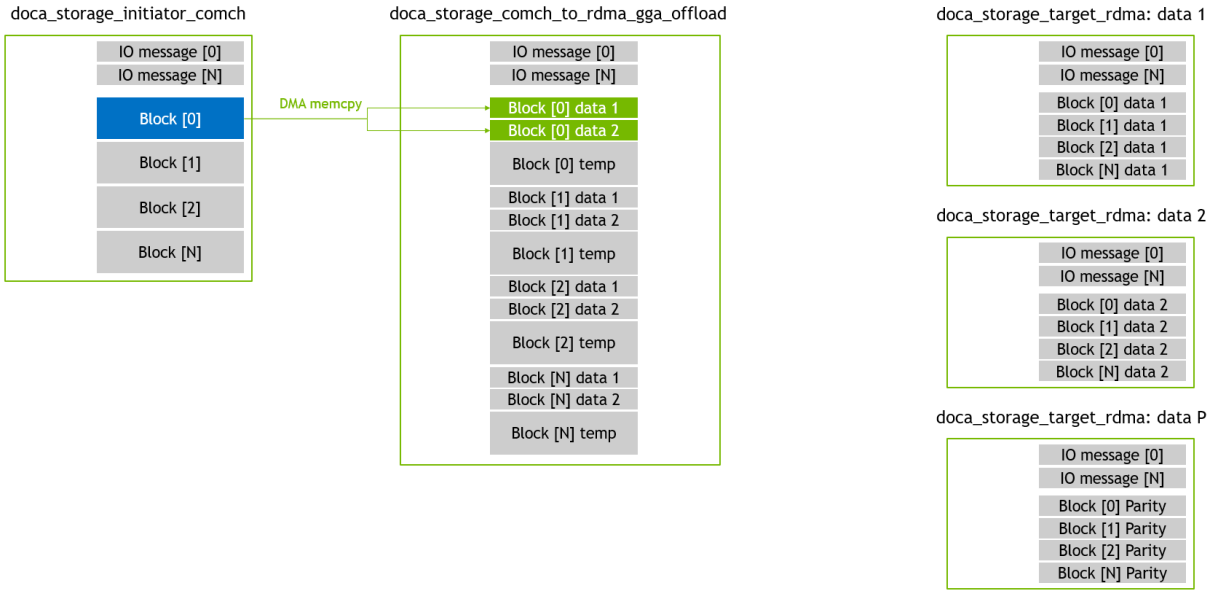
Initiator Request

The initiator sends an I/O request to the GGA offload application.



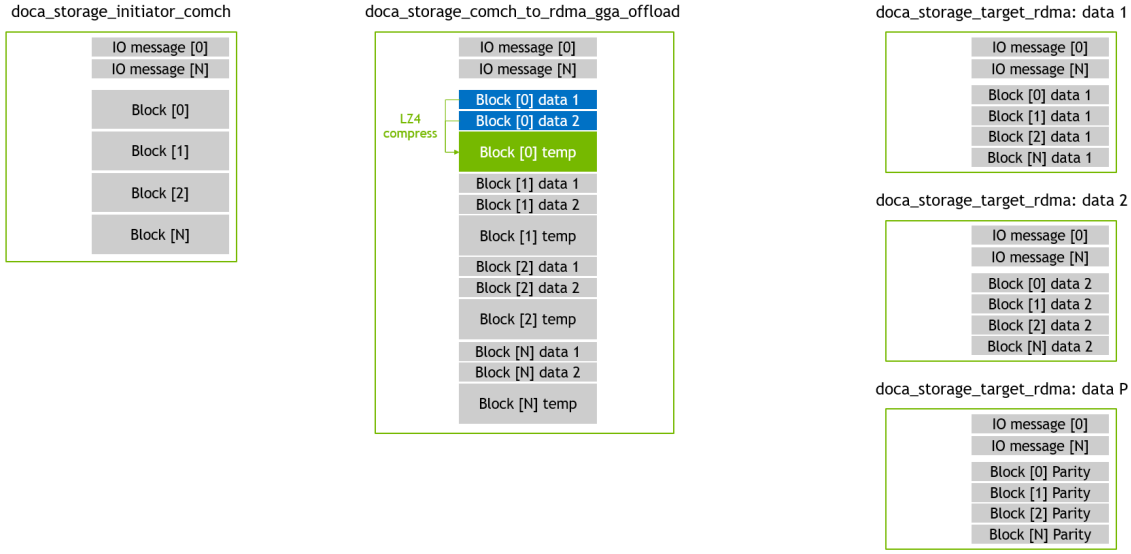
Service Fetches Data

The service fetches the data from the initiator as a single DMA read.

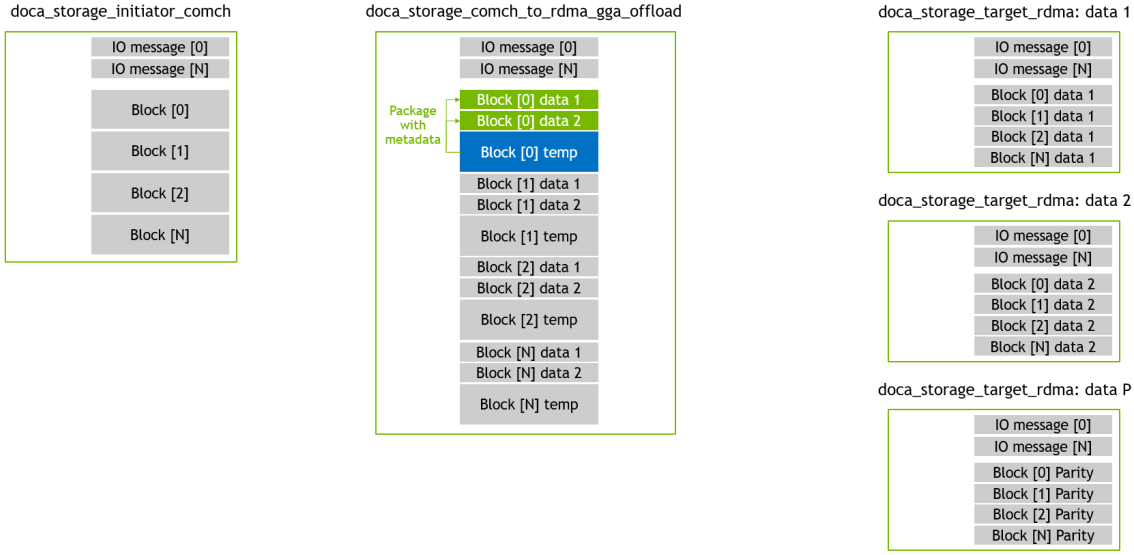


Data Compression

1. The service uses a `liblz4` to compress the data from block data1 and data 2 into the temp storage space.

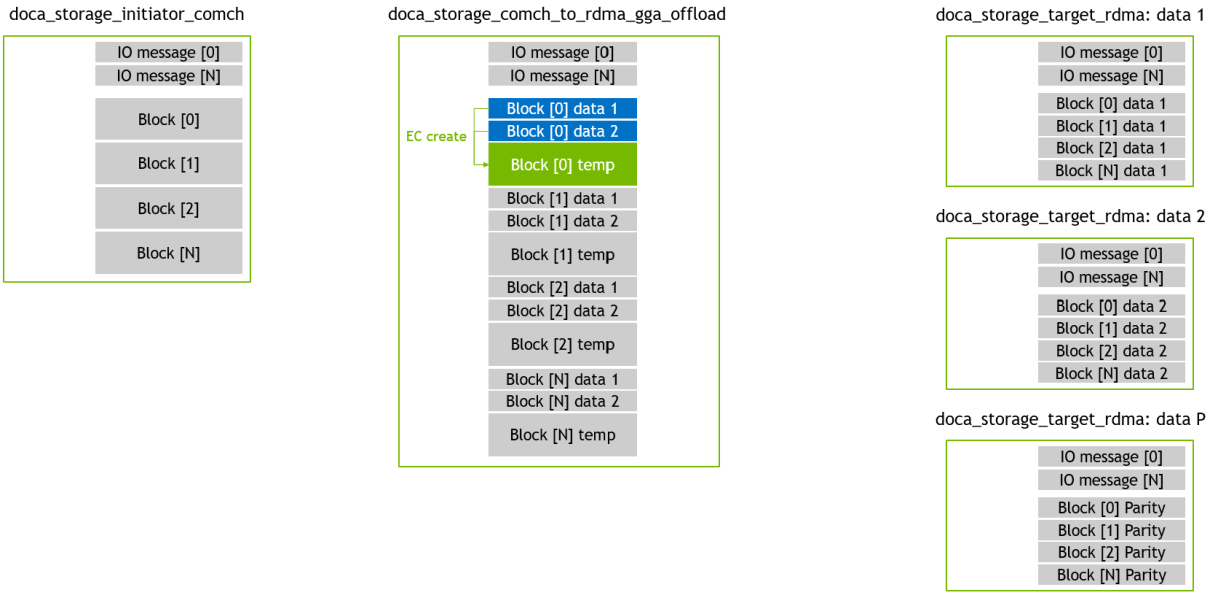


2. The compressed bytes are copied back to data 1 and data 2 location but with a metadata header and trailer added.



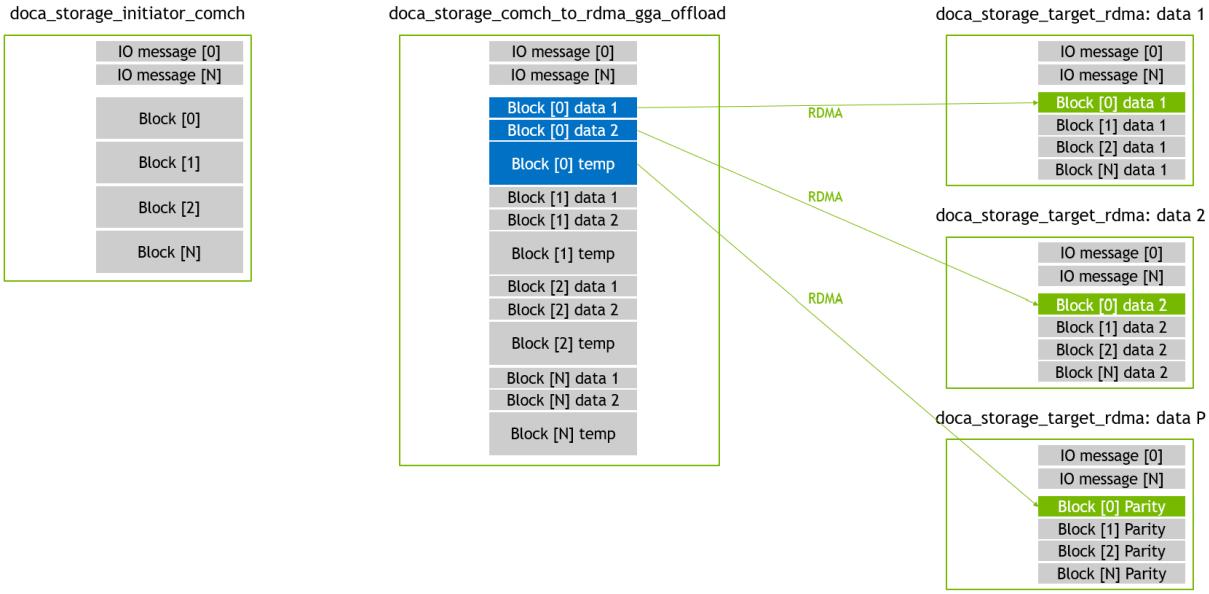
Parity Block Creation

A half block worth of EC redundancy bytes are created from the compressed data (including its metadata).



IO Requests Sent to Storage Targets

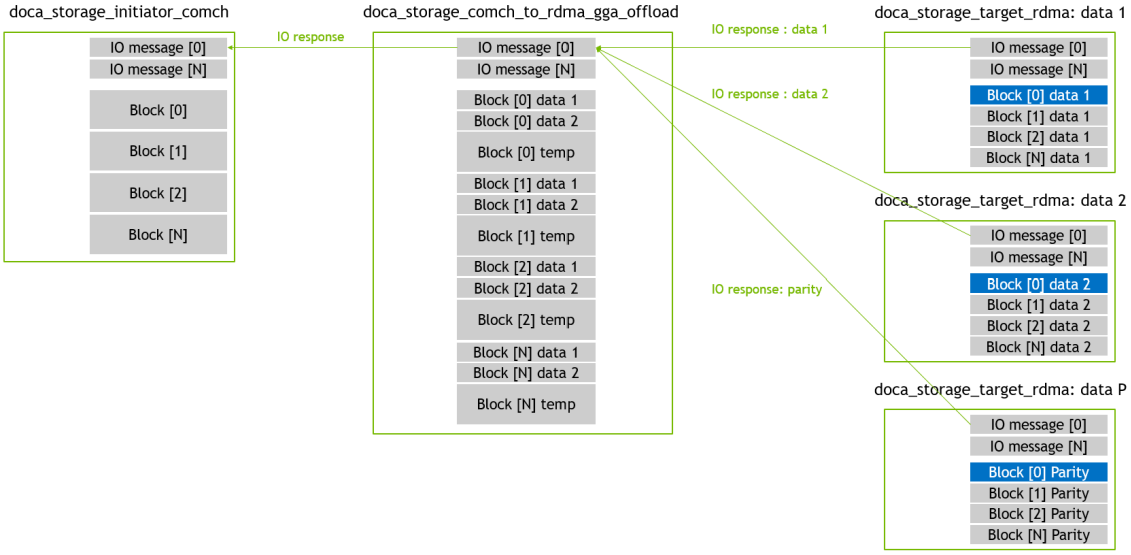
Each of the storage targets are sent an IO write request to store the appropriate half block of data (data 1, data 2, or parity data).



IO Responses

1. All three storage targets reply with I/O responses.
2. The GGA offload application waits for all three to complete.

3. The GGA offload application sends an IO response to the initiator.



6.20.8.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Comch
- DOCA Compress
- DOCA DMA
- DOCA Erasure Coding
- DOCA RDMA

6.20.8.5 Compiling the Application

This application is compiled as part of the set of storage applications. For compilation instructions, refer to the DOCA Storage Applications page.

6.20.8.6 Running the Application

6.20.8.6.1 Application Execution

This application can only run within the NVIDIA® BlueField® DPU.

DOCA Storage Comch to RDMA GGA Offload is provided in source form. Therefore, compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_storage_comch_to_rdma_gga_offload [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device                      Device identifier
  -r, --representor                 Device host side representor identifier
  --cpu                             CPU core to which the process affinity can be set
  --data-1-storage                  Storage server addresses in <ip_addr>:<port> format
  --data-2-storage                  Storage server addresses in <ip_addr>:<port> format
  --data-p-storage                  Storage server addresses in <ip_addr>:<port> format
  --matrix-type                     Type of matrix to use. One of: cauchy, vandermonde Default: vandermonde
  --command-channel-name            Name of the channel used by the doca_comch_client. Default:
"doca_storage_comch"
  --control-timeout                 Time (in seconds) to wait while performing control operations. Default:
5
  --trigger-recovery-read-every-n   Trigger a recovery read flow every N th request. Default: 0 (disabled)
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_storage_comch_to_rdma_gga_offload -h
```

For additional information, refer to section "Command-line Flags".

- CLI example for running the application on the BlueField:

```
./doca_storage_comch_to_rdma_gga_offload -d 03:00.0 -r 3b:00.0 --data-1-storage 172.17.0.1:12345 --data-2-
storage 172.17.0.2:12345 --data-p-storage 172.17.0.3:12345 --cpu 0
```

Both the DOCA Comch device PCIe address (`03:00.0`) and the DOCA Comch device representor PCIe address (`3b:00.0`) should match the addresses of the desired PCIe devices.

Storage target IP `address:port` tuples should be updated to refer to the running storage target applications.

6.20.8.6.2 Command-line Flags

6.20.8.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.20.8.6.2.2 Program Flags

Short Flag	Long Flag/JSON Key	Description
`d`	`device`	DOCA device identifier. One of: • PCIe address: `3b:00.0` • InfiniBand name: `mlx5_0` • Network interface name: `en3f0pf0sf0` ⚠ This flag is a mandatory.
`r`	`representor`	DOCA Comch device representor PCIe address ⚠ This flag is a mandatory.

Short Flag	Long Flag/JSON Key	Description
N/A	`--cpu`	Index of CPU to use. One data path thread is spawned per CPU. Index starts at 0. ⚠ The user can specify this argument multiple times to create more threads. ⚠ This flag is a mandatory.
N/A	`--data-1-storage`	IP address and port to use to establish the control TCP connection to the target. ⚠ This flag is a mandatory.
N/A	`--data-2-storage`	IP address and port to use to establish the control TCP connection to the target. ⚠ This flag is a mandatory.
N/A	`--data-p-storage`	IP address and port to use to establish the control TCP connection to the target. ⚠ This flag is a mandatory.
N/A	`--matrix-type`	Type of matrix to use. One of: • `cauchy` • `vandermonde`
N/A	`--command-channel-name`	Allows customizing the server name used for this application instance if multiple comch servers exist on the same device.
N/A	`--control-timeout`	Time, in seconds, to wait while performing control operations
N/A	`--trigger-recovery-read-every-n`	Trigger a recovery read flow every Nth request. Set to 0 to disable recovery reads entirely. For example, a value of 1 triggers a recovery read for every request, while a value of 10 triggers a recovery read for one out of every ten requests.

6.20.8.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.20.8.7 Application Code Flow

The flow of the application is broken down into key functions and steps:

```
gga_offload_app app{parse_cli_args(argc, argv)};

storage::install_ctrl_c_handler([&app]() {
    app.abort("User requested abort");
});

app.connect_to_storage();
app.wait_for_comch_client_connection();
app.wait_for_and_process_query_storage();
app.wait_for_and_process_init_storage();
app.wait_for_and_process_start_storage();
app.wait_for_and_process_stop_storage();
app.wait_for_and_process_shutdown();
app.display_stats();
```

6.20.8.7.1 Main/Control Thread Flow

1. ```
   gga_offload_app app{parse_cli_args(argc, argv)}
   ```

   Parse CLI arguments and use these to create the application instance. Initial resources are also created at this stage:

   a. ```
      DOCA_LOG_INFO("Open doca_dev: %s", m_cfg.device_id.c_str());
      m_dev = storage::open_device(m_cfg.device_id);
      ```

      Open a `doca_dev` as specified by the CLI argument: `-d` or `--device`

   b. ```
      DOCA_LOG_INFO("Open doca_dev_rep: %s", m_cfg.representor_id.c_str());
      m_dev_rep = storage::open_representor(m_dev, m_cfg.representor_id);
      ```

      Open a `doca_dev_rep` as specified by the CLI argument: `-r` or `--representor`

   c. ```
      m_all_ctrl_channels[connection_role::data_1] = storage::control::make_tcp_client_control_channel(
          m_cfg.storage_server_address[connection_role::data_1]);

      m_all_ctrl_channels[connection_role::data_2] = storage::control::make_tcp_client_control_channel(
          m_cfg.storage_server_address[connection_role::data_2]);

      m_all_ctrl_channels[connection_role::data_p] = storage::control::make_tcp_client_control_channel(
          m_cfg.storage_server_address[connection_role::data_p]);
      ```

      Create three TCP client control channels (control channel objects provide a unified API so that a TCP client, TCP server, `doca_comch_client`, and `doca_comch_server` all have a consistent API)

      > See `storage_common/control_channel.hpp` for more information about the control channel abstraction.

   d. ```
      m_all_ctrl_channels[connection_role::client] =
          storage::control::make_comch_server_control_channel(m_dev,
                                      m_dev_rep,
                                      m_cfg.command_channel_name.c_str(),
                                      this,
                                      new_comch_consumer_callback,
                                      expired_comch_consumer_callback);
      ```

      Create a comch server control channel (containing a `doca_comch_server` instance) using the device, representor, and channel name as specified by
      ```

the CLI argument `--command-channel-name` or the default value if none was specified.

2.
```
storage::install_ctrl_c_handler([&app]() {
    app.abort("User requested abort");
});
```
Set a signal handler for Ctrl+c keyboard inputs so the app can shutdown gracefully.

3.
```
app.connect_to_storage();
```
Connect to the TCP server hosted by each of the three storage targets as defined by the CLI arguments: `--data-1-storage`, `--data-2-storage`, and `--data-p-storage`

   a.
```
void gga_offload_app::connect_to_storage(void)
{
    for (auto *storage_channel : m_storage_ctrl_channels) {
        DOCA_LOG_DBG("Connect control channel...");
        for (;;) {
            if (m_abort_flag) {
                throw storage::runtime_error{DOCA_ERROR_CONNECTION_ABORTED,
                                "Aborted while connecting to storage"};
            }

            if (storage_channel->is_connected())
                break;
        }
    }
}
```
For each storage control channel (the TCP contexts) poll each context in an infinite loop until either it connects, or the user aborts the application. (The servers should have been started before the service, so no delay is desired between polls of the control context).

4.
```
app.wait_for_comch_client_connection();
```
Wait for a `doca_comch_client` to connect.

   a.
```
void gga_offload_app::wait_for_comch_client_connection(void)
{
    while (!m_all_ctrl_channels[connection_role::client]->is_connected()) {
        std::this_thread::sleep_for(std::chrono::milliseconds{100});
        if (m_abort_flag) {
            throw storage::runtime_error{DOCA_ERROR_CONNECTION_ABORTED,
                            "Aborted while connecting to client"};
        }
    }
}
```
Poll the Comch server control channel until a `doca_comch_client` has connected, or the user aborts the application. If any further Comch client attempts to connect to the server it will be automatically rejected by the control channel which is designed for a 1:1 relationship between clients and servers. A sleep is placed in this loop as it may take the user / operator a few seconds to start the client so there is no gain to polling any faster.

5.
```
app.wait_for_and_process_query_storage();
```

Wait for the initiator to send a `query_storage_request` control message and then perform the required actions to fulfill the request:

a.
```
for (auto *storage_ctrl : m_storage_ctrl_channels) {
    auto storage_request = storage::control::message{
        storage::control::message_type::query_storage_request,
        storage::control::message_id{m_message_id_counter++},
        client_request.correlation_id,
        {},
    };

    msg_ids.push_back(storage_request.message_id);
    storage_ctrl->send_message(storage_request);
}
```
Send a query storage request to each storage target server.

b.
```
wait_for_responses(msg_ids, default_control_timeout_seconds);
```
Wait for storage targets to respond.

c. Check the response from each storage target.
    i. If they all report the same dimensions (block size and block count) respond to the initiator with a `query_storage_response` message reporting double the values returned by each storage target (as each storage holds half blocks not full blocks) I.E. If the storage target reports "64K capacity 2K block size" report "128K capacity 4K block size".
    ii. If the dimensions do not match or any other error occurs respond to the initiator with a `error_response` message detailing the error that occurred.

6.
```
app.wait_for_and_process_init_storage();
```
Wait for the initiator to send a `init_storage_request` control message and then perform the required actions to fulfill the request:

a. Use the `init_storage_payload` data to:
    i. Set core count (`m_core_count`) as the number of cores requested by the initiator (number of `--cpu` arguments provided to the initiator) OR fail if this is more than the number of `--cpu` arguments provided to the service.
    ii. Set number of transactions per core (`m_num_transactions`) to: the number of transactions requested by the initiator doubled. This is doubled to allow for batched task submission and avoid race conditions where the initiator can see a response to a transaction and try to re-submit it before the associated comch producer event callback is received by the server meaning the initiator will continually re-try to send the task and degrade performance until the service catches up and re-submits the consumer task. This should be uncommon, but to make sure it can never happen double the transaction count is allocated so even if every single transaction on

the initiator hit this issue there is a full second set of transactions ready on the service side to receive the tasks and avoid any contention. A user can experiment with reducing this value to save memory if desired).

iii. Calculate the per transaction storage block size (`m_per_transaction_chunk_size`) as: `block size * 2.5` if write flow is enabled or `block size * 1.5` when the write flow is disabled.

iv. Allocate storage memory blocks (`m_local_io_region`) as an array of `m_core_count * m_num_transactions * m_per_transaction_chunk_size` bytes.

v.
```
m_remote_io_mmap = storage::make_mmap(m_dev,
                     init_storage_details->mmap_export_blob.data(),
                     init_storage_details->mmap_export_blob.size(),
                     storage::thread_safety::yes);
```

Import the initiator mmap so that its IO blocks can be accessed by the service.

vi.
```
m_local_io_mmap = storage::make_mmap(m_dev,
                    reinterpret_cast<char *>(m_local_io_region),
                    local_storage_size,
                    DOCA_ACCESS_FLAG_LOCAL_READ_WRITE | DOCA_ACCESS_FLAG_PCI_READ_WRITE |
                        DOCA_ACCESS_FLAG_RDMA_WRITE | DOCA_ACCESS_FLAG_RDMA_READ,
                    storage::thread_safety::yes);

std::vector<uint8_t> mmap_export_blob = [this]() {
    uint8_t const *reexport_blob = nullptr;
    size_t reexport_blob_size = 0;
    auto const ret = doca_mmap_export_rdma(m_local_io_mmap,
                           m_dev,
                           reinterpret_cast<void const **>(&reexport_blob),
                           &reexport_blob_size);
    if (ret != DOCA_SUCCESS) {
        throw storage::runtime_error{ret, "Failed to re-export host mmap for rdma"};
    }

    return std::vector<uint8_t>{reexport_blob, reexport_blob + reexport_blob_size};
}();
```

Create and export the service IO blocks memory region. This will be shared with the storage targets so they can access storage service IO blocks memory for RDMA read / write operations.

vii.
```
for (auto *storage_ctrl : m_storage_ctrl_channels) {
    auto storage_request = storage::control::message{
        storage::control::message_type::init_storage_request,
        storage::control::message_id{m_message_id_counter++},
        client_request.correlation_id,
        std::make_unique<storage::control::init_storage_payload>(m_num_transactions,
                                    init_storage_details->core_count,
                                    mmap_export_blob),
    };

    storage_ctrl->send_message(storage_request);
}
```

Send an init storage request to each storage target using:

1. The service transaction count (double the initiator value).
2. The initiator core count.
3. The service IO blocks mmap.

viii. Wait for storage targets to respond.

ix. Send a response to the initiator:

1. Send a `init_storage_response` message upon success or an `error_response` message if anything failed

x. Perform the first stages of the worker threads initialization. These steps are carried out for each thread, but only one thread performs the steps at any time this simplifies the sending and receiving of control messages, the user could modify this flow to execute in parallel if they so desired.

1. Create thread bound to the N^{th} CPU provided to the service via the `--cpu` CLI arguments.

2.
```
m_workers[ii].execute_control_command(
    worker_create_objects_control_command {
        m_dev,
        comch_channel->get_comch_connection(),
        m_local_io_mmap,
        m_remote_io_mmap,
        m_num_transactions,
        m_storage_block_size,
        m_cfg.ec_matrix_type,
        m_cfg.recover_freq}
    );
```
Initialize thread context (asynchronously).

3.
```
connect_rdma(ii, storage::control::rdma_connection_role::io_data, cid);
```
Create RDMA data connections (asynchronously) The thread will connect to each of the three storage targets and create a RDMA context which will be idle from the service's point of view, but is used by the storage target to perform RDMA read / write operations. See the DOCA Storage Target RDMA Application Guide for an explanation why there are two RDMA contexts per thread.

4.
```
connect_rdma(ii, storage::control::rdma_connection_role::io_control, cid);
```
Create RDMA data connections (asynchronously) The thread will connect to each of the three storage targets and create a RDMA context which will be used to exchange IO requests and responses using RDMA send / recv tasks. See the DOCA Storage Target RDMA Application Guide for an explanation why there are two RDMA contexts per thread.

7.
```
app.wait_for_and_process_start_storage();
```
Wait for the initiator to send a `start_storage_request` control message and then perform the required actions to fulfill the request:

a. Forward the start storage request to each of the storage targets.
b. Wait for storage targets to respond.
c. Signal all work threads to begin data path operation.
d. Send a response to the initiator:

i. Send a `start_storage_response` message upon success or an `error_response` message if anything failed.

8. Data path execution takes place now until either the user abort the program or a stop message is received.

9. ```
   app.wait_for_and_process_stop_storage();
   ```

   Wait for the initiator to send a `stop_storage_request` control message and then perform the required actions to fulfill the request:
   a. Forward the stop storage request to each of the storage targets.
   b. Wait for storage targets to respond.
   c. Signal all work threads to stop data path operation.
   d. Collect run time stats.
   e. Send a response to the initiator:
      i. Send a `stop_storage_response` message upon success or an `error_response` message if anything failed.

10. ```
    app.wait_for_and_process_shutdown();
    ```

    Wait for the initiator to send a `shutdown_request` control message and then perform the required actions to fulfill the request:
    a. Forward the shutdown request to each of the storage targets.
    b. Wait for storage targets to respond.
    c. Destroy worker thread objects.
    d. Send a response to the initiator:
       i. Send a `stop_storage_response` message upon success or an `error_response` message if anything failed.

11. ```
    app.display_stats()
    ```

    Display runtime statistics.
12. Application destructor is triggered:
    a. Destroy control channels.
    b. Destroy storage IO blocks `doca_mmap`.
    c. Destroy storage IO block memory.
    d. Destroy initiator IO blocks `doca_mmap`.
    e. Close `doca_dev_rep`.
    f. Close `doca_dev`.
13. Program exits.
    ```

6.20.8.7.2 Worker/Data Path Thread Flow

The work thread proc executes in two phases: Control / configuration phase, followed by data path phase where read, write, and recovery operations take place.

6.20.8.7.2.1 Worker Init Process

```
void gga_offload_app_worker::thread_proc(gga_offload_app_worker *self, uint16_t core_idx) noexcept
```

The worker starts by executing a loop of:

1. Lock mutex
2. If message pointer is not null:
    a. Process the configuration message.
    b. Set the operation result.
3. Unlock the mutex.
4. Yield.

The following configuration operations can be performed by the worker thread:

1. ```
   void gga_offload_app_worker::create_worker_objects(worker_create_objects_control_command const &cmd)
   ```

   Create general worker objects:
    a. Creates LZ4 software library context for compression operations (when enabled).
    b. Create N transaction objects.
    c. Create IO message memory.
    d. Create IO message `doca_mmap` (to allow the messages to be accessed by comch and RDMA).
    e. Create `doca_buf_inventory`.
    f. Create `doca_pe` to drive the DOCA contexts (`doca_rdma`, `doca_comch_consumer`, `doca_comch_producer`, `doca_compress`, `doca_ec`, `doca_dma`).
    g. Create `doca_comch_consumer`, `doca_comch_producer`, `doca_compress`, `doca_ec`, and `doca_dma` contexts.
    h. Initialize and start contexts.

2. ```
   void gga_offload_app_worker::export_local_rdma_connection_blob(worker_export_local_rdma_connection_command &cmd)
   ```

   Export RDMA context connection binary blob.

3. ```
   void gga_offload_app_worker::import_remote_rdma_connection_blob(worker_import_local_rdma_connection_command const &cmd)
   ```

   Import remote RDMA context connection binary blob.
   ```

4.
```
void gga_offload_app_worker::are_contexts_ready(worker_are_contexts_ready_control_command &cmd) const
 noexcept
```
Poll all contexts to check they are ready to perform data path operations.

5.
```
void gga_offload_app_worker::prepare_tasks(worker_prepare_tasks_control_command const &cmd)
```
Prepare transaction contexts by:
   a. Allocating `doca_buf` objects.
   b. Allocating `doca_task` objects.
   c. Setting task user data.
   d. Setting task pointers into the transaction context.
   e. Setting per transaction IO block addresses.

6.
```
void gga_offload_app_worker::start_data_path(void)
```
Break out of the wait for configuration event loop and start the data path loop.

> After the configuration phase the mutex is not used again

After breaking out of the initial configuration loop, the thread submits receive tasks (Comch consumer tasks, and RDMA recv tasks) then enters the data path function: `run_data_path_ops`.

6.20.8.7.2.2 Worker Data Path Process

```
void gga_offload_app_worker::run_data_path_ops(gga_offload_app_worker::hot_data &hot_data)
{
    DOCA_LOG_INFO("Core: %u running", hot_data.core_idx);

    while (hot_data.run_flag) {
        doca_pe_progress(hot_data.pe) ? ++(hot_data.pe_hit_count) : ++(hot_data.pe_miss_count);
    }

    while (hot_data.error_flag == false && hot_data.in_flight_transaction_count != 0) {
        doca_pe_progress(hot_data.pe) ? ++(hot_data.pe_hit_count) : ++(hot_data.pe_miss_count);
    }
}
```

During the data path phase the thread simply polls the `doca_pe` as quickly as possible to check for a task completion from one of the thread DOCA contexts (`doca_rdma`, `doca_comch_consumer`, `doca_comch_producer`, `doca_compress`, `doca_ec`, `doca_dma`) The interesting work is done in the callbacks of these tasks. The flow will always start with a consumer task completion. This is the reception of the IO message from the initiator.

doca_comch_consumer_task_post_recv_cb

```
void gga_offload_app_worker::doca_comch_consumer_task_post_recv_cb(doca_comch_consumer_task_post_recv *task,
                                   doca_data task_user_data,
                                   doca_data ctx_user_data) noexcept
{
    static_cast<void>(task_user_data);

    auto const transaction_idx = doca_task_get_user_data(doca_comch_consumer_task_post_recv_as_task(task)).u64;
    auto *const hot_data = static_cast<gga_offload_app_worker::hot_data *>(ctx_user_data.ptr);
```

```
    auto const ret = hot_data->start_transaction(hot_data->transactions[transaction_idx]);
    if (ret != DOCA_SUCCESS) {
        DOCA_LOG_ERR("Failed to start transaction: %s", doca_error_get_name(ret));
    }
}
```

This callback simply interprets the task callback parameters to call the `start_transaction` function. The start transaction flow performs the following steps:

1. Check transaction request type
2. Set transaction action flags based on the transaction type (read, write)
3. Calls the `progress_transaction` function to execute as many of the pending actions as possible. Some actions like sending IO requests to the storage targets, decompressing data, creating erasure coding blocks, amongst others are themselves asynchronous so processing will stop until a future task callback resumes the processing.

The transaction will result in a read or write operation being performed. A read operation may result in a regular read or a recovery read depending on value provides by the `--trigger-recovery-read-every-n` CLI argument. When non 0 even Nth read will perform a recovery read flow.

The flow of these operations are:

- Write flow
    - Fetch data from initiator memory using DMA
    - Compress data
    - Generate EC redundancy blocks
    - Store `data_1`, `data_2`, and `data_p` to the respective storage targets
    - Respond with IO response
- Regular read flow
    - Fetch `data_1` and `data_2` from the respective storage targets
    - Decompress the data into initiator memory
    - Respond with IO response
- Recovery read flow
    - Fetch `data_1` OR `data_2` from the respective storage target
    - Fetch `data_p` from the `data_p` storage target
    - Recover the missing data half using the existing data and the redundancy data
    - Decompress the data into initiator memory
    - Respond with IO response

doca_comch_producer_task_send_cb

```
void gga_offload_app_worker::doca_comch_producer_task_send_cb(doca_comch_producer_task_send *task,
                                doca_data task_user_data,
                                doca_data ctx_user_data) noexcept
{
    static_cast<void>(task);

    auto *const hot_data = static_cast<gga_offload_app_worker::hot_data *>(ctx_user_data.ptr);
```

```
    auto &transaction = hot_data->transactions[task_user_data.u64];
    transaction.pending_actions = 0;
    --(hot_data->in_flight_transaction_count);
    ++(hot_data->completed_transaction_count);

    static_cast<void>(
        doca_buf_reset_data_len(doca_comch_consumer_task_post_recv_get_buf(transaction.host_request_task)));

    auto const ret = doca_task_submit(doca_comch_consumer_task_post_recv_as_task(transaction.host_request_task));
    if (ret != DOCA_SUCCESS) {
        DOCA_LOG_ERR("Failed to submit doca_comch_consumer_task_post_recv: %s", doca_error_get_name(ret));
        hot_data->error_flag = true;
        hot_data->run_flag = false;
    }
}
```

The producer task completion callback signals that the transaction response has been delivered to the initiator. The transaction can now be re-used by re-submitting the transaction consumer task.

doca_rdma_task_send_cb

```
void gga_offload_app_worker::doca_rdma_task_send_cb(doca_rdma_task_send *task,
                            doca_data task_user_data,
                            doca_data ctx_user_data) noexcept
{
    static_cast<void>(task);

    auto *const hot_data = static_cast<gga_offload_app_worker::hot_data *>(ctx_user_data.ptr);
    auto &transaction = hot_data->transactions[task_user_data.u64];

    --(transaction.pending_storage_response_count);
    if (transaction.pending_storage_response_count == 0) {
        transaction.pending_actions ^= static_cast<uint32_t>(transaction_action::wait_for_storage_completion);
        hot_data->progress_transaction(transaction);
    }
}
```

The RDMA send task callback signals that an IO request has been delivered to one of the storage target machines. A counter is decremented to know when all IO requests and IO responses have been received so that the next step of processing the transaction can be carried out. For a read IO operation this could be data recovery, or decompression next, for a write operation the transaction is completed and the IO response to the initiator can be sent.

doca_rdma_task_receive_cb

```
void gga_offload_app_worker::doca_rdma_task_receive_cb(doca_rdma_task_receive *task,
                              doca_data task_user_data,
                              doca_data ctx_user_data) noexcept
{
    static_cast<void>(task_user_data);

    auto *const hot_data = static_cast<gga_offload_app_worker::hot_data *>(ctx_user_data.ptr);

    auto *const rdma_io_message = storage::get_buffer_bytes(doca_rdma_task_receive_get_dst_buf(task));
    auto const transaction_idx = storage::io_message_view::get_user_data(rdma_io_message).u64;

    auto &transaction = hot_data->transactions[transaction_idx];

    auto const io_result = storage::io_message_view::get_result(rdma_io_message);
    if (io_result != DOCA_SUCCESS) {
        // store error
        storage::io_message_view::set_result(io_result, transaction.initiator_io_message);
    }

    --(transaction.pending_storage_response_count);
    if (transaction.pending_storage_response_count == 0) {
        transaction.pending_actions ^= static_cast<uint32_t>(transaction_action::wait_for_storage_completion);
        hot_data->progress_transaction(transaction);
    }

    if (hot_data->run_flag) {
        static_cast<void>(doca_buf_reset_data_len(doca_rdma_task_receive_get_dst_buf(task)));
        auto const ret = doca_task_submit(doca_rdma_task_receive_as_task(task));
        if (ret != DOCA_SUCCESS) {
            DOCA_LOG_ERR("Failed to resubmit doca_rdma_task_receive");
            hot_data->run_flag = false;
            hot_data->error_flag = true;
        }
    }
}
```

The RDMA receive task callback signals that an IO response has been received from one of the storage targets. As with a send task completion the counter is decremented to know if processing can continue. In addition the IO response status is inspected as if the storage operation failed then the transaction result should be marked as a failure. The receive task is then re-submitted to be ready to receive another message from that storage target in a future transaction.

doca_ec_task_recover_cb

```
void gga_offload_app_worker::doca_ec_task_recover_cb(doca_ec_task_recover *task,
                             doca_data task_user_data,
                             doca_data ctx_user_data) noexcept
{
    static_cast<void>(task);
    auto *hot_data = static_cast<gga_offload_app_worker::hot_data *>(ctx_user_data.ptr);
    auto &transaction = hot_data->transactions[task_user_data.u64];

    transaction.pending_actions &= ~(static_cast<uint32_t>(transaction_action::recover_a) |
                    static_cast<uint32_t>(transaction_action::recover_b));
    hot_data->progress_transaction(transaction);
}
```

The EC recover task callback signals the completion of data recovery using erasure coding blocks. The transaction can now proceed to the next setp, which will be data decompression to continue the read process.

doca_compress_task_decompress_lz4_stream_cb

```
void gga_offload_app_worker::doca_compress_task_decompress_lz4_stream_cb(doca_compress_task_decompress_lz4_stream
*task,
                                    doca_data task_user_data,
                                    doca_data ctx_user_data) noexcept
{
    static_cast<void>(task);
    static_cast<void>(task_user_data);

    auto *hot_data = static_cast<gga_offload_app_worker::hot_data *>(ctx_user_data.ptr);
    auto &transaction = hot_data->transactions[task_user_data.u64];

    transaction.pending_actions ^= static_cast<uint32_t>(transaction_action::decompress);
    hot_data->progress_transaction(transaction);
}
```

The decompress LZ4 stream task callback signals the completion of data decompression. As the decompressed data is stored directly into initiator memory the transaction can continue to send the IO response to the initiator.

doca_ec_task_create_cb

```
void gga_offload_app_worker::doca_ec_task_create_cb(doca_ec_task_create *task,
                            doca_data task_user_data,
                            doca_data ctx_user_data) noexcept
{
    static_cast<void>(task);
    static_cast<void>(task_user_data);

    auto *hot_data = static_cast<gga_offload_app_worker::hot_data *>(ctx_user_data.ptr);
    auto &transaction = hot_data->transactions[task_user_data.u64];

    transaction.pending_actions ^= static_cast<uint32_t>(transaction_action::produce_ec_blocks);
    hot_data->start_commit_to_storage(transaction);
}
```

The EC create task callback signals the completion of the generation of EC redundancy data. The transaction processing can now continue by sending IO requests to all three storage targets to store the three half blocks: `data_1`, `data_2`, and `data_p` in the respective storage targets IO blocks.

doca_dma_task_memcpy_cb

```
void gga_offload_app_worker::doca_dma_task_memcpy_cb(doca_dma_task_memcpy *task,
                             doca_data task_user_data,
                             doca_data ctx_user_data) noexcept
{
    static_cast<void>(task);
    static_cast<void>(task_user_data);

    auto *hot_data = static_cast<gga_offload_app_worker::hot_data *>(ctx_user_data.ptr);
    auto &transaction = hot_data->transactions[task_user_data.u64];

    transaction.pending_actions ^= static_cast<uint32_t>(transaction_action::fetch_from_initiator);

    auto const ret = hot_data->compress_data(transaction);
    if (ret != DOCA_SUCCESS) {
        transaction.set_error(ret);
    }

    hot_data->progress_transaction(transaction);
}
```

The DMA memcpy task callback signals that the fetch of initiator data into service memory is now complete. The software compression of the data is immediately executed to completion as the software LZ4 library does not use events to signal completion. The transaction processing now continues which will start the creation of EC redundancy data.

6.20.9 DOCA Storage Comch to RDMA Zero Copy Application Guide

6.20.9.1 Introduction

The `doca_storage_comch_to_rdma_zero_copy` application serves as a bridge between the initiator and a single storage target. It's only role in the data path is to forward the io requests and io responses between the initiator and storage target.

6.20.9.2 System Design

The `doca_storage_comch_to_rdma_zero_copy` application performs the following functions:

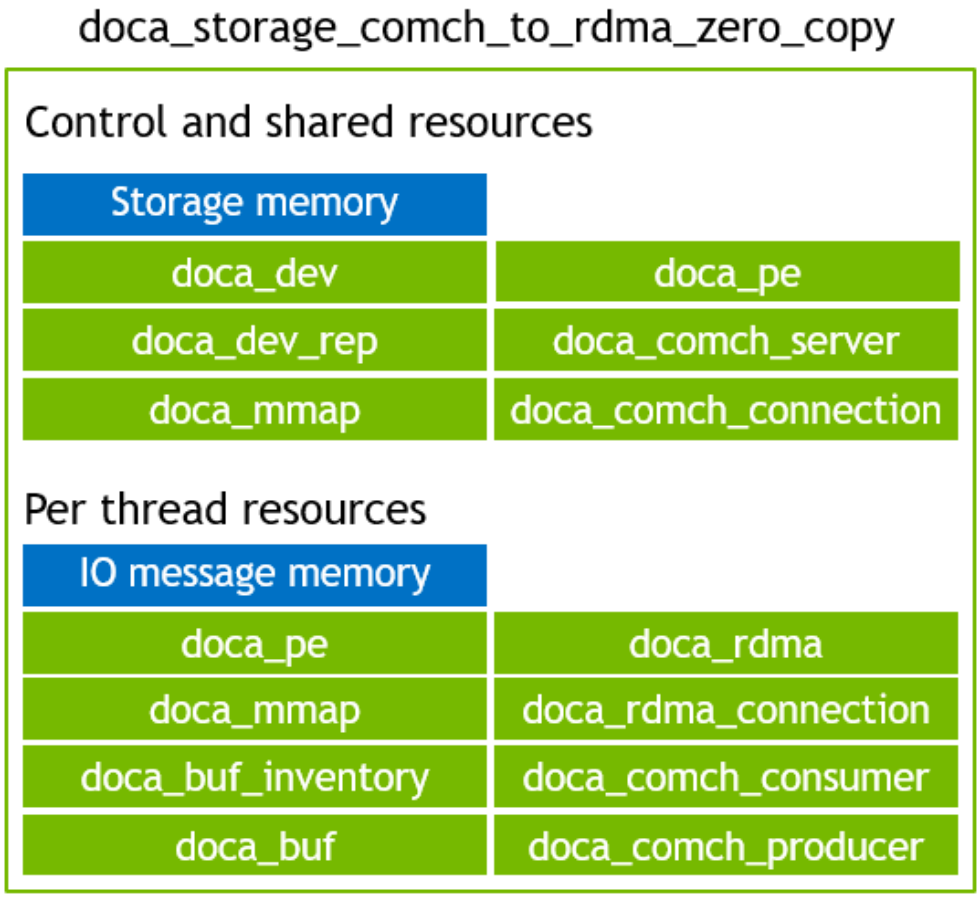
- Relay of io requests from the initiator to the storage target
- Relay of io responses from the storage target to the initiator

To achieve this it expects to be able to connect to a storage target using TCP connections and will then listen for an incoming connection from a single initiator using `doca_comch_server`.

6.20.9.3 Architecture

The `doca_storage_comch_to_rdma_zero_copy` application is split into to two functional areas:

- Control time and shared resources
- Per thread data path resources



The flow of the application similarity executes in two main phases:

- Control phase
- Data path phase

6.20.9.3.1 Control Phase

The state starts by connecting to the storage target, then waiting for a client connection. Once all connections are established the application waits for the appropriate control commands:

- Query storage
- Init storage
- Start storage

Processing each control command follows a similar pattern of:

- Relay the command to the storage target
- Wait for the storage target to respond
- Do the required post processing and consistency checks on the storage responses
- Respond to the client

The start storage control command will kick off the data path phase. Data threads will begin executing while the main thread proceeds to wait for the final control messages to complete the application lifecycle:

- Stop storage
- Shutdown

6.20.9.3.2 Data Path Phase

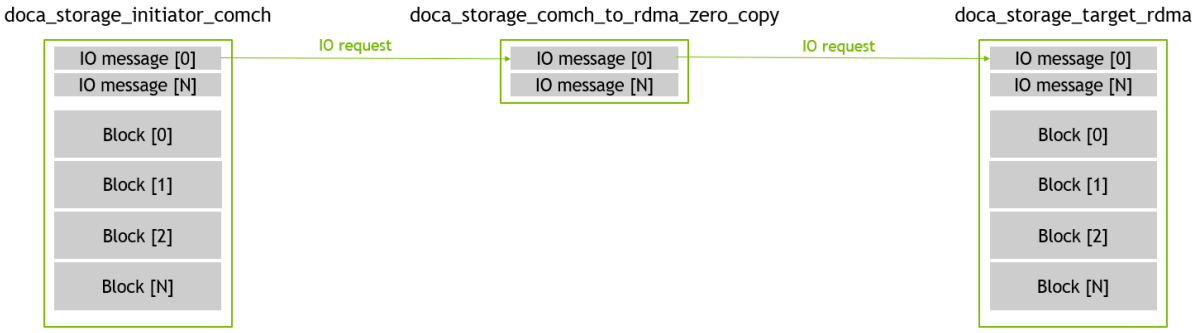
This phase happens per thread and involves each thread performing the requested IO operations requested by the client. Read and write requests are simply forwarded to the storage target, no actual processing is carried out by the data threads.

6.20.9.3.2.1 Read Data Flow

The regular read flow consists of the stages detailed in the following subsections.

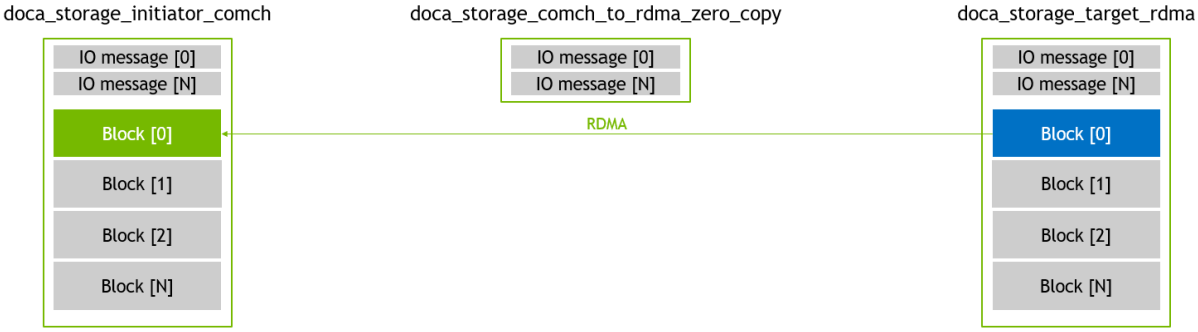
1. Initiator Request

1. The initiator sends an I/O request to the zero copy application.
2. The zero copy application forwards the request verbatim to the storage target



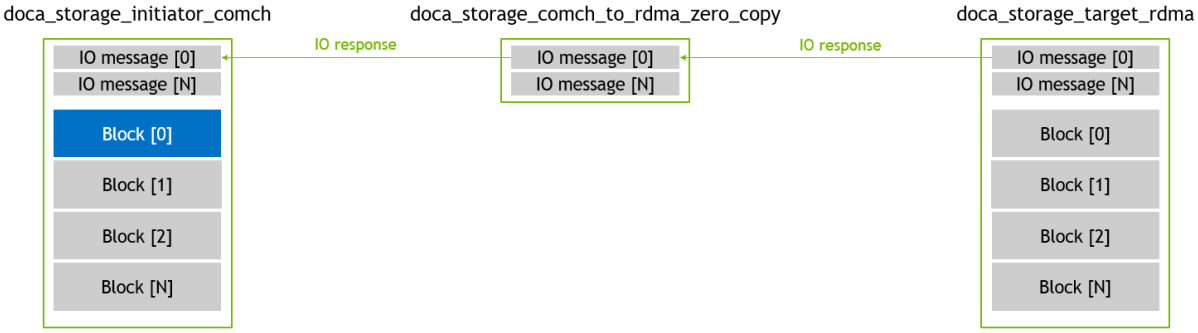
2. RDMA Transfer

1. The storage target performs a RDMA write operation



3. Target Response

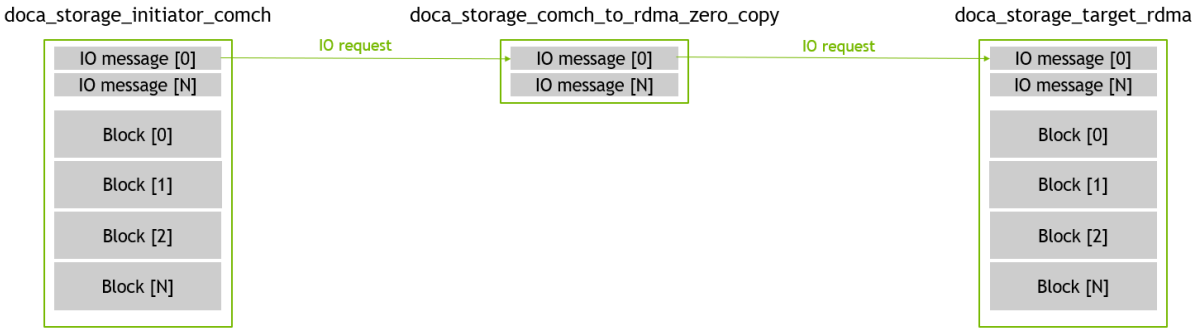
1. The zero copy application receives a response from the storage target
2. The zero copy application forwards the request verbatim to the initiator



6.20.9.3.2.2 Write Data Flow

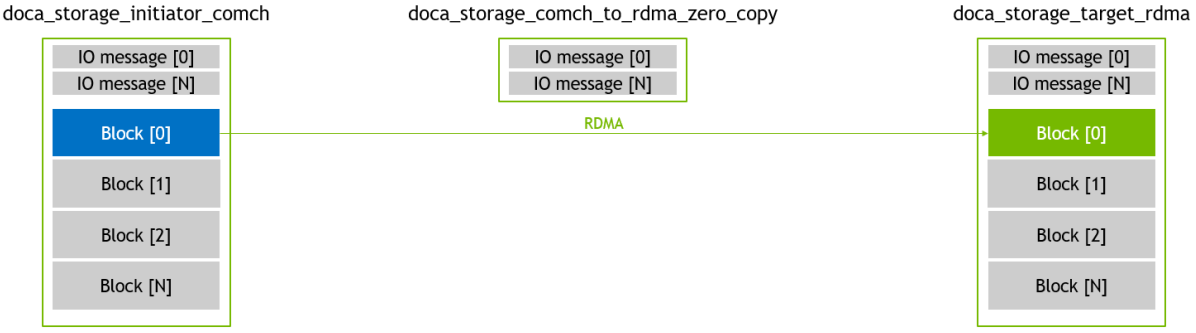
1. Initiator Request

1. The initiator sends an I/O request to the zero copy application.
2. The zero copy application forwards the request verbatim to the storage target



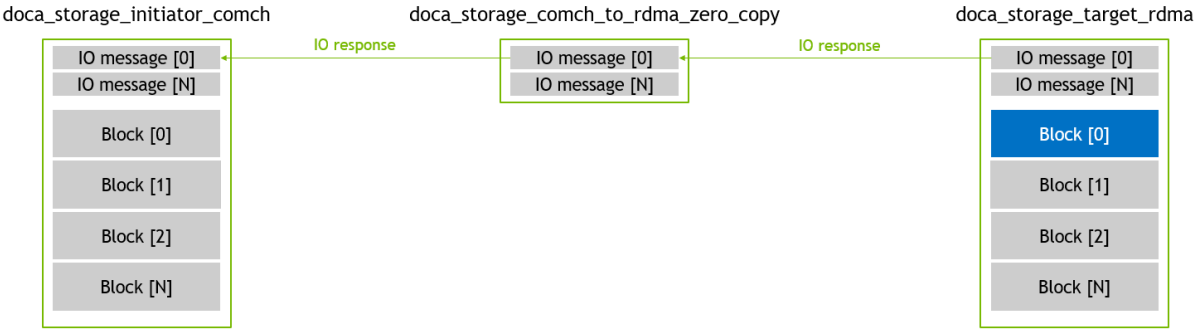
2. RDMA Transfer

The storage target performs a RDMA read operation.



3. Target Response

1. The zero copy application receives a response from the storage target
2. The zero copy application forwards the request verbatim to the initiator



6.20.9.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Comch
- DOCA RDMA

6.20.9.5 Compiling the Application

This application is compiled as part of the set of storage applications. For compilation instructions, refer to the DOCA Storage page.

6.20.9.6 Running the Application

6.20.9.6.1 Application Execution

This application can only run within the NVIDIA® BlueField® DPU.

DOCA Storage Comch to RDMA Zero Copy is provided in source form. Therefore, compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_storage_comch_to_rdma_zero_copy [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device                      Device identifier
  -r, --representor                 Device host side representor identifier
  --cpu                             CPU core to which the process affinity can be set
  --storage-server                  Storage server addresses in <ip_addr>:<port> format
  --command-channel-name            Name of the channel used by the doca_comch_client. Default:
"doca_storage_comch"
  --control-timeout                 Time (in seconds) to wait while performing control operations. Default:
5
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_storage_comch_to_rdma_zero_copy -h
```

For additional information, refer to section "Command-line Flags".

- CLI example for running the application on the BlueField:

```
./doca_storage_comch_to_rdma_zero_copy -d 03:00.0 -r 3b:00.0 --storage-server 172.17.0.1:12345 --cpu 0
```

Both the DOCA Comch device PCIe address (`03:00.0`) and the DOCA Comch device representor PCIe address (`3b:00.0`) should match the addresses of the desired PCIe devices.

Storage target IP `address:port` tuples should be updated to refer to the running storage target applications.

6.20.9.6.2 Command-line Flags

6.20.9.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.20.9.6.2.2 Program Flags

Short Flag	Long Flag	Description
`d`	`device`	DOCA device identifier. One of: • PCIe address: `3b:00.0` • InfiniBand name: `mlx5_0` • Network interface name: `en3f0pf0sf0` ⚠ This flag is a mandatory.
`r`	`representor`	DOCA Comch device representor PCIe address ⚠ This flag is a mandatory.
N/A	`--cpu`	Index of CPU to use. One data path thread is spawned per CPU. Index starts at 0. ⚠ The user can specify this argument multiple times to create more threads. ⚠ This flag is a mandatory.
N/A	`--storage-server`	IP address and port to use to establish the control TCP connection to the target. ⚠ This flag is a mandatory.
N/A	`--command-channel-name`	Allows customizing the server name used for this application instance if multiple comch servers exist on the same device.
N/A	`--control-timeout`	Time, in seconds, to wait while performing control operations

6.20.9.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.20.9.7 Application Code Flow

The flow of the application is broken down into key functions / steps:

```
zero_copy_app app{parse_cli_args(argc, argv)};

storage::install_ctrl_c_handler([&app]() {
    app.abort("User requested abort");
});
```

```
app.connect_to_storage();
app.wait_for_comch_client_connection();
app.wait_for_and_process_query_storage();
app.wait_for_and_process_init_storage();
app.wait_for_and_process_start_storage();
app.wait_for_and_process_stop_storage();
app.wait_for_and_process_shutdown();
app.display_stats();
```

6.20.9.7.1 Main/Control Thread Flow

1. ```
   zero_copy_app app{parse_cli_args(argc, argv)};
   ```

   Parse CLI arguments and use these to create the application instance. Initial resources are also created at this stage:

   a. ```
      DOCA_LOG_INFO("Open doca_dev: %s", m_cfg.device_id.c_str());
      m_dev = storage::open_device(m_cfg.device_id);
      ```

      Open a `doca_dev` as specified by the CLI argument: `-d` or `--device`

   b. ```
      DOCA_LOG_INFO("Open doca_dev_rep: %s", m_cfg.representor_id.c_str());
      m_dev_rep = storage::open_representor(m_dev, m_cfg.representor_id);
      ```

      Open a `doca_dev_rep` as specified by the CLI argument: `-r` or `--representor`

   c. ```
      m_storage_control_channel =
      storage::control::make_tcp_client_control_channel(m_cfg.storage_server_address);
      ```

      Create TCP client control channels (Control channel objects provide a unified API so that a TCP client, TCP server, `doca_comch_client`, and `doca_comch_server` all have a consistent API)

      > See `storage_common/control_channel.hpp` for more information about the control channel abstraction.

   d. ```
      m_client_control_channel =
          storage::control::make_comch_server_control_channel(m_dev,
                                      m_dev_rep,
                                      m_cfg.command_channel_name.c_str(),
                                      this,
                                      new_comch_consumer_callback,
                                      expired_comch_consumer_callback);
      ```

      Create a Comch server control channel (Containing a `doca_comch_server` instance) using the device, representor and channel name as specified by the CLI argument `--command-channel-name` or the default value if none was specified.

2. ```
   storage::install_ctrl_c_handler([&app]() {
       app.abort("User requested abort");
   });
   ```

Set a signal handler for Ctrl+c keyboard inputs so the app can shutdown gracefully.

3. `app.connect_to_storage();`

   Connect to the TCP server hosted by the storage target as defined by the CLI argument: `--storage-server`

   a.
   ```
   void zero_copy_app::connect_to_storage(void)
   {
       while (!m_storage_control_channel->is_connected()) {
           std::this_thread::sleep_for(std::chrono::milliseconds{100});
           if (m_abort_flag) {
               throw storage::runtime_error{DOCA_ERROR_CONNECTION_ABORTED,
                                "Aborted while connecting to storage"};
           }
       }
   }
   ```

   Poll the storage target control channel until either it connects, or the user aborts the application.

4. `app.wait_for_comch_client_connection();`

   Wait for a `doca_comch_client` to connect.

   a.
   ```
   void zero_copy_app::wait_for_comch_client_connection(void)
   {
       while (!m_client_control_channel->is_connected()) {
           std::this_thread::sleep_for(std::chrono::milliseconds{100});
           if (m_abort_flag) {
               throw storage::runtime_error{DOCA_ERROR_CONNECTION_ABORTED,
                                "Aborted while connecting to client"};
           }
       }
   }
   ```

   Poll the Comch server control channel until a `doca_comch_client` has connected, or the user aborts the application. If any further Comch client attempts to connect to the server it will be automatically rejected by the control channel which is designed for a 1:1 relationship between clients and servers. A sleep is placed in this loop as it may take the user / operator a few seconds to start the client so there is no gain to polling any faster.

5. `app.wait_for_and_process_query_storage();`

   Wait for the initiator to send a `query_storage_request` control message and then perform the required actions to fulfill the request:

   a. Forward the query storage request to the storage target.
   b. Wait for storage target to respond.
   c. Send a response to the initiator:
      i. Send a `start_storage_response` message upon success or an `error_response` message if anything failed

6. `app.wait_for_and_process_init_storage();`

Wait for the initiator to send a `init_storage_request` control message and then perform the required actions to fulfill the request:

a. use the `init_storage_payload` data to:

i. Set core count (`m_core_count`) as the number of cores requested by the initiator (number of `--cpu` arguments provided to the initiator) OR fail if this is more than the number of `--cpu` arguments provided to the service.

ii. Set number of transactions per core (`m_transaction_count`) to: the number of transactions requested by the initiator doubled. This is doubled to allow for batched task submission and avoid race conditions where the initiator can see a response to a transaction and try to re-submit it before the associated Comch producer event callback is received by the server meaning the initiator will continually re-try to send the task and degrade performance until the service catches up and re-submits the consumer task. This should be uncommon, but to make sure it can never happen double the transaction count is allocated so even if every single transaction on the initiator hit this issue there is a full second set of transactions ready on the service side to receive the tasks and avoid any contention. A user can experiment with reducing this value to save memory if desired).

iii. Import then re-export initiator IO blocks mmap, this allows the storage target to read / write directly to / from the initiator memory.

iv. Send init storage request to storage target using:

1. The service transaction count (double the initiator value).
2. The initiator core count.
3. The re-exported IO blocks mmap.

v. Send a response to the initiator:

1. Send a `init_storage_response` message upon success or an `error_response` message if anything failed

vi. Perform the first stages of the worker threads initialization. These steps are carried out for each thread, but only one thread performs the steps at any time this simplifies the sending and receiving of control messages, the user could modify this flow to execute in parallell if they so desired.

1. Create thread bound to the N^{th} CPU provided to the service via the `--cpu` CLI arguments

2.
```
m_workers[ii].execute_control_command(
    worker_create_objects_control_command {
        m_dev,
        m_client_control_channel->get_comch_connection(),
        m_transaction_count}
    );
```

Initialize thread context (asychronously)

3. ```
   connect_rdma(ii, storage::control::rdma_connection_role::io_data, cid);
   ```

   Create RDMA data connections (asynchronously) The thread will connect to the storage target and create a RDMA context which will be idle from the service's point of view, but is used by the storage target to perform RDMA read / write operations. See the DOCA Storage Target RDMA Application Guide for an explanation why there are two RDMA contexts per thread

4. ```
   connect_rdma(ii, storage::control::rdma_connection_role::io_control, cid);
   ```

   Create RDMA data connections (asynchronously) The thread will connect to the storage target and create a RDMA context which will be used to exchange IO requests and responses using RDMA send/recv tasks. See the DOCA Storage Target RDMA Application Guide for an explanation why there are two RDMA contexts per thread.

7. ```
   app.wait_for_and_process_start_storage();
   ```

   Wait for the initiator to send a `start_storage_request` control message and then perform the required actions to fulfill the request:
   a. Forward the start storage request to the storage target.
   b. Wait for storage target to respond.
   c. Signal all work threads to begin data path operation.
   d. Send a response to the initiator:
      i. Send a `start_storage_response` message upon success or an `error_response` message if anything failed.
8. Data path execution takes place now until either the user abort the program or a stop message is received.
9. ```
   app.wait_for_and_process_stop_storage();
   ```

   Wait for the initiator to send a `stop_storage_request` control message and then perform the required actions to fulfill the request:
   a. Forward the stop storage request the storage target.
   b. Wait for storage target to respond.
   c. Signal all work threads to stop data path operation.
   d. Collect run time stats.
   e. Send a response to the initiator:
      i. Send a `stop_storage_response` message upon success or an `error_response` message if anything failed.

10.
```
app.wait_for_and_process_shutdown();
```
Wait for the initiator to send a `shutdown_request` control message and then perform the required actions to fulfill the request:
    a. Forward the shutdown request the storage target.
    b. Wait for storage target to respond.
    c. Destroy worker thread objects.
    d. Send a response to the initiator:
        i. Send a `stop_storage_response` message upon success or an `error_response` message if anything failed.

11.
```
app.display_stats();
```
Display runtime statistics.
12. Application destructor is triggered:
    a. Destroy control channels.
    b. Destroy initiator IO blocks `doca_mmap`.
    c. Close `doca_dev_rep`.
    d. Close `doca_dev`.
13. Program exits.

6.20.9.7.2 Worker/Data Path Thread Flow

The work thread proc executes in two phases: Control / configuration phase, followed by data path phase where read, write, and recovery operations take place.

6.20.9.7.2.1 Worker Init Process

```
void zero_copy_app_worker::thread_proc(zero_copy_app_worker *self, uint16_t core_idx) noexcept
```

The worker starts by executing a loop of:

1. Lock mutex.
2. If message pointer is not null:
    a. Process the configuration message.
    b. Set the operation result.
3. Unlock the mutex.
4. Yield.

The following configuration operations can be performed by the worker thread:

1.
```
void zero_copy_app_worker::create_worker_objects(worker_create_objects_control_command const &cmd)
```
Create general worker objects:
    a. Create IO message memory.

b. Create IO message mmap (to allow the messages to be accessed by DOCA comch and DOCA RDMA).
c. Allocate doca buffer inventory.
d. Create `doca_pe` to drive the DOCA contexts (`doca_rdma` , `doca_comch_consumer` , `doca_comch_producer`).
e. Create `doca_comch_consumer` and `doca_comch_producer` contexts.
f. Initialize and start contexts.

2.
```
void zero_copy_app_worker::export_local_rdma_connection_blob(worker_export_local_rdma_connection_command &cmd)
```
Export RDMA context connection binary blob.

3.
```
void zero_copy_app_worker::import_remote_rdma_connection_blob(worker_import_local_rdma_connection_command const &cmd)
```
Import remote RDMA context connection binary blob.

4.
```
void zero_copy_app_worker::are_contexts_ready(worker_are_contexts_ready_control_command &cmd) const noexcept
```
Poll all contexts to check they are ready to perform data path operations.

5.
```
void zero_copy_app_worker::prepare_tasks(worker_prepare_tasks_control_command const &cmd)
```
Prepare transaction contexts by:
a. Allocating `doca_buf` objects.
b. Allocating `doca_task` objects.
c. Setting task user data.

6.
```
void zero_copy_app_worker::start_data_path(void)
```
Break out of the wait for configuration event loop and start the data path loop.

> After the configuration phase the mutex is not used again

After breaking out of the initial configuration loop, the thread submits receive tasks (comch consumer tasks, and RDMA recv tasks) then enters the data path function: `run_data_path_ops` .

6.20.9.7.2.2 Worker Data Path Process

```
void zero_copy_app_worker::run_data_path_ops(zero_copy_app_worker::hot_data &hot_data)
{
    DOCA_LOG_INFO("Core: %u running", hot_data.core_idx);

    while (hot_data.run_flag) {
        doca_pe_progress(hot_data.pe) ? ++(hot_data.pe_hit_count) : ++(hot_data.pe_miss_count);
    }

    while (hot_data.error_flag == false && hot_data.in_flight_transaction_count != 0) {
        doca_pe_progress(hot_data.pe) ? ++(hot_data.pe_hit_count) : ++(hot_data.pe_miss_count);
    }

    DOCA_LOG_INFO("Core: %u complete", hot_data.core_idx);
```

```
}
```

During the data path phase the thread simply polls the `doca_pe` as quickly as possible to check for a task completion from one of the thread DOCA contexts (`doca_rdma` , `doca_comch_consumer` , `doca_comch_producer`) The interesting work is done in the callbacks of these tasks. The flow will always start with a consumer task completion. This is the reception of the IO message from the initiator. For the zero copy use-case the callbacks simply forward the IO requests:

- Comch consumer → RDMA send
- RDMA recv → Comch producer

6.20.10 DOCA Storage GGA Offload SBC Generator Application Guide

6.20.10.1 Introduction

The `doca_storage_gga_offload_sbc_generator` application provides a utility for generating storage-ready binary content files for use with DOCA storage target applications in the GGA offload use case.

This tool processes a single input file, breaks it into chunks, compresses the data, generates parity, and outputs three `.sbc` files suitable for use by the GGA Offload pipeline.

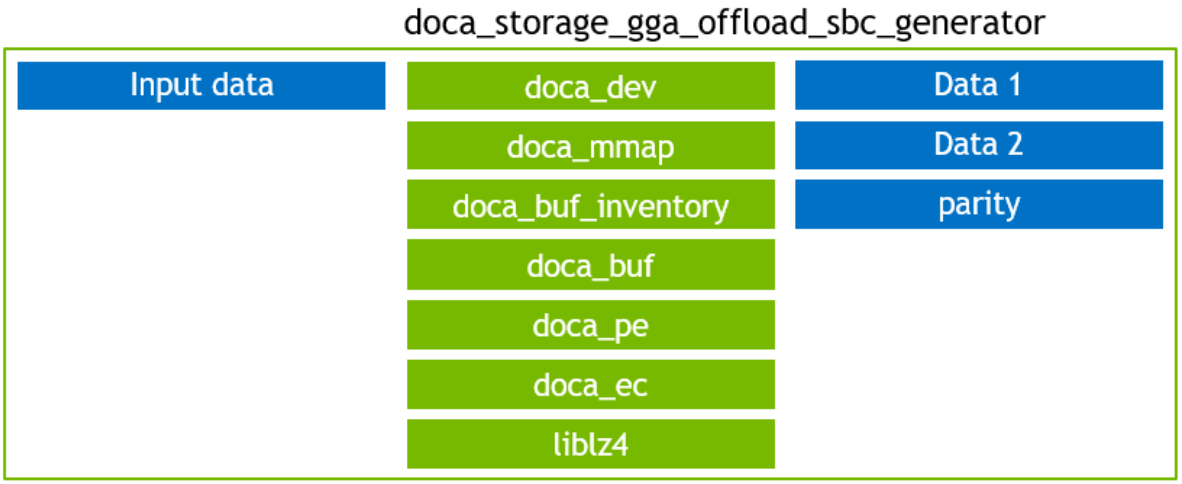
6.20.10.2 System Design

The application performs the following operations in sequence:

1. Load input data from disk.
2. Compress data using the LZ4 compression algorithm.
3. Generate parity data via error correction coding (2:1 ratio).
4. Write the resulting binary output files to disk, organized into three partitions.

6.20.10.3 Architecture

The `doca_storage_gga_offload_sbc_generator` is not performance-critical and follows a straightforward, linear processing flow. The application comprises the following key steps:



1. Load the source file from disk.
2. Divide the file content into chunks.
3. Compress each chunk using the LZ4 library.
    - If a chunk is not compressible enough (i.e., it cannot be reduced by at least the size of the metadata header and trailer), the application reports an error and exits.
4. Wrap each compressed chunk with a metadata header and trailer to form a storage block.
    - This metadata enables the GGA Offload application to correctly reconstruct decompression tasks.
5. Generate EC (Erasure Coding) parity for each storage block.
    - The parity is generated at a 2:1 ratio: for every 2 bytes of data, 1 byte of parity is produced. This allows for 50% of the data to be lost and still be recoverable using the parity.
6. Split the content into three logical partitions:
    - Data 1 and Data 2 are currently identical copies.
    - Parity contains duplicated parity data.

    > ⚠ This replication strategy is for simplicity and does not reflect a realistic storage deployment.

7. Write each partition to disk, including high-level metadata such as:
    - Storage block size
    - Number of storage blocks

6.20.10.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Erasure Coding

6.20.10.5 Compiling the Application

This application is compiled as part of the set of storage applications. For compilation instructions, refer to the DOCA Storage page.

6.20.10.6 Running the Application

6.20.10.6.1 Application Execution

DOCA Storage GGA Offload SBC Generator is provided in source form. Therefore, compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_storage_gga_offload_sbc_generator [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device                      Device identifier
  --original-input-data             File containing the original data that is represented by the storage
  --block-size                      Size of each block. Default: 4096
  --matrix-type                     Type of matrix to use. One of: cauchy, vandermonde Default: vandermonde
  --data-1                          First half of the data in storage
  --data-2                          Second half of the data in storage
  --data-p                          Parity data (used to perform recovery flow)
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_storage_gga_offload_sbc_generator -h
```

For additional information, refer to section "Command-line Flags".

- CLI example for running the application on the BlueField:

```
./doca_storage_gga_offload_sbc_generator -d 03:00.0 --original-input-data original_data.txt --block-size
4096 --data-1 data_1.sbc --data-2 data_2.sbc --data-p data_p.sbc
```

The device PCIe address (`03:00.0`) should match the addresses of the desired PCIe device.

6.20.10.6.2 Command-line Flags

6.20.10.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.20.10.6.2.2 Program Flags

Short Flag	Long Flag	Description
`d`	`device`	DOCA device identifier. One of: • PCIe address: `3b:00.0` • InfiniBand name: `mlx5_0` • Network interface name: `en3f0pf0sf0` ⚠ This flag is a mandatory.
N/A	`--original-input-data`	File containing the original data that is represented by the storage ⚠ This flag is a mandatory.
N/A	`--block-size`	IP address and port to use to establish the control TCP connection to the target. ⚠ This flag is a mandatory.
N/A	`--data-1`	File in which to store the data 1 partition ⚠ This flag is a mandatory.
N/A	`--data-2`	File in which to store the data 2 partition ⚠ This flag is a mandatory.
N/A	`--data-p`	File in which to store the parity partition ⚠ This flag is a mandatory.
N/A	`--matrix-type`	Type of matrix to use. One of: • `cauchy` • `vandermonde`

6.20.10.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.20.10.7 Application Code Flow

6.20.10.7.1 General Application Flow

The high-level flow of the `doca_storage_gga_offload_sbc_generator` application proceeds as follows:

1. The high level application flow is as follows:

```
auto const cfg = parse_cli_args(argc, argv);
gga_offload_sbc_gen_app app{cfg.device_id, cfg.ec_matrix_type, cfg.block_size};
```

2. Load input data from disk:

```
auto input_data = storage::load_file_bytes(cfg.original_data_file_name);
```

3. Pad input data to ensure it aligns with the block size:

```
pad_input_to_multiple_of_block_size(input_data, cfg.block_size);
```

4. Transform the data (compression, metadata wrapping, parity generation):

```
app.generate_binary_content(input_data);
```

5. Write the output partitions to disk:

```
storage::write_binary_content_to_file(
    cfg.data_1_file_name,
    storage::binary_content{cfg.block_size, results.block_count, std::move(results.data_1_content)}
);

storage::write_binary_content_to_file(
    cfg.data_2_file_name,
    storage::binary_content{cfg.block_size, results.block_count, std::move(results.data_2_content)}
);

storage::write_binary_content_to_file(
    cfg.data_p_file_name,
    storage::binary_content{cfg.block_size, results.block_count, std::move(results.data_p_content)}
);
```

6.20.10.7.2 Transform Process

1. Compress the chunk using LZ4:

```
auto const compresed_size =
    m_lz4_ctx.compress(
        input_data.data() + (ii * m_block_size),
        m_block_size,
        m_compressed_bytes_buffer.data() + metadata_header_size,
        m_compressed_bytes_buffer.size() - metadata_overhead_size
    );
```

2. Create and insert the metadata header:

```
storage::compressed_block_header const hdr{
    htobe32(m_block_size),
    htobe32(compresed_size),
```

```
};

std::copy(
    reinterpret_cast<char const *>(&hdr),
    reinterpret_cast<char const *>(&hdr) + sizeof(hdr),
    m_compressed_bytes_buffer.data()
);
```

3. Set input buffer for parity generation and reset the output buffer:

```
doca_buf_set_data(m_input_buf, m_compressed_bytes_buffer.data(), m_block_size);
doca_buf_reset_data_len(m_output_buf);
```

4. Submit the parity generation task to the DOCA EC engine:

```
doca_task_submit(doca_ec_task_create_as_task(m_ec_task));
```

6.20.11 DOCA Storage Initiator ComCh Application Guide

6.20.11.1 Introduction

The `doca_storage_initiator_comch` application functions as a client to the DOCA storage service. It benchmarks the performance of data transfers over the ComCh interface, providing detailed measurements of throughput, bandwidth, and latency.

6.20.11.2 System Design

The `doca_storage_initiator_comch` application performs the following key tasks:

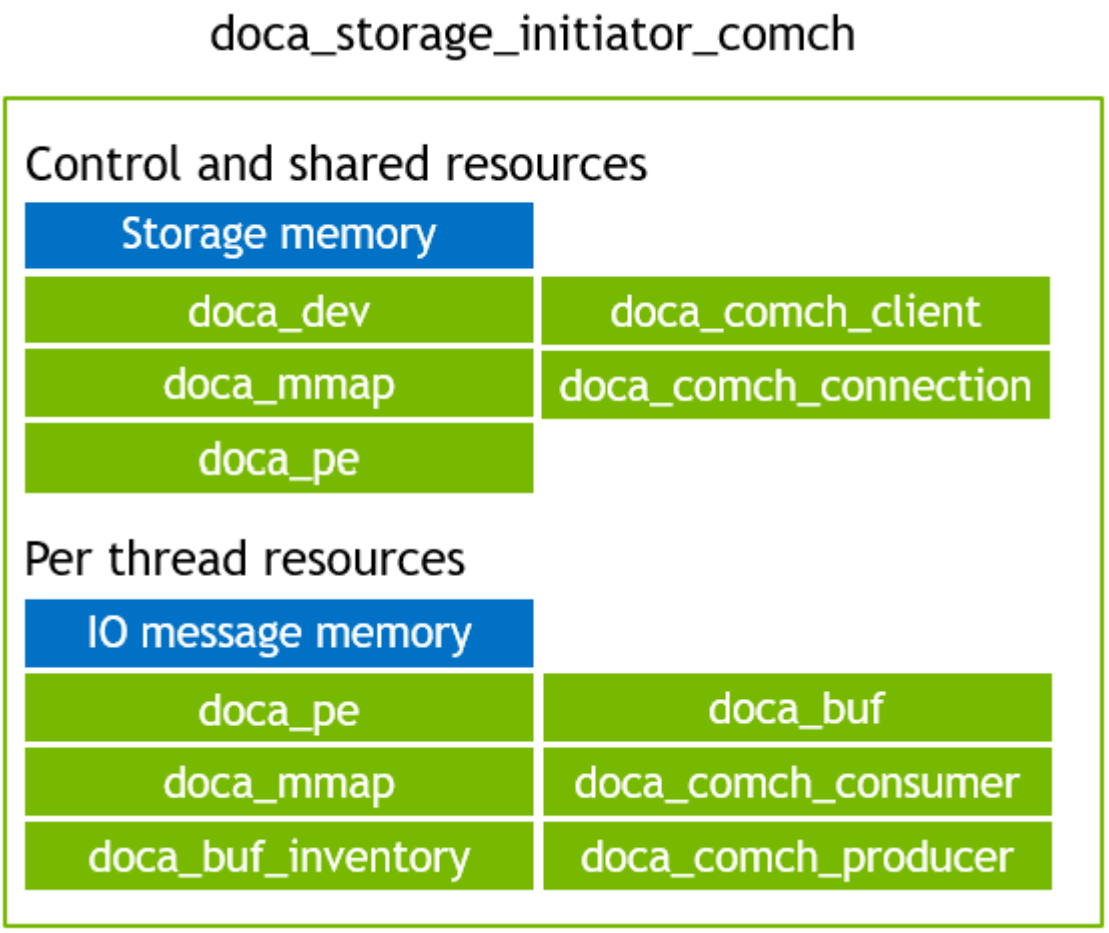
- Initiates a sequence of I/O requests to exercise the DOCA storage service.
- Measures and reports storage performance, including:
  - Millions of I/O operations per second (IOPS)
  - Effective data bandwidth
  - I/O operation latency:
    - Minimum latency
    - Maximum latency
    - Mean latency

The application establishes a connection to the storage service running on an NVIDIA® BlueField® platform using the `doca_comch_client` interface.

6.20.11.3 Architecture

The application is logically divided into two functional areas:

- Control-time and shared resources
- Per-thread data path resources



The execution consists of two main phases:

- Control Phase
- Data Path Phase

6.20.11.3.1 Control Phase

The control phase is responsible for establishing and managing the storage session lifecycle. It performs the following steps:

1. Query storage – Retrieve storage service metadata.
2. Init storage – Initialize the storage window and prepare for data transfers.
3. Start storage – Begin the data path phase and launch data threads.

Once the data phase is initiated, the main thread waits for test completion. Afterward, it issues final cleanup commands:

1. Stop storage – Stop data movement.
2. Shutdown – Tear down the session and release resources.

6.20.11.3.2 Data Path Phase

The selected `--execution-strategy` is used to pre-initialise a set of per task flags. These flags are used to decide which action the task should take next. This allows the task to perform any combination of; read, write, memory set, memory clear, and validate. The order of exectuion of each action is hard coded for simplicity. The order of actions is:

1. Initialise transaction:
    a. Set actions bitmask to match `--execution-strategy`.
    b. Get a local memory address from the pool (of initiator IO blocks assigned to this thread).
    c. Get a remote address from the pool (of storage IO blocks assigned to this thread).
2. Set memory to initial value:
    a. Copy content from the data provided by `--storage-plain-content` at the address defined by the storage IO block and place it in the memory defined by initiator IO block.
3. Start an IO write:
    a. Send an IO write operation request.
    b. Wait for the IO response.
4. Clear current memory content:
    a. Clear the Initiator memory defined by initiator IO block.
5. Start an IO read:
    a. Send an IO write operation request.
    b. Wait for the IO response.
6. Validate memory content:
    a. Compare the content of the initiator IO block against the expected value in `--storage-plain-content`.
7. Finish transaction:
    a. Calculate and record stats.
    b. Return initiator IO block and storage IO block to the pool.
    c. End the test if the `--run-limit-operation-count` has been reached.

d. Recycle the transaction (go back to step 1).

6.20.11.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Comch

6.20.11.5 Compiling the Application

This application is compiled as part of the set of storage applications. For compilation instructions, refer to the DOCA Storage page.

6.20.11.6 Running the Application

6.20.11.6.1 Application Execution

This application can only run from the host.

DOCA Storage Initiator Comch is provided in source form. Therefore, compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_storage_initiator_comch [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device                      Device identifier
  --cpu                             CPU core to which the process affinity can be set
  --storage-plain-content           File containing the plain data that is represented by the storage
  --execution-strategy              Define what to run. One of: read_throughput_test |
write_throughput_test | read_write_data_validity_test | read_only_data_validity_test
  --run-limit-operation-count       Run N operations (per thread) then stop. Default: 1000000
  --transaction-count               Number of concurrent IO transactions (per thread) to use. Default: 64
  --command-channel-name            Name of the channel used by the doca_comch_client. Default:
"doca_storage_comch"
  --control-timeout                 Time (in seconds) to wait while performing control operations. Default:
5
  --local-io-region-size            Size in bytes of the local region. Value can be 0 meaning automatically
size to the same size as the storage target. Default: 0
  --blocks-per-io                   Use multiple blocks per IO request. Default: 1
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_storage_initiator_comch -h
```

For additional information, refer to section "Command-line Flags".

- CLI example for running the application on the BlueField:

```
./doca_storage_initiator_comch -d 3b:00.0 --execution-strategy read_throughput_test --run-limit-operation-count 1000000 --cpu 0
```

Both the DOCA Comch device PCIe address (`3b:00.0`) should match the addresses of the desired PCIe devices.

6.20.11.6.2 Command-line Flags

6.20.11.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.20.11.6.2.2 Program Flags

Short Flag	Long Flag	Description
`d`	`device`	DOCA device identifier. One of: • PCIe address: `3b:00.0` • InfiniBand name: `mlx5_0` • Network interface name: `en3f0pf0sf0` ⚠ This flag is a mandatory.
N/A	`--execution-strategy`	The data path routine to run. One of: • `read_throughput_test` • `write_throughput_test` • `read_only_data_validity_test` • `read_write_data_validity_test` ⚠ This flag is a mandatory.
N/A	`--cpu`	Index of CPU to use. One data path thread is spawned per CPU. Index starts at 0. ⚠ The user can specify this argument multiple times to create more threads. ⚠ This flag is a mandatory.
N/A	`--storage-plain-content`	Expected plain content that is expected to be read from storage during a `read_only_data_validity_test`
N/A	`--run-limit-operation-count`	Number of IO operations to perform when performing a throughput test
N/A	`--transaction-count`	Number of parallel tasks per thread to use
N/A	`--command-channel-name`	Allows customizing the server name used for this application instance if multiple comch servers exist on the same device.
N/A	`--control-timeout`	Time, in seconds, to wait while performing control operations
N/A	`--local-io-region-size`	Set the size of the local memory region size, allows for asymetric memory setups where the local application using the storage engine has more or less memory thatn the storage target.

Short Flag	Long Flag	Description
N/A	`--blocks-per-io`	Allow for testing the case where multiple sequential data blocks are read or written in a single IO operation.

6.20.11.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.20.11.7 Application Code Flow

The flow of the application is broken down into key functions / steps:

```
initiator_comch_app app{parse_cli_args(argc, argv)};

storage::install_ctrl_c_handler([&app]() {
    app.abort("User requested abort");
});

app.connect_to_storage_service();
app.query_storage();
app.init_storage();
app.prepare_threads();
app.start_storage();
auto const run_success = app.run();
app.join_threads();
app.stop_storage();

if (run_success) {
    app.display_stats();
} else {
    exit_value = EXIT_FAILURE;
    fprintf(stderr, "+=================================================+\n");
    fprintf(stderr, "| Test failed!!\n");
    fprintf(stderr, "+=================================================+\n");
}

app.shutdown();
```

6.20.11.7.1 Main/Control Thread Flow

1. ```
   initiator_comch_app app{parse_cli_args(argc, argv)};
   ```

   Parse CLI arguments and use these to create the application instance. Initial resources are also created at this stage:

   a. ```
      DOCA_LOG_INFO("Open doca_dev: %s", m_cfg.device_id.c_str());
      m_dev = storage::open_device(m_cfg.device_id);
      ```

      Open a `doca_dev` as specified by the CLI argument: `-d` or `--device`

   b. ```
      m_service_control_channel =
          storage::control::make_comch_client_control_channel(m_dev,
                                      m_cfg.command_channel_name.c_str(),
                                      this,
                                      new_comch_consumer_callback,
                                      expired_comch_consumer_callback);
      ```
      ```

Create a comch client control channel (Containing a `doca_comch_client` instance) using the device and channel name as specified by the CLI argument `--command-channel-name` or the default value if none was specified. (Control channel objects provide a unified API so that a TCP client, TCP server, `doca_comch_client`, and `doca_comch_server` all have a consistent API)

> See `storage_common/control_channel.hpp` for more information about the control channel abstraction.

2. ```
   storage::install_ctrl_c_handler([&app]() {
       app.abort("User requested abort");
   });
   ```

   Set a signal handler for control+c keyboard inputs so the app can shutdown gracefully.

3. ```
   app.connect_to_storage_service();
   ```

   Connect to the `doca_comch_server` in the service.

4. ```
   app.query_storage();
   ```

   Query the storage details:

   a. Send a `query_storage_request` to the service.
   b. Wait for the service to respond.
   c. Set the iop size (`m_effective_block_size`) based on the reported storage block size and the `--blocks-per-io` CLI argument.
   d. If performing a `read_write_data_validity_test` create storage for the "expected content" (if `--storage-plain-content` CLI argument was not provided).
   e. Verify that the size of the "expected content" matches the size of the reported storage capacity.

5. ```
   app.init_storage();
   ```

   Prepare to use the storage:

   a. Allocate IO block memory.
   b. Create IO block `doca_mmap`.
   c. Export IO block `doca_mmap`.
   d. Send `init_storage_request` to the service.
   e. Wait for the service to respond.
   f. Create worker thread objects.
   g. Configure the ops actions mask based on the `--execution-strategy` CLI argument

h. Partition local and storage IO blocks so that each worker gets a unique region of the IO blocks. This avoids race conditions when performing data validation. In a real use-case each thread could be allowed to access any region of the memory delegating the responsibility for the neccessary concurrency control to a higher level.
i. Perform the first stages of the worker threads initialization. These steps are carried out for each thread, but only one thread performs the steps at any time this simplifies the sending and receiving of control messages, the user could modify this flow to execute in parallell if they so desired.
    i. Create thread bound to the N^{th} CPU provided to the service via the `--cpu` CLI arguments
    ii. Init the worker thread:

> Init actions are performed by the thread itself after its core affinity has been set to improve memory allocation efficiency as the memory allocator is NUMA aware so allocating from the core that will be using the memory allows the allocator to pick memory that is local / closest to that core

        1. Create local IO address pool.
        2. Create remote IO address pool.
        3. Allocation IO messages memory.
        4. Allocate N transaction contexts.
        5. Create IO messages `doca_mmap`.
        6. Create `doca_buf_inventory`.
        7. Create `doca_pe`.
        8. Create `doca_comch_consumer`.
        9. Create `doca_comch_producer`.

j. Wait for all threads to be ready:
    i. Consumer and producer contexts are connected.

6.
```
app.prepare_threads();
```

Prepare thread for data path operations:

a. Prepare `doca_buf` objects.
b. Prepare `doca_task` objects.
c. Initialise IO message content.

7.
```
app.start_storage();
```

Start the storage service:

a. Send a `start_storage_request` to the service.
b. Wait for the service to respond.

8.
```
app.run();
```
Run the initiator data path:
    a. Signal all worker threads to end configuration phase and begin data path phase.
    b. Data path execution takes place now until either the user abort the program or a stop message is received.
    c. Infinitly loop; polling workers utill all workers have finished performing data path operations.
    d. Collect workers exit codes.
    e. If all workers completed successfully collect runtime stats.

9.
```
app.join_threads();
```
Join the worker threads.

10.
```
app.stop_storage();
```
Stop the storage service:
    a. Send a `stop_storage_request` to the service.
    b. Wait for the service to respond.

11.
```
if (run_success) {
    app.display_stats();
} else {
    exit_value = EXIT_FAILURE;
    fprintf(stderr, "+=================================================+\n");
    fprintf(stderr, "| Test failed!!\n");
    fprintf(stderr, "+=================================================+\n");
}
```
If the worker threads all succeeded (encountered no errors while running data path operations) display stats, else display an error banner

12.
```
app.shutdown();
```
Destroy resources:
    a. Destroy worker objects.
    b. Send `shutdown_request` to the service.
    c. Wait for storage consumers to complete de-registration (Don't tear down the `comch_client` ↔ `comch_server` yet as they use that to de-register)
13. Application destructor is triggered:
    a. IO `doca_mmap` is destroyed
    b. IO blocks memory is destroyed
    c. Comch client control channel is destroyed (`doca_comch_client is destroyed`)
    d. Close `doca_dev`
14. Application exits

6.20.12 DOCA Storage Target RDMA Application Guide

6.20.12.1 Introduction

The `doca_storage_target_rdma` application provides a simple, volatile memory-backed RDMA storage target. It is designed to interact with a DOCA storage service, offering direct read and write access to a dedicated memory region using RDMA.

6.20.12.2 System Design

The `doca_storage_target_rdma` application performs the following core functions:

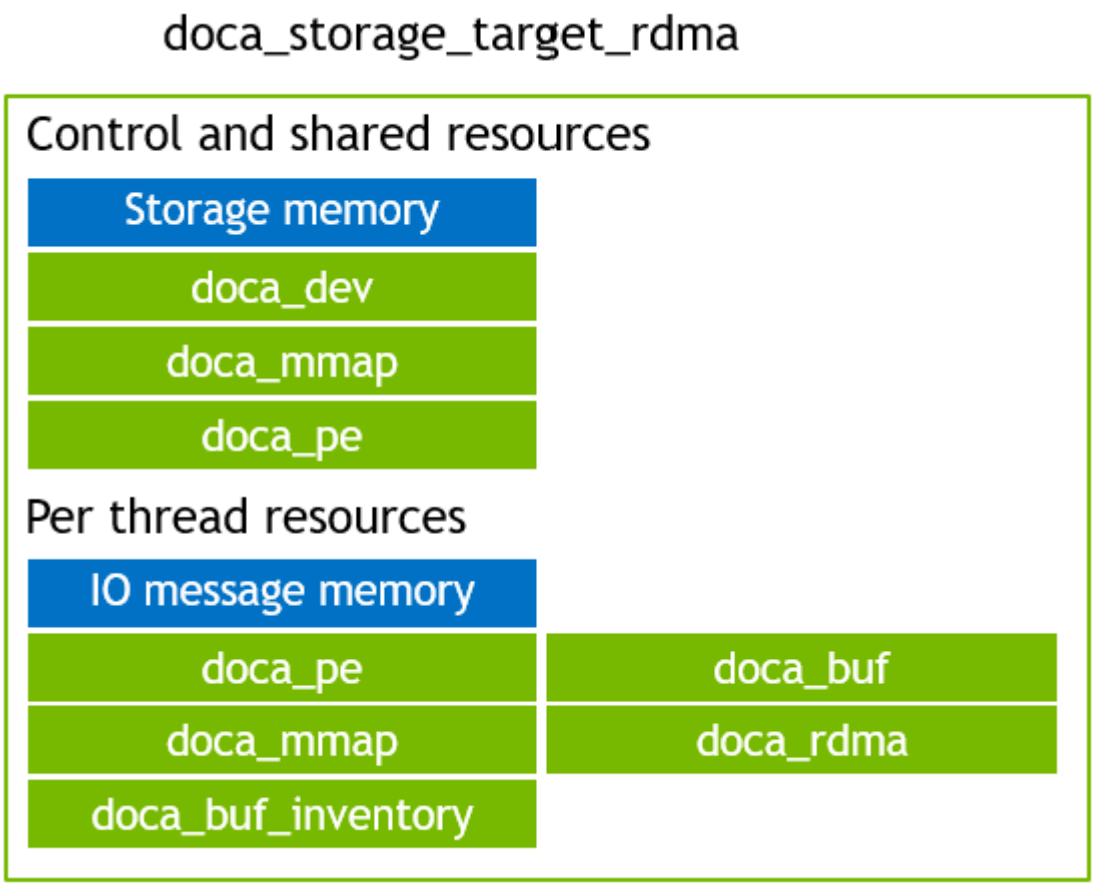
- Exposes a memory-backed storage region for use by the storage service client.
- Handles RDMA-based I/O operations (reads and writes) using the DOCA RDMA library.

To perform these tasks, the application acts as a TCP server, waiting for an incoming connection from a storage service initiator. Once connected, it handles control and data path interactions as in this page.

6.20.12.3 Architecture

The application is divided into two main functional areas:

- Control-Time and Shared Resources – Includes TCP server setup, memory registration, and RDMA connection handling.
- Per-Thread Data Path Resources – Includes thread-local RDMA resources and task management structures.



The application executes in two main phases:

- Control Phase
- Data Path Phase

6.20.12.3.1 Control Phase

This phase begins when a connection is established with a storage service over TCP. The application then processes a sequence of control commands:

1. Query Storage
    - Reports the size and layout of the exposed storage region.
2. Init Storage
    - Validates the requested number of worker threads.
    - Allocates and registers local memory for RDMA operations.
    - Imports remote memory handles provided by the initiator.
    - Creates internal worker objects for task execution.
3. Wait for RDMA Connection Requests
    - Waits for one RDMA connection per requested core/thread.
    - Ensures each RDMA session is fully established before proceeding.
4. Start Storage

- Waits for all RDMA connections to be ready.
- Submits initial tasks to prepare the data path phase.
- Launches the data path threads.

Once the Start Storage command is received and all threads are active, the application transitions to the data path phase. The main thread remains active, waiting for final control commands:

1. Stop Storage
    - Terminates active data threads cleanly.
2. Shutdown
    - Performs cleanup and resource deallocation, shutting down the application.

6.20.12.3.2 Data Path Phase

Each data path thread performs I/O processing independently based on client requests. The typical per-thread flow is:

1. Receive I/O Request
    - Handle incoming requests from the initiator via RDMA.
2. Perform RDMA Operation
    - Depending on the request type, either:
        - Execute an RDMA read from the local memory region.
        - Execute an RDMA write to the local memory region.
3. Send I/O Response
    - Return a response back to the initiator, indicating success or failure of the operation.

6.20.12.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA RDMA

6.20.12.5 Compiling the Application

This application is compiled as part of the set of storage applications. For compilation instructions, refer to the DOCA Storage page.

6.20.12.6 Running the Application

6.20.12.6.1 Application Execution

DOCA Storage Target RDMA is provided in source form. Therefore, compilation is required before the application can be executed.

- Application usage instructions:

```
Usage: doca_storage_target_rdma [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device                      Device identifier
  --cpu                             CPU core to which the process affinity can be set
  --listen-port                     TCP listen port number
  --binary-content                  Path to binary.sbc file containing the initial content to be
represented by this storage instance
  --block-count                     Number of available storage blocks. (Ignored when using content binary
file) Default: 128
  --block-size                      Block size used by the storage. (Ignored when using content binary
file) Default: 4096
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_storage_target_rdma -h
```

For additional information, refer to section "Command-line Flags".

- CLI example for running the application:

```
./doca_storage_target_rdma -d 3b:00.0 --listen-port 12345 --block-size 4096 --block-count 64 --cpu 0
```

The user DOCA device PCIe address (`3b:00.0`) should match the addresses of the desired PCIe device.

6.20.12.6.2 Command-line Flags

6.20.12.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.20.12.6.2.2 Program Flags

Short Flag	Long Flag	Description
`d`	`device`	DOCA device identifier. One of: • PCIe address: `3b:00.0` • InfiniBand name: `mlx5_0` • Network interface name: `en3f0pf0sf0` ⚠ This flag is a mandatory.
N/A	`--cpu`	Index of CPU to use. One data path thread is spawned per CPU. Index starts at 0. ⚠ The user can specify this argument multiple times to create more threads. ⚠ This flag is a mandatory.

Short Flag	Long Flag	Description
N/A	`--listen-port`	Port to listen upon for incomming TCP connections ⚠ This flag is a mandatory.
N/A	`--binary-content`	Path to a file to be used to provide initial content to the storage instance.
N/A	`--block-count`	Number of storage blocks to provide
N/A	`--block-size`	Size of each storage block

A user should provide one of:

- `--binary-content` : Where the file is a.sbc file
  - The sbc file provides storage dimmensions and data to populate the blocks

OR (Random / uninitialisaed bytes with a user defined dimmension)

- `--block-count`
- `--block-size`

OR (Initialised bytes with a user defined dimmension)

- `--block-count`
- `--block-size`
- `--binary-content` : Where the file is plain content to be distributed across the storage and its size == block count * block size

6.20.12.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.20.12.7 Application Code Flow

The flow of the application is broken down into key functions / steps:

```
target_rdma_app app{parse_target_rdma_app_cli_args(argc, argv)};

storage::install_ctrl_c_handler([&app]() {
    app.abort("User requested abort");
});

app.wait_for_client_connection();
app.wait_for_and_process_query_storage();
app.wait_for_and_process_init_storage();
app.wait_for_and_process_create_rdma_connections();
app.wait_for_and_process_start_storage();
```

```
app.wait_for_and_process_stop_storage();
app.wait_for_and_process_shutdown();
app.display_stats();
```

6.20.12.7.1 Main/Control Thread Flow

1. ```
   initiator_comch_app app{parse_cli_args(argc, argv)};
   ```

   Parse CLI arguments and use these to create the application instance. Initial resources are also created at this stage:

   a.

   Open a doca_dev as specified by the CLI argument: -d or `--device`.

   b. ```
      m_storage_block_count = m_cfg.block_count;
      m_storage_block_size = m_cfg.block_size;

      auto const page_size = storage::get_system_page_size();
      m_local_io_region_size = uint64_t{m_storage_block_count} * m_storage_block_size;
      m_local_io_region = static_cast<uint8_t *>(storage::aligned_alloc(page_size,
      m_local_io_region_size));
      ```

      Allocate storage IO blocks memory.

   c. ```
      if (!m_cfg.content.empty()) {
          std::copy(std::begin(m_cfg.content), std::end(m_cfg.content), m_local_io_region);
      }
      ```

      Copy user defined content into the storage IO blocks memory if it was provided.

   d. ```
      m_control_channel = storage::control::make_tcp_server_control_channel(m_cfg.listen_port);
      ```

      Create a TCP server control channel using the listen port specified by the CLI argument `--listen-port`. (Control channel objects provide a unified API so that a TCP client, TCP server, `doca_comch_client`, and `doca_comch_server` all have a consistent API).

      > See `storage_common/control_channel.hpp` for more information about the control channel abstraction.

2. ```
   storage::install_ctrl_c_handler([&app]() {
       app.abort("User requested abort");
   });
   ```

   Set a signal handler for control+c keyboard inputs so the app can shutdown gracefully.

3. ```
   app.wait_for_client_connection();
   ```

   Wait for a TCP client (the storage service) to connect.

4.
```
app.wait_for_and_process_query_storage();
```
Wait for the storage service to send a `query_storage_request` control message and then perform the required actions to fulfill the request:
   a. Populate a `query_storage_response` with the storage capacity (block count * block size) and the block size.
   b. Send response to the storage service.

5.
```
app.wait_for_and_process_init_storage();
```
Wait for the storage service to send a `init_storage_request` control message and then perform the required actions to fulfill the request:
   a. Use the `init_storage_payload` data to:
      i. Set core count (`m_core_count`) as the number of cores requested by the initiator (number of `--cpu` arguments provided to the initiator) OR fail if this is more than the number of `--cpu` arguments provided to the service.
      ii. Set number of transactions per core (`m_num_transactions`).
      iii. Create `doca_mmap` object from the provided export blob.
      iv. Create `m_core_count` worker threads.
      v. Perform the first stages of the worker threads initialization. These steps are carried out for each thread, but only one thread performs the steps at any time this simplifies the sending and receiving of control messages, the user could modify this flow to execute in parallel if they so desired.
         1. Create thread bound to the N^{th} CPU provided to the service via the `--cpu` CLI arguments.
         2.
```
m_workers[ii].execute_control_command(
    worker_create_objects_control_command {
        m_dev,
        m_transaction_count,
        m_remote_io_mmap,
        m_local_io_mmap}
    );
```
         Initialize thread context (asychronously).
      vi. Send a response to the storage service:
         1. Send an `init_storage_response` message upon success or an `error_response` message if anything failed.

6.
```
app.wait_for_and_process_create_rdma_connections();
```
Wait for the storage service to send a `create_rdma_connection_request` control message and then perform the required actions to fulfill the request:

   a.
```
void const *blob = nullptr;
size_t blob_size = 0;
```

```
doca_rdma_export(rdma_ctx, &blob, &blob_size, &rdma_conn);
```

Create local side of the RDMA connection by exporting RDMA context and store the created connection blob.

b.
```
doca_rdma_connect(rdma_ctx, cmd.import_blob.data(), cmd.import_blob.size(), rdma_conn);
```

Connect to remote RDMA side of the RDMA connection.

> This RDMA connection activity will be performed twice per worker thread. This allows for the IO control messages to be transferred over one connection while the other is used for data transfer. The reason for this is to reduce latency as with a single connection `doca_rdma_task_send`, `doca_rdma_task_read`, and `doca_rdma_task_write` tasks execute in submission order. This could mean that if, for example, 32 IO requests arrive in close succession and the corresponding 32 read / write tasks are submitted, once the first operation completes its response is blocked until all of the remaining 31 data transfers complete. This can cause significant delay in responding to the service / initiator and greatly increases the round trip latency of a storage request. Having two connections means in the previous scenario when the first of the N tasks completes its IO response can be sent immediately while the remaining N-1 read / write operations continue to execute.

c. Send a response to the storage service:
   i. Send a `create_rdma_connection_response` message upon success or an `error_response` message if anything failed.

7.
```
app.wait_for_and_process_start_storage();
```

Wait for the storage service to send a `start_storage_request` control message and then perform the required actions to fulfill the request:

a.
```
doca_error_t result;
doca_ctx_states ctx_state;

result = doca_ctx_get_state(doca_rdma_as_ctx(rdma_ctx), &ctx_state);
if (result == DOCA_SUCCESS && ctx_state == DOCA_CTX_STATE_RUNNING) {
    // RDMA connection is ready
}
```

Poll all worker connections until RDMA connections are fully established.

b. Signal all work threads to begin data path operation.
c. Send a response to the storage service:
   i. Send a `start_storage response` message upon success or an `error_response` message if anything failed.

8. Data path execution takes place now until either the user abort the program or a stop message is received.

9. `app.wait_for_and_process_stop_storage();`

   Wait for the storage service to send a `stop_storage_request` control message and then perform the required actions to fulfill the request:
   a. Join all work threads.
   b. Send a response to the storage service:
      i. Send a `stop_storage_response` message upon success or an `error_response` message if anything failed.

10. `app.wait_for_and_process_shutdown();`

    Wait for the storage service to send a `shutdown_request` control message and then perform the required actions to fulfill the request:
    a. Collect runtime stats.
    b. Destroy workers.
    c. Send a response to the storage service:
       i. Send a `shutdown_response` message upon success or an `error_response` message if anything failed.

11. `app.display_stats();`

    Display runtime statistics.
12. Application destructor
    a. Destroy TCP control channel
    b. Destroy `doca_mmap` objects.
    c. Destroy IO blocks memory.
    d. Close `doca_dev`.
13. Application exits.

6.20.12.7.2 Worker/Data Path Thread Flow

The work thread proc executes in two phases: Control / configuration phase, followed by data path phase where read and write operations take place.

6.20.12.7.2.1 Worker Init Process

```
void target_rdma_worker::thread_proc(target_rdma_worker *self, uint16_t core_idx) noexcept
```

The worker starts by executing a loop of:

1. Lock mutex
2. If message pointer is not null:
   a. Process the configuration message.
   b. Set the operation result.

3. Unlock the mutex.
4. Yield.

The following configuration operations can be performed by the worker thread:

1. ```
   void target_rdma_worker::create_worker_objects(worker_create_objects_control_command const &cmd)
   ```
   Create the objects required by the worker to carry out data path operations:
   a. Create IO messages memory.
   b. Create IO messages `doca_mmap` (to allow the messages to be accessed by RDMA)..
   c. Create `doca_buf_inventory`.
   d. Create `doca_pe` to drive the DOCA contexts.
   e. Create two `doca_rdma` contexts.
   f. Configure and start RDMA contexts.

2. ```
   void target_rdma_worker::create_rdma_connection(worker_create_rdma_connection_command &cmd)
   ```
   Create an RDMA connection from one of the two RDMA contexts held by the worker (which one to use is specified by the command):
   a. Call `doca_rdma_connect` to create the connection object, and connection blob.
   b. Call `doca_rdma_connect` to start connecting to the remote side of the connection.
   c. Store the local connection blob in the command object for use by the control thread to respond to the service.

3. ```
   void target_rdma_worker::are_contexts_ready(worker_are_contexts_ready_control_command &cmd) const noexcept
   ```
   Check each RDMA context and report when both are both ready for use.

4. ```
   void target_rdma_worker::prepare_tasks(void)
   ```
   Final preparations for data path execution:
   a. Cache frequently used static values into hot data (a single cache line).
   b. Allocate transaction objects.
   c. Allocate `doca_buf` objects.
   d. Allocate `doca_task` objects.
   e. Set task user data.
   f. Set task pointers into the transaction context.

5. ```
   void target_rdma_worker::start_data_path()
   ```
   Break out of the wait for configuration event loop and start the data path loop.
   ```

After the configuration phase the mutex is not used again

After breaking out of the initial configuration loop, the thread submits receive tasks (RDMA recv tasks) then enters the data path function: `run_data_path_ops`.

6.20.12.7.2.2 Worker Data Path Process

```
void target_rdma_worker::run_data_path_ops(target_rdma_worker::hot_data &hot_data)
{
    DOCA_LOG_INFO("Core: %u running", hot_data.core_idx);

    while (hot_data.run_flag) {
        doca_pe_progress(hot_data.pe) ? ++(hot_data.pe_hit_count) : ++(hot_data.pe_miss_count);
    }

    while (hot_data.error_flag == false && hot_data.in_flight_transaction_count != 0) {
        doca_pe_progress(hot_data.pe) ? ++(hot_data.pe_hit_count) : ++(hot_data.pe_miss_count);
    }
}
```

During the data path phase the thread simply polls the `doca_pe` as quickly as possible to check for a task completion from one of the RDMA contexts. The interesting work is done in the callbacks of these tasks. The flow will always start with a RDMA recv task completion. This is the reception of the IO message from the storage service.

doca_comch_consumer_task_post_recv_cb

```
void target_rdma_worker::doca_rdma_task_receive_cb(doca_rdma_task_receive *task,
                                                   doca_data task_user_data,
                                                   doca_data ctx_user_data) noexcept
```

This callback is the main driver of the storage target. It carries out the following steps:

1.
```
auto *const io_message = storage::get_buffer_bytes(doca_rdma_task_receive_get_dst_buf(task));
auto const message_type = storage::io_message_view::get_type(io_message);
```
Interpret the type of IO request that has been received.

2.
```
char *const remote_addr = hot_data->remote_memory_start_addr +
storage::io_message_view::get_requester_offset(io_message);

char *const local_addr = hot_data->local_memory_start_addr +
storage::io_message_view::get_storage_offset(io_message);

uint32_t const transfer_size = storage::io_message_view::get_io_size(io_message);
```
Extract IO addresses and transfer size from the IO request.

3.
```
auto *const transfer_ctx = static_cast<transfer_context *>(task_user_data.ptr);
```
Get a reference to the transaction object from the task user data.

4.
```
switch (message_type) {
    case storage::io_message_type::read: {
        oca_buf_inventory_buf_reuse_by_data(transfer_ctx->storage_buf, local_addr, transfer_size);
        doca_buf_inventory_buf_reuse_by_addr(transfer_ctx->host_buf, remote_addr, transfer_size);

        doca_task_submit(doca_rdma_task_write_as_task(transfer_ctx->write_task));
    } break;
    case storage::io_message_type::write: {
        doca_buf_inventory_buf_reuse_by_data(transfer_ctx->host_buf, remote_addr, transfer_size);
        doca_buf_inventory_buf_reuse_by_addr(transfer_ctx->storage_buf, local_addr, transfer_size);

        doca_task_submit(doca_rdma_task_read_as_task(transfer_ctx->read_task));
```

```
        } break;
```

Submit the appropriate RDMA task.

a. IO read is moving data from storage IO blocks to the remote IO blocks; so from the storage point of view its a write.

b. IO write is moving data from the remote IO blocks to the storage IO blocks; so from the storage point of view its a read.

5. If the any action in this process has failed send an IO error response to the caller, otherwise wait for the RDMA read / write task to complete.

on_transfer_complete

```
void target_rdma_worker::on_transfer_complete(doca_task *task,
                                              doca_data task_user_data,
                                              doca_data ctx_user_data) noexcept
{
    auto *const hot_data = static_cast<target_rdma_worker::hot_data *>(ctx_user_data.ptr);
    auto *const response_task = static_cast<doca_rdma_task_send *>(task_user_data.ptr);
    auto *const io_message =
        storage::get_buffer_bytes(const_cast<doca_buf *>(doca_rdma_task_send_get_src_buf(response_task)));

    ++(hot_data->completed_transaction_count);

    storage::io_message_view::set_type(storage::io_message_type::result, io_message);
    storage::io_message_view::set_result(DOCA_SUCCESS, io_message);

    auto const ret = doca_task_submit(doca_rdma_task_send_as_task(response_task));
    if (ret != DOCA_SUCCESS) {
        DOCA_LOG_ERR("Failed submit response task: %s", doca_error_get_name(ret));
}
```

A callback that is re-used for both `doca_rdma_task_read` and `doca_rdma_task_write`. The work is the same regardless of which task type completed and more detailed task type info is not required. This callback will simply update the IO message to change its type to a response, and set the result to success. The IO message is then sent back to the storage service.

doca_rdma_task_send_cb

```
void target_rdma_worker::doca_rdma_task_send_cb(doca_rdma_task_send *task,
                                                doca_data task_user_data,
                                                doca_data ctx_user_data) noexcept
{
    auto *const request_task = static_cast<doca_rdma_task_receive *>(task_user_data.ptr);

    doca_buf_reset_data_len(doca_rdma_task_receive_get_dst_buf(request_task));

    auto const ret = doca_task_submit(doca_rdma_task_receive_as_task(request_task));
    if (ret != DOCA_SUCCESS) {
        DOCA_LOG_ERR("Failed re-submit request task: %s", doca_error_get_name(ret));
    }

    auto *const hot_data = static_cast<target_rdma_worker::hot_data *>(ctx_user_data.ptr);
    --(hot_data->in_flight_transaction_count);
}
```

The RDMA task send callback resets the task data and resubmits the recv task allowing the transaction to be reused.

6.21 DOCA Stream Receive Performance Application Guide

This guide outlines the implementation of the DOCA Stream Receive Performance application, built on top of the NVIDIA® BlueField® DPU.

6.21.1 Introduction

The Stream Receive Performance application is designed to measure and evaluate RX performance using the NVIDIA DOCA RMAX library. It leverages the capabilities of DOCA RMAX and NVIDIA Rivermax to support efficient, high-performance media and data streaming.

6.21.1.1 Key Technologies

- DOCA RMAX API – A component of the NVIDIA DOCA framework, optimized for networking tasks in media streaming use cases.
- NVIDIA Rivermax SDK – Built to exploit BlueField DPU hardware acceleration, enabling direct data transfers between the NIC and GPU, minimizing CPU load.

This architecture delivers high throughput, ultra-low latency, and minimal CPU utilization making it an ideal solution for demanding real-time streaming workloads.

6.21.1.2 Deployment Notes

- DOCA Rivermax applications must run on BlueField target DPUs with root privileges or other additional permissions and capabilities
- Ensure the DPU has a valid IP address configured
- Allocate an appropriate number of huge pages for optimal performance. Refer to "*Rivermax Performance-oriented Development Guidelines*" for details.

  > To access this document, join the NVIDIA Rivermax SDK developers' program and access documentation in the Rivermax Developer page.

- Runtime configurations can be tuned even after the application starts, allowing dynamic performance optimization

For complete setup steps and advanced configurations, refer to DOCA RMAX documentation.

6.21.2 System Design

The application is designed to receive and process network packets using the DOCA library. It is structured around three core components:

- Configuration management – Manages the initialization, parsing, validation, and cleanup of application configuration parameters
- Global resources management – Handles the allocation and management of shared resources such as memory maps, buffer inventories, and progress engines
- Stream management – Manages the lifecycle of data streams used for packet reception, including setup, execution, and teardown

6.21.3 Architecture

The architecture comprises several key modules and their responsibilities.

6.21.3.1 Main Application

- Initialization – Sets up logging, parses command-line arguments, and initializes the configuration.
- Device listing – If the `--list` flag is passed, it enumerates and prints available devices, then exits.
- Stream processing – Initializes global resources, configures the stream, and enters the packet reception loop.

6.21.3.2 Configuration Management

- Initialization – Applies default values and creates the CPU affinity mask.
- Argument parsing – Parses command-line arguments and updates the configuration accordingly.
- Validation – Verifies that all required parameters are provided.
- Destruction – Frees any configuration-related resources.

6.21.3.3 Global Resources Management

- Initialization – Sets up shared memory maps, buffer inventories, and progress engines required for data handling
- Destruction – Cleans up and releases global resources

6.21.3.4 Stream Management

- Initialization – Configures and starts the stream, allocates memory buffers, and attaches the necessary flows
- Packet reception loop – Processes incoming packets, manages events, and collects runtime statistics
- Destruction – Detaches flows, stops the stream, and releases associated buffers

6.21.3.5 Application Functions and Roles

Function(s)	Role
`main`	Entry point of the application, handles overall flow control
`init_config`; `destroy_config`	Manage application configuration
`register_argp_params`	Register command-line arguments
`init_globals`; `destroy_globals`	Manage global resources
`init_stream`; `destroy_stream`	Manage stream setup and teardown
`run_recv_loop`	Main loop for receiving and processing packets
`handle_completion`; `handle_error`	Event handlers for packet reception and errors

6.21.3.6 Data Structures

- `app_config` – Holds configuration parameters for the application
- `globals` – Holds global resources required by the application
- `stream_data` – Manages the state and data associated with streaming

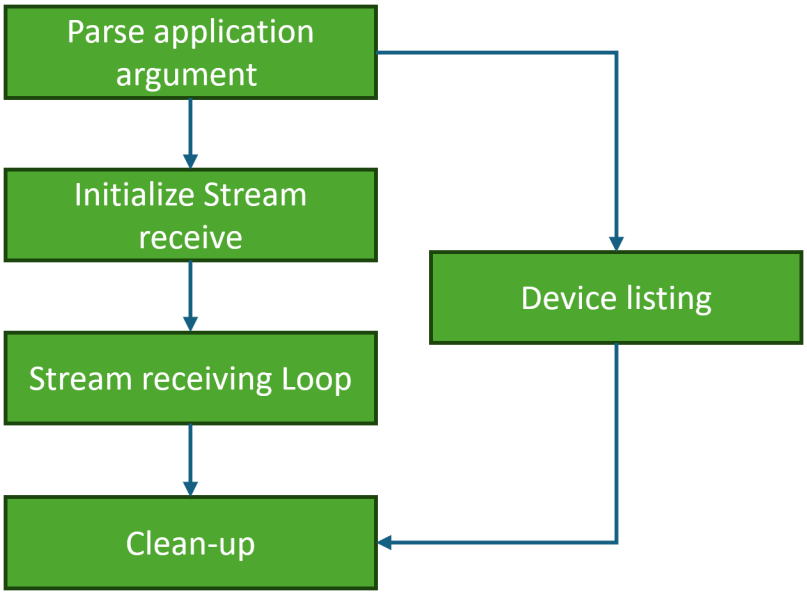
6.21.3.7 Event Handling

- Completion Events – Handled by `handle_completion`, updates statistics and optionally dumps packet content
- Error Events – Handled by `handle_error`, logs errors and stops the receive loop

6.21.3.8 Flow

1. Initialization – Set up logging, configuration, and global resources.

2. Device listing – Optionally list available devices.
3. Stream setup – Configure and initialize the stream.
4. Packet reception – Enter the main loop to receive and process packets.
5. Teardown – Clean up resources and exit.



6.21.4 DOCA Libraries

This application leverages the following DOCA library:

- DOCA RMAX

6.21.5 Dependencies

The RMAX library must be compiled and run, and a Rivermax license is required to run this application, as is the case with every application using DOCA RMAX. Refer to NVIDIA Rivermax SDK page to obtain that license.

6.21.6 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/stream_receive_perf/
```

6.21.6.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_stream_receive_perf` is created under `/tmp/build/stream_receive_perf/`.

6.21.6.2 Compiling Only the Current Application

1. To directly build only the stream receive performance application:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build -Denable_all_applications=false -Denable_stream_receive_perf=true
   ninja -C /tmp/build
   ```

   `doca_stream_receive_perf` is created under `/tmp/build/stream_receive_perf/`.
2. Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:
   a. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
      - Set `enable_all_applications` to `false`
      - Set `enable_stream_receive_perf` to `true`
   b. The same compilation commands should be used, as were shown in the previous section:

      ```
      cd /opt/mellanox/doca/applications/
      meson /tmp/build
      ```

```
ninja -C /tmp/build
```

`doca_stream_receive_perf` is created under `/tmp/build/stream_receive_perf/`.

6.21.7 Running the Application

6.21.7.1 Prerequisites

> This application can run on the target DPU only.

> This application must be run with root privileges or other additional permissions and capabilities.
>
> For detailed instructions on running without root privileges, please refer to the Environment section in DOCA Rivermax.

- An IP address to the device being used must be set up .
- It is recommended to have at least 800 huge pages enabled to achieve maximum performance:

```
dpu> echo 1000000000 > /proc/sys/kernel/shmmax
dpu> echo 800 > /proc/sys/vm/nr_hugepages
```

6.21.7.2 Application Execution

The stream receive performance application is provided in source form, hence a compilation is required before the application can be executed.

- Application usage instructions

```
 Usage: doca_stream_receive_perf  [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
   --list                            List available devices
   --scatter-type                    Scattering type: RAW (default) or ULP
   --tstamp-format                   Timestamp format: raw (default), free-running or synced
    -s, --src-ip                      Source address to read from
    -d, --dst-ip                      Destination address to bind to
    -i, --local-ip                    IP of the local interface to receive data
    -p, --dst-port                    Destination port to read from
    -K, --packets                     Number of packets to allocate memory for (default 262144)
    -y, --payload-size                Packet's payload size (default 1500)
    -e, --app-hdr-size                Packet's application header size (default 0)
```

```
    -a, --cpu-affinity              Comma separated list of CPU affinity cores for the application main
thread
    --sleep                         Amount of microseconds to sleep between requests (default 0)
    --min                           Block until at least this number of packets are received (default 0)
    --max                           Maximum number of packets to return in one completion
    --dump                          Dump packet content
```

For additional information, please refer to the "Command Line Flags" section below.

The above usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_stream_receive_perf -h
```

- CLI example for listing available devices:

```
./doca_stream_receive_perf --list
```

- CLI example for receiving a stream sent from `1.1.63.5` to the local NIC address `1.1.64.67` and port `7000`:

```
./doca_stream_receive_perf --local-ip 1.1.64.67 --dst-ip 1.1.64.67 --src-ip 1.1.63.5 --dst-port 7000
```

- CLI example for receiving a stream receiving a stream sent on `239.0.0.1` to the local NIC `1.1.64.67` from `1.1.63.5` and port `7000`:

```
./doca_stream_receive_perf --local-ip 1.1.64.67 --dst-ip 239.0.0.1 --src-ip 1.1.63.5 --dst-port 7000
```

- CLI example for receiving a stream using header-data split mode. This example receives a stream sent from `1.1.63.5` to the local NIC address `1.1.64.67` and port `7000`. The application header size is 20 bytes, and the payload size is 1200 bytes:

```
./doca_stream_receive_perf --local-ip 1.1.64.67 --dst-ip 1.1.64.67 --src-ip 1.1.63.5 --dst-port 7000 --app-
hdr-size 20 --payload-size 1200
```

> Setting the application header size enables header-data split mode which separates the application header from the payload.

6.21.7.3 Command Line Flags

6.21.7.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.21.7.3.2 Program Flags

Short Flag	Long Flag	Description
N/A	`list`	List all available devices, dump their IPv4 addresses, and tell whether or not the PTP clock is supported
N/A	`scatter-type`	Scattering type: • RAW (default) • ULP
N/A	`tstamp-format`	Timestamp format: • raw (default) • free-running • synced
`s`	`src-ip`	Source IP address to read from
`d`	`dst-ip`	Destination IP address to bind to
`i`	`local-ip`	IP of the local interface to receive data

Short Flag	Long Flag	Description
`p`	`dst-port`	Destination port to read from
`K`	`packets`	Number of packets to allocate memory for (default 262144)
`y`	`payload-size`	Packet's payload size (default 1500)
`e`	`app-hdr-size`	Packet's application header size (default 0)
`a`	`cpu-affinity`	list of CPU affinity cores for the application main thread
N/A	`sleep`	Amount of microseconds to sleep between requests
N/A	`min`	Block until at least this number of packets are received
N/A	`max`	Maximum number of packets to return in one completion
N/A	`dump`	Dump packet content

6.21.7.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.21.8 Application Code Flow

a. Parse application argument.
   i. Initialize arg parser resources and register DOCA general parameters.

```
init_config();
```

   ii. Register stream receive performance application parameters.

```
register_argp_params();
```

   iii. Parse the arguments.

```
doca_argp_start();
```

      1. Parse app parameters.

b. Device listing.
   If the list parameter is set to true, the application lists all available devices.
   i. Initializes the DOCA RMAX library.

```
doca_rmax_init();
```

ii. Enumerates and lists all available devices.

```
list_devices();
```

c. Stream receive: if the list parameter is not set, the application proceeds to receive stream.

i. Mandatory Arguments Check.

```
mandatory_args_set();
```

ii. CPU Affinity Mask (if it is set).

```
doca_rmax_set_cpu_affinity_mask();
```

iii. Initializes the DOCA RMAX library.

```
doca_rmax_init();
```

iv. Device opening.

```
open_device();
```

v. Global Resources Initialization.

```
init_globals();
```

vi. Stream Initialization.

```
init_stream();
```

d. Main Loop.

```
run_recv_loop();
```

e. Clean-up.

i. Cleans up and destroys the stream.

```
destroy_stream();
```

ii. Releases and destroys global application resources.

```
destroy_globals();
```

iii. Closes the device.

```
doca_dev_close();
```

iv. Releases the DOCA RMAX library.

```
doca_rmax_release();
```

v. Destroys the ARGP resources.

```
doca_argp_destroy();
```

i. Releases resources allocated by the application configuration.

```
destroy_config();
```

6.21.9 References

6.22 DOCA Switch Application Guide

This guide provides an example of switch implementation on top of NVIDIA® BlueField® DPU.

6.22.1 Introduction

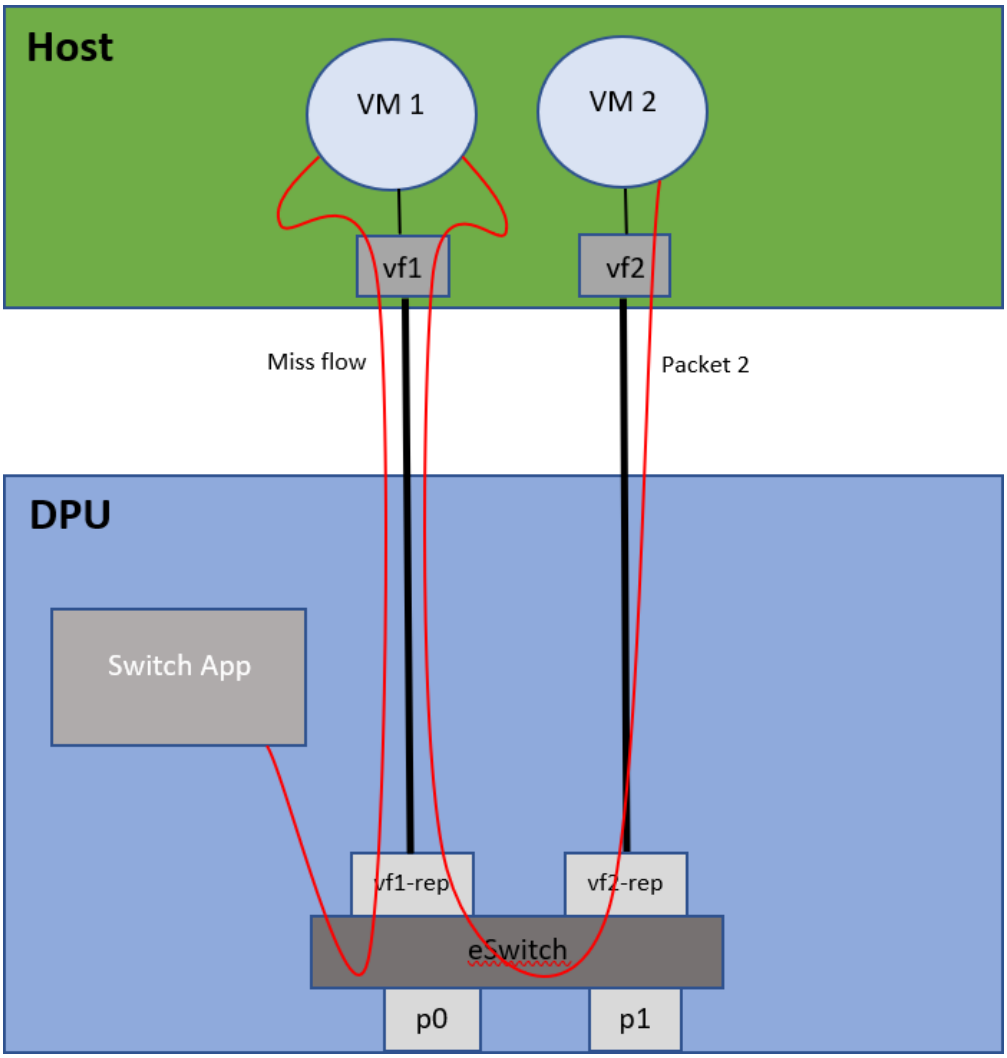
DOCA Switch is a network application that leverages the DPU's hardware capability for internal switching between representor ports on the DPU.

DOCA Switch is based on the DOCA Flow library. As such, it exposes a command line interface which receives DOCA Flow like commands to allow adding rules in real time.

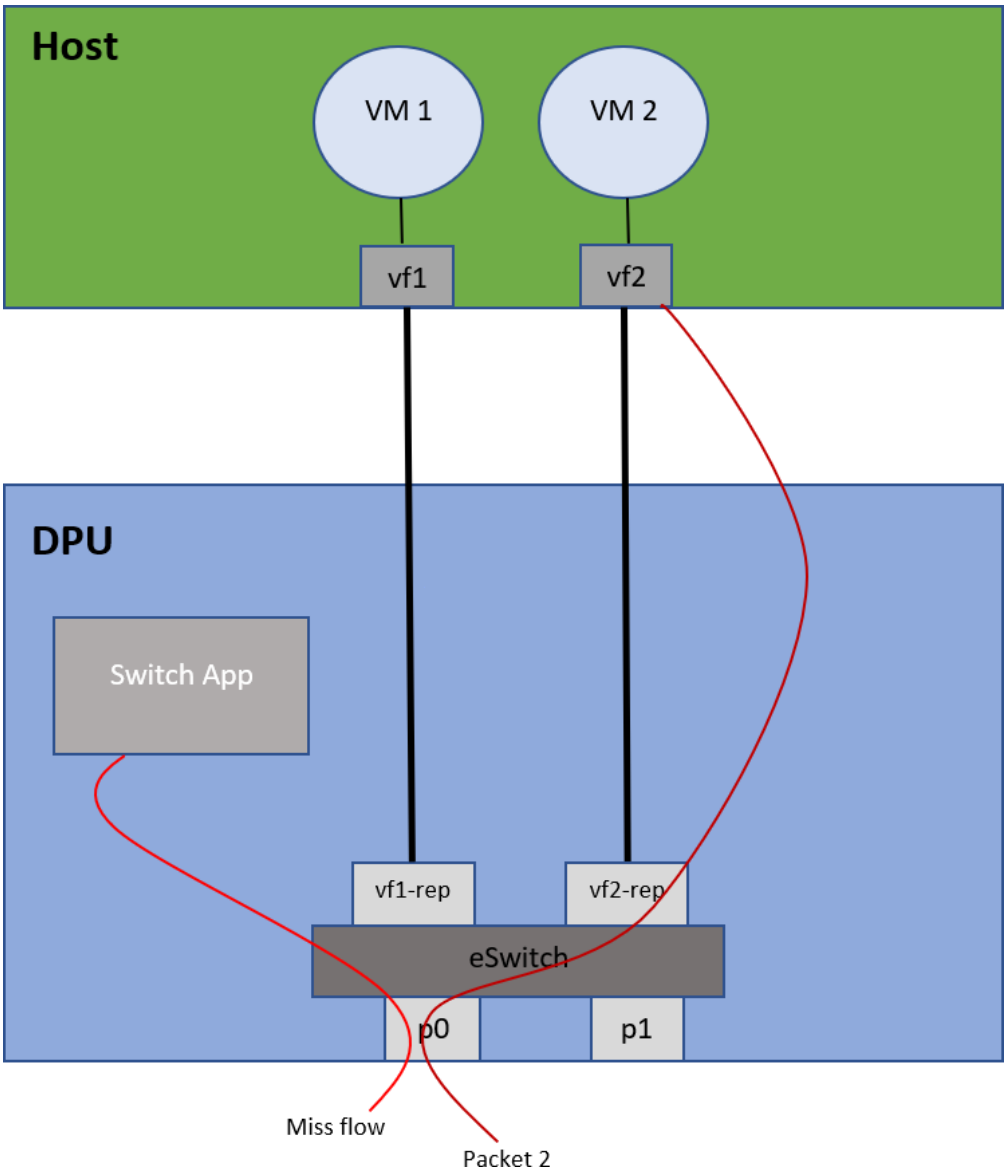
6.22.2 System Design

DOCA Switch is designed to run on the DPU as a standalone application (all network traffic goes directly through it).

Traffic flows between two VMs on the host:



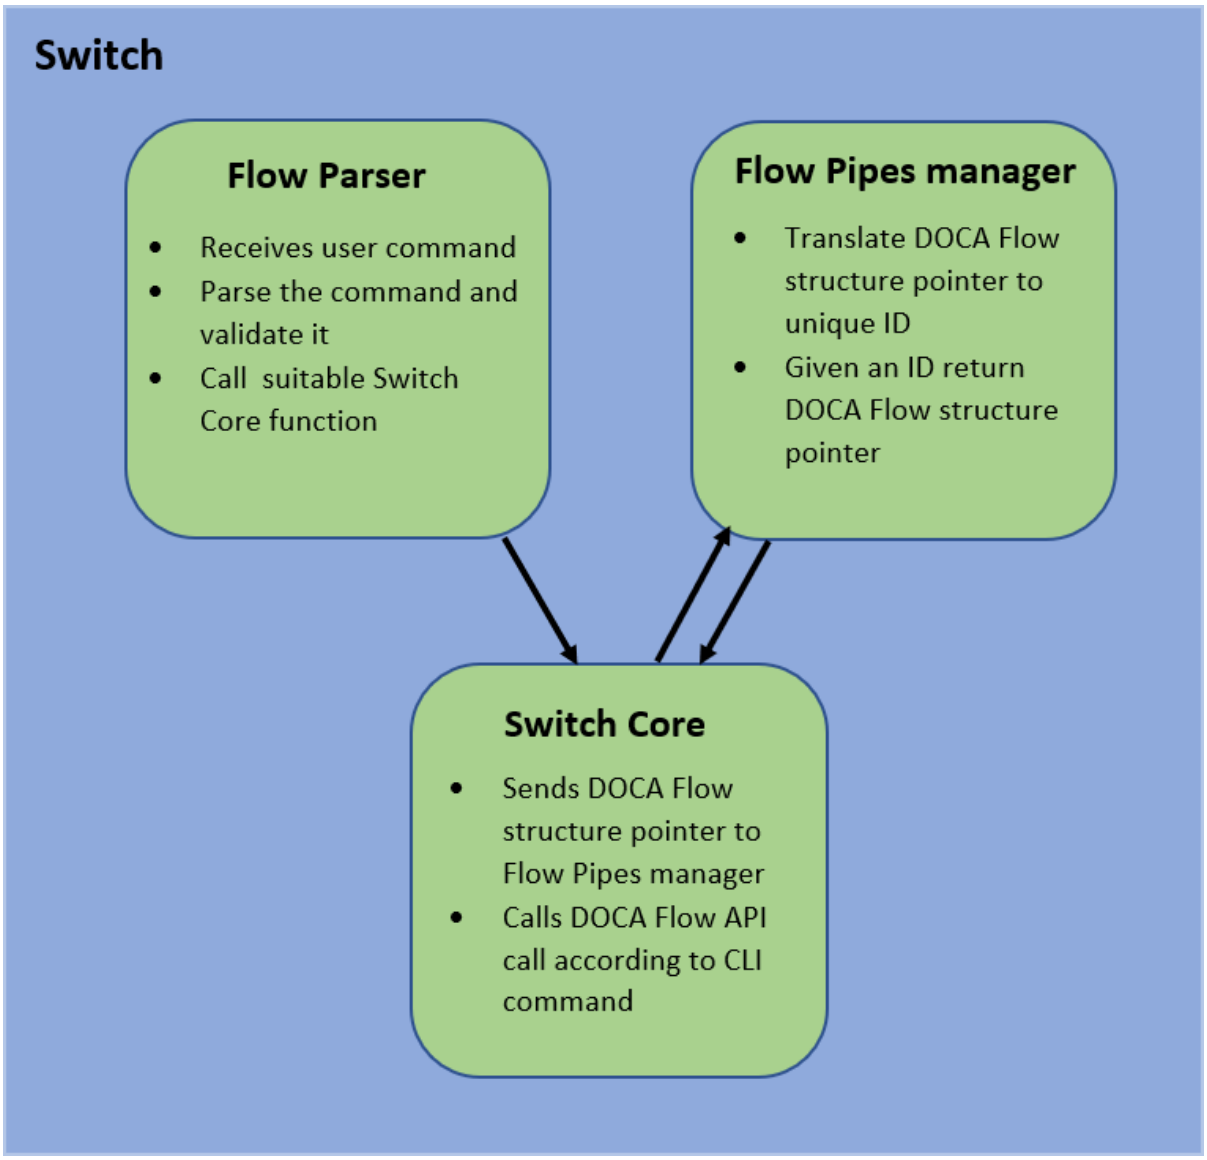
Traffic flow from a physical port to a VM on the host:



6.22.3 Application Architecture

DOCA Switch is based on 3 modules:

- Command line interface – receives pre-defined DOCA Flow-like commands and parses them
- Flow pipes manger – generates a unique identification number for each DOCA Flow structure created
- Switch core – combines all modules together and calls necessary DOCA Flow API



Port initialization cannot be made dynamically. All ports must be defined when running the application with standard DPDK flags.

- When adding a pipe or an entry, the user must run commands to create the relevant structs beforehand
- Optional parameters must be specified by the user in the command line; otherwise, `NULL` is used
- After a pipe or an entry is created successfully, the relevant ID is printed for future use

6.22.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Flow

Refer to its respective programming guide for more information.

6.22.5 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/switch/
```

6.22.5.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> `doca_switch` is created under `/tmp/build/switch/`.

6.22.5.2 Recompiling Only the Current Application

To directly build only the switch application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_switch=true
ninja -C /tmp/build
```

`doca_switch` is created under `/tmp/build/switch/`.

Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_switch` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_switch` is created under `/tmp/build/switch/`.

6.22.6 Running the Application

6.22.6.1 Prerequisites

The switch application is based on DOCA Flow. Therefore, the user is required to allocate huge pages.

```
$ echo '1024' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

6.22.6.2 Application Execution

The switch application is provided in source form. Therefore, hence a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_switch [DPDK Flags] -- [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
```

```
-a, --device                    device
-r, --rep                       device representor
-exp, --expert-mode             set expert mode
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_switch -- -h
```

For additional information, refer to section "Command Line Flags".

2. CLI example for running the application on BlueField:

```
./doca_switch -- -r pci/03:00.0,pf0vf[0-1] -l 60
```

The PCIe address (`03:00.0`) should match the address of the desired PCIe device.

For additional information regarding the command line syntax of the device and device representor identifiers, please referr to the matching section in the DOCA Arg Parser Guide.

6.22.6.3 Command Line Flags

6.22.6.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)

Short Flag	Long Flag	Description
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.22.6.3.2 Program Flags

Short Flag	Long Flag	Description
`a`	`device`	Device identifier
`r`	`rep`	Device representor identifiers for the ports indices
exp	expert-mode	Run switch in expert mode

6.22.6.4 Supported Commands

- `create pipe port_id=[port_id][,<optional_parameters>]`
  Available optional parameters:
  - `name=<pipe-name>`
  - `root_enable=[1|0]`
  - `monitor=[1|0]`
  - `match_mask=[1|0]`
  - `fwd=[1|0]`
  - `fwd_miss=[1|0]`
  - `type=[basic|control]`
- `add entry pipe_id=<pipe_id>,pipe_queue=<pipe_queue>[,<optional_parameters>]`
  Available optional parameters:
  - `monitor=[1|0]`

- `fwd=[1|0]`

- `add control_pipe entry priority=<priority>,pipe_id=<pipe_id>,pipe_queue=<pipe_queue>[,<optional_parameters>]`
  Available optional parameters:
  - `match_mask=[1|0]`
  - `fwd=[1|0]`
- `destroy pipe pipe_id=<pipe_id>`
- `rm entry pipe_queue=<pipe_queue>,entry_id=[entry_id]`
- `port pipes flush port_id=[port_id]`
- `port pipes dump port_id=[port_id],file=[file_name]`
- `query entry_id=[entry_id]`
- `create [struct] [field=value,…]`
  Struct options: `pipe_match`, `entry_match`, `match_mask`, `actions`, `monitor`, `fwd`, `fwd_miss`
  - Match struct fields:

Fields	Field Options
`flags`	
`port_meta`	
`outer.eth.src_mac`	
`outer.eth.dst_mac`	
`outer.eth.type`	
`outer.vlan_tci`	
`outer.l3_type`	`ipv4`, `ipv6`
`outer.src_ip_addr`	
`outer.dst_ip_addr`	
`outer.l4_type_ext`	`tcp`, `udp`, `gre`
`outer.tcp.flags`	`FIN`, `SYN`, `RST`, `PSH`, `ACK`, `URG`, `ECE`, `CWR`
`outer.tcp_src_port`	
`outer.tcp_dst_port`	
`outer.udp_src_port`	
`outer.udp_dst_port`	
`tun_type`	
`vxlan_tun_id`	

Fields	Field Options
`gre_key`	
`gtp_teid`	
`inner.eth.src_mac`	
`inner.eth.dst_mac`	
`inner.eth.type`	
`inner.vlan_tci`	
`inner.l3_type`	`ipv4`, `ipv6`
`inner.src_ip_addr`	
`inner.dst_ip_addr`	
`inner.l4_type_ext`	`tcp`, `udp`
`inner.tcp.flags`	`FIN`, `SYN`, `RST`, `PSH`, `ACK`, `URG`, `ECE`, `CWR`
`inner.tcp_src_port`	
`inner.tcp_dst_port`	
`inner.udp_src_port`	
`inner.udp_dst_port`	

- Actions struct fields:

Fields	Field Options
`decap`	`true`, `false`
`mod_src_mac`	
`mod_dst_mac`	
`mod_src_ip_type`	`ipv4`, `ipv6`
`mod_src_ip_addr`	
`mod_dst_ip_type`	`ipv4`, `ipv6`
`mod_dst_ip_addr`	
`mod_src_port`	
`mod_dst_port`	
`ttl`	
`has_encap`	`true`, `false`
`encap_src_mac`	
`encap_dst_mac`	

Fields	Field Options
encap_src_ip_type	ipv4, ipv6
encap_src_ip_addr	
encap_dst_ip_type	ipv4, ipv6
encap_dst_ip_addr	
encap_tup_type	vxlan, gtpu, gre
encap_vxlan-tun_id	
encap_gre_key	
encap_gtp_teid	

- FWD struct fields:

Fields	Field Options
type	rss, port, pipe, drop
rss_flags	
rss_queues	
num_of_queues	
port_id	
next_pipe_id	

- Monitor struct fields:
  - flags
  - cir
  - cbs
  - aging

The physical port number (only one physical port is supported) will always be 0 and all representor ports are numbered from 1 to N where N is the number of representors being used. For example:

- Physical port ID: 0
- VF0 representor port ID: 1
- VF1 representor port ID: 2
- VF2 representor port ID: 3

The following is an example of creating a pipe and adding one entry into it:

```
create fwd type=port,port_id=0xffff
create pipe port_id=0,name=p0_to_vf1,root_enable=1,fwd=1
create fwd type=port,port_id=1
add entry pipe_queue=0,fwd=1,pipe_id=1012
```

```
....
rm entry pipe_queue=0,entry_id=447
```

1. Pipe is configured on port ID 0 (physical port).
2. Entry is configured to forward all traffic directly into port ID 1 (VF0).
3. When the forwarding rule is no longer needed, the entry is deleted.
4. Ultimately, both entries are deleted, each according to the unique random ID it was given:

6.22.6.5 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the installation or execution of the DOCA applications.

6.22.7 Application Code Flow

1. Parse application argument.
    a. Initialize the arg parser resources and register DOCA general parameters.

    ```
    doca_argp_init();
    ```

    b. Register DOCA Flow switch mode application parameters.

    ```
    register_doca_flow_switch_param();
    ```

    c. Parse app parameters.

    ```
    doca_argp_start();
    ```

2. Initiate DOCA Flow switch mode application parameters.

    ```
    init_doca_flow_switch_common();
    ```

3. Initialize DPDK ports and queues.

    ```
    dpdk_queues_and_ports_init();
    ```

4. Initialize DOCA Switch.

    ```
    switch_init();
    ```

    a. Initialize DOCA Flow.
    b. Create port pairs.
    c. Create Flow Pipes Manger module.
    d. Register an action for each relevant CLI command.
5. Initialize Flow Parser.

```
flow_parser_init();
```

   a. Reset all internal Flow Parser structures.
   b. Start the command line interface.
   c. Receive user commands, parse them, and call the required DOCA Flow API command.
   d. Close the interactive shell once a "quit" command is entered.

6. Clean Flow Parser resources.

```
flow_parser_cleanup();
```

7. Destroy Switch resources.

```
switch_destroy();
```

   a. Destroy Flow Pipes Manager resources.

8. Destroy DOCA Flow.

```
switch_destroy();
```

9. Destroy DPDK ports and queues.

```
dpdk_queues_and_ports_fini();
```

10. DPDK finish.

```
dpdk_fini();
```

    a. Call `rte_eal_destroy()` to destroy initialized EAL resources.

11. Arg parser destroy.

```
doca_argp_destroy();
```

6.23 DOCA Accelerated UPF Reference Application Guide

6.23.1 Terms and Abbreviations

Abbreviation	Definition
DN	Data Network
DPI	Deep Packet Inspection
FAR	Forwarding Action Rule
gNB	Next Generation NodeB
GTP-U	GPRS Tunneling Protocol User Plane
N3	Interface connecting the Radio Access Network (gNB) to the User Plane Function (UPF) in 5G networks. Responsible for transporting user data using GTP-U protocol.
N6	Interface connection the User Plane Function (UPF) to external data networks (e.g. internet, enterprise network, cloud services), serving as the gateway between 5G network and external networks.
PDR	Packet Detection Rule
PDU	Protocol Data Unit
PSC	PDU Session Container. An extension header in GTP that is being used in 5G core networks.
QER	QoS Enforcement Rule
QoS	Quality of Service
RAN	Radio Access Network
RAP	Reference Application
RSS	Receive Side Scaling. A functionality that enables dispatching of packets into multiple queues.
SMF	Session Management Function
UE	User Equipment
UPF	User Plane Function
URR	Usage Reporting Rule
WAN	Wide Area Network

6.23.2 Introduction

The Accelerated UPF-RAP provides a reference implementation of an accelerated data path of UPF on top of the NVIDIA® BlueField-3®.

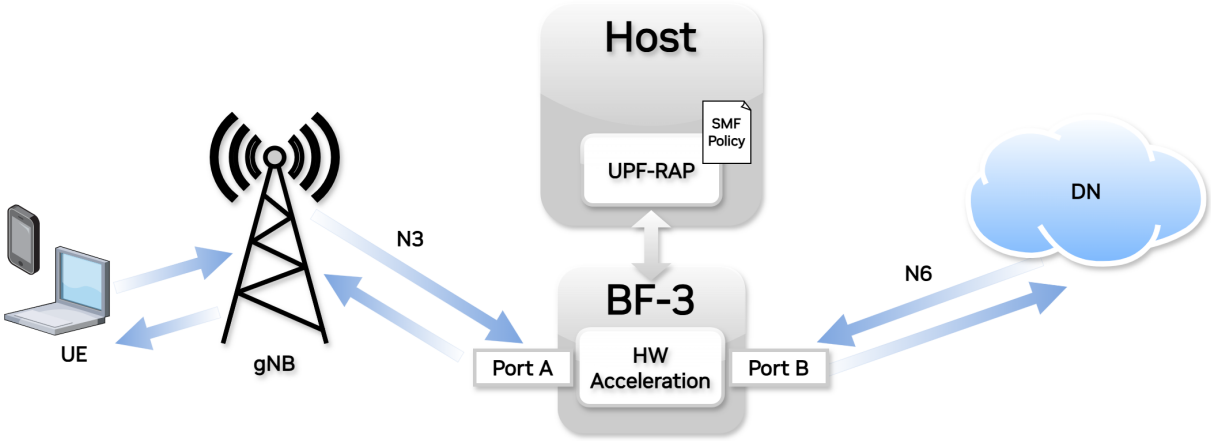
This project is intended for UPF vendors looking to hardware accelerate their UPF data-plane. It provides a reference implementation for developers as well as a platform to evaluate the functionality and performance. It is important to note that this project is not a UPF implementation by itself, and users should not expect it to work as a full-fledged UPF or comply fully with the 3GPP standard.

The Accelerated UPF RAP optimizes data traffic handling between RAN (gNB) and WAN (DN) by leveraging BlueField-3 hardware acceleration capabilities. Using DOCA Flow API, the application programs UPF's domain-specific network pipelines directly into BlueField-3's hardware, significantly reducing CPU overhead by processing packets in hardware rather than software.

Bidirectional Processing (Uplink, Downlink):

- RAN to DN Flow (Uplink):
  - Ingress: All N6 traffic is received on BlueField-3 Port A.
  - Processing: BlueField-3 applies appropriate processing to the N6 traffic, including GTP encapsulation, routing, policy enforcement, quota management, or any other relevant actions based on the traffic characteristics and network configuration.
  - Egress: After processing, BlueField-3 forwards the N6 traffic to Port B.
- DN to RAN Flow (Downlink):
  - Ingress: All N3 traffic is received on BlueField-3 Port B.
  - Processing: BlueField-3 processes the N3 traffic, applying actions such as GTP decapsulation, QoS enforcement, user-plane policy application, or routing as per the core network's requirements.
  - Egress: After processing, BueField-3 forwards the N3 traffic to Port A.

This flow ensures efficient and streamlined traffic processing and forwarding for both N6 and N3 interfaces, enabling robust user-plane functionality with clear traffic flow paths.



The Accelerated UPF-RAP is designed to efficiently handle and manage traffic while incorporating key features for functionality, performance, observability, and resource optimization. The detailed operation and capabilities are as follows:

HW Accelerated Features:

- Rate Meters: Configurable rate meters monitor and enforce traffic throughput on N3 and N6 interfaces.
- Quota Counters: Per-subscriber quota management is enabled, tracking data usage against assigned limits. Actions (e.g., throttling or redirecting traffic) can be applied when quotas are exceeded.
- Flow Aging: A flow aging mechanism efficiently tracks active flows and removes inactive ones based on configurable timeouts, ensuring resource efficiency and preventing stale flow accumulation.

Software Features with Hardware Assistance:

- Configurable Slow Path Packet Redirection: Allows configuring the number of packets from a flow to be processed by software before the flow is accelerated to hardware, which fits to use cases such as DPI.
- Connection Tracking Infrastructure: Maintains a shared software context for N3 and N6 flows of the same connection.
  This is achieved in a performance-oriented manner by utilizing symmetric RSS, which ensures that both flows are processed on the same core.
  This approach enables lock-free database access, enhancing efficiency and reducing latency.
- Debuggability and Telemetry: Real-time debug counters provide visibility into flow-level and packet-level operations.

The Accelerated UPF-RAP does not enforce a specific traffic type (N3/N6) on either port. Instead, it is designed to handle both traffic types on any port interchangeably.

These advanced features ensures the UPF is capable of meeting modern network demands with high efficiency, robust observability, and optimal resource management for N3 and N6 flows.

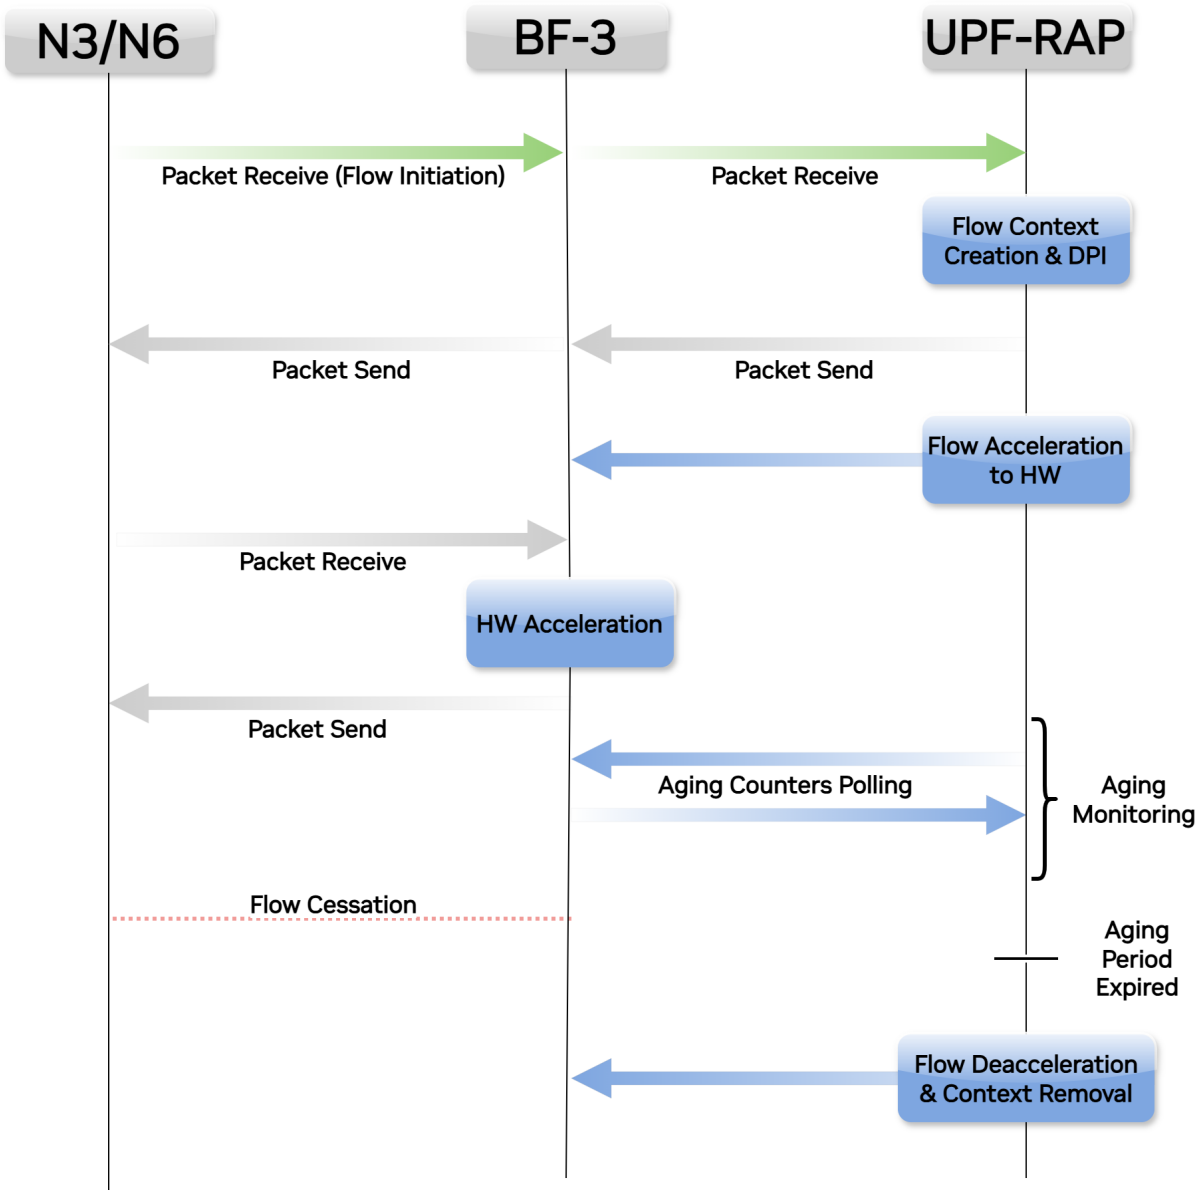
6.23.3 System Design

The Accelerated UPF-RAP runs on the host system and programs acceleration policies into the BlueField-3 acceleration engine.

6.23.4 Application Architecture

This Accelerated UPF-RAP architecture leverages DOCA Flow to efficiently manage N3 and N6 traffic by accelerating flow processing inside BlueField-3's steering mechanism.

The architecture is designed to optimize performance, reduce CPU utilization, reducing memory usage, and maintain efficient scale of flows by aging out inactive flows from the system, enabling rooms for newly added flows.



6.23.4.1 Key Features in UPF-RAP

- DOCA Flow Framework:
  - Acts as the foundational API for the Accelerated UPF-RAP, enabling direct interaction with BlueField-3 for rules (add/remove) and counters management.
  - Facilitates high-performance packet processing, flow steering, and HW acceleration operations.
- Flow Management Logic:
  - Packet Forwarding Acceleration:
    - DOCA Flow's pipes are pre-allocated with fixed size to contain future rules insertion.

        - New flows are identified by the Accelerated UPF-RAP and accelerated BlueField-3 via DOCA Flow APIs.
        - BlueField-3 handles packet forwarding, flow-specific actions (e.g., QoS), and telemetry collection.
    - Flow Aging and Removal:
        - Inactive flows are monitored using timeouts and telemetry feedback.
        - Flows that exceed their inactivity threshold are automatically removed from BlueField-3, freeing resources.
- Bidirectional Traffic Management Logic:
    - Uplink traffic (gNB → N3 → UPF → N6 → DN):
        - Received from the RAN and processed for interaction with the core network.
        - Managed via DOCA Flow to accelerate user-plane traffic to BlueField-3 for low-latency forwarding (QoS, decapsulation).
    - Downlink traffic (DN→ N6 → UPF → N3 → gNB):
        - Received from DN and processed for delivery to the RAN or other destinations.
        - Accelerated to BlueField-3 for efficient handling (QoS, encapsulation).
    - The Accelerated UPF-RAP leverages symmetric RSS to run multithreaded, enabling the following capabilities:
        - Processing N3 and N6 Traffic on the Same Core: Symmetric RSS ensures that both N3 and N6 traffic of the same flow are directed to the same CPU core.
          This is achieved by hashing packet headers in a way that packets belonging to the same flow are consistently mapped to the same core. This reduces the overhead of context switching and improves cache efficiency, leading to better performance.
          RSS is applied on both GTP-tunneled and non-tunneled directions of the traffic
        - Single Software Context for a Flow: With symmetric RSS, a single software context is maintained for each flow. This means that both N3 and N6 traffic of the same flow are handled within the same thread or process.
          This unified context simplifies flow management and ensures that all operations related to a flow are executed sequentially, avoiding race conditions and reducing synchronization overhead.
        - Lock-Free Data Access: To further enhance performance, the Accelerated UPF-RAP implements lock-free data structures for managing flow state information.
          This approach minimizes contention and latency, ensuring that database operations are performed efficiently.

- RSS is applicable for new packets of a flow only, once a flow is accelerated it will be handled by HW.

6.23.4.2 SMF

The SMF is a crucial component of the 5G core network architecture. It is responsible for managing user sessions, including establishing, modifying, and terminating data sessions between UE and the DN.

The Accelerated UPF-RAP uses static SMF policies for entities creation provided by a JSON file, bypassing the need to integrate with a real SMF through N4 interface. Production-based UPF shall implement and accommodate the N4 interface in order to dynamically update the rules, following network updates.

An example configuration can be found here.

The Accelerated UPF-RAP supports the following fields:

- PDR

Field Path	Comments
`createPdr.pdrId`	PDR ID
`createPdr.pdi.sourceInterface.type`	Determines packet direction (Source Interface), supported values: 0 (Access/DL), 2 (SGi-LAN/N6-LAN).
`createPdr.pdi.localFT`	Defines the packet header matching the PDR
`createPdr.pdi.localFT.teid_start`, `createPdr.pdi.LocalFT.teid_end`	Defines GTPU TEID range to match
`createPdr.pdi.localFT.ip.v4`	Defines the outer IPV4 source/destination address to match, depending on “sourceInterface” value (2 or 0 respectively)
`createPdr.pdi.qfi`	Defines the match of QFI field in GTPU header
`createPdr.pdi.userEquipment.ip.v4`	Defines the outer IPV4 source/destination address to match, depending on “sourceInterface” value (0 or 2 respectively)
`createPdr.pdi.sdf.description`	Defines the criteria for packet matching
`createPdr.farId`, `createPdr.urrIds`, `createPdr.qerIds`	The FAR and lists of the URRs and a list of the QERs.

- FAR

Field Path	Comments
`createFar.farId`	FAR ID
`createFar.fp.outerHeader.ip.v4`, `CreateFar.fp.outerHeader.teid`	Defines the outer header that needs to be added to the packet (Outer Header Creation).

- URR

Field Path	Comment
`createUrr.urrId`	URR ID
`createUrr.volumeQuota.totalVolume`	Defines the total quota in bytes

- QER

Field Path	Comments
`createQer.qurId`	QER ID
`createQer.maxBitRate.ulMBR`, `createQer.maxBitRate.dlMBR`	Defines the UL/DL Maximum Bit Rate allowed in 1kbps units.
`createQer.qfi`	Identifies the QFI field in GTPU header

6.23.4.2.1 SMF Policy Example

The following JSON example is provided under the following license:

        }
    ]
}
```

6.23.4.3 Flow Processing

In the Accelerated UPF-RAP, the process from the moment the flow initiates by its first packet to the point it gets accelerated involves several key steps. Here's a detailed description of this process:

1. Initial Packet Reception: When a new packet of a flow arrives it will be forwarded to the Accelerated UPF-RAP, then the application identifies the flow and applies initial packet processing rules.
   The Accelerated UPF-RAP uses the PDR to recognize the flow and determine the necessary actions, such as forwarding, buffering, or dropping the packet.
2. Hardware Acceleration: With the flow identified and classified the UPF programs BlueField-3 to process this flow data plane. This hardware acceleration significantly reduces the CPU load and enhances the overall efficiency of the UPF. Tasks like GTP-U encapsulation/decapsulation, flow tagging, QoS enforcement, and packet forwarding are handled by the NIC, providing deterministic performance and scalability.
3. Accelerated Flows: Subsequent packets of that flow will be fully processed by Bluefiled-3 HW and forward to their destination without going through the host/ UPF-RAP.
4. Flow Removal: If a flow remains inactive for the duration of its configured inactive time (e.g. 15 seconds). The Accelerated UPF-RAP then removes the flow from its tables and freeing up the associated resources.

6.23.4.4 Test Environment and Setup

The Accelerated UPF-RAP was tested in the following environment and setup.

Item	Description
Test Description	NVIDIA BlueField-3 DPU. Throughput and packet rate test at maximum 0.01% packet loss.
Server	Intel(R) Xeon(R) Platinum 8362 CPU @ 2.80GHz

Item	Description
DPU	Nvidia BlueField-3 P-Series DPU 200GbE/NDR200 VPI dual-port QSFP112; PCIe Gen5.0 x16 FHHL with x16 PCIe extension option; Crypto Enabled; SB Enabled 32GB on-board DDR; integrated BMC. Part Number: 900-9D3B6-00CV-AAA_DK_Ax
Operating System	Ubuntu 22.04
DPU firmware version	32.43.1014
DPDK version	22.11
DOCA version	2.10
Test Configuration	1 NIC/DPU, 2 ports. The ports receive a stream of IP flows from the traffic generator. 1 queue assigned per each core with a total of 10 cores. Port 0 receives RAN traffic of the form: `Ether() / IP() / UDP() / GTP_U_Header() / IP() / UDP()` Port 1 receives WAN traffic of the form: `Ether() / IP() / UDP()`
DPDK Settings	Compile DPDK using: meson ; ninja -C
Command Line	./doca_upf_accel -l 0-9 -- -a <PORT_0>,dv_flow_en=2 -a <PORT_1>,dv_flow_en=2 -f <SMF_POLICY_JSON>

6.23.5 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Flow

For additional information about the used DOCA libraries, please refer to the respective programming guides.

6.23.6 Dependencies

- NVIDIA BlueField-3 DPU
- Ubuntu 22.04 host (x86)

6.23.7 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/upf_accel/
```

The application relies on the `json-c` open source, requiring the following to be installed:

- Ubuntu/Debian:

```
$ sudo apt install libjson-c-dev
```

- CentOS/RHEL:

```
$ sudo yum install json-c-devel
```

6.23.7.1 Compiling All Applications

All DOCA applications are defined under a single Meson project. By default, the build process compiles all of them.

To build all applications:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

6.23.7.2 Compiling Only the Current Application

To build the Accelerated UPF-RAP:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_upf_accel=true
ninja -C /tmp/build
```

`doca_upf_accel` is created under `/tmp/build/applications/upf_accel/`.

Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
    a. Set `enable_all_applications` to `false`
    b. Set `enable_upf_accel` to `true`
2. Execute:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_upf_accel` is created under `/tmp/build/applications/upf_accel/`.

6.23.8 Running the Application

6.23.8.1 Runtime Prerequisites

- The Accelerated UPF-RAP is based on DOCA Flow. Therefore, the user is required to allocate huge pages.

```
$ echo '1024' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
$ sudo mkdir /mnt/huge
$ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
```

- The Flex Parser Profile is a setting that enables flexible protocol parsing on NVIDIA NICs/DPUs. To enable GTP protocol support, set the Flex Parser Profile to 3 using mlxconfig. This configuration is mandatory and must be done manually in the system:

```
$ sudo mlxconfig -d <pcie_address> s FLEX_PARSER_PROFILE_ENABLE=3
```

Changing this configuration using mlxconfig requires a system (cold) reboot for the changes to take effect. For more information, refer to mlxconfig documentation.

6.23.8.2 Application Execution

The Accelerated UPF-RAP is provided in source form, hence a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_upf_accel [DPDK Flags] -- [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                      Print a help synopsis
  -v, --version                   Print program version information
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                    Filter logs from specific modules, separated by comma
  -j, --json <path>               Parse command line flags from an input json file

Program Flags:
  -a, --device                    device
  -r, --rep                       device representor
  -f, --smf-config-file-path      SMF JSON definitions file path
  -x, --vxlan-config-file-path    VXLAN JSON definitions file path
  -t, --aging-time-sec            Aging period in seconds
  -o, --dpi-packet-threshold      Number of packets processed in software before accelerating to
hardware, enabling DPI on initial packets
  -p, --fixed-port                UL port number in fixed-port mode
```

For additional information, please refer to the Command Line Flags section below.

> ⚠ The above usage printout can be printed to the command line using the `-h` (or `--help`) options:
>
> ```
> /tmp/build/upf_accel/doca_upf_accel -- -h
> ```

2. CLI example for running the application:

```
/tmp/build/upf_accel/doca_upf_accel -l 0-10 -- -a pci/03:00.0,dv_flow_en=2 -a pci/03:00.1,dv_flow_en=2 -f
<SMF_POLICY_JSON>
```

> ⚠ For additional information regarding the command line syntax of the device and device representor identifiers, please refer to the matching section in the DOCA Arg Parser Guide.

6.23.8.3 Command Line Flags

6.23.8.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis

Short Flag	Long Flag	Description
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.23.8.3.2 Program Flags

Short Flag	Long Flag	Description
`a`	`device`	Device identifier
`r`	`rep`	Device representor identifiers for the ports indices
`f`	`smf-config-file-path`	Path to the SMF policy JSON file, see SMF Policy Example This is a mandatory flag.
`t`	`aging-time-sec`	Aging period in seconds, Optional; default is 15.
`o`	`dpi-packet-threshold`	Specifies the number of packets processed in software before accelerating to hardware, enabling DPI on initial packets. Optional; default is 2.

6.23.8.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.24 DOCA UROM RDMO Application Guide

This guide provides a DOCA Remote Direct Memory Operation implementation on top of NVIDIA® BlueField® DPU using Unified Communication X (UCX).

6.24.1 Introduction

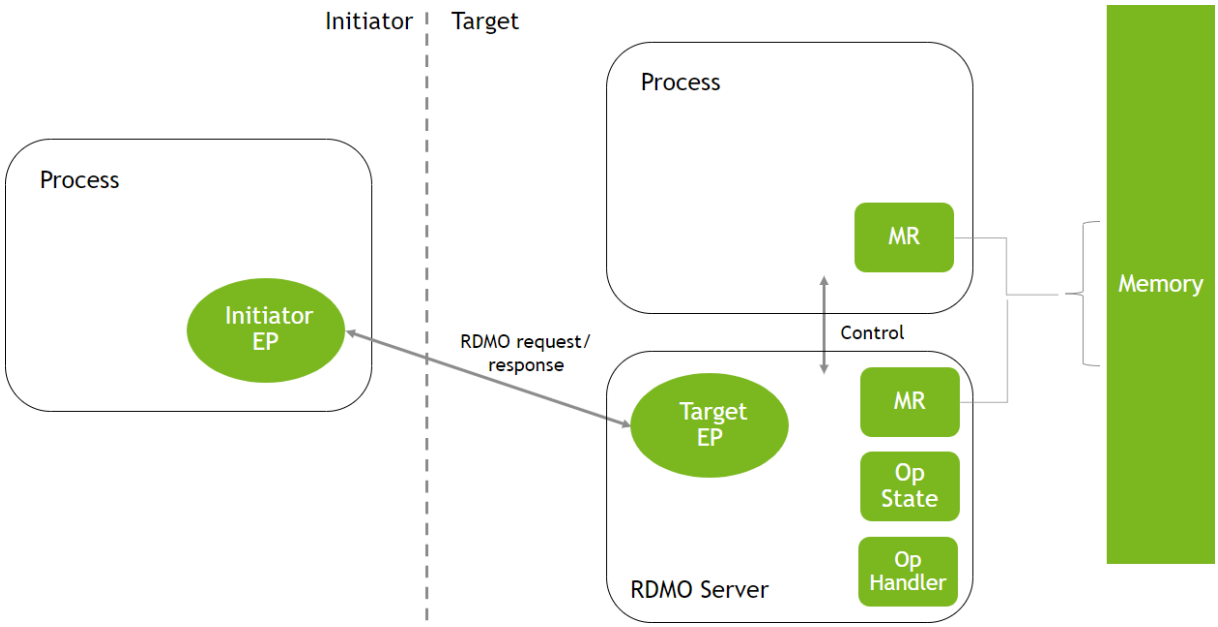
A remote direct memory operation (RDMO) is conceptionally an active message which is executed outside the context of the target process.

An RDMO involves the following entities:

- Target – establishes a connection to the server to use as the control path. The target interacts with the server to define target endpoints and memory regions. The target exchanges endpoint and memory region information with an initiator to facilitate its connection.
- Initiator – establishes a connection to the server to use as the data path. An RDMO is initiated by sending an RDMO command with an optional payload to the server. The server parses the commands and runs an associated RDMO handler. An RDMO handler interacts with the target process by performing one-sided memory accesses to target-defined memory regions.
- Server – responsible for executing RDMOs asynchronously from the target process. The server implements an RDMO handler for each supported operation. RDMO handlers may maintain a state within the server for optimization.

The DOCA UROM RDMO application includes the above three entities, split into the following parts:

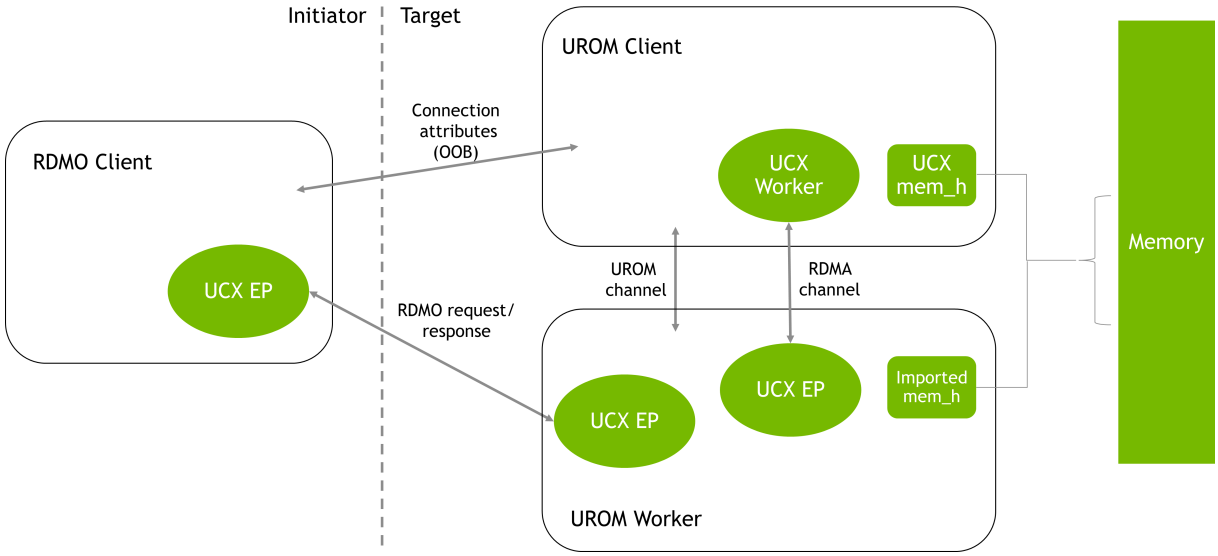
- BlueField side – the implementation of RDMO plugin component to be loaded by the DOCA UROM worker (which is the RDMO server)
- Host side – host application that runs using two modes: target and initiator



RDMOs are designed to take advantage of extra computing resources on a platform. While application processes run on the primary compute resources, an RDMO server can run on idle resources on the same host or be offloaded to run on a separate device (i.e., BlueField).

6.24.2 System Design

The application demonstrates the implementation of RDMO operations as a DOCA UROM worker plugin component. A target process would use the DOCA UROM API to create a worker with RDMO capabilities. An initiator process establishes an RDMO connection to the UROM worker. The plugin uses UCX as its transport.



6.24.2.1 Bootstrap Procedure

To connect the RDMO initiator and target, on the target side, UROM is used to retrieve an address for each created RDMO worker. This address would need to be delivered to the RDMO initiator side for connection establishment. The initiator address is obtained from the UCX worker created explicitly by the RDMO application. Both addresses are exchanged over the out-of-band (OOB) network and used to establish the connection:

- On the RDMO initiator side, a UCX endpoint is created using UCX API
- On the RDMO target side, the initiator's address is communicated to the RDMO worker using the UROM command channel

6.24.2.2 Memory Management

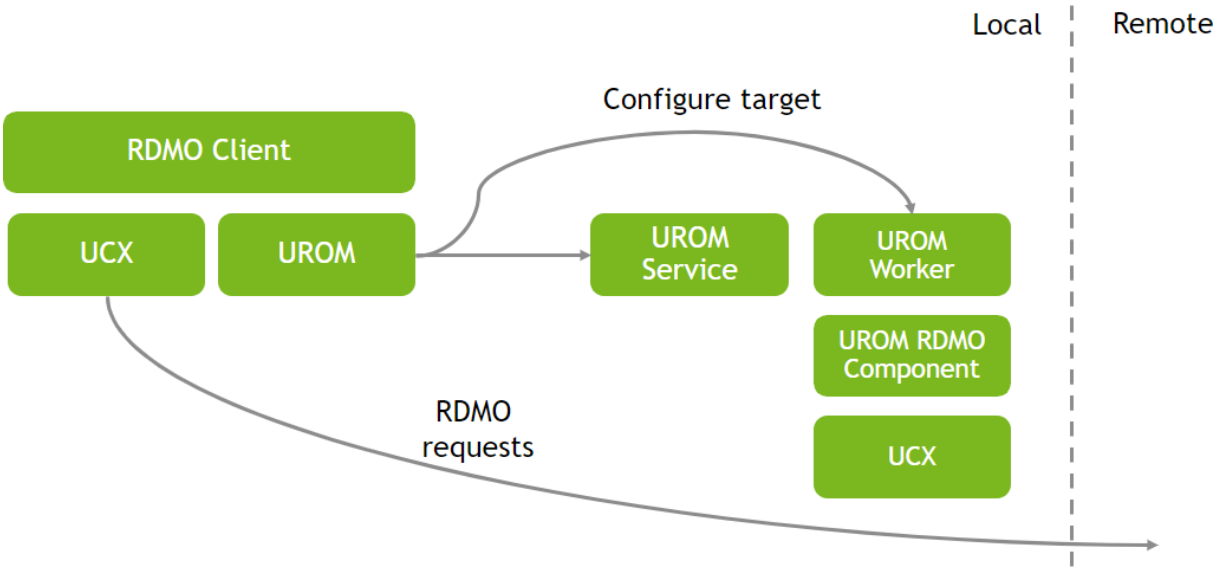
UROM returns an identifier (ID) for each memory region imported to the RDMO plugin component. This ID is used to refer to a target memory region in RDMO requests. It must be exchanged with the initiator process OOB.

6.24.2.3 RDMO UROM Worker Operation

Communication between the RDMO initiator and worker is implemented on top of UCX active messages. The worker’s active message handler is the entry point that identifies the type of the RDMO operation based on the RDMO request header. The request is then forwarded to the corresponding RDMO operation handler which determines the operation parameters by inspecting the operation-specific sub-header in the request.

UCX active messages support eager and rendezvous protocols. When using a rendezvous protocol, the worker can choose whether to pull data to the server or move it directly to a target memory using a UCX-imported memory handle.

An RDMO operation handler may perform any combination of computation, initiator and target memory accesses, server state updates, or responses.



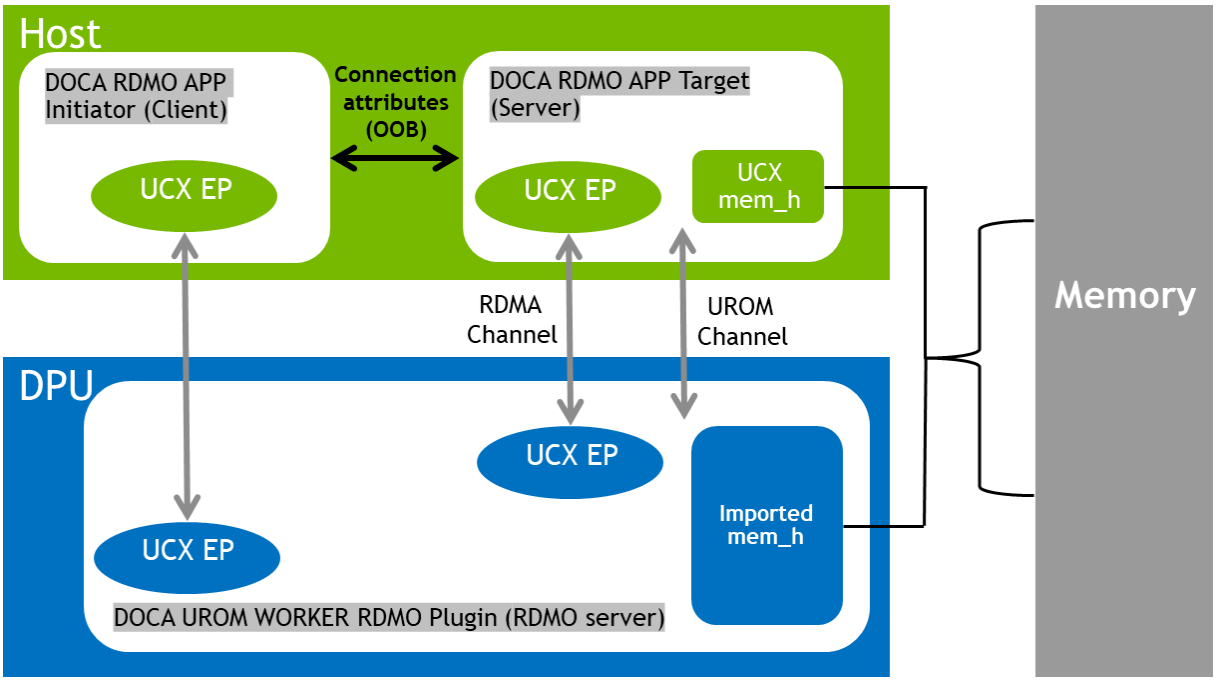
The RDMO client uses UROM to instantiate an RDMO worker and to configure target endpoints and memory regions. The client uses UCX directly to connect endpoints to the RDMO server. The client uses UCX to send formatted RDMO messages.

6.24.3 Architecture

DOCA's UROM RDMO application implementation uses UCX to support data exchange between endpoints. It utilizes UCX's sockaddr-based connection establishment and the UCX active messages (AM) API for communications, and UCX is responsible for all RDMO communications (control and data path).

The RDMO server application initiates a DOCA UROM worker RDMO component via the DOCA UROM service and shares the UROM worker UCX EP with the DOCA UROM RDMO client application. The RDMO server application imports memory regions into the UROM worker to facilitate RDMA operations from the BlueField on host memory.

The RDMO client application performs RDMO operations via the DOCA UROM worker. Upon receiving the UCX EP address from the server, the client application initially establishes a connection with the worker. It then proceeds to request the worker to execute the operation without the server application's awareness.



6.24.3.1 UROM RDMO Worker Component

The UROM RDMO worker plugin component defines a small set of commands to enable the target to:

- Establish a UCX communication channel between the client and the worker
- Create a UCX endpoint capable of receiving RDMO request
- Import memory regions that can be used as a source or target for RDMA initiated by the worker

The set of commands are:

```
enum urom_worker_rdmo_cmd_type {
    UROM_WORKER_CMD_RDMO_CLIENT_INIT,
    UROM_WORKER_CMD_RDMO_RQ_CREATE,
    UROM_WORKER_CMD_RDMO_RQ_DESTROY,
    UROM_WORKER_CMD_RDMO_MR_REG,
    UROM_WORKER_CMD_RDMO_MR_DEREG,
};
```

The associated notification types are:

```
enum urom_worker_rdmo_notify_type {
    UROM_WORKER_NOTIFY_RDMO_CLIENT_INIT,
    UROM_WORKER_NOTIFY_RDMO_RQ_CREATE,
    UROM_WORKER_NOTIFY_RDMO_RQ_DESTROY,
    UROM_WORKER_NOTIFY_RDMO_MR_REG,
    UROM_WORKER_NOTIFY_RDMO_MR_DEREG,
};
```

6.24.3.1.1 Init

The Client Init command initializes the client to receive RDMOs. This includes establishing a connection between worker and host to allow the RDMO worker to access client memory.

The command is of type `UROM_WORKER_CMD_RDMO_CLIENT_INIT`. Command format:

```
struct urom_worker_rdmo_cmd_client_init {
    uint64_t id;
    void *addr;
    uint64_t addr_len;
};
```

- `id` – client ID used to identify the target process in RDMO commands
- `addr` – pointer to the client's UCP worker address to use for a worker-to-host connection
- `addr_len` – length of the address

This command returns a notification of type `UROM_WORKER_NOTIFY_RDMO_CLIENT_INIT`. Notification format:

```
struct urom_worker_rdmo_notify_client_init {
    void *addr;
    uint64_t addr_len;
```

- `addr` – pointer to the component's UCP worker address to use for initiator-to-server connections
- `addr_len` – length of the address

6.24.3.1.2 RQ Create

This Receive Queue (RQ) Create command creates and connects a new endpoint on the server. The endpoint may be targeted by formatted RDMO messages.

This command is of type `UROM_WORKER_CMD_RDMO_RQ_CREATE`. Command format:

```
struct urom_worker_rdmo_cmd_rq_create {
    void *addr;
    uint64_t addr_len;
};
```

- `addr` – the UCP worker address to use to connect the new endpoint
- `addr_len` – the length of address

The command returns a notification of type `UROM_WORKER_NOTIFY_RDMO_RQ_CREATE`. Notification format:

```
struct urom_worker_rdmo_notify_rq_create {
    uint64_t rq_id;
```

```
};
```

- `rq_id` – the RQ ID to use to destroy the RQ

6.24.3.1.3 RQ Destroy

The RQ Destroy command destroys an RQ.

The RQ Destroy command is of type `UROM_WORKER_CMD_RDMO_RQ_DESTROY`. Command format:

```
struct urom_worker_rdmo_cmd_rq_destroy {
    uint64_t rq_id;
};
```

- `rq_id` – the ID of a previously created RQ

The RQ destroy command returns a notification of type `UROM_WORKER_NOTIFY_RDMO_RQ_DESTROY`. Notification format:

```
struct urom_worker_rdmo_notify_rq_destroy {
    uint64_t rq_id;
};
```

- `rq_id` – the destroyed receive queue id

6.24.3.1.4 MR Register

The Memory Region (MR) Register command registers a UCP memory handle with the RDMO component. An MR must be registered with the RDMO component before use in RDMOs.

The command is of type `UROM_WORKER_CMD_RDMO_MR_REG`. Command format:

```
struct urom_worker_rdmo_cmd_mr_reg {
    uint64_t va;
    uint64_t len;
    void *packed_rkey;
    uint64_t packed_rkey_len;
    void *packed_memh;
    uint64_t packed_memh_len;
};
```

- `va` – the virtual address of the MR
- `len` – the length of the MR
- `packed_rkey` – pointer to the UCP packed R-key for the MR
- `packed_rkey_len` – the length of `packed_rkey`
- `packed_mem_h` – pointer to the UCP-packed memory handle for the MR. The memory handle must be packed with flag `UCP_MEMH_PACK_FLAG_EXPORT`.
- `packed_memh_len` – the length of `packed_memh`

The command returns a notification of type `UROM_WORKER_NOTIFY_RDMO_MR_REG`. Notification format:

```
struct urom_worker_rdmo_notify_mr_reg {
    uint64_t rkey;
};
```

- `rkey` – the ID used in RDMOs to refer to the MR

6.24.3.1.5 MR Deregister

The MR deregister command deregisters an MR from the RDMO component.

The command is of type `UROM_WORKER_CMD_RDMO_MR_DEREG`. Command format:

```
struct urom_worker_rdmo_cmd_mr_dereg {
    uint64_t rkey;
};
```

- `rkey` – the ID of a previously registered MR

The command returns a notification of type `UROM_WORKER_NOTIFY_RDMO_MR_DEREG`. Notification format:

```
struct urom_worker_rdmo_notify_mr_dereg {
    uint64_t rkey;
};
```

- `rkey` – the deregistered memory region remote key

6.24.3.2 Command Format

An RDMO is initiated by sending an RDMO request via UCP active message to a UROM RDMO worker server.

The RDMO request format is:

The RDMO header identifies the operation type and flags, modifying how the RDMO is processed. The operation (op) header includes arguments specific to the operation type. Optionally, the operation type may include an arbitrary-sized payload.

RDMO header format:

```
struct urom_rdmo_hdr {
    uint32_t id;
    uint32_t op_id;
    uint32_t flags;
};
```

- `id` – the client ID
- `op_id` – the RDMO operation type ID
- `flags` – flags modifying how the RDMO is processed by the server

Valid flag values:

```
enum urom_rdmo_req_flags {
    UROM_RDMO_REQ_FLAG_FENCE,
};
```

- `UROM_RDMO_REQ_FLAG_FENCE` – Complete all outstanding RDMO requests on the connection before executing this request. This flag is required to implement a flush operation that guarantees remote completion.

Optionally, an operation may return a response to the initiator.

Response header format:

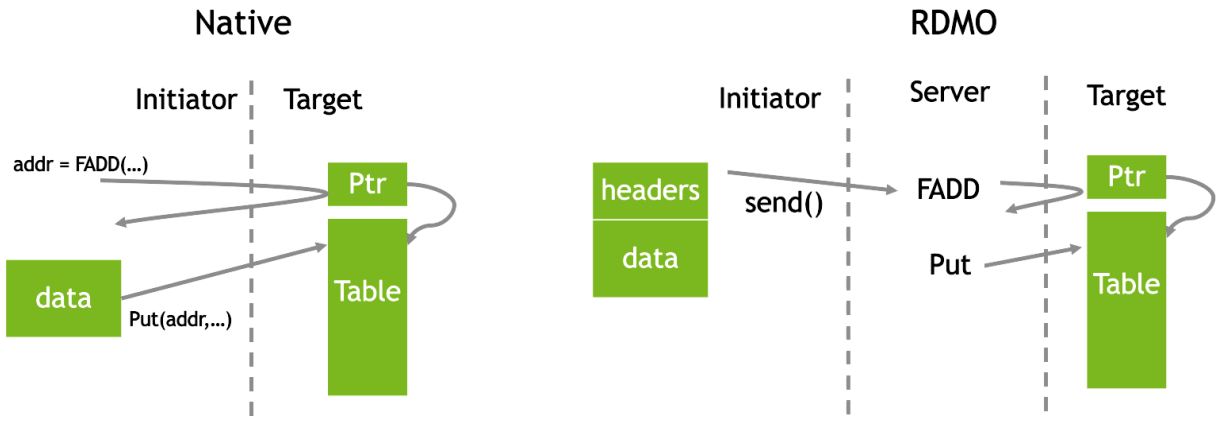
```
struct urom_rdmo_rsp_hdr {
    uint16_t op_id;
};
```

- `op_id` – the RDMO response type ID

6.24.3.2.1 Append

RDMO Append atomically appends data to a queue in remote memory. This can be achieved in a one-sided programming model with a Fetching-Add operation to the location of a pointer in remote memory, followed by a Put to the fetched address. RDMO Append allows these dependent operations to be offloaded to the target.

The following diagram provides a comparison of native and RDMO approaches to the Append operation:



Combining two dependent operations into a single RDMO allows the non-blocking implementation of Append, as the initiator does not need to wait between the Fetching

Atomic and the data write operations. Using RDMO, the initiator can create a pipeline of operations and achieve a higher message rate.

The rate at which the RDMO server can perform operations on the target memory is expected to be a bottleneck. To improve the rate, the following optimizations can be looked at:

- The result of the Fetch-and-ADD (FADD) after the initial Append is performed can be cached in the server. Subsequent Appends can re-use the cached value, eliminating the atomic FADD operation. The modified pointer value is required to be synchronized during the flush command.
- For small Append sizes, the Append data can be cached in the RDMO server and coalesced into a single Put. As a result, the server requires, on average, a single Put access to target memory to execute several RDMOs.
- To avoid extra memory usage and lost bandwidth for large Append operations, the RDMO server may initiate direct transfers from the initiator to the target memory bypassing the acceleration device memory.

The Append operation uses an operation of type `UROM_RDMO_OP_APPEND`. Append header format:

```
struct urom_rdmo_append_hdr {
    uint64_t ptr_addr;
    uint16_t ptr_rkey;
    uint16_t data_rkey;
};
```

- `ptr_addr` – the address of the queue pointer in target memory
- `ptr_rkey` – the R-key used to access `ptr_addr`
- `data_rkey` – the R-key used to access the queue data

The RDMO payload is the local data buffer.

6.24.3.2.2 Flush

RDMO Flush is used to implement synchronization between the initiator and server. On execution, Flush sends a response message back to the initiator. Flush can be used to guarantee remote completion of a previously issued RDMO.

To achieve this, the initiator sends an in-order Flush command including the RDMO flag `UROM_RDMO_REQ_FLAG_FENCE`. This flag causes the server to complete all previously received RDMOs before executing the Flush. To complete previous operations, the server must write any cached data and make it visible in the target memory. Once complete, the server executes the Flush. Flush sends a response to the initiator. When the initiator receives the flush message, the result of all previously sent RDMOs is guaranteed to be visible in the target memory.

The Flush operation uses operation type `UROM_RDMO_OP_FLUSH`. Flush header format:

```
struct urom_rdmo_flush_hdr {
    uint64_t flush_id;
};
```

- `flush_id` – local ID used to track completion

Flush returns a response with the following header format:

```
struct urom_rdmo_flush_rsp_hdr {
    uint64_t    flush_id;
};
```

- `flush_id` – the ID of the completed Flush

Flush requests and responses do not include a payload.

6.24.3.2.3 Scatter

RDMO Scatter is used to support aggregating non-contiguous memory Puts. An RDMO may be defined to map non-contiguous virtual addresses into a single memory region using a network interface at the target platform, and then return a memory key for this region. The initiator may then perform Puts to this memory region, which are scattered by target hardware. Alternatively, an RDMO may be defined to post an IOV Receive. The initiator could then post a matching Send to scatter data at the target.

The Scatter operation uses operation type `UROM_RDMO_OP_SCATTER`. Scatter header format:

```
struct urom_rdmo_scatter_hdr {
    uint64_t count; /* Number of IOVs in the payload */
};
```

- `count` – Number of IOVs in the RDMO payload

IOVs are packed into the Scatter request payload, descriptor followed by data:

```
struct urom_rdmo_scatter_iov {
    uint64_t addr; /* Scattered data address */
    uint64_t rkey; /* Data remote key */
    uint16_t len;  /* Data length */
};
```

- `addr` – scattered data address
- `rkey` – data remote key
- `len` – data length

6.24.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA UROM

- UCX Framework DOCA Driver

Refer to their respective programming guide for more information.

6.24.5 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/urom_rdmo/
```

6.24.5.1 Compiling All Applications

All DOCA applications are defined under a single Meson project. By default, the build process compiles all of them.

To build all applications:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> On the host, `doca_urom_rdmo` is created under `/tmp/build/urom_rdmo/host/`. On the BlueField side, the RDMO worker plugin `worker_rdmo.so` is created under `/tmp/build/urom_rdmo/dpu/`.

6.24.5.2 Compiling Only the Current Application

To directly build only the UROM RDMO application (host) or plugin (DPU):

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_urom_rdmo=true
```

```
ninja -C /tmp/build
```

> On the host, `doca_urom_rdmo` is created under `/tmp/build/urom_rdmo/host/`. On the BlueField side, the RDMO worker plugin `worker_rdmo.so` is created under `/tmp/build/urom_rdmo/dpu/`.

Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_urom_rdmo` to `true`
2. Run the following compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

> On the host, `doca_urom_rdmo` is created under `/tmp/build/urom_rdmo/host/`. On the BlueField side, the RDMO worker plugin `worker_rdmo.so` is created under `/tmp/build/urom_rdmo/dpu/`.

6.24.6 Running the Application

6.24.6.1 Host Application Execution

The UROM RDMO application is provided in source form; therefore, a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_urom_rdmo [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                      Print a help synopsis
  -v, --version                   Print program version information
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                    Filter logs from specific modules, separated by comma
  -j, --json <path>               Parse command line flags from an input json file

Program Flags:
  -d, --device <IB device name>     IB device name.
  -s, --server-name <server name>   server name.
  -m, --mode {server, client}       Set mode type {server, client}
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_urom_rdmo -h
```

For additional information, refer to section "Command Line Flags".

2. CLI example for running the application with server mode:

```
./doca_urom_rdmo -d mlx5_0 -m server
```

3. CLI example for running the application with client mode:

```
./doca_urom_rdmo -m clinet -s <server_host_name>
```

6.24.6.2 RDMO DPU Plugin Component

The UROM RDMO plugin component is provided in source form, hence a compilation is required before the application can be executed in order when spawning UROM worker could load the plugin in runtime and it is compiled as `.so` file.

The plugin exposes the following symbols:

- Get DOCA worker plugin interface for RDMO plugin:

```
doca_error_t urom_plugin_get_iface(struct urom_plugin_iface *iface);
```

- Get the RDMO plugin version which will be used to verify that the host and DPU plugin versions are compatible:

```
doca_error_t urom_plugin_get_version(uint64_t *version);
```

6.24.6.3 Command Line Flags

6.24.6.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis

Short Flag	Long Flag	Description
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.24.6.3.2 Program Flags

Short Flag	Long Flag	Description
`d`	`device`	DOCA UROM IB device name
`s`	`server-name`	RDMO server name
`m`	`mode`	RDMO application mode [server, client]

6.24.6.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.24.7 Application Code Flow

1. Parse application argument.

a. Initialize arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

b. Register UROM RDMO application parameters.

```
register_urom_rdmo_params();
```

c. Parse the arguments.

```
doca_argp_start();
```

2. Run main logic:
   - If the application mode is server:
     i. Create UROM objects and spawn UROM worker on the BlueField.
     ii. Initialize UCP with features: `UCP_FEATURE_AM`, `UCP_FEATURE_EXPORTED_MEMH`.
     iii. Create a UCP worker and query the worker address
     iv. Initialize the RDMO worker client with the command `UROM_WORKER_CMD_RDMO_CLIENT_INIT`.
     v. Send UROM RDMO worker address to the initiator via OOB channel and receive the intiator's UCP worker address
     vi. Create a UCP memory handle and register it with the RDMO server using the command `UROM_WORKER_CMD_RDMO_MR_REG`. Receive an R-key in return.
     vii. Send the RDMO key to the initiator
     viii. Create an RDMO RQ by passing the initiator's UCP worker address to the UROM command `UROM_WORKER_CMD_RDMO_RQ_CREATE`.
     ix. Wait till the RDMO append operation is done and next validate the memory data.
     x. Wait till the RDMO scatter operation is done and next validate the memory data.
     xi. Destroy the UCP resources.
     xii. Destroy UROM RDMO worker and UROM objects.
   - If the application mode is client:
     i. Create UCP worker using UCX API directly.
     ii. Receive the UROM RDMO worker address via OOB channel and send the initiator's UCP worker address.
     iii. Create a UCP endpoint using the RDMO worker address.
     iv. Install an Active Message handler on the endpoint to receive RDMO responses.
     v. Send an RDMO requests via UCP Active Message protocol with the header pointing to the serialized RDMO and Op headers, and data pointing to the payload. The request parameter flag:

`UCP_AM_SEND_FLAG_REPLY` will be set to allow the RDMO server to identify the sender.

vi. Once the RDMO operations are done, Destroy UCP resources.

3. Arg parser destroy.

```
doca_argp_destroy();
```

6.25 DOCA YARA Inspection Application Guide

This guide provides YARA inspection implementation on top of NVIDIA® BlueField® DPU.

6.25.1 Introduction

YARA inspection monitors all processes in the host system for specific YARA rules using the DOCA App Shield library.

This security capability helps identify malware detection patterns in host processes from an independent and trusted DPU. This is an innovative Intrusion Detection System (IDS) as it is designed to run independently on the DPU's Arm cores without hindering the host.

This DOCA App Shield based application provides the capability to read, analyze, and authenticate the host (bare metal/VM) memory directly from the DPU.

Using the library, this application scans host processes and looks for pre-defined YARA rules. After every scan iteration, the application indicates if any of the rules matched. Once there is a match, the application reports which rules were detected in which process. The reports are both printed to the console and exported to the DOCA Telemetry Service (DTS) using inter-process communication (IPC).

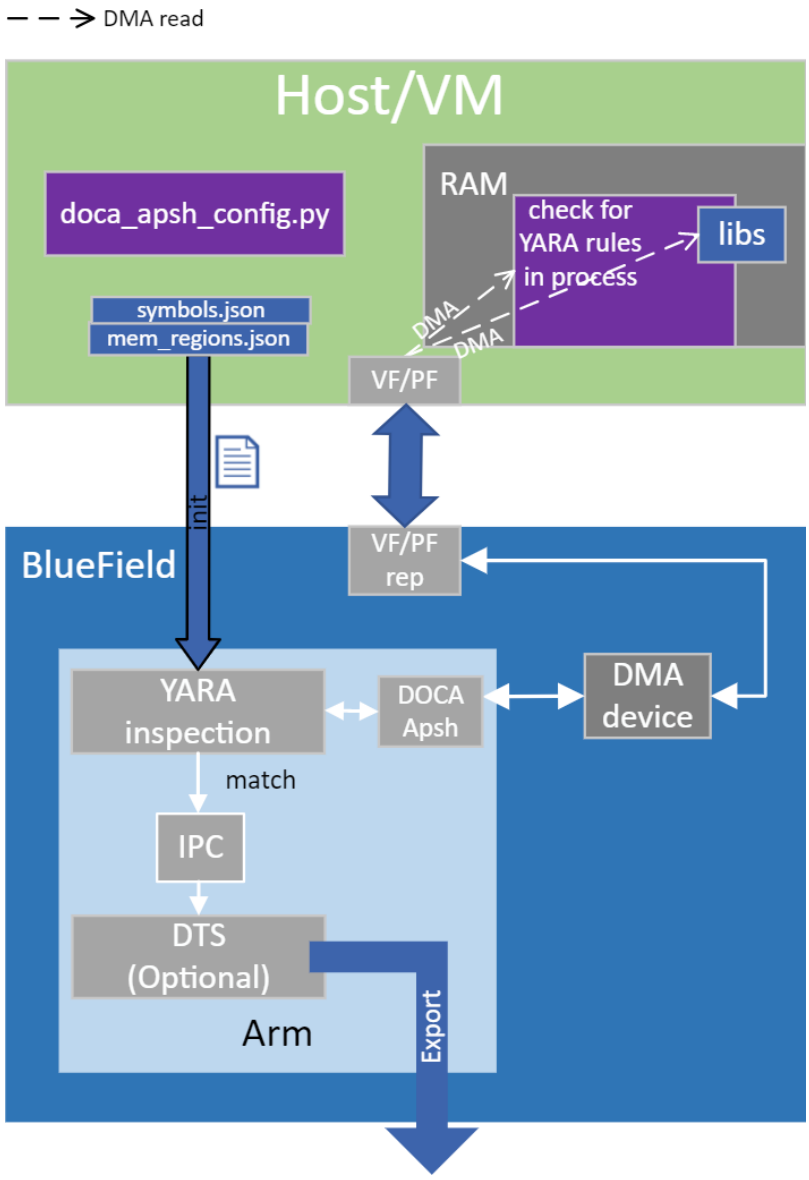
This guide describes how to build YARA inspection using the DOCA App Shield library which leverages DPU abilities such as hardware-based DMA, integrity, and more.

As the DOCA App Shield library only supports the YARA API for Windows hosts, this application can only be used to inspect Windows hosts.

6.25.2 System Design

The host's involvement is limited to generating the required ZIP and JSON files to pass to the DPU. This is done before the app is triggered, when the host is still in a "safe" state.

Generating the needed files can be done by running DOCA App Shield's `doca_apsh_config.py` tool on the host. See DOCA App Shield for more info.

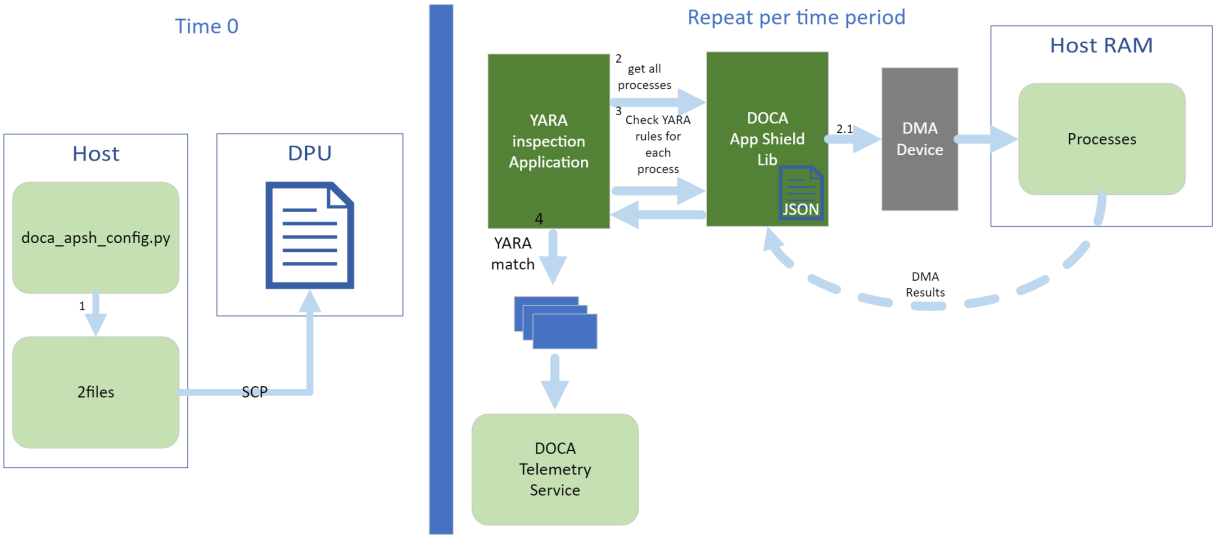


6.25.3 Application Architecture

The user creates the ZIP and JSON files using the DOCA tool `doca_apsh_config.py` and copies them to the DPU.

The application can report YARA rules detection to the:

- File
- Terminal
- DTS



1. The files are generated by running `doca_apsh_config.py` on the host against the process at time zero.
2. The following steps recur at regular time intervals:
    a. The YARA inspection app requests a list of all apps from the DOCA App Shield library.
    b. The app loops over all processes and checks for YARA rules match using the DOCA App Shield library.
    c. If YARA rules are found (1 or more), the YARA attestation app reports results with a timestamp and details about the process and rules to:
        - Local telemetry files – a folder and files representing the data a real DTS would have received

          ⚠ These files are used for the purpose of this example only as normally this data is not exported into user-readable files.

        - DOCA log
        - DTS IPC interface (even if no DTS is active)
3. The App Shield agent exits on first YARA rule detection.

6.25.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA App Shield
- 2024-10-09_07-10-18_DOCA Telemetry

Refer to their respective programming guide for more information.

6.25.5 Limitations

- The application is only available on Ubuntu 22.04 environments
- The application only supports the inspection of Windows hosts

6.25.6 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

The installation of DOCA's reference applications contains the sources of the applications, alongside the matching compilation instructions. This allows for compiling the applications "as-is" and provides the ability to modify the sources, then compile a new version of the application.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The sources of the application can be found under the application's directory: `/opt/mellanox/doca/applications/yara_inspection/`.

6.25.6.1 Compiling All Applications

All DOCA applications are defined under a single meson project. So, by default, the compilation includes all of them.

To build all the applications together, run:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

`doca_yara_inspection` is created under `/tmp/build/yara_inspection/`.

6.25.6.2 Compiling Only the Current Application

To directly build only the YARA inspection application:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_yara_inspection=true
ninja -C /tmp/build
```

`doca_yara_inspection` is created under `/tmp/build/yara_inspection/`.

Alternatively, one can set the desired flags in the `meson_options.txt` file instead of providing them in the compilation command line:

1. Edit the following flags in `/opt/mellanox/doca/applications/meson_options.txt`:
   - Set `enable_all_applications` to `false`
   - Set `enable_yara_inspection` to `true`
2. Run the following compilation commands:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build
   ninja -C /tmp/build
   ```

   `doca_yara_inspection` is created under `/tmp/build/yara_inspection/`.

6.25.7 Running the Application

6.25.7.1 Prerequisites

1. Configure the BlueField's firmware
   a. On the BlueField system, configure the PF base address register and NVME emulation. Run:

      ```
      dpu> mlxconfig -d /dev/mst/mt41686_pciconf0 s PF_BAR2_SIZE=2 PF_BAR2_ENABLE=1
       NVME_EMULATION_ENABLE=1
      ```

   b. Perform a BlueField system reboot for the `mlxconfig` settings to take effect.

c. This configuration can be verified using the following command:

```
dpu> mlxconfig -d /dev/mst/mt41686_pciconf0 q | grep -E "NVME|BAR"
```

2. Download target system (host/VM) symbols.
   - For Ubuntu:

```
host> sudo tee /etc/apt/sources.list.d/ddebs.list << EOF
deb http://ddebs.ubuntu.com/ $(lsb_release -cs) main restricted universe multiverse
deb http://ddebs.ubuntu.com/ $(lsb_release -cs)-updates main restricted universe multiverse
deb http://ddebs.ubuntu.com/ $(lsb_release -cs)-proposed main restricted universe multiverse
EOF
host> sudo apt install ubuntu-dbgsym-keyring
host> sudo apt-get update
host> sudo apt-get install linux-image-$(uname -r)-dbgsym
```

   - For CentOS:

```
host> yum install --enablerepo=base-debuginfo kernel-devel-$(uname -r) kernel-debuginfo-$(uname -r)
kernel-debuginfo-common-$(uname -m)-$(uname -r)
```

   - No action is needed for Windows
3. Perform IOMMU passthrough. This stage is only needed on some of the cases where IOMMU is not enabled by default (e.g., when the host is using an AMD CPU).

> ⚠ Skip this step if you are not sure whether you need it. Return to it only if DMA fails with a message in `dmesg` similar to the following:
>
> ```
> host> dmesg
> [ 3839.822897] mlx5_core 0000:81:00.0: AMD-Vi: Event logged [IO_PAGE_FAULT domain=0x0047
>  address=0x2a0aff8 flags=0x0000]
> ```

   - Locate your OS's `grub` file (most likely `/boot/grub/grub.conf`, `/boot/grub2/grub.cfg`, or `/etc/default/grub`) and open it for editing. Run:

```
host> vim /etc/default/grub
```

   - Search for the line defining `GRUB_CMDLINE_LINUX_DEFAULT` and add the argument `iommu=pt`. For example:

```
GRUB_CMDLINE_LINUX_DEFAULT="iommu=pt <intel/amd>_iommu=on"
```

   - Run:

> ⚠ Prior to performing a power cycle, make sure to do a graceful shutdown.

     - For Ubuntu:

```
host> sudo update-grub
host> ipmitool power cycle
```

     - For CentOS:

```
host> grub2-mkconfig -o /boot/grub2/grub.cfg
host> ipmitool power cycle
```

- For Windows targets: Turn off Hyper-V capability.

4. The DOCA App Shield library uses hugepages for DMA buffers. Therefore, the user must allocate 42 huge pages.
   a. Run:

```
dpu> nr_huge=$(cat /sys/devices/system/node/node0/hugepages/hugepages-2048kB/nr_hugepages)
     nr_huge=$((42+$nr_huge))
     echo $nr_huge | sudo tee -a /sys/devices/system/node/node0/hugepages/hugepages-2048kB/
nr_hugepages
```

   b. Create the ZIP and JSON files. Run:

```
target-system> cd /opt/mellanox/doca/tools/
target-system> python3 doca_apsh_config.py <pid-of-process-to-monitor> --os <windows/linux> --path
<path to dwarf2json executable  or pdbparse-to-json.py>
target-system> cp /opt/mellanox/doca/tools/*.* <shared-folder-with-baremetal>
dpu> scp <shared-folder-with-baremetal>/* <path-to-app-shield-binary>
```

   If the target system does not have DOCA installed, the script can be copied from the BlueField.
   The required `dwaf2json` and `pdbparse-to-json.py` are not provided with DOCA.

   If the kernel and process `.exe` have not changed, there no need to redo this step.

6.25.7.2 Application Execution

The YARA inspection application is provided in source form. Therefore, a compilation is required before the application can be executed.

1. Application usage instructions:

```
Usage: doca_yara_inspection [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -m, --memr <path>                 System memory regions map
  -f, --vuid                        VUID of the System device
  -d, --dma                         DMA device name
  -o, --osym <path>                 System OS symbol map path
  -t, --time <seconds>              Scan time interval in seconds
```

This usage printout can be printed to the command line using the `-h` (or `--help`) options:

```
./doca_yara_inspection -h
```

For additional information, refer to section "Command Line Flags".

2. CLI example for running the application on the BlueField:

```
./doca_yara_inspection -m mem_regions.json -o symbols.json -f MT2125X03335MLNXS0D0F0VF1 -d mlx5_0 -t 3
```

All used identifiers (`-f` and `-d` flags) should match the identifier of the desired devices.

6.25.7.3 Command Line Flags

6.25.7.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.25.7.3.2 Program Flags

Short Flag	Long Flag	Description
`m`	`memr`	Path to the pre-generated `mem_regions.json` file transferred from the host

`f`	`pcif`	System PCIe function vendor unique identifier (VUID) of the VF/PF exposed to the target system. Used for DMA operations.
		To obtain this argument, run:
		`target-system> lspci -vv | grep "\[VU\] Vendor specific:"`
		Example output:
		`[VU] Vendor specific: MT2125X03335MLNXS0D0F0`
		`[VU] Vendor specific: MT2125X03335MLNXS0D0F1`
		Two VUIDs are printed for each DPU connected to the target system. The first is of the DPU on `pf0` and the second is of the DPU on port `pf1`.
		⚠ Running this command on the DPU outputs VUIDs with an additional "EC" string in the middle. You must remove the "EC" to arrive at the correct VUID.
		The VUID of a VF allocated on PF0/1 is the VUID of the PF with an additional suffix, `VF<vf-number>`, where `vf-number` is the VF index +1.
		For example, for the output in the example above:
		• PF0 VUID = MT2125X03335MLNXS0D0F0
		• PF1 VUID = MT2125X03335MLNXS0D0F1
		• VUID of VF0 on PF0 = MT2125X03335MLNXS0D0F0VF1
		VUIDs are persistent even on reset.

`d`	`dma`	DMA device name to use
`o`	`osym`	Path to the pre-generated `symbols.json` file transferred from the host
`t`	`time`	Number of seconds to sleep between scans

6.25.7.4 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.25.8 Application Code Flow

1. Parse application argument.
    a. Initialize arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

    b. Register application parameters.

```
register_apsh_params();
```

    c. Parse the arguments.

```
doca_argp_start();
```

2. Initialize DOCA App Shield lib context.
    a. Create lib context.

```
doca_apsh_create();
```

    b. Set DMA device for lib.

```
open_doca_device_with_ibdev_name();
doca_apsh_dma_dev_set();
```

    c. Start the context

```
doca_apsh_start();
apsh_system_init();
```

3. Initialize DOCA App Shield lib system context handler.
    a. Get the representor of the remote PCIe function exposed to the system.

```
open_doca_device_rep_with_vuid();
```

    b. Create and start the system context handler.

```
doca_apsh_system_create();
doca_apsh_sys_os_symbol_map_set();
doca_apsh_sys_mem_region_set();
doca_apsh_sys_dev_set();
doca_apsh_sys_os_type_set();
doca_apsh_system_start();
```

4. Telemetry initialization.

```
telemetry_start();
```

    a. Initialize a new telemetry schema.
    b. Register YARA type event.
    c. Set up output to file (in addition to default IPC).
    d. Start the telemetry schema.

e. Initialize and start a new DTS source with the `gethostname()` name as source ID.

5. Loop until YARA rule is matched.
   a. Get all processes from the host.

```
doca_apsh_processes_get();
```

   b. Check for YARA rule identification and send a DTS event if there is a match.

```
doca_apsh_yara_get();
if (yara_matches_size != 0) {
    /* event fill logic
    doca_telemetry_exporter_source_report();
DOCA_LOG_INFO();
sleep();
```

6. Telemetry destroy.

```

6.26 DOCA Pipeline Language Runtime Controller Gateway SHM Application Guide

This document describes the usage of the NVIDIA DOCA Pipeline Language (DPL) Runtime Controller Gateway SHM sample application.

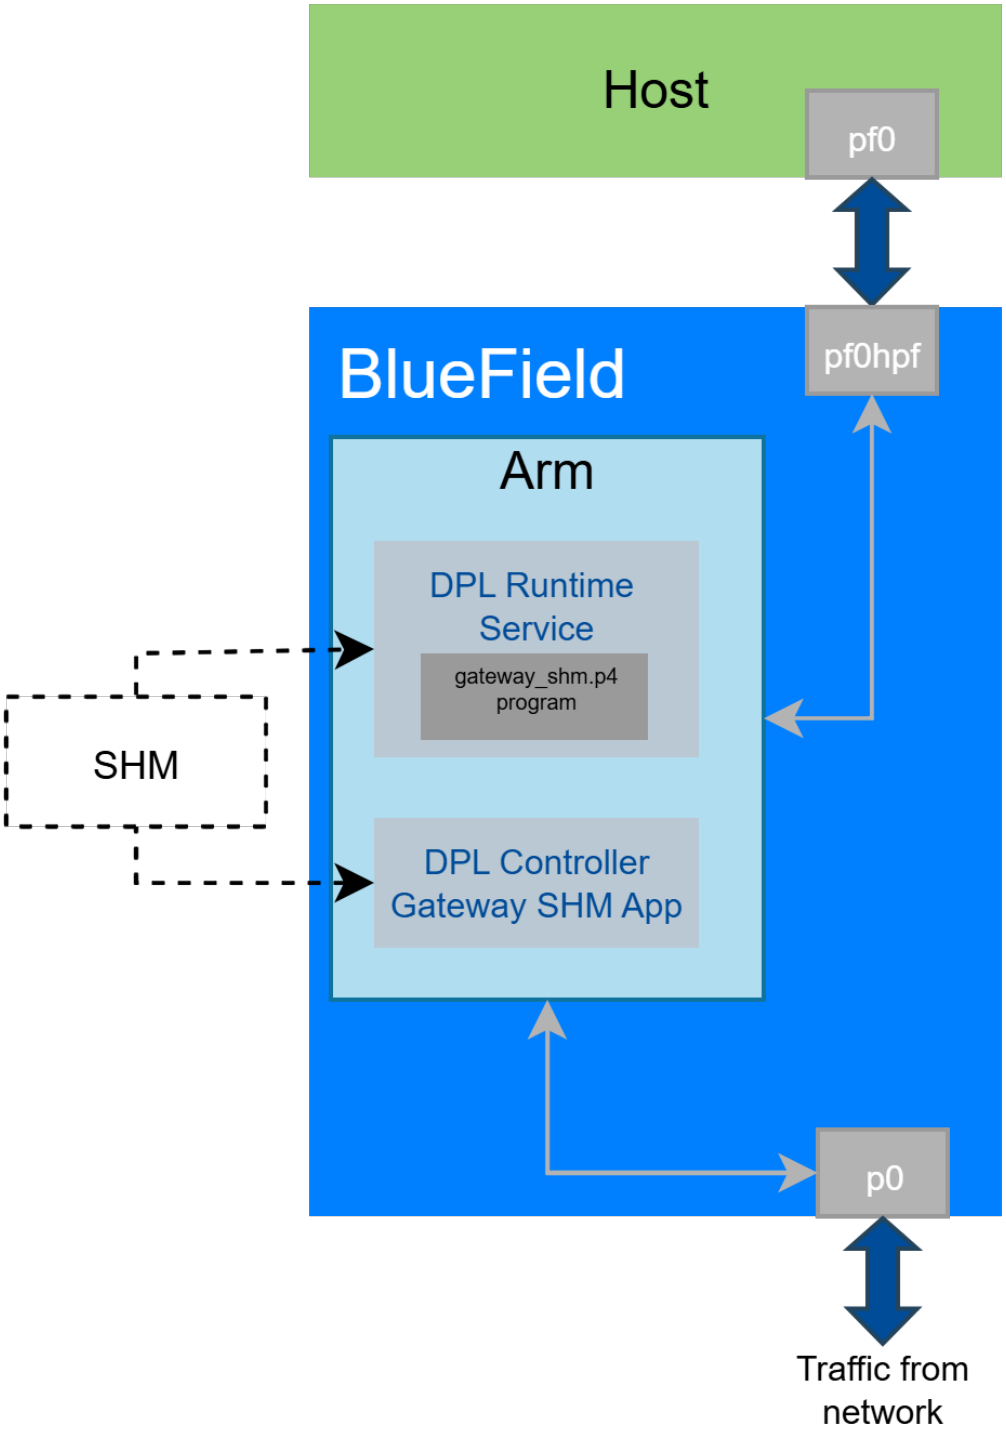
6.26.1 Introduction

This sample application leverages the capabilities of DOCA Pipeline Languages (DPL) Services combined with the DPL Runtime Controller SDK to implement a VXLAN gateway application . It provides encapsulation/decapsulation logic and interactive packet/counter management.

6.26.2 System Design

The following diagram illustrates the connections between the DPL Runtime Controller-based application and the DPL Runtime Service (DPL daemon). The DPL daemon is loaded with a DPL `gateway_shm.p4` program that implements the gateway logic.

The controller communicates with the DPL daemon through gRPC or Shared Memory (SHM) interfaces to insert, query, and delete HW steering rules. Traffic arriving from the wire or the VFs is processed according to the gateway program and passed to the relevant port based on the loaded program.



6.26.3 Architecture

The application is based on two major components that work together to define and manage the forwarding state:

6.26.3.1 DPL Program (gateway_shm.p4)

A DPL program loaded onto the DPL Runtime Service:

gateway_shm.p4

     * A hit means this is an RX packet, miss means a TX packet
    */
    table direction_table {
        key = {
            std_meta.ingress_port : exact;
        }
        actions = {
            NoAction;
        }
        default_action = NoAction;
        const entries = {
            (WIRE_PORT) : NoAction();
        }
    }

    apply {
        if (direction_table.apply().hit) {
            under.apply(headers, std_meta, user_meta, pkt_out_meta);
        }
        else {
            over.apply(headers, std_meta, user_meta, pkt_out_meta);
        }
    }
}

NvDocaPipeline(
    packet_parser(),
    gateway()
) main;
```

This P4 application implements a basic VXLAN termination and origination function for IPv4 traffic. Its primary goal is to differentiate between incoming packets from the underlay network (Rx/Decapsulation) and packets originating from a host (Tx/Encapsulation), applying the necessary L2 overlay policies in each direction.

The program logic is separated into three distinct Control Blocks: `gateway`, `underlay_decap`, and `overlay_encap`.

- `gateway`: Responsible for directing packets into the relevant control block (`underlay_decap` or `overlay_encap`) by matching on the ingress port.
- `underlay_decap`: Responsible for L2 decapsulation of packets from wire to host (Rx).
- `overlay_encap`: Responsible for the overlay policy, including L2 VXLAN encapsulation of packets from host to wire (Tx).

6.26.3.1.1 P4 Tables

Table Name	Control Block	Match Field	Actions	Purpose
`direction_table`	`gateway`	ingress_port	`NoAction` (default)	Determines the processing direction (Rx or Tx)
`decap_v4_table` [1]	`underlay_decap`	VxLAN.vni	`decap`, `to_port`, `decap_to_port`, `deny`, `NoAction` (default)	Core policy table for decapsulation; identifies the tenant context
`encap_v4_table` [1]	`overlay_encap`	IPv4.dst_addr	`vxlan_v4_encap`, `to_port`, `deny` (default)	Core policy table for encapsulation; determines the tunnel endpoint and VNI

1. High update rate table

6.26.3.1.2 Direct Counters

Counter Name	Tied to Table	Actions Tracked	Function
`decap_counter`	`decap_v4_table`	`decap`, `deny`	Counts successfully decapsulated packets and denied packets
`encap_counter`	`encap_v4_table`	`vxlan_v4_encap`, `deny`	Counts successfully encapsulated packets and denied packets

6.26.3.2 Control Application (gateway.entries.json)

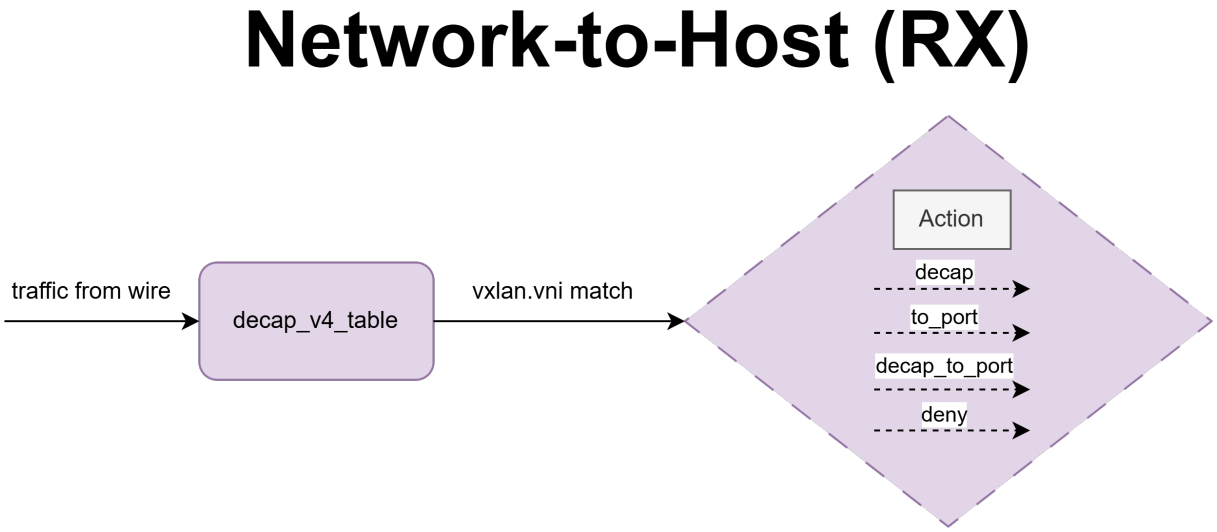
A control application manages the daemon's HW steering rules from a JSON input file that describes the desired rules.

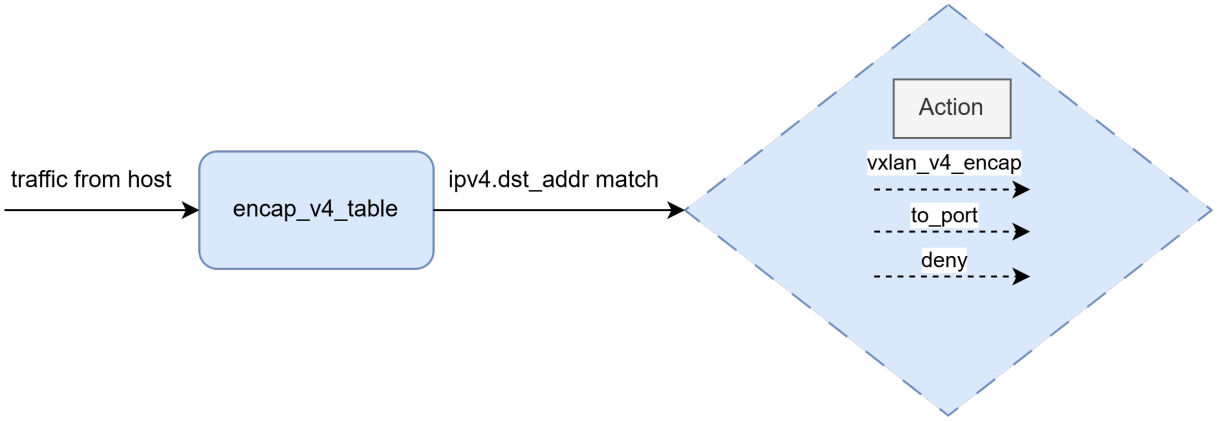
`gateway.entries.json`

```
{
    "doctype" : "gateway_shm.p4",
    "tables": {
    "encap_v4_table": {
        "entries": [
            {
                "match": {
                    "headers.ipv4.dst_addr": "6.6.6.4"
                },
                "action": "vxlan_v4_encap_encap_v4_table",
                "params": {
                    "underlay_src_mac": "3C:6D:66:11:11:11",
                    "underlay_dst_mac": "ff:ff:ff:ff:ff:ff",
                    "underlay_sip": "6.6.6.3",
                    "underlay_dip": "6.6.6.2",
                    "vni": "1",
                    "port": "0"
                }
            },
            {
                "match": {
                    "headers.ipv4.dst_addr": "6.6.6.5"
                },
                "action": "vxlan_v4_encap_encap_v4_table",
                "params": {
                    "underlay_src_mac": "3C:6D:66:11:11:11",
                    "underlay_dst_mac": "ff:ff:ff:ff:ff:ff",
                    "underlay_sip": "6.6.6.3",
                    "underlay_dip": "6.6.6.2",
                    "vni": "1",
                    "port": "0"
                }
            }
        ]
    },
    "decap_v4_table": {
        "entries": [
            {
                "match": {
                    "headers.vxlan.vni": "1"
                },
                "action": "decap_to_port_decap_v4_table",
                "params": {
                    "port": "1"
                }
            },
            {
                "match": {
                    "headers.vxlan.vni": "2"
                },
                "action": "deny_decap_v4_table"
            }
        ]
    }
    }
}
```

6.26.3.3 Pipeline

The following diagram shows a schematic of the `gateway_shm.p4` program. The program defines dynamic `decap_v4_table` and `encap_v4_table` tables with no pre-defined rules. The DPL Runtime Controller uses `gateway.entries.json` to insert custom rules with the desired match values and actions into these tables.





6.26.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DPL Runtime Controller SDK

Refer to their respective programming guide for more information.

6.26.5 Compiling the Application

> Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

> For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/dpl_rt_controller/samples/gateway_shm/
```

6.26.5.1 Prerequisites

- The application relies on the `dpl_rt_controller` library.
- The application relies on the `json-c` open source, requiring the following package to be installed:

  ```
  sudo apt install libjson-c-dev
  ```

- DPL Development Container installed on the host. See the DPL Installation Guide for more details.

6.26.5.2 Compiling the Application

To build the Gateway application using the dpl-dev container and the DPL compiler:

1. On the x86 host, compile the DPL `gateway_shm.p4` program:

   ```
   dplp4c.sh --target doca --odir /tmp/gateway_shm_out gateway_shm.p4
   ```

   > Because this application relies on the Shared Memory (SHM) Interface, it is mandatory for the application to run directly on the DPU . Therefore, the compiler's output must be copied from the x86 host to the DPU's file system (e.g., `/tmp/gateway_shm_out`) before compiling the application

2. On the DPU Arm, compile the Gateway "C" application:

```
cd /opt/dpl_rt_controller/samples/gateway_shm
meson /tmp/gateway_shm -Dsample_programs_out=/tmp/gateway_shm_out
ninja -C /tmp/gateway_shm
```

The `dpl_sample_gateway_shm` application is created in `/tmp/gateway_shm`.

6.26.6 Running the Application

The application is provided in source form and requires compilation before execution . For details, refer to section "Compiling the Application".

6.26.6.1 Prerequisites

- The DPL Runtime Service must be ready to run on the BlueField (Arm side)

6.26.6.2 Application Execution

1. Start the DPL Runtime Service as detailed in the DPL Container Deployment.
2. Run the gateway application. Usage:

```
Application usage instructions
```

```
./dpl_sample_gateway_shm <device_id> <p4info path> <program path> <json_entries_path>
```

The device id (first argument) should match the ID of the DPL device as configured at `/etc/dpl_rt_service/devices.d/`.

Example:

```
sudo /tmp/gateway_shm/dpl_sample_gateway_shm 1000 /tmp/gateway_shm_out/gateway_shm.p4info.txt /tmp/
gateway_shm_out/gateway_shm.dplconfig gateway.entries.json
```

6.26.7 Application Code Flow

1. gateway_main.cc:
   Parses the received arguments and executes `doca_error_t gateway(uint32_t device_id, const char *p4info_path, const char *blob_path, const char *json_entries_path)`, responsible for the main logic.
2. gateway_sample.cc:
   Implements `doca_error_t gateway()` and runs the main logic:
   a. Load the compiled program and p4info using gRPC:

```
DPL_P4RT_Controller::Controller ctrl = DPL_P4RT_Controller::Controller(device_id,
"localhost:9559");
ctrl.LoadProgram(p4info_path, blob_path);
```

   b. Connect to the DPL device:

```
dpl_rt_controller_connect(&connect_attr, &device);
```

   c. Insert the entries from `gateway.entries.json` using the SHM interface:

```
doca_error_t insert_entries_from_json(device, json_entries_path, entries) {
    ...
    // Process encap_v4_table/decap_v4_table entries
    for (int i = 0; i < entries_count; i++) {
        json_object *entry_obj = json_object_array_get_idx(entries_array, i);
        struct dpl_rt_controller_entry *dpl_entry = nullptr;
        dpl_shm_gateway_shm_gateway_over_encap_v4_table_entry_t *table_entry = nullptr;
        dpl_shm_gateway_shm_gateway_over_encap_v4_table_alloc_entry_mem(device, &dpl_entry,
&table_entry);
        ...
        /* Parse match fields, actions and parameters to construct the table_entry */
        ...
        // Insert the entry using the SHM API
        dpl_shm_gateway_shm_insert_entry(dpl_entry, nullptr);
        ...
    }
}
```

   d. The program enters an interactive loop:

```
while (!quit) {
    std::cout << "Press a key (e=entries, c=counters, q=quit): " << std::flush;
    ...
    // Display all entries on 'E'/'e' key press
    display_all_entries(entries);
    ...
    // Read counter data on 'C'/'c' key press
    read_entry_counters(device, entries);
    ...
}
```

   e. The system is now configured. Test packets can be sent (e.g., via `scapy`):

```
sendp(Ether(src=\"00:11:11:11:11:11\", dst=\"00:22:22:22:22:22\") / IP(src=\"192.168.1.1\",
dst=\"192.168.1.2\"), iface=\"eth2\", count=50)
```

   f. On 'E'/'e' key press, all table entries are displayed:

```
void display_all_entries(entries) {
    ...
    // Iterate over entries per table ("encap_v4_table"/"decap_v4_table")
    for (const auto& table_pair : entries) {
        const std::string& table_name = table_pair.first;
        const std::vector<struct dpl_rt_controller_entry*>& table_entries = table_pair.second;
        ...
        // Iterate over entry handles
        for (size_t i = 0; i < table_entries.size(); i++) {
```

```
            void *shm_entry = dpl_rt_controller_table_entry_get_shm(table_entries[i]);
            ...
            /* Extract & display entry data using the controller interface */
            ...
        }
    }
}
```

g. On 'C'/'c' key press, counter data for each entry is read:

```
```

> The application displays counter values for each entry because `gateway_shm.p4` uses `direct_counters`. However, counters are only actively updated by the `decap`, `deny`, and `vxlan_v4_encap` actions. Therefore, only entries using these actions will show updated values.

h. On quit:

i. Cleanup entries:

```
doca_error_t cleanup_entries(entries) {
    ...
    // Iterate over entries per table
    for (const auto& table_pair : entries) {
        ...
        // Iterate over entry handles
        for (size_t i = 0; i < table_entries.size(); i++) {
            // Delete entry using the controller interface
            dpl_rt_controller_table_entry_delete(table_entries[i]);
            ...
        }
    }
}
```

ii. Disconnect from device and detach:

```
dpl_rt_controller_disconnect(device);
dpl_rt_controller_detach();
```

6.27 DOCA DPU GPU Remote Offload Application Guide

6.27.1 Introduction

The DOCA DPU GPU Remote Offload applications serve as a reference implementation, demonstrating how to develop a GPU offload application using DOCA Comch and DOCA GPUNetIO on the NVIDIA BlueField platform with NVIDIA GPUs.

These applications are simplified for clarity. A real-world solution would require more complexity tailored to a specific use case.

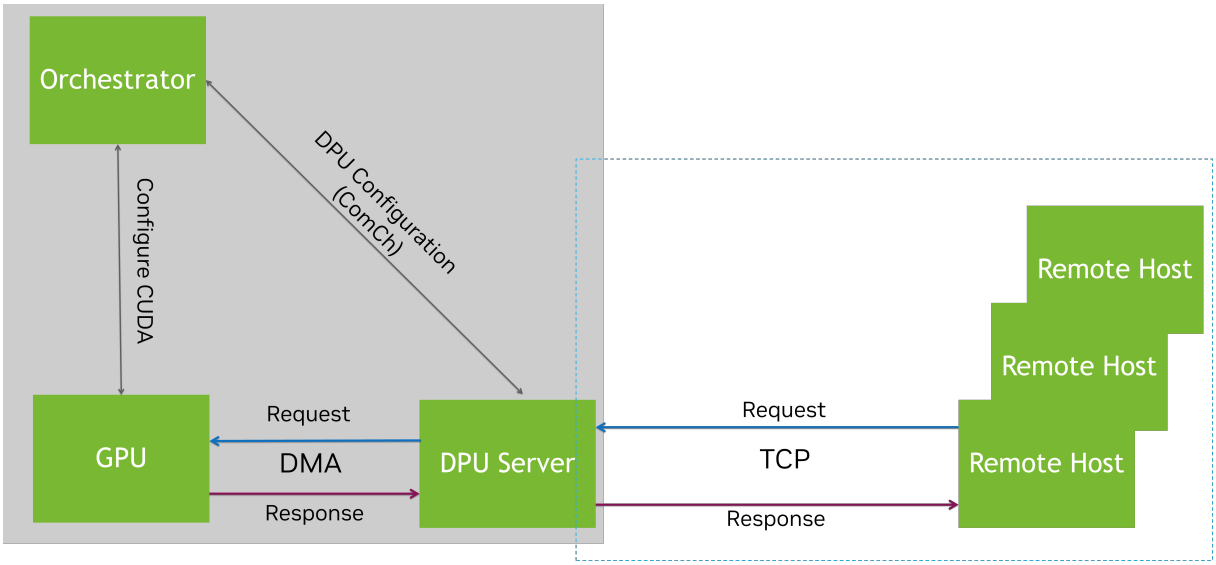
The general architecture involves:

- A server application running on the DPU.
- An orchestrator application running on the host CPU, which launches a CUDA Kernel.

The server receives TCP requests from remote clients and forwards them to the GPU via DOCA Comch. The GPU processes the message (in this reference, by reversing the byte order) and returns a response to the server. The server then forwards this response to the remote clients over TCP.

6.27.2 Applications

DOCA DPU GPU Remote Offload consists of three separate applications that work together to offload work from a DPU to a host-side GPU.



6.27.2.1 doca_dpu_gpu_remote_offload_server

This application runs on the BlueField DPU and acts as both a DOCA Comch server and a TCP server.

- DOCA Comch: Used to communicate with the Orchestrator and GPU.
- TCP: Used to communicate with remote clients for requests and responses

6.27.2.2 doca_dpu_gpu_remote_offload_orchestrator

This application configures and launches the CUDA Kernel for processing. It connects to the server via DOCA Comch, exchanges configuration information, and then launches the kernel . The Orchestrator application continues to run, monitoring the Comch connection and CUDA Kernel, and handles clean shutdown.

6.27.2.3 doca_dpu_gpu_remote_offload_client

This application sends requests to and receives responses from the server. It validates the responses and displays throughput figures.

6.27.3 Architecture

6.27.3.1 doca_dpu_gpu_remote_offload_server

The server application executes in two main phases: a Control Phase and a TCP Server Phase.

6.27.3.1.1 Control Phase

This phase begins when the application is launched. It configures the DOCA Comch server, waits for the orchestrator application to connect, and spawns threads to handle incoming messages. Once producers and consumers are connected, it creates a TCP listening socket.

A typical flow is:

1. Open the required DOCA device.
2. Create the DOCA Comch Server.
3. Wait for the Orchestrator application to connect.
4. Prepare the appropriate number of Socket threads. Each thread will:

- Create DOCA Comch Producers and Consumers.
- Wait for Producers and Consumers to be connected.
- Create and pool `doca_comch_producer_send_tasks`.
- Create and submit `doca_comch_consumer_post_recv_tasks`.

5. Create a TCP socket to listen for connections.
6. Start the TCP Server phase.

6.27.3.1.2 TCP Server Phase

In this phase, the application listens on the configured TCP port for incoming connections. When a client connects, its thread forwards messages to the GPU via DOCA Comch. It continues sending until the socket has no more data or the `send_task` pool is empty. It then waits for a response from the GPU, which is forwarded back to the remote client.

A typical per-thread flow loop is:

1. Poll the DOCA PE
   - If a `doca_comch_producer_send_task` completion is received, add the task back to the task pool.
   - If a `doca_comch_consumer_post_recv_task` completion is received:
     - Extract the response data.
     - Write the response to the TCP socket.
2. Poll TCP socket
   - If data can be read from the socket:
     - Read data from the socket.
     - Get the next available `doca_comch_consumer_post_recv` task (this should be `doca_comch_producer_send_task` based on context).
     - Copy message contents into the send task's data buffer.
     - Submit the send task.

In this phase, the application also listens for DOCA Comch control messages from the orchestrator or a CTRL-C signal to ensure a clean shutdown.

6.27.3.2 doca_dpu_gpu_remote_offload_orchestrator

This application executes in two phases: a Control Phase and a GPU Processing Phase.

6.27.3.2.1 Control Phase

This phase configures the DOCA Comch client and connects to the server. It creates producers and consumers, allocates GPU memory, waits for connections, and then launches the CUDA Kernel.

1. Open the required DOCA device.
2. Open the required GPU device.
3. Create the DOCA Comch client.
4. Connect to the DOCA Comch server.
5. Allocate the appropriate GPU memory.
6. Prepare the appropriate number of Producers and Consumers.
7. Launch the CUDA Kernel.

6.27.3.2.2 GPU Processing Phase

Once the CUDA Kernel is launched, the CPU portion of the application remains running. It monitors the kernel's execution and listens for DOCA Comch control shutdown messages (from the server or a user CTRL-C signal). If a shutdown is detected, it stops the kernel and cleans up memory.

The GPU processing portion initially submits multiple `post_recv` buffers. It then enters a loop, polling for messages. When a message is received, it processes it (reverses the bytes), sends the response back to the server, and resubmits the buffer. This continues until a fatal error or a global stop flag is set by the CPU.

A typical CUDA thread loop is:

1. Poll for `post_recv` messages
    - If a message is received:
        - Extract the data.
        - Verify the message is a client request.
        - Reverse the order of the bytes in the data.
        - Record the buffer in the `inflight_messages` array.
        - Submit the response to the server using `doca_dev_gpu_comch_producer_send`.
2. Poll for producer send message completions
    - If a send completion is indicated:
        - Use `user_msg_id` to determine which buffer was sent.
        - Submit this buffer to receive a new message with `doca_dev_gpu_comch_consumer_post_recv`.

6.27.3.3 doca_dpu_gpu_remote_offload_client

This application is simpler than the other two in the use case. Its purpose is to initiate TCP connections to the `doca_dpu_gpu_remote_offload_server`, using one connection per thread.

Each thread sends a specified number of request messages while recording throughput. Upon receiving a response, the client validates its content against the expected response; if they do not match, the application exits with an error.

If all requests are sent and successfully validated, the application outputs final statistics for the run, including:

- Run length
- Operation count
- Transmit and receive data rates
- IO rate

6.27.4 DOCA Libraries

6.27.4.1 Server

The `doca_dpu_gpu_remote_offload_server` application leverages the following DOCA libraries:

- DOCA Comch

6.27.4.2 Orchestrator

The `doca_dpu_gpu_remote_offload_server` application leverages the following DOCA libraries:

- DOCA Comch
- DOCA GPUNetIO

6.27.4.3 Client

The `doca_dpu_gpu_remote_offload_client` application does not leverage any DOCA libraries, however it does utilize DOCA Arg Parser.

6.27.5 Compiling the Applications

The `doca_dpu_gpu_remote_offload_orchestrator` application requires CUDA version 13. Compilation will fail if an older version is used.

The `doca_dpu_gpu_remote_offload_server` application will only compile on the DPU, and the `doca_dpu_gpu_remote_offload_orchestrator` will only compile on x86 hosts. The `doca_dpu_gpu_remote_offload_client` application compiles on all architectures.

6.27.5.1 Compiling All Applications

To build all DOCA applications together:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

The applications are created under `/tmp/build/dpu_gpu_remote_offload/`.

6.27.5.2 Compiling Only DPU GPU Remote Offload Applications

To directly build only the storage applications:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_dpu_gpu_remote_offload=true
ninja -C /tmp/build
```

Alternatively, you can edit `/opt/mellanox/doca/applications/meson_options.txt`:

1. Set `enable_all_applications` to `false`.
2. Set `enable_dpu_gpu_remote_offload` to `true`.
3. Run the compilation commands:

   ```
   cd /opt/mellanox/doca/applications/
   meson /tmp/build
   ninja -C /tmp/build
   ```

The applications are created under `/tmp/build/dpu_gpu_remote_offload/`.

6.27.6 Running the Applications

The DOCA DPU GPU Remote Offload applications are provided in source form and must be compiled before execution.

6.27.6.1 Server

> ⚠ The server application must run on the NVIDIA BlueField DPU and must be started before the orchestrator or client.

6.27.6.1.1 Application Usage Instructions

```
Usage: doca_dpu_gpu_remote_offload_server [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device-id <DEV ID>          Device ID (mandatory).
  -r, --representor-id <REPRESENTOR ID> Representor ID (mandatory).
  -c, --comch-channel-name <DEV ID> Comch channel name (optional).
  -p, --server-listen-port <PORT>   Server listen port (mandatory).
  --cpu <CPU>                       CPU to use when executing data path operations (mandatory). May be repeated for
 more cores
  --max-concurrent-messages <NUM_MESSAGES> Set the maximum number of concurrent messages that can be processed per
thread (optional).
  --max-message-length <LENGTH>     Set the maximum length of a message that can be processed (exclusive of header)
(optional).
```

6.27.6.1.2 CLI Example of the Application

```
./doca_dpu_gpu_remote_offload_server --device-id 03:00.0 --representor-id d8:00.0 \
    -p 12345 --max-concurrent-messages 128 --cpu 1 --cpu 2
```

> ⚠ The DOCA Comch device PCIe address (`03:00.0`) and the representor PCIe address (`d8:00.0`) must match the addresses of the desired devices.

6.27.6.1.3 Command Line Flags

6.27.6.1.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.27.6.1.3.2 Program Flags

Short Flag	Long Flag	Description
`d`	`device-id`	Comm Channel DOCA device PCIe address. ⚠ This is a mandatory flag
`r`	`representor-id`	Comm Channel DOCA device representor PCIe address. ⚠ This is a mandatory flag
`c`	`comm-channel-name`	A custom name for the DOCA Comch connection, this must be the same on both server and orchestrator.
`c`	`server-listen-port`	The TCP port the server will use to listen for client connections.

Short Flag	Long Flag	Description
N/A	`cpu`	CPU to use when executing data path operations, this option can be repeated to use multiple CPU cores in execution. ⚠ This is a mandatory flag
N/A	`max-concurrent-messages`	The maximum number of concurrent messages that can be processed by each thread.
N/A	`max-message-length`	The maximum length or message, in bytes, that can be supported.

6.27.6.2 Orchestrator

⚠ The orchestrator application runs on the host CPU and must be started after the server application.

6.27.6.2.1 Application Usage Instructions

```
Usage: doca_dpu_gpu_remote_offload_orchestrator [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -d, --device-id <DEV ID>          Device ID (mandatory).
  -g, --gpu-pci-addr <PCI ADDRESS>  GPU PCIe Address (mandatory).
  -c, --comch-channel-name <DEV ID> Comch channel name (optional).
  -t, --num-gpu-threads <NUM>       Number of GPU threads to use when executing data path operations (mandatory).
Must be the same as core count on server.
  --max-concurrent-messages <NUM_MESSAGES> Set the maximum number of concurrent messages that can be processed per
thread (optional).
  --max-message-length <LENGTH>     Set the maximum length of a message that can be processed (exclusive of header)
(optional).
```

6.27.6.2.2 CLI Example of the Application

```
./doca_dpu_gpu_remote_offload_orchestrator --device-id d8:00.0 --gpu-pci-addr b5:00.0 \
    --max-concurrent-messages 128 --num-gpu-threads 2
```

⚠ The device PCIe address (`d8:00.0`) and GPU PCIe address (`b5:00.0`) must match your devices.

The number of GPU threads should be the same as the total number of CPU cores provided to the server.

6.27.6.2.3 Command Line Flags

6.27.6.2.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.27.6.2.3.2 Program Flags

Short Flag	Long Flag	Description
`d`	`device-id`	Comm Channel DOCA device PCIe address. This is a mandatory flag

Short Flag	Long Flag	Description
`g`	`gpu-pci-addr`	The PCIe address of the GPU to process messages ⚠ This is a mandatory flag
`c`	`comm-channel-name`	A custom name for the DOCA Comch connection, this must be the same on both server and orchestrator.
`t`	`num-gpu-threads`	The number of GPU threads to use in processing messages. This number should be the same as the total number of CPU cores assigned to the server ⚠ This is a mandatory flag
N/A	`max-concurrent-messages`	The maximum number of concurrent messages that can be processed by each thread.
N/A	`max-message-length`	The maximum length or message, in bytes, that can be supported.

6.27.6.3 Client

⚠ The client must be started after the server and orchestrator have established their Comch connection.

6.27.6.3.1 Application Usage Instructions

```
Usage: doca_dpu_gpu_remote_offload_client [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                      Print a help synopsis
  -v, --version                   Print program version information
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                    Filter logs from specific modules, separated by comma
  -j, --json <path>               Parse command line flags from an input json file

Program Flags:
  -s, --server-ip-address <IP ADDR> Server IP address (mandatory).
  -p, --server-ip-port <IP PORT>    Server IP port (mandatory).
  -t, --thread-count <THREAD_COUNT> Thread count (mandatory).
  -i, --iteration-count <ITERATION_COUNT> Iteration count (mandatory).
  -m, --message-string <MESSAGE>    message string (mandatory).
  -e, --expected-response <EXPECTED RESPONSE> Expected response (mandatory).
  --max-concurrent-messages <NUM_MESSAGES> Set the maximum number of concurrent messages that can be processed per
thread (optional).
```

6.27.6.3.2 CLI Example of the Application

```
./doca_dpu_gpu_remote_offload_client -s 172.17.0.1 -p 12345 -t 1 -i 1 -m "ABCD" -e "DCBA"
```

The GPU message response will contain the bytes in the request in reverse order.

6.27.6.3.3 Command Line Flags

6.27.6.3.3.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.27.6.3.3.2 Program Flags

Short Flag	Long Flag	Description
`s`	`server-ip-address`	The IP address of the `doca_dpu_gpu_remote_offload_server`. ⚠ This is a mandatory flag
`p`	`server-ip-port`	The TCP port assigned to the `doca_dpu_gpu_remote_offload_server`. ⚠ This is a mandatory flag
`t`	`thread-count`	The number of threads to use in execution. Each thread will send `iteration-count` number of messages. ⚠ This is a mandatory flag
`i`	`iteration-count`	The number requests to be sent from each execution thread. ⚠ This is a mandatory flag
`m`	`message-string`	The message to be sent to the server ⚠ This is a mandatory flag
`i`	`expected-response`	The expected response that should be received back from the server. ℹ This should be the bytes of the initial message in reverse order. ⚠ This is a mandatory flag
N/A	`max-concurrent-messages`	The maximum number of concurrent messages that can be processed by each thread.

6.28 DOCA Time Sync Application Guide

This guide provides an example of a Time Sync implementation on top of NVIDIA® BlueField® DPU.

6.28.1 Introduction

The DOCA Time Sync reference application demonstrates how to trigger and correlate events across processors operating on different clock domains within a BlueField DPU environment.

The application triggers events on the x86 host, the BlueField Arm cores, and the Data Path Accelerator (DPA) subsystem. It then leverages the DOCA Clock cross-timestamping functionality (available in DOCA Core) to correlate these events against the NVIDIA® ConnectX® real-time clock (RTC). This allows the application to determine the precise chronological ordering of events occurring across the different subsystems.

The ConnectX RTC must be enabled for this application to function. To enable the RTC, run the following command (replacing `<device>` with your specific PCIe address or MST device):

```
sudo mlxconfig -d <device> set REAL_TIME_CLOCK_ENABLE=1
```

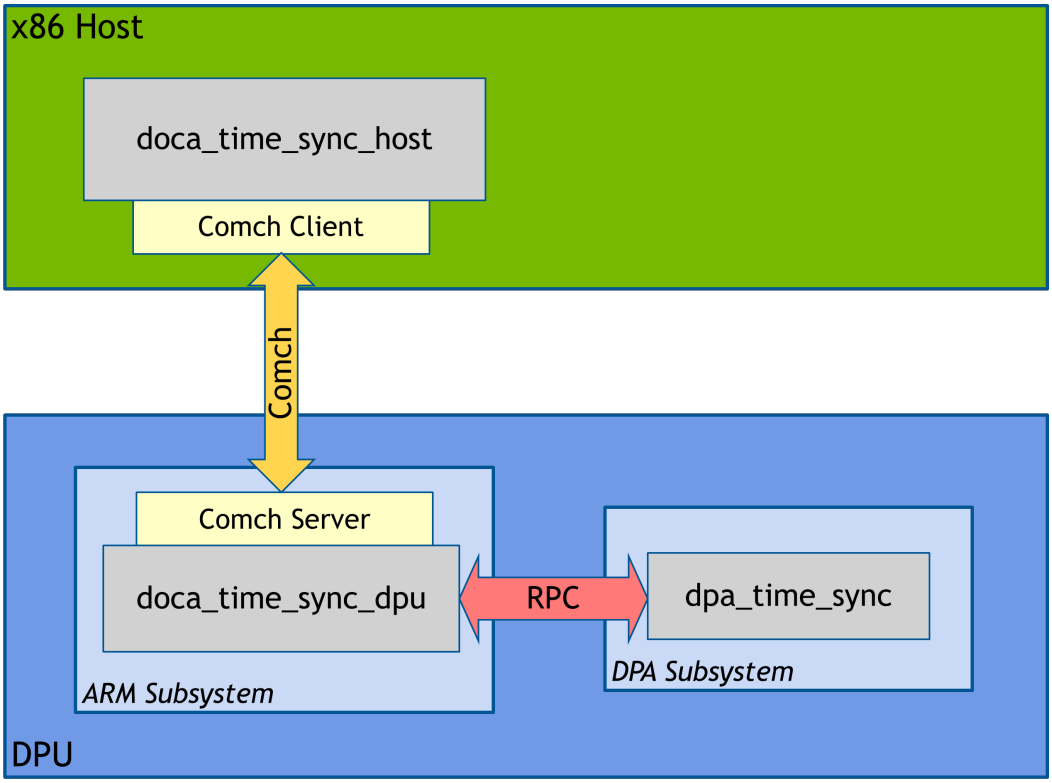
6.28.2 System Design

The DOCA Time Sync architecture consists of two distinct applications:

- DPU application (`doca_time_sync_dpu`) – Runs on the BlueField DPU Arm cores.
- Host application (`doca_time_sync_host`) – Runs on the x86 host system.

Operational workflow:

1. The DPU application must be started first. It establishes a DOCA Comch server to listen for incoming connections.
2. The Host application connects to the Comch server on the DPU.
3. Event triggering:
    a. Host to Arm: The Host application sends a message via the Comch connection to the DPU Arm cores, triggering the first event.
    b. Arm to DPA: The DPU application loads a DOCA DPA kernel and communicates with it to trigger a second event on the DPA subsystem.
4. All event timestamps are relayed back to the Host application, where they are correlated and ordered based on the common DOCA Clock.



6.28.3 Application Architecture

The DOCA Time Sync application generates a sequence of four events across three distinct processors, inserting variable delays between each step to simulate real-world processing latency.

6.28.3.1 Event Sequence

The application tracks the following four events:

1. x86 Host: Packages and sends a request message to the DPU
2. BlueField Arm Cores: Receives the message from the Host
3. DPA Subsystem: Executes a Remote Procedure Call (RPC) triggered by the Arm cores
4. x86 Host: Receives the response message from the DPU

6.28.3.2 Clock Synchronization and Correlation

Each event records a timestamp using its processor's local clock:

- x86 Host & Arm Cores: Use the system RTC.

- DPA Subsystem: Uses its internal local timer.

To order these events chronologically, all timestamps are correlated against a single common reference clock: the ConnectX RTC embedded in the BlueField DPU.

6.28.3.2.1 Host and Arm Core Synchronization

Both the x86 and DPU applications utilize the DOCA Clock cross-timestamping library (part of DOCA Core). This library captures the local clock time and the common NIC clock time simultaneously to establish a precise correlation.

6.28.3.2.2 DPA Subsystem Synchronization

The DPA kernel can only capture time using its local timer. To synchronize this local DPA timestamp with the common NIC clock, the Host application performs a retrospective calculation:

1. Uses DOCA Clock to capture the current relationship between the NIC clock and the DPA timer.
2. Determines the duration (in seconds/nanoseconds) between the current DPA time and the recorded event time.
3. Subtracts this delta from the current NIC time to derive the precise NIC time when the DPA event occurred.

6.28.3.3 Output Logging

The Host application aggregates all data and outputs it to a log file (`time_sync.log`). Each entry includes:

- Synchronized time: The calculated time on the common NIC RTC.
- Local time: The raw timestamp from the processor's local clock.
- Accuracy: The margin of error for the synchronization.
- Event description: A label identifying the specific event step.\

6.28.4 DOCA Libraries

This application leverages the following DOCA libraries:

- DOCA Comch
- DOCA DPA

Refer to their respective programming guide for more information.

6.28.5 Compiling the Application

Please refer to the DOCA Installation Guide for Linux for details on how to install BlueField-related software.

DOCA reference applications are installed with full source code and build instructions. This allows you to compile them as-is or modify the source code to create custom versions.

For more information about the applications as well as development and compilation tips, refer to the DOCA Reference Applications page.

The source code for the application is located in the following directory:

```
/opt/mellanox/doca/applications/time_sync/
```

6.28.5.1 Compiling All Applications

All DOCA applications are defined under a single Meson project. By default, the build process compiles all of them.

To build all applications:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

The build system automatically detects the platform architecture.

- On x86 Host, it generates `doca_time_sync_host`
- On BlueField DPU, it generates `doca_time_sync_dpu`

The binary is created in `/tmp/build/time_sync/`.

6.28.5.2 Compiling Only the Current Application

To reduce build time, you can configure Meson to build only the Time Sync application.

Regardless of the method used, the binary (`doca_time_sync_host` or `doca_time_sync_dpu`) is created in `/tmp/build/time_sync/`.

6.28.5.2.1 Option 1: Command Line Configuration

Run the following commands to disable all applications and explicitly enable Time Sync:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build -Denable_all_applications=false -Denable_time_sync=true
ninja -C /tmp/build
```

6.28.5.2.2 Option 2: Configuration File

edit the configuration file directly:

1. Edit `/opt/mellanox/doca/applications/meson_options.txt`.
    - Set `enable_all_applications` to `false`
    - Set `enable_time_sync` to `true`
2. Run the standard compilation commands:

```
cd /opt/mellanox/doca/applications/
meson /tmp/build
ninja -C /tmp/build
```

6.28.6 Running the Application

6.28.6.1 Application Execution

The Time Sync application is distributed as source code and must be compiled before execution.

6.28.6.1.1 Running on x86 Host

- Usage syntax:

```
Usage: doca_time_sync_host [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI address
  -d, --delay                       Delay (msecs) to insert between event triggers (optional)
```

- Example execution:

```
sudo ./doca_time_sync_host -p 3b:00.0 -d 1000
```

Root Privileges

The application requires `sudo` (root privileges) to access cross-timestamping system calls.

PCIe Addresses

Ensure `3b:00.0` matches your specific device's PCIe address.

6.28.6.1.2 Running on BlueField DPU

- Usage syntax:

```
Usage: doca_time_sync_dpu [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -v, --version                     Print program version information
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE,
20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file

Program Flags:
  -p, --pci-addr                    DOCA device PCI address
  -r, --repr-addr                   DOCA device representor PCI address (optional)
```

- Example execution:

```
sudo ./doca_time_sync_dpu -p 03:00.0 -r 3b:00.0
```

Root Privileges

The application requires `sudo` (root privileges) to access cross-timestamping system calls.

PCIe Addresses

Ensure the device address (`03:00.0`) and representor address (`3b:00.0`) match your system configuration.

6.28.6.2 Command Line Flags

6.28.6.2.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

6.28.6.2.2 Host Program Flags

Short Flag	Long Flag	Description
`p`	`pci-addr`	PCIe address of device to connect DOCA Comch client to, and to cross-timestamp against. ⚠ This is a mandatory flag.

Short Flag	Long Flag	Description
`d`	`delay`	Value in milliseconds of a delay to insert between the triggering of events. ⚠ The parameter is optional. A default of 1 second (1000 msecs) will be used if excluded.

6.28.6.2.3 DPU Program Flags

Short Flag	Long Flag	Description
`p`	`pci-addr`	PCIe address of device to setup DOCA Comch server on, and to cross-timestamp against. ⚠ This is a mandatory flag.
`r`	`repr-addr`	Representor address of the DOCA Comch device to use. ⚠ This is an optional flag. If excluded, the first found representor associated with PCIe address will be used.

6.28.6.3 Troubleshooting

Refer to the NVIDIA BlueField Platform Software Troubleshooting Guide for any issue encountered with the compilation, installation, or execution of the DOCA applications.

6.28.7 Application Code Flow

6.28.7.1 Common

1. Parse application argument.
   a. Initialize arg parser resources and register DOCA general parameters.

```
doca_argp_init();
```

   b. Register Time Sync application parameters.

```
time_sync_common_reg_params();
```

   c. Parse the arguments.

```
doca_argp_start();
```

2. Open DOCA devices for use in the application:

```
time_sync_common_open_dev_with_caps();

// DPU only
time_sync_common_open_repr();
```

   a. Parse PCIe address for associated DOCA device
   b. Verify the selected device has the required capabilities
      i. Comch support
      ii. Real-time NIC clock support
      iii. DPA timer support
      iv. DOCA DPA support (DPU only)
      v. Repr Support (DPU only)
   c. Open valid device
   d. On DPU, parse and open repr device
3. Create a DOCA Clock Context:

```
time_sync_common_create_clock();
```

4. Run Host or DPU-specific code.
5. Destroy DOCA Clock Context:

```
time_sync_common_destroy_clock();
```

6. Close DOCA devices:

```
time_sync_common_close_devs();
```

7. Destroy Arg Parser:

```
doca_argp_destroy();
```

6.28.7.2 Host (x86) App

1. Initialize Comch client.

```
time_sync_host_init_comch_client();
```

   a. Create progress engine
   b. Create DOCA Comch Client context
   c. Configure taskpool/callbacks for sending and receiving messages
   d. Start Comch Client
2. Run main loop.

```
time_sync_host_main_loop();
```

   a. Progress until Client is fully connected to Comch Server on DPU

b. Get event time (on host and NIC) before sending a message
c. Create and send a message to DPU containing the input delay time in milliseconds
d. Wait to receive a response from the DPU containing DPU and DPA event times
e. Get event time (on host and NIC) of message receive
f. Convert received DPA time to NIC time using cross-timestamping functions
g. Log the local and synchronized time of all events to 'time_sync.log'

3. Clean up Comch Client

```
time_sync_host_close_comch_client();
```

a. Stop the DOCA Comch Client
b. Progress until connection is fully shut down and context is IDLE
c. Destroy Client context and progress engine

6.28.7.3 DPU App

1. Load DPA application.

```
time_sync_dpu_load_dpa_app();
```

a. Create a new DOCA DPA context
b. Add an app to the context (app with given name is compiled alongside DPU app - source in /opt/mellanox/doca/applications/time_sync/dpu_device/time_sync_dev.c)
c. Start the DPA context

2. Initiate Comch Server.

```
time_sync_dpu_init_comch_server();
```

a. Create progress engine
b. Create DOCA Comch Server context
c. Configure taskpool/callbacks for sending and receiving messages
d. Configure callback for connection events
e. Start Comch Server

3. Run main loop.

```
time_sync_dpu_main_loop();
```

a. Progress until an x86 client has established a connection to the Comch Server
b. Receive a message from Client
    i. Extract the delay from request message
    ii. Sleep for 'delay' milliseconds

iii. Get event time (on ARM and NIC) of message receive
iv. Sleep for 'delay' milliseconds
v. Trigger a remote procedure call to the loaded DPA app which will return its local time from running kernel
vi. Sleep for 'delay' milliseconds
vii. package event times from ARM/DPA and send response message back to host

c. Progress until x86 has finished and closed Client Comch connection

4. Clean up Comch Server

```
time_sync_dpu_close_comch_server();
```

a. Stop the DOCA Comch Server
b. Progress until context is IDLE
c. Destroy Server context and progress engine

5. Clean up DPA application

```
time_sync_dpu_unload_dpa_app();
```

a. Stop the DOCA DPA context
b. Destroy DPA context

6.28.8 References

7 DOCA Tools

This is an overview of the set of tools provided by DOCA and their purpose.

7.1 Introduction

DOCA tools are a set of executables/scripts that are needed to produce inputs to some of the DOCA libraries and applications.

All tools are installed with DOCA, as part of the doca-tools package, and can either be directly accessed from the terminal or can be found at `/opt/mellanox/doca/tools`. Refer to DOCA Installation Guide for Linux for more information.

> For questions, comments, and feedback, please contact us at doca-feedback@nvidia.com.

7.2 Tools

7.2.1 DOCA Bench

CLI name: `doca_bench`

DOCA Bench allows users to evaluate the performance of DOCA applications, with reasonable accuracy for real-world applications. It provides a flexible architecture to evaluate multiple features in series with multi-core scaling to provide detailed throughput and latency analysis.

7.2.2 Capabilities Print

CLI name: `doca_caps`

DOCA Capabilities Print is used to print the available devices and their representor devices (in the DPU), all their capabilities, and the available DOCA libraries.

7.2.3 DPA Tools

DOCA DPA tools are a set of executables that enable the DPA application developer and the system administrator to manage and monitor DPA resources and to debug DPA applications.

7.2.4 Flow Tune

CLI name: `doca_flow_tune`

DOCA Flow Tune serves as a powerful, one-stop-shop solution, providing visibility and analysis capabilities for DOCA Flow programs.

7.2.5 DOCA Ngauge

CLI name: `doca_ngauge`

DOCA Ngauge is a tool designed for probing NIC hardware counters and storing the collected data in HDF5 format, along with relevant metadata, for subsequent processing.

7.2.6 PCC Counter

CLI name: `pcc_counters.sh`

DOCA PCC Counter is used to print PCC-related hardware counters. The output counters help debug the PCC user algorithm embedded in the DOCA PCC application.

7.2.7 Socket Relay

CLI name: `doca_socket_relay`

DOCA Socket Relay allows Unix Domain Socket (AF_UNIX family) server applications to be offloaded to Bluefield while communication between the two sides is proxied by DOCA Comch.

7.2.8 DOCA Telemetry Utils

CLI name: `doca_telemetry_utils`

DOCA Telemetry Utils can be used to display all available counters and to generate counter IDs which can be used in other DOCA Tools.

7.3 DOCA Bench

7.3.1 Introduction

NVIDIA DOCA Bench allows users to evaluate the performance of DOCA applications, with reasonable accuracy for real-world applications. It provides a flexible architecture to evaluate multiple features in series with multi-core scaling to provide detailed throughput and latency analysis.

This tool can be used to evaluate the performance of multiple DOCA operations, gain insight into each stage in complex DOCA operations and understand how items such as buffer sizing, scaling, and GGA configuration affect throughput and latency.

7.3.2 Feature Overview

DOCA Bench is designed as a unified testing tool for all BlueField accelerators. It, therefore, provides these major features:

- BlueField execution, utilizing the Arm cores and GGAs "locally"
- Host (x86) execution, utilizing x86 cores and the GGAs on the BlueField over PCIe
- Support for the following DOCA/DPU features:
    - DOCA AES GCM
    - DOCA Comch
    - DOCA Compress
    - DOCA DMA
    - DOCA EC
    - DOCA Eth
    - DOCA RDMA
    - DOCA SHA
    - DOCA GPUNetIO
- Multi-core/multi-thread support
- Schedule executions based on time, job counts, etc.
- Ability to construct complex pipelines with multiple GGAs (where data moves serially through the pipeline)
- Various data sources (random data, file data, groups of files, etc.)
- Remote memory operations
    - Use data location on the host x86 platform as input to GGAs
- Comprehensive output to screen or CSV

- Query function to report supported software and hardware feature
- Sweeping of parameters between a start and end value, using a specific increment each time
- Specific attributes can be set per GGA instance, allowing fine control of GGA operation
- Batching of jobs

7.3.3 Installation

DOCA Bench is installed and available in both DOCA-for-Host and DOCA BlueField Arm packages. It is located under the `/opt/mellanox/doca/tools` folder.

7.3.3.1 Prerequisites

DOCA 2.7.0 and higher.

7.3.3.2 Granular Build Support

DOCA Bench supports a granular build environment which allows users to determine which DOCA libraries are installed on any target system. During initialization, DOCA Bench probes all available and supported DOCA libraries, and provides the ability to test those libraries. For example, if the DOCA SHA library is not present then DOCA Bench does not allow SHA to be tested.

DOCA Bench provides a query system where device capabilities can be queried to see if the library is indeed installed and supported (under the "installed : yes / no" section of each library). Please see section "Queries" for details.

7.3.4 Operating Modes

DOCA Bench measures performance of either throughput (bandwidth) or latency.

7.3.5 Throughput Measurements

In this mode, DOCA Bench measures the maximum performance of a given pipeline (see "Core Principles"). At the end of the execution, a short summary along with more detailed statistics is presented:

```
Aggregate stats
        Duration:      3000049 micro seconds
        Enqueued jobs: 17135128
```

```
Dequeued jobs: 17135128
Throughput:    5712042 Operations/s
Ingress rate:  063.832 Gib/s
Egress rate:   063.832 Gib/s
```

7.3.5.1 Latency Measurements

Latency is the measurement of time taken to perform a particular operation. In this instance, DOCA Bench measures the time taken between submitting a job and receiving a response.

DOCA Bench provides two different types of latency measurement figures:

- Bulk latency mode – attempts to submit a group of jobs in parallel to gain maximum throughput, while reporting latency as the time between the first job submitted in the group and the last job received.
- Precision latency mode – used to ensure that only one job is submitted and measured before the next job is scheduled.

7.3.5.1.1 Bulk Latency

This latency mode effectively runs the pipelines at full rate, trying to maintain the maximum throughput of any pipeline while also recording latency figures for jobs submitted.

To record latency, while operating at the pipeline's maximum throughput, users must place the latency figures inside groups or "buckets" (rather than record each individual job latency). Using this method, users can avoid the large memory and CPU overheads associated with recording millions of latency figures per second (which would otherwise significantly reduce the performance).

As each pipeline operation is different, and therefore has different latency characteristics, the user can supply the boundaries of the latency measure. DOCA Bench internally creates 100 buckets, of which the user can specify the starting value and the width or size of each bucket. The first and last bucket have significance:

- The first bucket contains all jobs that executed faster than the starting period
- The last bucket contains a count of jobs that took longer than the maximum time allowed

The command line option `--latency-bucket-range` is used to supply two values representing the starting time period of the first bucket, and the width of each sequential bucket. For example, `--latency-bucket-range 10us,100us` would start with the lowest bucket measuring <10µs response times, then 100 buckets which are 100µs wide, and a final bucket for results taking longer than 10010µs.

The report generated by bulk mode visualizes the latency data in two methods:

1. A bar graph is provided to visually show the spread of values across the range specified by the `--latency-bucket-range` option:

```
Latency report:
                    :
                    :
                    :
                    :
                    :
                    ::
                    ::
                    ::
                    ::
                  .:::.  .    .    ..
-----------------------------------------------------------------------------------------------------
```

2. A breakdown of the number of jobs per bucket is presented. This example shortens the output to show that the majority of values lie between 27000ns and 31000ns.

```
[25000ns -> 25999ns]: 0
[26000ns -> 26999ns]: 0
[27000ns -> 27999ns]: 128
[28000ns -> 28999ns]: 2176
[29000ns -> 29999ns]: 1152
[30000ns -> 30999ns]: 128
[31000ns -> 31999ns]: 0
[32000ns -> 32999ns]: 0
[33000ns -> 33999ns]: 128
[34000ns -> 34999ns]: 0
[35000ns -> 35999ns]: 0
```

7.3.5.1.2 Precision Latency

This latency mode operates on a single job at a time. At the cost of greatly reduced throughput, this allows the minimum latency to be precisely recorded. As shown below, the statistics generated are precise and include various fields such as min, max, median, and percentile values.

```
Aggregate stats

        ....
        min:            1878 ns
        max:            4956 ns
        median:         2134 ns
        mean:           2145 ns
        90th %ile:      2243 ns
        95th %ile:      2285 ns
        99th %ile:      2465 ns
        99.9th %ile:    3193 ns
        99.99th %ile:   4487 ns
```

7.3.6 Core Principles

The following subsections elaborate on principles which are essential to understand how DOCA Bench operates.

7.3.6.1 Host or BlueField Arm Execution

Whether executing DOCA Bench on an x86 host or BlueField Arm, the behavior of DOCA Bench is identical. The performance measured is dependent on the environment.

> Only execution on x86 hosts is supported.

7.3.6.2 Pipelines

DOCA Bench is a highly flexible tool, providing the ability to configure how and what operations occur and in what order. To accomplish this, DOCA Bench uses a pipeline of operations, which are termed "steps". These steps can be a particular function (e.g., Ethernet receive, SHA hash generation, data compression). Therefore, a pipeline of steps can accomplish a number of sequential operations. DOCA Bench can measure the throughput performance or latency of these pipelines, whether running on single or multiple cores/threads.

> Currently, DOCA supports running only one pipeline at a time.

7.3.6.3 Warm-up Period

To ensure correct measurement, the pipelines must be run "hot" (i.e., any initial memory, caches, and hardware subsystems must be running prior to actual performance measurements begin). This is known as the "warm-up" period and, by default, runs approximately 250 jobs through the pipeline before starting measurements.

7.3.6.4 Defaults

DOCA Bench has a large number of parameters but, to simplify execution, only a few must be supplied to commence a performance measurement. Therefore various parameters have defaults which should be sufficient for most cases. To fine tune performance, users should pay close attention to any default parameters which may affect their pipeline's operation.

> When executed, DOCA Bench reports a full list of all parameters and configured values.

7.3.6.5 Optimizing Performance

To obtain maximum performance, a certain amount of tuning is required for any given environment. While outside the scope of this documentation, it is recommended for users to:

- Avoid using CPU 0 as most OS processes and interrupt request (IRQ) handlers are scheduled to execute on this core
- Enable CPU/IRQ isolation in the kernel boot parameters to remove kernel activities from any cores they wish to execute performance tests on
- On hosts, ensure to not cross any non-uniform memory access (NUMA) regions when addressing the BlueField
- Understand the memory allocation requirements of scenarios, to avoid over-allocating or running into near out-of-memory situations

7.3.7 Supported BlueField Feature Matrix

DOCA Bench can be executed on both host and BlueField Arm environments, and can target BlueField networking platforms.

The following table shows which operations are possible using either DOCA Bench. It also provides two columns showing whether remote memory can be used as an input or output to that operation. For example, DMA operations on the BlueField Arm can access remote memory as an input to pull memory from the host into the BlueField Arm).

	BlueField-2 Networking Platform	BlueField-3 Networking Platform	Execute on Host Side	Execute on BlueField Arm	Remote Memory as Input Allowed?	Remote Memory as Output Allowed?
doca_compress::compress	✓		✓	✓	✓	✓
doca_compress::decompress	✓	✓	✓	✓	✓[1]	✓
doca_dma	✓	✓	✓	✓	✓	✓
doca_ec::create		✓	✓	✓	✓	✓

doca_gpunetio::eth_rx	✓	✓	✓			
doca_gpunetio::eth_bidir	✓	✓	✓			

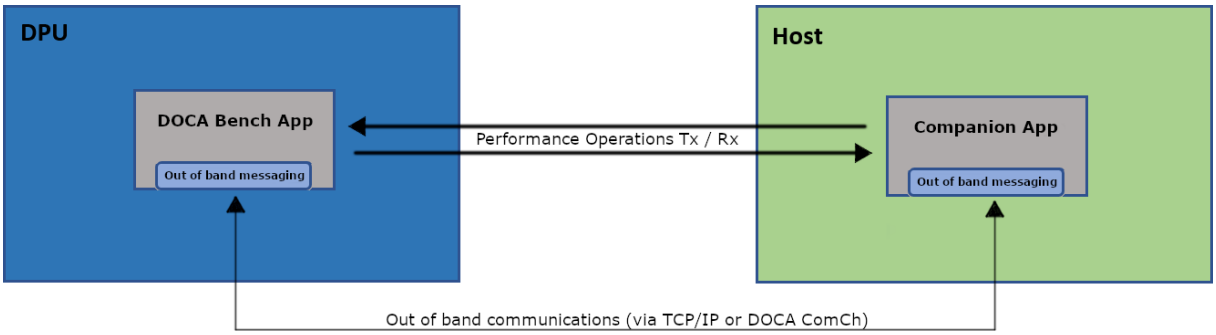
1. Input remote memory is not supported for lz4 decompression

7.3.8 Remote Operations

A subset of BlueField operations have a remote element, whether this is an RDMA connection, Ethernet connectivity, or memory residing on an x86 host. All these operations require an agent to be present on the far side to facilitate the benchmarking of that particular feature.

In DOCA Bench, this agent is an additional standalone application called the "companion app". It provides the remote benchmarking facilities and is part of the standard DOCA Bench installation.

The following diagram provides an overview of the function and communications between DOCA Bench and the companion app:



In this particular setup, the BlueField executes "DOCA Bench" while the host (x86) is executes the companion App.

DOCA Bench also acts as the controller of the tests, instructing the companion app to perform the necessary operations as required. There is an out-of-band communications channel operating between the two applications that utilizes either standard TCP/IP sockets or a DOCA Comch channel (depending on the test scenario/user preferences).

DOCA Bench tool is not intended to be used in a production deployment. If choosing to do so, please be aware that the out-of-band communications might contain sensitive information and thus should be done over a secure channel when using the standard TCP/IP sockets

7.3.9 CPU Core and Thread Selection

Selection of the correct CPU cores and threads has a significant impact on the performance or latency obtained. Read this section carefully.

A key requirement to scale any application is the number of CPU cores or threads allocated to any given activity. DOCA Bench provides the ability to specify the numbers of cores, and the number of threads to be created per core, to maximize the number of jobs submitted to a given pipeline.

The following care should be given when selecting the number of CPU's or threads:

- Threads that are on cores located on distant NUMA regions (i.e., not the same NUMA region the BlueField is connected to) will experience lower performance and higher latency
- Core 0 is often most used by the OS and should be avoided
- Standard Linux Kernel installations allow the OS to move processes on any CPU core resulting in unexpected drops in performance, or higher latency, due to process switching

The selection of CPU cores is provided through the `--core-mask`, `--core-list`, `--core-count` parameters, while thread selection is made via the `--threads-per-core` parameter.

7.3.10 Device Selection

7.3.10.1 BlueField Devices

When executing from a host (x86) environment DOCA Bench can target one or more BlueField devices within an installed environment. When executing from the BlueField Arm, the target is always the local BlueField.

The default method of targeting a given BlueField from either the host or the BlueField Arm is using the `--device` or `-A` parameters, which can be provided as:

- Device PCIe address (i.e., `03:00.0`);
- Device IB name (`mlx5_0`); or
- Device interface name (`ens4f0`)

From the BlueField Arm environment, DOCA Bench should be targeted at the local PCIe address (i.e., `--device 03:00.0`) or the IB device name (i.e., `mlx5_0`).

7.3.10.2 GPU Devices

When executing a DOCA GPUNetIO benchmark, a GPU device must be specified. This can be done using the `--gpu` or `-G` parameters, which can only be provided as a device PCIe address (i.e., `03:00.0`).

7.3.11 Input Data Selection and Sizing of Jobs

DOCA Bench supports different methods of supplying data to jobs and providing information on the amount of data to process per job. These are referred to as "Data Providers".

7.3.11.1 Input Data Selection

The following subsections provide the modes available to provide data for input into any operation.

7.3.11.1.1 File

A single file is used as input to the operation. The contents of the file are not important for certain operations (e.g., DMA, SHA, etc.) but must be valid and specific for others (e.g., decompress, etc). The data may be used multiple times and repeated if the operations required more data than the single file contains. For more information on how file data is handled in complex operations, see section "Command-line Parameters".

7.3.11.1.2 File Sets

File sets are a group of files that are primarily used for structured data. The data in the file set is effectively a list of files, separated by a new line that is used sequentially as input data for jobs. Each file pointed to by the file set would have its entire contents read into a single buffer. This is useful for operations that require structured data (i.e., a complete valid block of data, such as decompression or AES).

7.3.11.1.3 Random Data

Random data is provided when the actual data required for the given operation is not specific (e.g., DMA).

> ⚠ The use of random data for certain operations may reduce the maximum performance obtained. For example, compressing random data results in lower performance than compressing actual file data (due to the lack of repeating patterns in random data).

7.3.11.2 Job Sizing

Each job in DOCA Bench consists of three buffers: An original input buffer, an output, and an intermediate buffer.

The input buffer is provided by the data provider for the first step in the pipeline to use, after which the following steps use the output and intermediate buffers (can be sized by using `--job-output-buffer-size`) in a ping-pong fashion. This means, the pipeline can always start with the same deterministic data while allowing for each step to provide its newly generated output data to be used as input to the next step.

The input buffer is specified in one of two ways: using uniform-job-size to make every input buffer the exact same size, or using a file set to size each buffer based on the size of the selected input data file(s). Users should ensure the data generated by each step in the pipeline will fit in the provided output buffer.

7.3.12 Controlling Test Duration

DOCA Bench has a variety of ways to control the length of executing tests—whether based on data or time limit.

7.3.12.1 Limit to Specific Number of Seconds

Using the `--run-limit-seconds` or `-s` parameter ensures that the execution continues for a specific number of seconds.

7.3.12.2 Limited Through Total Number of Jobs

It may be desirable to measure a specific number of jobs passing through a pipeline. The `--run-limit-jobs` or `-J` parameter is used to specify the exact number of jobs submitted to the pipeline and allowed to complete before execution finishes.

7.3.13 GGA-specific Attributes

As DOCA Bench supports a wide range of both GGA and software based DOCA libraries, the ability to fine tune their invocation is important. Command-line parameters are generally used for configuration options that apply to all aspects of DOCA Bench, without being specific to a particular DOCA library.

Attributes are the method of providing configuration options to a particular DOCA Library, whilst some shared attributes exist the majority of libraries have specific attributes designed to control their specific behavior.

For example, the attribute `doca_ec.data_block_count` allows you to set the data block count for the DOCA EC library, whilst the attribute `doca_sha.algorithm` controls the selection of the SHA algorithm.

For a full list of support attributes, see the "Command-line Parameters" section.

Due to batching it is possible that more than the supplied jobs are executed.

7.3.14 Command-line Parameters

DOCA Bench allows users to specify a series of operations to be performed and then scale that workload across multiple CPU cores/threads to get an estimation of how that workload performs and some insight into which stage(s), if any, cause performance

problems for them. The user can then modify various configuration properties to explore how issues can be tuned to better serve their need.

When running, DOCA Bench creates a number of execution threads with affinities to the specific CPU specified by the user. Each thread creates, uniquely for themselves, a jobs pool (with job data initialized by a data provider) and a pipeline of workload steps.

7.3.14.1 CPU Core and Thread Count Configuration

There are many factors involved when carrying out performance tests, one of these is the CPU selection:

- The user should consider NUMA regions when selecting which cores to use, as using a CPU which is distant from the device under test can impact the performance achievable
- The user may also wish to avoid core 0 as this is typically the default core for kernel interrupt handlers.

> ⚠ CPU core selection has an impact on the total memory footprint of the test. See section "Test Memory Footprint" for more details.

7.3.14.1.1 --core-mask

Default value: 0x02

Core mask is the simplest way to specify which cores to use but is limited in that it can only specify up to 32 CPUs (0-31). Usage example: `--core-mask 0xF001` selects CPU cores 0, 12, 13, 14, and 15.

7.3.14.1.2 --core-list

Core list can specify any/all CPU cores in a given system as a list, range, or combination of the two. Usage example: `--core-list 0,3,6-10` selects CPU cores 0, 3, 6, 7, 8, 9, and 10.

7.3.14.1.3 --core-count

The user can select the first N cores from a given core set (list or mask) if desired. Usage example: `--core-count N`.

> ℹ Sweep testing is supported. See section "Sweep Tests" for more details.

7.3.14.1.4 --threads-per-core -t

To test the impacts of contention within a single CPU core, the user can specify this value so that instead of only one thread being created per core, N threads are created with their affinity mask set to the given core for each core selected. For example, 3 cores and 2 threads per core create 6 threads total.

> Sweep testing is supported. See section "Sweep Tests" for more details.

7.3.14.2 Device Configuration

The test requires the use of at least one BlueField to execute. With remote system testing, a second device may be required.

7.3.14.2.1 --device -A

Specify the device to use from the perspective of the system under test. The value can be for any one of either the device PCIe address (e.g., `03:00.0`), the device IB device name (e.g., `mlx5_0`), or the device interface name (e.g., `ens4f0`).

7.3.14.2.2 --representor -R

This option is used only when performing remote memory operations between a BlueField device and its host using DOCA Comch. This is typically automated by the companion connection string but exists for some developer debug use-cases.

> This option used to be important before the companion connection string property was introduced but now is rarely used.

7.3.14.3 Input Data and Buffer Size Configuration

DOCA Bench supports multiple methods of acquiring data to use to initialize job buffers. The user can also configure the output/intermediate buffers associated with each job.

> Input data and buffer size configuration has an impact on the total memory footprint of the test. See section "Test Memory Footprint" for more details.

7.3.14.3.1 --data-provider -I

DOCA Bench supports several different input data sources:

- `file`
- `file-set`
- `random-data`

7.3.14.3.1.1 File Data Provider

The file data provider produces uniform/non-structured data buffers by using a single input file. The input data is stripped and or repeated to fill each data buffer as required, returning back to the start of the file each time it is exhausted to collect more data. This is desirable when the performance of the component(s) under test is meant to show different performance characteristics depending on the input data supplied.

For example, `doca_dma` and `doca_sha` would execute in constant time regardless of the input data. Whereas `doca_compress` would be faster with data with more duplication and slower for truly random data and would produce different output depending on the input data.

Example 1 – Small Input File with Large Buffers

Given a small input data (i.e., smaller than the data buffer size), the file contents are repeated until the buffer is filled and then continue onto the next buffer(s). So, if the input file contained the data `012345` and the user requested two 20-byte buffers, the buffers would appear as follows:

- `01234501234501234501`
- `23450123450123450123`

Example 2 – Large Input File with Smaller Buffers

Given a large input data (i.e., greater than the data buffer size), the file contents are distributed across the data buffers. If the the input file contained the data `0123456789abcdef` and the user requested three 12-byte buffers, the buffers would appear as follows:

- `0123456789ab`
- `cdef01234567`
- `89abcdef0123`

7.3.14.3.1.2 File Set Data Provider

The file set data provider produces structured data. The file set input file itself is a file containing one or more filenames (relative to the input `"command working directory (cwd)"` not relative to the file set file). Each file listed inside the file set would have its

entire contents used as a job buffer. This is useful for operations where the data must be a complete valid data block for the operation to succeed like decompression with `doca_compress` or decryption with `doca_aes`.

Example – File Set and Its Contents

Given a file set in the `"command working directory (cwd)"` referring to `data_1.bin` and `data_2.bin` (one file name per line), and `data_1.bin` contains 33 bytes and `data_2.bin` contains 69 bytes, then the data required by the buffers would be filled with these two files in a round-robin manner until the buffers are full. Unlike uniform (non-structured) data each task can have different lengths.

7.3.14.3.1.3 Random-data Data Provider

The random data data provider provides uniform (non-structured) data from a random data source. Each buffer will have unique (pseudo) random bytes of content.

7.3.14.3.2 --data-provider-job-count

Default value: 128

Each thread in DOCA Bench has its own allocation of job data buffers to avoid memory contention issues. Users may select how many jobs should be created per thread using this parameter.

> Sweep testing is supported. See section "Sweep Tests" for more details.

7.3.14.3.3 --data-provider-input-file

For data providers which use an input file, the filename can be specified here. The filename is relative to the `input_cwd`.

> Sweep testing is supported. See section "Sweep Tests" for more details.

7.3.14.3.4 --uniform-job-size

Specify the size of uniform input buffers (in bytes) that should be created.

> Does not apply and should not be specified when using structured data input sources.

Sweep testing is supported. See section "Sweep Tests" for more details.

7.3.14.3.5 --job-output-buffer-size

Default value: 16384

Specify the size of output/intermediate buffers (in bytes). Each job has 3 buffers: immutable input buffer and two output/intermediate buffers. This allows for a pipeline to mutate the data an infinite number of times throughout the pipeline, while allowing for it to be reset and re-used at the end and allowing any step to use the new mutated data created by the previous step.

7.3.14.3.6 --input-cwd -i

To ease configuration management, the user may opt to use a separate folder for the input data for a given scenario outside of the DOCA build/install directory.

It is recommended to use relative file paths for the input files.

7.3.14.3.6.1 Example 1 - Running DOCA Bench from Current Working Directory

Considering a user executing DOCA Bench from `/home/bob/doca/build`, values specified in `--data-provider-input-file` and filenames within a file set would search relative to the shell's "command working directory (cwd)": `/home/bob/doca/build`. Their command might look something like:

```
doca_bench --data-provider file-set --data-provider-input-file my_file_set.txt
```

And assuming `my_file_set.txt` contains `data_1.bin`, the files that would be loaded by DOCA Bench after path resolution would be:

- `/home/bob/doca/build/my_file_set.txt`
- `/home/bob/doca/build/data_1.bin`

7.3.14.3.6.2 Example 2 - Running DOCA Bench from Another Directory

Considering the user executed that same test from one level up. Something like:

```
build/doca_bench --data-provider file-set --data-provider-input-file build/my_file_set.txt
```

The files to be loaded would be:

- `/home/bob/doca/build/my_file_set.txt`

- `/home/bob/doca/data_1.bin`

Notice how both files were loaded relative to the `"command working directory (cwd)"` and the data file was not loaded relative to the file set.

7.3.14.3.6.3 Example 3 - Example 2 Revisited Using input-cwd

The user can solve this easily by keeping all input files in a single directory and then referring to that directory using the parameter `input-cwd`. In this case, the command like may look something like:

```
build/doca_bench --data-provider file-set --data-provider-input-file my_file_set.txt --input-cwd build
```

Note that the value for `--data-provider-input-file` also changed to be relative to the new `"command working directory (cwd)"`.

The files loaded this time are back to being what is expected:

- `/home/bob/doca/build/my_file_set.txt`
- `/home/bob/doca/build/data_1.bin`

7.3.14.4 Test Execution Control

DOCA Bench supports multiple test modes and run execution limits to allow the user to configure the test type and duration.

7.3.14.4.1 --mode

Default value: throughput

Select which type of test is to be performed.

7.3.14.4.1.1 Throughput Mode

Throughput mode is optimized to increase the volume of data processed in a given period with little or no regard for latency impact. Throughput mode tries to keep each component under test as busy as possible. A summary of the bandwidth and job execution rate are provided as output.

7.3.14.4.1.2 Bulk-latency Mode

Bulk latency mode strikes a balance between throughout and latency, submitting a batch of jobs and waiting for them all to complete to measure the latency of each job. This mode uses a bucketing mechanism to allow DOCA Bench to handle many millions of jobs worth of results. DOCA Bench keeps a count of the number of jobs that

complete within each bucket to allow it to run for long periods of time. A summery of the distribution of results with an ASCII histogram of the results are provided as output. The latency reported is the time taken between the first job submission (for a batch of jobs) until the final job response is received (for that same batch of jobs).

7.3.14.4.1.3 Precision-latency Mode

Precision latency mode executes one job at a time to allow DOCA Bench to calculate the minimum possible latency of the jobs. This causes the components which can process many jobs in parallel to be vastly underutilized and so greatly reduces bandwidth. As this mode records every result individually, it should not be used to execute more than several thousand jobs. Precision latency mode requires 8 bytes of storage for each result, so be mindful of the memory overhead of the number of jobs to be executed.

A statistical analysis including minimum, maximum, mean, median and some percentiles of the latency value are provided as output.

7.3.14.4.2 --latency-bucket-range

Default value: 100ms,10ms

Only applicable to bulk-latency mode. Allows the user to specify the starting value of the buckets, and the width of each bucket. There are 100 buckets of the given size and an under flow and overflow bucket for results that fall outside of the central range.

For example:

```
--latency-bucket-range 10us,100us
```

This would start with the lowest bucket measuring <10µs response times, then 100 buckets which are 100µs wide, and a final bucket for results taking longer than >10010µs.

7.3.14.5 Blocking Mode

DOCA supports two methods of waiting on completion of tasks:

- Busy-wait (or polling) mode
- Notification-driven mode

> Refer to "DOCA SDK Architecture" documentation for more information.

By default, DOCA Bench uses the busy-wait to ensure maximum bandwidth (and low latency) for any given pipeline and its tasks with high utilization of any allocated CPU resources.

As with all high-performance software, utilizing GGAs or hardware accelerators, performance is usually CPU-bound at smaller packet sizes (i.e., at smaller payload sizes, the CPU spends a long time generating tasks and dealing with completions). For larger packet sizes, the CPU submits less tasks, as each task contains more data, therefore it may easily submit more data than the GGA or hardware accelerator can accept, resulting in periods where the CPU is busy-waiting on completions before being able to submit further tasks.

> To execute any tests using an "notification-driven mode", use the options detailed in the following subsections.

7.3.14.5.1 --use-blocking-mode

This option causes DOCA Bench to use the "notification-drive mode" method of waiting on task completion.

> At smaller packet sizes, the benchmark may still be CPU bound.

7.3.14.5.2 --record-cpu-usage

If specified, this option reports CPU statistics for any CPU cores DOCA Bench is executing on. This provides guidance on how much CPU time is returned, and thus available to other processes or threads, should the "notification-driven" mode be active.

> Short duration tests may not result in sufficient produced data to generate CPU usage statistics.

The statistics provided include min, max, median, and mean values for the CPU usage. Also included are a number of percentile results, showing 90th, 95th, and a number of 99th percentile values. Example output:

```
CPU Usage stats
        min:            25%
        max:            50%
        median:         50%
        mean:           45.8333%
        90th %ile:      50%
        95th %ile:      50%
        99th %ile:      50%
        99.9th %ile:    50%
        99.99th %ile:   50%
```

7.3.14.6 Execution Limits

By default, a test runs forever. This is typically undesirable so the user can specify a limit to the test.

⚠ Precision-latency mode only supports job limited execution.

7.3.14.6.1 --run-limit-seconds -s

Runs the test for N seconds as specified by the user.

7.3.14.6.2 --run-limit-jobs -J

Runs the test until at least N jobs have been submitted, then allowing in-flight jobs to complete before exiting. More jobs than N may be executed based on batch size.

7.3.14.6.3 --run-limit-bytes -b

Runs the test until at least N bytes of data have been submitted, then allowing in-flight jobs to complete before exiting. More data may be processed than desired if the limit is not a multiple of the job input buffer size.

7.3.14.7 Batching Support

DOCA Bench supports submission of jobs in batches to improve performance.

7.3.14.7.1 **--batch-mode**

Default value: none

Specifies the batching mode to use. The following options are available:

- `--batch-mode none` – no batching, ring the doorbell after each job is submitted
- `--batch-mode batch-submit` – submit a batch of jobs and then ring the doorbell. The number of jobs to be submitted is specified by the `--batch-size` parameter. If the number of jobs left to be submitted is fewer than `batch-size`, then the doorbell is rung after the last job is submitted.
- `batch-submit-minimal-reports` – submit a batch of jobs and ring the doorbell, but defer the completion callback of the job until a later time. Reduces the number of completion notifications received after submission of a batch of jobs by receiving a single completion notification for the entire batch.

7.3.14.7.2 **--batch-size**

Default value: 1

Specifies the number of jobs to be included in each batch before ringing the doorbell.

> ⚠ Batching is currently only supported for the `doca_sha` and `doca_dma` step types and can only be specified in the throughput mode of operation.

7.3.14.8 Gather/Scatter Support

Gather support involved breaking incoming input data from a single buffer into multiple buffers, which are "gathered" into a single gather list. Currently only gather is supported.

7.3.14.8.1 --gather-value

Default value: 1

Specifies the partitioning of input data from a single buffer into a gather list. The value can be specified in two flavors:

- `--gather-value 4` – splits input buffers into 4 parts as evenly as possible with odd bytes in the last segment
- `--gather-value 4KiB` – splits buffers after each 4KB of data. See `doca_bench/utility/byte_unit.hpp` for the list of possible units.

7.3.14.8.2 --scatter-value

Default value: 1

Specifies the partitioning of output data into a scatter list. The value can be specified in two flavors:

- `--scatter-value 4` – splits output buffers into 4 parts as evenly as possible with odd bytes in the last segment
- `--scatter-value 4KiB` – splits buffers after each 4KB of data. See `doca_bench/utility/byte_unit.hpp` for the list of possible units.

7.3.14.9 Stats Output

7.3.14.9.1 --rt-stats-interval

By default, DOCA Bench emits the results of an iteration once it completes. The user can ask for transient snapshots of the stats as the test progresses by providing the `--rt-stats-interval` argument with a value representing the number of milliseconds between stat prints. The end-result of the run is still displayed as normal.

⚠ This may produce a large amount of console output.

7.3.14.9.2 --csv-output-file

DOCA Bench can produce an output file as part of its execution which can contain stats and the configuration values used to produce that stat. This is enabled by specifying the `--csv-output-file` argument with a file path as the value. Providing a value for this argument enables CSV stats output (in addition to the normal console output). When performing a sweep test, one line per iteration of the sweep test is populated.

By default, the CSV output contains every possible value. The user can tune this by applying a filter.

7.3.14.9.3 --csv-stats

Provide one or more filters (positive or negative) to tune which stats are displayed. The value for this argument is a comma-separated list of filter strings. Negative filters start with a minus sign ('`-`').

7.3.14.9.3.1 Example 1 - Emit Only Statistical Values (No Configuration Values)

```
--csv-stats "stats.*"
```

⚠ The quotes around the `*` prevent the shell from interpreting it as a wild card for filenames in the command.

7.3.14.9.3.2 Example 2 - Emit Statistical Values and Some Configuration Values (Remove Attribute Values)

```
--csv-stats "stats.*,-attribute*
```

7.3.14.9.4 --csv-append-mode

Default: `false`

When enabled, DOCA Bench appends to a CSV file if it exists or creates a new one. It is assumed that all invocation uses the exact same set of output values. This is not verified by DOCA Bench. The user must ensure that all tests that append to the CSV use the same set of output values.

7.3.14.9.5 --csv-separate-dynamic-values

A special case which creates a non-standard CSV file. All values that are not supported by sweep tests are reported only once first, then a new line of headers for values emitted during the test, then a row for each test result. This is reserved for an internal use case and should not be relied upon by anyone else.

7.3.14.9.6 --enable-environment-information

Instructs DOCA Bench to collect some detailed system information as part of the test startup procedure which is then made available for output in the CSV. These also gather the same details from the companion side if the companion is in use.

> This collection can take a long time (up to a few minutes in some circumstances) to complete, so it is not recommended unless you know you need it.

7.3.14.10 Remote Memory Testing

Some libraries (e.g., `doca_dma`) support the use of remote memory. To enable this, the user can specify one or both of the remote memory flags `--use-remote-input-buffers` and `--use-remote-output-buffers`. This tells DOCA Bench to use the companion to create a remote mmap. This remote mmap is then used to create buffers that are submitted to the component under test.

> ⚠ These flags should be used with caution and an understanding that if the underlying components under test can support this scenario, there is no automated checking. It is user responsibility to ensure these are used appropriately.

7.3.14.10.1 --use-remote-input-buffers

Specifies that the memory used for the initial immutable job input buffers into a pipeline should be backed by an mmap on the remote side.

> ⚠ Requires the companion app to be configured.

7.3.14.10.2 --use-remote-output-buffers

Specifies that all output and translation buffers in use are backed by an mmap on the remote side.

> ⚠ Requires the companion app to be configured.

7.3.15 Network Options

7.3.15.1 --mtu-size

For use with `doca_rdma`. Value is an enum: `256B` `512B` `1KB` `2KB` `4KB` or `raw_eth`.

7.3.15.2 --receive-queue-size

For use with `doca_rdma`. Configure the RDMA RQ size independently of the SQ size.

7.3.15.3 --send-queue-size

For use with `doca_rdma`. Configure the RDMA SQ size independently of the RQ size.

7.3.15.4 DOCA Lib Configuration Options

7.3.15.4.1 --task-pool-size

Default value: 1024

Configure the maximum task pool size used when libraries initialize task pools.

7.3.15.5 Pipeline Configuration

DOCA Bench is based on a pipeline of operations, This allow for complex test scenarios where multiple components are tested in parallel. Currently only a single chain of operations in a pipeline is supported (but scaled across multiple cores or threads), future versions will allow for varied pipeline's per CPU core.

A pipeline is described as a series of steps. All steps have a few general characteristics:

- Step type: `doca_dma`, `doca_sha`, `doca_compress`, etc.
- An operation category – transformative or non-transformative
- An input data category – structured or non structured

Individual step types may also have some additional metadata information or configuration as defined on a per step basis.

Metadata examples:

- `doca_compress` requires an operation type: `compress` or `decompress`
- `doca_aes` requires an operation type: `encrypt` or `decrypt`
- `doca_ec` requires an operation type: `create`, `recover` or `update`
- `doca_rdma` requires a direction: `send`, `receive` or `bidir`

Configuration examples:

- `--pipeline-steps doca_dma`
- `--pipeline-steps doca_compress::compress,doca_compress::decompress`

7.3.15.5.1 --pipeline-steps

Define the step(s) (comma-separated list) to be executed by each thread of the test.

The following is the list of supported steps:

- `doca_compress::compress`
- `doca_compress::decompress`
- `doca_dma`

- `doca_ec::create`
- `doca_ec::recover`
- `doca_ec::update`
- `doca_sha`
- `doca_rdma::send`
- `doca_rdma::receive`
- `doca_rdma::bidir`
- `doca_aes_gcm::encrypt`
- `doca_aes_gcm::decrypt`
- `doca_cc::client_producer`
- `doca_cc::client_consumer`
- `doca_eth::rx`
- `doca_eth::tx`
- `doca_gpunetio::eth_tx`
- `doca_gpunetio::eth_rx`
- `doca_gpunetio::eth_bidir`

Some modules may be unavailable if they were not compiled as part of DOCA when DOCA Bench was compiled.

7.3.15.5.2 --attribute

Some of the options are very niche or specific to a single step/mmo type, so they are defined simply as attributes instead of a unique command-line argument.

The following is the list of supported options:

- `doption.mmp.log_qp_depth`
- `doption.mmo.log.num_qps`
- `doption.companion_app.path`
- `doca_compress.algorithm`
- `doca_ec.matrix_count`
- `doca_ec.data_block_count`
- `doca_ec.redundancy_block_count`
- `doca_sha.algorithm`
- `doca_rdma.gid-index`
- `doca_eth.max_burst_size`
- `doca_eth.l3_chksum_offload`

- `doca_eth.l4_chksum_offload`
- `doca_gpunetio.threads-per-block`
- `doca_gpunetio.num-blocks`
- `doca_gpunetio.eth-rx-timout-ns`
- `doca_gpunetio.eth-rx-max-rx-packets`

7.3.15.5.3 --warm-up-jobs

Default value: 100

Warm-up serves two purposes:

- Firstly, it runs N tasks in a round robin fashion to get the data path code, tasks memory, and tasks data buffers memory into the CPU caches before the measurement of the test begins
- Secondly, it uses `doca_task_try_submit` instead of `doca_task_submit` to validate the jobs. This validation is not desirable during the proper hot path as it costs time revalidating the task each execution.

The user should ensure their warmup count equals or exceeds the number of tasks being used per thread (see `--data-provider-job-count`).

7.3.15.6 Companion Configuration

Some tests require a remote system to function. For this purpose, DOCA Bench comes bundled with a companion application (this application is installed as part of the DOCA-for-Host or BlueField packages). The companion is responsible for providing services to DOCA Bench such as creating a `doca_mmap` on the remote side and exporting it for use with remote operations like `doca_dma` / `doca_sha`, or other `doca_libs` that support remote memory input buffers. DOCA Bench can also provide remote worker processes for libraries that require them such as `doca_rdma` and `doca_cc`. The companion is enabled by providing the `--companion-connection-string` argument. Companion remote workers are enabled by providing either of the arguments `--companion-core-list` or `--companion-core-mask`.

> DOCA Bench requires that an SSH key is configured to allow the user specified to SSH without a password to the remote system using the supplied address (to launch the companion). Refer to your OS's documentation for information on how to achieve this.

The companion connection may also specify the `no-launch` option.

This is reserved for expert developer use.

The user may also specify a path to a specific companion binary to allow them to test companion binaries not in the default install path using the following command:

```
--attribute doption.companion_app.path=/tmp/my_doca_build/tools/bench/doca_bench_companion
```

This is reserved for expert developer use.

7.3.15.6.1 --companion-connection-string

Specifies the details required to establish a connection to and execute the companion process.

- Example of running DOCA Bench from the host side using the BlueField for the remote side using `doca_comch` as the communications method:

  ```
  --companion-connection-string "proto=dcc,mode=DPU,user=bob,addr=172.17.0.1,dev=03:00.0,rep=d8:00.0"
  ```

- Example of running DOCA Bench from the BlueField side using the host for the remote side using `doca_comch` as the communications method:

  ```
  --companion-connection-string "proto=dcc,mode=host,user=bob,addr=172.17.0.1,dev=d8:00.0"
  ```

- Example of running DOCA Bench on one host with the companion on another host using TCP as the communications method:

  ```
  --companion-connection-string "proto=tcp,user=bob,addr=172.17.0.1,port=12345,dev=d8:00.0"
  ```

  For `doca_rdma` only.

7.3.15.6.2 --companion-core-list

Works the same way as `--core-list` but defines the cores to be used on the companion side.

Must be at least as large as the `--core-list`.

7.3.15.6.3 --companion-core-mask

Works the same way as `--core-mask` but defines the cores to be used on the companion side.

> ⚠ Must be at least as large as the `--core-mask`.

7.3.15.7 Sweep Tests

7.3.15.7.1 --sweep

DOCA Bench supports executing a set of tests based on a number of value ranges. For example, to understand the performance of multi-threading, the user may wish to run the same test for various CPU core counts. They may also wish to vary more than one aspect of the test. Providing one or more `--sweep` parameters activates sweep test mode where every combination of values is tested with a single invocation of DOCA Bench.

The following is a list of the supported sweep test options:

- `core-count`
- `data-provider-input-file`
- `data-provider-job-count`
- `gather-value`
- `mtu-size`
- `receive-queue-size`
- `send-queue-size`
- `threads-per-core`
- `task-pool-size`
- `uniform-job-size`
- `doption.mmo.log_qp_depth`
- `doption.mmo.log_num_qps`
- `doca_rdma.transport-type`
- `doca_rdma.gid-index`

Sweep test argument values take one of three forms:

- `--sweep param,start_value,end_value,+N`
- `--sweep param,start_value,end_value,*N`
- `--sweep param,value1,...,valueN`

Sweep core count and input file example:

```
--sweep core-count,1,8,*2 -sweep data-provider-input-file,file1.bin,file2.bin
```

This would sweep cores 1-8, inclusive, multiplying the value each time as 1,2,4,8 and two different input files resulting in a cumulative 8 test cases:

Iteration Number	Core Count	Input File
1	1	`file1.bin`
2	2	`file1.bin`
3	4	`file1.bin`
4	8	`file1.bin`
5	1	`file2.bin`
6	2	`file2.bin`
7	4	`file2.bin`
8	8	`file2.bin`

7.3.15.8 Queries

7.3.15.8.1 Device Capabilities

DOCA Bench allows the querying of a device to report which step types are available as well as information of valid configuration options for each step. A device must be specified:

```
tools/bench/doca_bench --device 03:00.0 --query device-capabilities
```

For each supported library, this would report:

- Capable – if that library is enabled in DOCA Bench at compile time (if not capable, installing the library would not make it become available to bench)
- Installed – if the library is installed on the machine executing the query (if not installed, installing it would make it available to bench)
- Library wide attributes
- A list of supported task types (~= step name)
    - If the task type is supported
    - Task specific attributes/capabilities

```
doca_compress:
    Capable: yes
    Installed: yes
    Tasks:
        compress::deflate:
```

```
            Supported: no
        compress::lz4:
            Supported: no
        compress::lz4_stream:
            Supported: no
        decompress::deflate:
            Supported: yes
            Max buffer length: 134217728
        decompress::lz4:
            Supported: yes
            Max buffer length: 134217728
        decompress::lz4_stream:
            Supported: yes
            Max buffer length: 134217728
```

In addition to querying BlueField devices, GPU devices can also be queried. This requires DOCA GPUNetIO and the DOCA Bench extension package to be installed. A GPU device must be specified:

```
tools/bench/doca_bench --gpu b5:00.0 --query device-capabilities
```

7.3.15.8.2 Supported Sweep Attributes

Shows the possible parameters that can be used with the sweep test parameter

```
tools/bench/doca_bench --query sweep-properties
```

Example output:

```
Supported query properties: [
        core-count

```

7.3.16 Test Memory Footprint

DOCA Bench allocates memory for all the tasks required by the test based on the input buffer size, output/intermediate buffer size, number of cores, number of threads, and number of jobs in use. All jobs contain an input buffer, an output buffer, and an intermediate buffer. The input buffer is immutable and sized based on the data provider in use. The output and intermediate buffers are sized based on the users specification or automatically calculated at the users request. For a library which produces the same amount of output as it consumes (e.g., `doca_dma`), typically the user should set the buffers all to the same size to make things as efficient as possible.

The memory footprint for job buffers can be calculated as: `(number-of-tasks) * (number-of-cores) * (number-of-threads-per-core) * (input-buffer-size +`

`(output/intermediate-buffer-size * 2))`. For a 1KB job with the default of 32 jobs, 1 core, and 1 core per thread, the memory footprint would be 96KB.

For sweep testing and structured data input, it can be difficult to pick a suitable output buffer size so the user may choose to specify 0 and have DOCA Bench try all the tasks once to calculate the required output buffer sizes. This only has a cost in terms of time taken to perform the calculation. After this, there is no difference between auto-sizing and manually sizing the jobs output buffers.

When running DOCA Bench on the BlueField and on some host OSs, it may be necessary to increase the limit of how much memory the process can acquire. Consult your OS's documentation for details of how to do this.

7.3.17 GPUNetIO Benchmarks

DOCA Bench supports benchmarks where task submission and processing are offloaded to a GPU using DOCA GPUNetIO.

Requirements:

- DOCA GPUNetIO, DOCA Bench Extension, and NVIDIA GDRCopy library..
- The `GDRCOPY_PATH_L` environment variable must be set.

Limitations:

- Both `doca_bench` and `doca_bench_companion` must run as `sudo` or root.
- Only throughput testing is currently supported. However, test duration can be defined by time, job count, or byte limits.
- Use of multiple CPU cores with `doca_bench` and `doca_bench_companion` is not supported.
- Multi-step tests are not supported.

7.3.17.1 Controlling CUDA Threads

You can control the number of CUDA threads used for execution by specifying the block count and threads per block.

- `--attribute doca_gpunetio.threads-per-block=<number>` (Default: 32)
- `--attribute doca_gpunetio.num-blocks=<number>` (Default: 1)

$$Total_Threads = threads_per_block \times num_blocks$$

7.3.17.2 GPUNetIO Eth

This benchmark uses DOCA GPUNetIO Eth to transmit or receive Ethernet packets to/from a remote host.

- A GPU is required only on the `doca_bench` side. The remote side runs `doca_bench_companion` as a CPU-driven packet generator or sink.
- Benchmark modes: Unidirectional Send, Unidirectional Receive, and Bidirectional

For unidirectional receive and bidirectional, two additional attributes can be configured:

- `--attribute doca_gpunetio.eth-rx-timout-ns=<number>` (default 2000)
- `--attribute doca_gpunetio.eth-rx-max-rx-packets=<number>` (default 2048)

Example DOCA Bench commands for GPUNetIO Eth bidirectional test:

```
tools/bench/doca_bench \
  --pipeline-steps doca_gpunetio::eth_bidir \
  --device b1:00.0 --gpu b5:00.0 \
  --data-provider random-data \
  --uniform-job-size 512 \
  --run-limit-seconds 1 \
  --job-output-buffer-size 512 \
  --companion-connection-string proto=tcp,dev=d8:00.0,user=bob,addr=172.17.0.1,port=12345 \
  --companion-core-mask 0x1
```

7.3.18 DOCA Bench Sample Invocations

7.3.18.1 Overview

This guide provides examples of various invocations of the tool to help provide guidance and insight into it and the feature under test.

> To make the samples clearer, certain verbose output and repeated information has been removed or shortened, in particular to output of the configuration or defaults when DOCA Bench is first executed is removed.

> The command line options may need to be updated to suit your environment (e.g., TCP addresses, port numbers, interface names, usernames). See the "Command-line Parameters" section for more information.

7.3.18.2 DOCA Eth Receive Sample

- This test invokes DOCA Bench to run in Ethernet receive mode, configured to receive Ethernet frames of size 1500 bytes.
- The test runs for 3 seconds using a single core and use a maximum burst size of 512 frames.
- The test runs in the default throughput mode, with throughput figures displayed at the end of the test run.
- The companion application uses 6 cores to continuously transmit Ethernet frames of size 1500 bytes until it is stopped by DOCA Bench.

7.3.18.2.1 Command Line

```
doca_bench --core-mask 0x02 \
                                --pipeline-steps doca_eth::rx \
                                    --device b1:00.1 \
                                    --data-provider random-data \
                                    --uniform-job-size 1500 \
                                    --run-limit-seconds 3 \
                                    --attribute doca_eth.max-burst-size=512 \
                                    --companion-connection-string
proto=tcp,addr=10.10.10.10,port=12345,user=bob,dev=ens4f1np1 \
                                    --attribute doption.companion_app.path=/opt/mellanox/doca/tools/
doca_bench_companion \
                                    --companion-core-list 6 \
                                    --job-output-buffer-size 1500 \
                                    --mtu-size raw_eth
```

7.3.18.2.3 Results Overview

As a single core is specified, there is a single section of statistics output displayed.

7.3.18.3 DOCA Eth Send Sample

- This test invokes DOCA Bench to run in Ethernet send mode, configured to transmit Ethernet frames of size 1500 bytes
- Random data is used to populate the Ethernet frames
- The test runs for 3 seconds using a single core and uses a maximum burst size of 512 frames
- L3 and L4 checksum offloading is not enabled
- The test runs in the default throughput mode, with throughput figures displayed at the end of the test run
- The companion application uses 6 cores to continuously receive Ethernet frames of size 1500 bytes until it is stopped by DOCA Bench

7.3.18.3.1 Command Line

```
doca_bench --core-mask 0x02 \
                                    --pipeline-steps doca_eth::tx \

7.3.18.3.3 Results Overview

As a single core is specified, there is a single section of statistics output displayed.

7.3.18.4 Host-side AES-GCM Decrypt Sample

- This test invokes DOCA Bench on the x86 host side to run the AES-GM Decryption step
- A file-set file is used to indicate which file is to be decrypted. The content of the file-set file lists the filename to be decrypted.
- The key to be used for the encryption and decryption is specified using the `doca_aes_gcm.key` -file attribute. This contains the key to be used.
- It will run until 5000 jobs have been processed
- It runs in the precision-latency mode, with latency and throughput figures displayed at the end of the test run
- A core mask is specified to indicate that cores 12, 13, 14, and 15 are to be used for this test

7.3.18.4.1 Command Line

```
doca_bench  --mode precision-latency \
            --core-mask 0xf000 \
            --warm-up-jobs 32 \
            --device 17:00.0 \
            --data-provider file-set \
            --data-provider-input-file aes_64_128.fileset \
            --run-limit-jobs 5000 \
            --pipeline-steps doca_aes_gcm::decrypt \
            --attribute doca_aes_gcm.key-file='aes128.key' \
            --job-output-buffer-size 80
```

```

7.3.18.4.3 Results Overview

Since a core mask is specified but no core count, then all cores in the mask are used.

There is a section of statistics displayed for each core used as well as the aggregate statistics.

7.3.18.5 BlueField-side AES-GCM Encrypt Sample

- This test invokes DOCA Bench on the BlueField side to run the AES-GM encryption step
- A text file of size 2KB is the input for the encryption stage
- The key to be used for the encryption and decryption is specified using the `doca_aes_gcm.key` attribute
- It runs until 2000 jobs have been processed
- It runs in the bulk-latency mode, with latency and throughput figures displayed at the end of the test run
- A single core is specified with 2 threads

7.3.18.5.1 Command Line

```
doca_bench  --mode bulk-latency \
            --core-list 3 \
            --threads-per-core 2 \
            --warm-up-jobs 32 \
            --device 03:00.0 \
            --data-provider file \
            --data-provider-input-file plaintext_2k.txt \
            --run-limit-jobs 2000 \
            --pipeline-steps doca_aes_gcm::encrypt \

7.3.18.5.3 Results Overview

Since a single core is specified, there is a single section of statistics output displayed.

7.3.18.6 Host-side AES-GCM Encrypt and Decrypt Sample

- This test invokes DOCA Bench on the host side to run 2 AES-GM steps in the pipeline, first to encrypt a text file and then to decrypt the associated output from the encrypt step
- A text file of size 2KB is the input for the encryption stage

- The `input-cwd` option instructs DOCA Bench to look in a different location for the input file, in the parent directory in this case
- The key to be used for the encryption and decryption is specified using the `doca_aes_gcm.key`-file attribute, indicating that the key can be found in the specified file
- It runs until 204800 bytes have been processed
- It runs in the default throughput mode, with throughput figures displayed at the end of the test run

7.3.18.6.1 Command Line

```
doca_bench  --core-mask 0xf00 \
            --core-count 1 \
            --warm-up-jobs 32 \
            --device 17:00.0 \
            --data-provider file \
            --input-cwd ../. \
            --data-provider-input-file plaintext_2k.txt \
            --run-limit-bytes 204800 \
            --pipeline-steps doca_aes_gcm::encrypt,doca_aes_gcm::decrypt \
            --attribute doca_aes_gcm.key-file='aes128.key' \
            --uniform-job-size 2048 \
            --job-output-buffer-size 4096
```

7.3.18.6.2 Results Output

```

7.3.18.7.3 Results Overview

As a single core has been specified with a thread count of 2, there are statistics displayed for each thread as well as the aggregate statistics.

It can also be observed that 2 threads are started on core 1 with each thread executing the warm-up jobs.

The contents of the `/tmp/sha_256_test.csv` are shown below. It can be seen that the configuration used for the test and the associated statistics from the test run are listed:

```
cfg.companion.connection_string,cfg.pipeline.steps,cfg.pipeline.use_remote_input_buffers,cfg.pipeline.use_remote_ou
tput_buffers,cfg.pipeline.bulk_latency.lower_bound,cfg.pipeline.bulk_latency.bucket_width,cfg.run_limit.duration,cf

```

7.3.18.8 Host-side SHA with CSV Appended Output File Sample

- This test invokes DOCA Bench on the Host side to execute the SHA operation using the SHA512 algorithm and to create a csv file containing the test configuration and statistics,
- The command is repeated with the added option of csv-append-mode. This instructs DOCA Bench to append the test run statistics to the existing csv file.
- A list of 1 core is provided with a count of 2 threads per core.

7.3.18.8.1 Command Line

1. Create the initial `/tmp/sha_512_test.csv` file:

```
doca_bench    --core-list 2 \
                --threads-per-core 2 \
                --pipeline-steps doca_sha \
                --device d8:00.0 \
                --data-provider random-data \
                --uniform-job-size 2048 \
                --job-output-buffer-size 2048 \
                --run-limit-seconds 3 \
                --attribute doca_sha.algorithm=sha512 \
                --warm-up-jobs 100 \
                --csv-output-file /tmp/sha_512_test.csv
```

2. The second command is:

```
./doca_bench    --core-list 2 \
                --threads-per-core 2 \
                --pipeline-steps doca_sha \
                --device d8:00.0 \
                --data-provider random-data \
                --uniform-job-size 2048 \
                --job-output-buffer-size 2048 \
                --run-limit-seconds 3 \
                --attribute doca_sha.algorithm=sha512 \
                --warm-up-jobs 100 \
                --csv-output-file /tmp/sha_512_test.csv \
                --csv-append-mode
```

   This causes DOCA Bench to append the configuration and statistics from the second command run to the `/tmp/sha_512_test.csv` file.

7.3.18.8.2 Results Output

This is a snapshot of the results output from the first command run:

7.3.18.9 BlueField-side SHA with Transient Statistics Sample

- This test invokes DOCA Bench on the BlueField side to execute the SHA operation using the SHA1 algorithm and to display statistics every 2000 milliseconds during the test run
- A list of 3 cores is provided with a count of 2 threads per core and a core-count of 1
- The core-count instructs DOCA Bench to use the first core number in the core list, in this case core number 2

7.3.18.9.1 Command Line

```
doca_bench    --core-list 2,3,4 \
                --core-count 1 \
                --threads-per-core 2 \
                --pipeline-steps doca_sha \
                --device 03:00.0 \
                --data-provider random-data \
                --uniform-job-size 2048 \
                --job-output-buffer-size 2048 \
                --run-limit-seconds 3 \
                -attribute doca_sha.algorithm=sha1 \
                --warm-up-jobs 100 \
                --rt-stats-interval 2000
```

7.3.18.9.3 Results Overview

Although a core list of 3 cores has been specified, the core-count value of 1 instructs DOCA Bench to use the first entry in the core list.

It can be seen that as a thread-count of 2 has been specified, there are 2 threads created on core 2.

A transient statistics interval of 2000 milliseconds has been specified, and the transient statistics per thread can be seen, as well as the final aggregate statistics.

7.3.18.10 Host-side Local DMA with Core Sweep Sample

- This test invokes DOCA Bench to execute a local DMA operation on the host
- It specifies that a core sweep should be carried out using core counts of 1, 2, and 4 using the option `--sweep core-count,1,4,*2`

- Test output is to be saved in a CSV file `/tmp/dma_sweep.csv` and a filter is applied so that only statistics information is recorded. No configuration information is to be recorded.

7.3.18.10.1 Command Line

```
doca_bench    --core-mask 0xff \
                --sweep core-count,1,4,*2 \
                --pipeline-steps doca_dma \
                --device d8:00.0 \
                --data-provider random-data \
                --uniform-job-size 2048 \
                --job-output-buffer-size 2048 \
                --run-limit-seconds 5 \
                --csv-output-file /tmp/dma_sweep.csv \
                --csv-stats "stats.*"
```

```

7.3.18.11 Host-side Local DMA with Job Size Sweep Sample

This test invokes DOCA Bench to execute a local DMA operation on the host.

It specifies that a uniform job size sweep should be carried out using job sizes 1024 and 2048 using the option `--sweep uniform-job-size,1024,2048`.

Test output is to be saved in a CSV file `/tmp/dma_sweep_job_size.csv` and collection of environment information is enabled.

7.3.18.11.1 Command Line

```
doca_bench    --core-mask 0xff \
                --core-count 1 \
                --pipeline-steps doca_dma \
                --device d8:00.0 \
                --data-provider random-data \
                --sweep uniform-job-size,1024,2048 \
                --job-output-buffer-size 2048 \
                --run-limit-seconds 5 \
                --csv-output-file /tmp/dma_sweep_job_size.csv \
                --enable-environment-information
```

7.3.18.12 BlueField-side Remote DMA Sample

- This test invokes DOCA Bench to execute a remote DMA operation on the host
- It specifies the companion connection details to be used on the host and that remote output buffers are to be used

7.3.18.12.1 Command Line

```
doca_bench  --core-list 12 \
            --pipeline-steps doca_dma \
            --device 03:00.0 \
            --data-provider random-data \
```

```
            --uniform-job-size 2048 \
            --job-output-buffer-size 2048 \
            --use-remote-output-buffers \
            --companion-connection-string proto=tcp,port=12345,mode=host,dev=17:00.0,user=bob,addr=10.10.10.10 \
            --run-limit-seconds 5
```

7.3.18.12.2 Results Overview

```

```

7.3.18.12.3 Results Overview

None.

7.3.18.13 Compress BlueField-side Sample

> ⚠ This test is relevant for BlueField-2 only.

- This test invokes DOCA Bench to run compression using random data as input
- The compression algorithm specified is "deflate"

7.3.18.13.1 Command Line

```
doca_bench    --core-list 2 \
                --pipeline-steps doca_compress::compress \
                --device 03:00.0 \
                --data-provider random-data \
                --uniform-job-size 2048 \
                --job-output-buffer-size 4096 \
                --run-limit-seconds 3 \
                --attribute doca_compress.algorithm="deflate"
```

7.3.18.13.2 Result Output

```

7.3.18.13.3 Results Overview

None

7.3.18.14 BlueField-side Decompress LZ4 Sample

- This test invokes DOCA Bench to run decompression using random data as input
- This test specifies a data provider of file set which contains the filename of an LZ4 compressed file
- Remote input buffers are specified to be used for the input jobs
- It specifies the companion connection details to be used on the host for the remote input buffers

7.3.18.14.1 Command Line

```
doca_bench --core-list 12 \
            --pipeline-steps doca_compress::decompress \
            --device 03:00.0 \
            --data-provider file-set \
            --data-provider-input-file lz4_compressed_64b_buffers.fs \
            --job-output-buffer-size 4096 \
            --run-limit-seconds 3 \
            --attribute doca_compress.algorithm="lz4" \
            --use-remote-output-buffers \
            --companion-connection-string proto=tcp,port=12345,mode=host,dev=17:00.0,user=bob,addr=10.10.10.10
```

7.3.18.14.2 Results Output

```
Executing...
Worker thread[0](core: 12) [doca_compress::decompress] started...
Worker thread[0] Executing 100 warm-up tasks using 100 unique tasks

7.3.18.14.3 Results Comment

None

7.3.18.15 Host-side EC Creation in Bulk Latency Mode Sample

- This test invokes DOCA Bench to run the EC creation step.
- It runs in bulk latency mode and specifies the `doca_ec` attributes of `data_block_count`, `redundancy_block_count`, and `matrix_type`

7.3.18.15.1 Command Line

```
doca_bench --mode bulk-latency \
            --core-list 12 \
            --pipeline-steps doca_ec::create \
            --device 17:00.0 \
            --data-provider random-data \
            --uniform-job-size 1024 \
            --job-output-buffer-size 1024 \
            --run-limit-seconds 3 \
            --attribute doca_ec.data_block_count=16 \
            --attribute doca_ec.redundancy_block_count=16 \
            --attribute doca_ec.matrix_type=cauchy
```

7.3.18.15.2 Results Output

Bulk latency output will be similar to that presented in section "BlueField-side Decompress LZ4 Sample".

7.3.18.15.3 Results Comment

Bulk latency output will be similar to that presented earlier on this page.

7.3.18.16 BlueField-side EC Creation in Precision Latency Mode Sample

- This test invokes DOCA Bench to run the EC creation step
- It runs in precision latency mode and specifies the `doca_ec` attributes of `data_block_count`, `redundancy_block_count`, and `matrix_type`

7.3.18.16.1 Command Line

```
doca_bench    --mode precision-latency \
              --core-list 12 \
              --pipeline-steps doca_ec::create \
              --device 03:00.0 \
              --data-provider random-data \
              --uniform-job-size 1024 \
              --job-output-buffer-size 1024 \
              --run-limit-jobs 5000 \
              --attribute doca_ec.data_block_count=16 \
              --attribute doca_ec.redundancy_block_count=16 \
```

```
                --attribute doca_ec.matrix_type=cauchy
```

7.3.18.16.2 Results Output

None

7.3.18.16.3 Results Comment

Precision latency output will be similar to that presented earlier on this page.

7.3.18.17 Comch Consumer from Host Side Sample

- This test invokes DOCA Bench in Comch consumer mode using a core-list on host side and BlueField side
- The run-limit is 500 jobs

7.3.18.17.1 Command Line

```
./doca_bench --core-list 4 --warm-up-jobs 32 --pipeline-steps doca_comch::consumer --device ca:00.0 --data-provider
random-data --run-limit-jobs 500 --core-count 1 --uniform-job-size 4096 --job-output-buffer-size 4096 --companion-
connection-string proto=tcp,mode=dpu,dev=03:00.0,user=bob,addr=10.10.10.10,port=12345 --attribute
dopt.companion_app.path=<path to DPU doca_bench_companion application location> --data-provider-job-count 256 --
companion-core-list 12
```

7.3.18.17.2 Results Output

```
[main] Completed! tearing down...
Aggregate stats
        Duration:      1415 micro seconds
        Enqueued jobs: 500
        Dequeued jobs: 500
        Throughput:    000.353 MOperations/s
        Ingress rate:  000.000 Gib/s
        Egress rate:   010.782 Gib/s
```

7.3.18.17.3 Results Comment

The aggregate statistics show the test completed after 500 jobs were processed.

7.3.18.18 Host-side Comch Producer Sample

- This test invokes DOCA Bench in Comch producer mode using a core-mask on the host side and BlueField side

- The run-limit is 1000 jobs

7.3.18.18.1 Command Line

```
doca_bench    --core-list 4 \
                --warm-up-jobs 32 \
                --pipeline-steps doca_comch::producer \
                --device ca:00.0 \
                --data-provider random-data \
                --run-limit-jobs 500 \
                --core-count 1 \
                --uniform-job-size 4096 \
                --job-output-buffer-size 4096 \
                --companion-connection-string proto=tcp,mode=dpu,dev=03:00.0,user=bob,addr=10.10.10.10,port=12345 \
                --attribute dopt.companion_app.path=<path to DPU doca_bench_companion location> \
                --data-provider-job-count 256 \
                --companion-core-list 12
```

7.3.18.18.2 Results Overview

```
[main] Completed! tearing down...
Aggregate stats
        Duration:       407 micro seconds
        Enqueued jobs: 500
        Dequeued jobs: 500
        Throughput:     001.226 MOperations/s
        Ingress rate:   037.402 Gib/s
        Egress rate:    000.000 Gib/s
```

7.3.18.18.3 Results Comment

The aggregate statistics show the test completed after 500 jobs were processed.

7.3.18.19 Host-side RDMA Send Sample

- This test invokes DOCA Bench in RDMA send mode using a core-list on the send and receive side
- The send queue size is configured to 50 entries

7.3.18.19.1 Command Line

```
doca_bench  --pipeline-steps doca_rdma::send \
            --device d8:00.0 \
            --data-provider random-data \
            --uniform-job-size 2048 \
            --job-output-buffer-size 2048 \
            --run-limit-seconds 3 \
            --send-queue-size 50 \
            --companion-connection-string proto=tcp,addr=10.10.10.10,port=12345,user=bob,dev=ca:00.0 \
            --companion-core-list 12 \
            --core-list 12
```

7.3.18.19.2 Results Output

```
Test permutations: [
        Attributes: []
        Uniform job size: 2048
        Core count: 1
        Per core thread count: 1
        Task pool size: 1024
        Data provider job count: 128
        MTU size: -- not configured --
        SQ depth: 50
        RQ depth: -- not configured --
        Input data file: -- not configured --
]
```

7.3.18.19.3 Results Comment

The configuration output shows the send queue size configured to 50.

7.3.18.20 Host-side RDMA Receive Sample

- This test invokes DOCA Bench in RDMA receive mode using a core-list on the send and receive side
- The receive queue size is configured to 100 entries

7.3.18.20.1 Command Line

```
doca_bench  --pipeline-steps doca_rdma::receive \
            --device d8:00.0 \
            --data-provider random-data \
            --uniform-job-size 2048 \
            --job-output-buffer-size 2048 \
            --run-limit-seconds 3 \
            --receive-queue-size 100 \
            --companion-connection-string proto=tcp,addr=10.10.10.10,port=12345,user=bob,dev=ca:00.0 \
            --companion-core-list 12 \
            --core-list 12
```

7.3.18.20.2 Results Output

```
Test permutations: [
        Attributes: []
        Uniform job size: 2048
        Core count: 1
        Per core thread count: 1
        Task pool size: 1024
        Data provider job count: 128
        MTU size: -- not configured --
        SQ depth: -- not configured --
        RQ depth: 100
        Input data file: -- not configured --
]
```

7.3.18.20.3 Results Overview

The configuration output shows the receive queue size configured to 100.

7.4 DOCA Capabilities Print Tool

This document provides instruction on the usage of the DOCA Capabilities Print Tool.

7.4.1 Introduction

This tool is used to print all the available DOCA libraries and devices. For each DOCA device, the tool prints its representor devices and the capabilities it supports in each DOCA library.

7.4.2 Prerequisites

DOCA 2.6.0 and higher.

7.4.3 Description

This tool can be executed on the host or Arm sides.

The following capabilities are supported by this tool:

- DOCA device list – print the PCIe device of every available DOCA device and its attributes
- DOCA representor device list – for every DOCA device, print the PCIe device of every available DOCA representor device and its attributes
- DOCA library list – print the available DOCA libraries supported by the running OS and their availability for specific OSs
- DOCA library capabilities – for every DOCA device, print the capabilities it supports in every DOCA library
- DOCA logger list – print the available logger names of DOCA libraries

7.4.4 Execution

- To print all the available DOCA devices and their capabilities, run:

```
/opt/mellanox/doca/tools/doca_caps --list-devs
```

Printing the capabilities of a specific DOCA device can be done using the `--pci-addr` flag.

Example output:

```
/opt/mellanox/doca/tools/doca_caps --list-devs
PCI: 0000:08:00.0

- To print the available logger names of DOCA libraries, run:

```
/opt/mellanox/doca/tools/doca_caps --list-loggers
```

Example output:

```
/opt/mellanox/doca/tools/doca_caps --list-loggers
    CORE
    ARGP
    AES_GCM
    DMA
    APSH
    COMCH
    COMPRESS
    DEVEMU
    DPA
    DPDK_BRIDGE
    ERASURE_CODING
    ETH
    FLOW
    FLOW::DRIVER
    FLOW::DRIVER::RUNTIME
    MGMT
    PCC
    RDMA
    SHA
    TELEMETRY
    UROM
```

7.5 DOCA Comm Channel Admin Tool

This document provides instructions on the usage of the DOCA Comm Channel Admin Tool.

7.5.1 Introduction

The Comm Channel Admin Tool is used to print a snapshot of DOCA Comch (comm channel) connections:

- On the BlueField Arm side, it includes DOCA Comch servers and their current connection information
- On the host side, it includes all active client connections and the server they are connected to
- Only client-to-server control channels are reported; fast path producer/consumer channels are not.

7.5.2 Prerequisites

The Comm Channel Admin Tool is for Linux only and requires an up-to-date BFB bundle or DOCA host packages of at least 2.7, which include in the Resource dump binary.

7.5.3 Description and Execution

The Comm Channel Admin Tool can be executed on the host or Arm CPUs. By default, the tool scans all available PCIe slots to detect supported DOCA devices and reports any Comch information available.

The tool can be run on BlueField Arm or x86 host using the following command:

```
/opt/mellanox/doca/tools/doca_comm_channel_admin
```

7.5.3.1 Sample Output from BlueField Arm

On the BlueField Arm side, any active DOCA Comch servers are be reported:

```
SERVERS:
+-------------------------------------------------------------------------------------+
| Server name      | PID        | Connections   | PCIe          | Interface Name      |
+=====================================================================================+
| comch1           | 1898009    | 2/512         | 0000:03:00.0  | p0                  |
+-------------------------------------------------------------------------------------+
| comch3           | 1898011    | 1/512         | 0000:03:00.0  | p0                  |
+-------------------------------------------------------------------------------------+
| comch6           | 1898014    | 3/512         | 0000:03:00.0  | p0                  |
+-------------------------------------------------------------------------------------+
| comch2           | 1898010    | 1/512         | 0000:03:00.0  | p0                  |
+-------------------------------------------------------------------------------------+
| comch7           | 1898015    | 1/512         | 0000:03:00.0  | p0                  |
+-------------------------------------------------------------------------------------+
| comch5           | 1898013    | 4/512         | 0000:03:00.0  | p0                  |
+-------------------------------------------------------------------------------------+
| comch8           | 1898016    | 2/512         | 0000:03:00.0  | p0                  |
+-------------------------------------------------------------------------------------+
| comch4           | 1898012    | 0/512         | 0000:03:00.0  | p0                  |
+-------------------------------------------------------------------------------------+
```

The following information is available:

- Server Name – the name assigned to the server
- PID – the Linux process ID of the application which created the server
- Connections – the number of connections active on the server out of the total allowed (e.g., 2/512 means 2 active connections of a maximum of 512)
- PCIe – the PCIe address of the device which the server has been detected on
- Interface Name – the interface name associated with the PCIe address

Connections may also be displayed on the BlueField Arm like on x86. This occurs if SF ports are detected here. The interface name associated with the PCIe address indicates the SF port.

7.5.3.2 Sample Output from x86

The x86 host cannot run DOCA Comch servers. Therefore, individual client connections are reported:

```
CONNECTIONS:
+-------------------------------------------------------------------+
| Server name      | PID        | PCIe          | Interface Name     |
+===================================================================+
| comch6           | 299693     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch3           | 299688     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch2           | 299687     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch5           | 299689     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch5           | 299692     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch7           | 299696     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch5           | 299690     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch6           | 299694     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch8           | 299697     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch6           | 299695     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch8           | 299698     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch1           | 299686     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch5           | 299691     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
| comch1           | 299685     | 0000:3b:00.0  | ens1f0np0          |
+-------------------------------------------------------------------+
```

The following information is available:

- Server Name – the name of the BlueField Arm server that a client has connected to
- PID – the Linux process ID of the application running a DOCA Comch client
- PCIe – the PCIe address of the BlueField networking platform which the destination server is running on
- Interface Name – the interface name associated with the PCIe address

7.6 DPA Tools

7.6.1 Introduction

DPA tools are a set of executables that enable the DPA application developer and the system administrator to manage and monitor DPA resources and to debug DPA applications.

7.6.2 List of Tools

Tool	CLI Name
DPACC Compiler	`dpacc`

This document describes DOCA DPACC compiler and provides instructions about DPA toolchain setup and usage.

7.6.3.1 Introduction

DPACC is a high-level compiler for the DPA processor which compiles code targeted for the data-path accelerator (DPA) processor into a device executable and generates a DPA program.

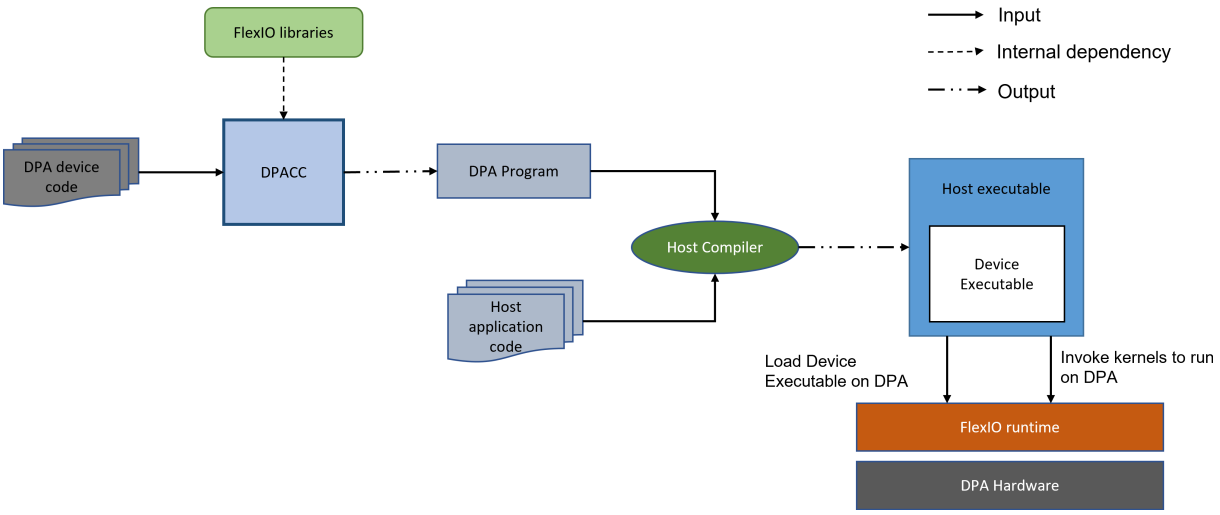
The DPA program is a host library with interfaces encapsulating the device executable. This DPA program is linked with the host application to generate a host executable. The host executable can invoke the DPA code through FlexIO runtime API.

DPACC uses DPA compiler (`dpa-clang`) to compile code targeted for DPA. `dpa-clang` is part of the DPA toolchain package which is an LLVM-based, cross-compiling, bare-metal toolchain. It provides Clang compiler, LLD linker targeting DPA architecture, and other utilities.

Glossary

Term	Definition
Device	DPA as present on the BlueField DPU
Host	CPU that launches the device code to run on the DPA
Device function	Any C function that runs on the DPA device
DPA global function	Device function that is the point of entry when offloading any work on DPA
Host compiler	Compiler used to compile the code targeting the host CPU
Device compiler	Compiler used to compile code targeting the DPA
Fatbinary	File that contains code for multiple target DPA architectures
DPA program	Host library that encapsulates the DPA device executable (`.elf`) and host stubs which are used to access the device executable

7.6.3.1.1 Offloading Work on DPA



To invoke a DPA function from a host, the following things are required:

- DPA device code – C programs, targeted to run on the DPA. The DPA device code may contain one or more entry functions.
- Host application code – the corresponding host application. Refer to DPA Subsystem for more details
- Runtime – FlexIO or DOCA DPA library provides the runtime

The generated DPA program, when linked with a host application results in a host executable which also contains the device executable. The host application oversees loading the device executable on the device.

7.6.3.1.2 DPACC Predefined Macros

DPACC predefines the following macros:

`__DPA__`	Defined when compiling device code file
`__NV_DPA`	Defined to the target DPA hardware identifier macros See Architecture Macros for more details.
`__DPA_MAJOR__`	Defined to the major version number of DPACC
`__DPA_MINOR__`	Defined to the minor version number of DPACC
`__DPA_PATCH__`	Defined to the patch version number of DPACC

7.6.3.1.3 Writing DPA Applications

DPA device code is a C code with some restrictions and special definitions.

FlexIO or DOCA-DPA APIs provide interfaces to DPA.

7.6.3.1.3.1 Language Support

The DPA is programmed using a subset of the C11 language standard. The compiler documents any constructs that are not available. Language constructs, where available, retain their standard definitions.

7.6.3.1.3.2 Restrictions on DPA Code

- Use of C thread local storage is not allowed for any variables
- Identifiers with `_dpacc/__dpacc` prefix are reserved by the compiler. Use of such identifiers may result in an error or undefined behavior
- DPA processor does not have native floating-point support; floating-point operations are disabled

7.6.3.1.3.3 DPA RPC Functions

A remote procedure call function is a synchronous call that triggers work in DPA and waits for its completion. These functions return a type `uint64_t` value. They are annotated with a `__dpa_rpc__` attribute.

7.6.3.1.3.4 DPA Global Functions

A DPA global function is an event handler device function referenced from the host code. These functions do not return anything. They are annotated with a `__dpa_global__` attribute.

For more information, refer to DPA Subsystem.

7.6.3.1.3.5 Characteristics of Annotated Functions

- Global functions must have `void` return type and RPC functions must have `uint64_t` return type
- Annotated functions cannot accept C pointers and arrays as arguments (for example, `void glob_func (int *ptr, int arr[])`)
- Annotated functions cannot accept a variable number of arguments
- Inline specifier is not allowed on annotated functions

7.6.3.1.3.6 Handling User-defined Data Types

User-defined data types, when used as global function arguments, require special handling. They must be annotated with a `__dpa_global__` attribute.

If the user-defined data type is `typedef`'d, the `typedef` statement must be annotated with a `__dpa_global__` attribute along the data type itself.

7.6.3.1.3.7 Characteristics of Annotated Types

- They must have a copy of the definition in all translation units where they are used as global function arguments
- They cannot have pointers, variable length arrays, and flexible arrays as members
- Fixed-size arrays as C structure members are supported
- These characteristics apply recursively to any user-defined/ `typedef` 'd types that are members of an annotated type

DPACC processes all annotated functions along with annotated types and generates host and device interfaces to facilitate the function launch.

7.6.3.1.3.8 DPA Intrinsics

DPA features such as fences and processor-specific instructions are exposed via intrinsics by the DPA compiler. All intrinsics defined in the header file `dpaintrin.h` are guarded by the `DPA_INTRIN_VERSION_USED` macro. The current `DPA_INTRIN_VERSION` is `1.3`.

Example:

```
#define DPA_INTRIN_VERSION_USED (DPA_INTRIN_VERSION(1, 3))
#include <dpaintrin.h>
…
__dpa_thread_writeback_window();   // Fence for write barrier
```

For more information, refer to DPA Subsystem.

7.6.3.2 Prerequisites

Package	Instructions
Host compiler	Compiler specified through `hostcc` option. Both `gcc` and `clang` are supported. ⚠ Minimum supported version for `clang` as `hostcc` is `clang 3.8.0`.
Device compiler	The default device compiler is "DPA compiler". Installing the DPACC package also installs the DPA compiler binaries `dpa-clang`, `dpa-ar`, `dpa-nm` and `dpa-objdump`. ⚠ `dpa-clang` is the only supported device compiler.
FlexIO SDK and C library	Available as part of the DOCA software package. The DPA toolchain does not provide a C library and corresponding headers. Users are expected to use the C library for DPA from the FlexIO SDK.

7.6.3.3 Description

7.6.3.3.1 DPACC Inputs and Outputs

DPACC can produce DPA programs in a single command by accepting all source files as an input. DPACC also offers the flexibility of producing DPA object files or libraries from input files.

DPA object files contain both host-stub objects (DPACC-generated interfaces) and device objects. These DPA object files can later be given to DPACC as input to produce the DPA library.

Phase	Option Name	Default Output File Name
Compile input device code files to DPA object files	`--compile` or `-c`	`.dpa.o` appended to the name of each input source file
Compile and link the input device code files/ DPA object files, and produce a DPA program	No specific option	No default name, output file name must be specified
Compile and build DPA library from input device code files/DPA object files	`--gen-libs` or `-gen-libs`	No default name, output library name must be specified

DPACC can accept the following file types as input:

Input File Extension	File Type	Description
`.c`	C source file	DPA device code
`.dpa.o`	DPA object file	Object file generated by DPACC, containing both host and device objects
`.a`	DPA object archive	An archive of DPA object files. User can generate this archive from DPACC-generated DPA objects.

Based on the mode of operations, DPACC can generate the following output files:

Output File Type	Input Files
DPA object file	C source files
DPA program	C source files, DPA object files, and/or DPA object archives
DPA library (DPA host library and DPA device library)	C source files, DPA object files, and/or DPA object archives

The following provides the commands to generate different kinds of supported output file types for each input file type:

Input	Output	DPACC Command
C source file	DPA program	`dpacc -hostcc=<cc> -mcpu=<targets> in.c -o libprog.a`

Input	Output	DPACC Command
	DPA object	`dpacc -hostcc=<cc> -mcpu=<targets> in.c -c`
	DPA library	`dpacc -hostcc=<cc> -mcpu=<targets> in.c -o lib<name> -gen-libs`
DPA object	DPA program	`dpacc -hostcc=<cc> -mcpu=<targets> in.dpa.o -o libprog.a`
	DPA library	`dpacc -hostcc=<cc> -mcpu=<targets> in.dpa.o -o lib<name> -gen-libs`
DPA object archive	DPA program	`dpacc -hostcc=<cc> -mcpu=<targets> in.a -o libprog.a`
	DPA library	`dpacc -hostcc=<cc> -mcpu=<targets> in.a -o lib<name> -gen-libs`

7.6.3.3.1.1 DPA Program

DPACC produces a DPA program in compile-and-link mode. A DPA program is a host library which contains:

- DPACC-generated host stubs which registering the DPA application and facilitate invoking an entry-point function from the host application
- Device executable, generated by DPACC by compiling and linking input DPA device code

DPA program library must be linked with the host application that contains appropriate runtime APIs to load the device executable onto the device.

A DPA program can contain device executables for multiple targets. All the target-specific device executables are encapsulated in a special fatbinary container format and this container is embedded as a section into the host object which is present in the host library.

7.6.3.3.1.2 DPA Object

DPACC produces DPA object files in compile-only mode. A DPA object is a host object file which has a similar layout to the DPA program where it contains DPACC-generated host stubs and device object which is generated by compiling input device code.

A DPA object can contain device objects for multiple targets, similar to a DPA program. All the target-specific device objects are encapsulated in a special fatbinary container format and this container is embedded as a section into the host object.

7.6.3.3.1.3 DPA Library

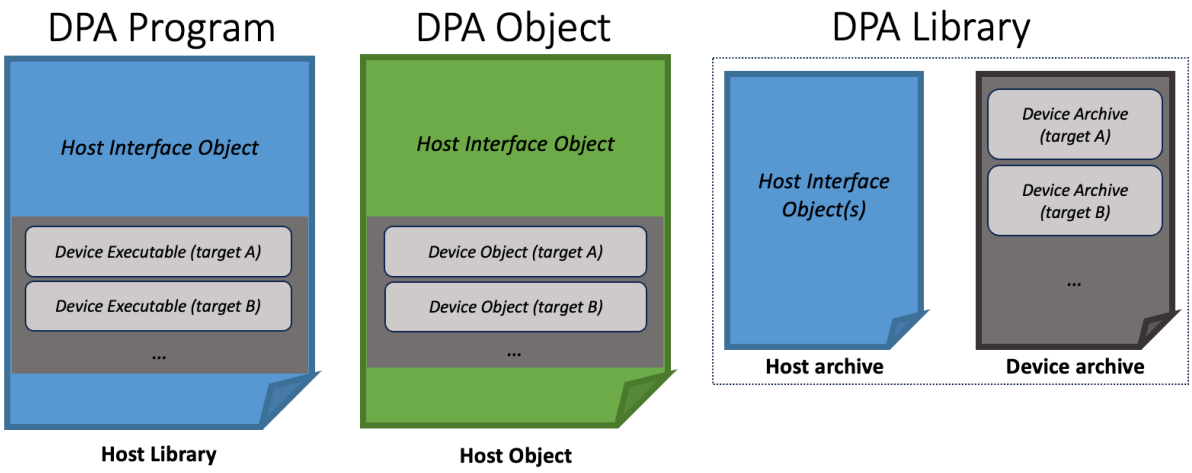
A DPA library is a collection of two separate libraries:

- DPA host library: contains host interface objects corresponding to the device objects in a DPA device library

- DPA device library: contains device objects generated by compiling the input device code files

The DPA device library is consumed by DPACC during DPA-program generation and the DPA host library can optionally be linked with other host code and be distributed as the host library. Both libraries are generated as static archives.

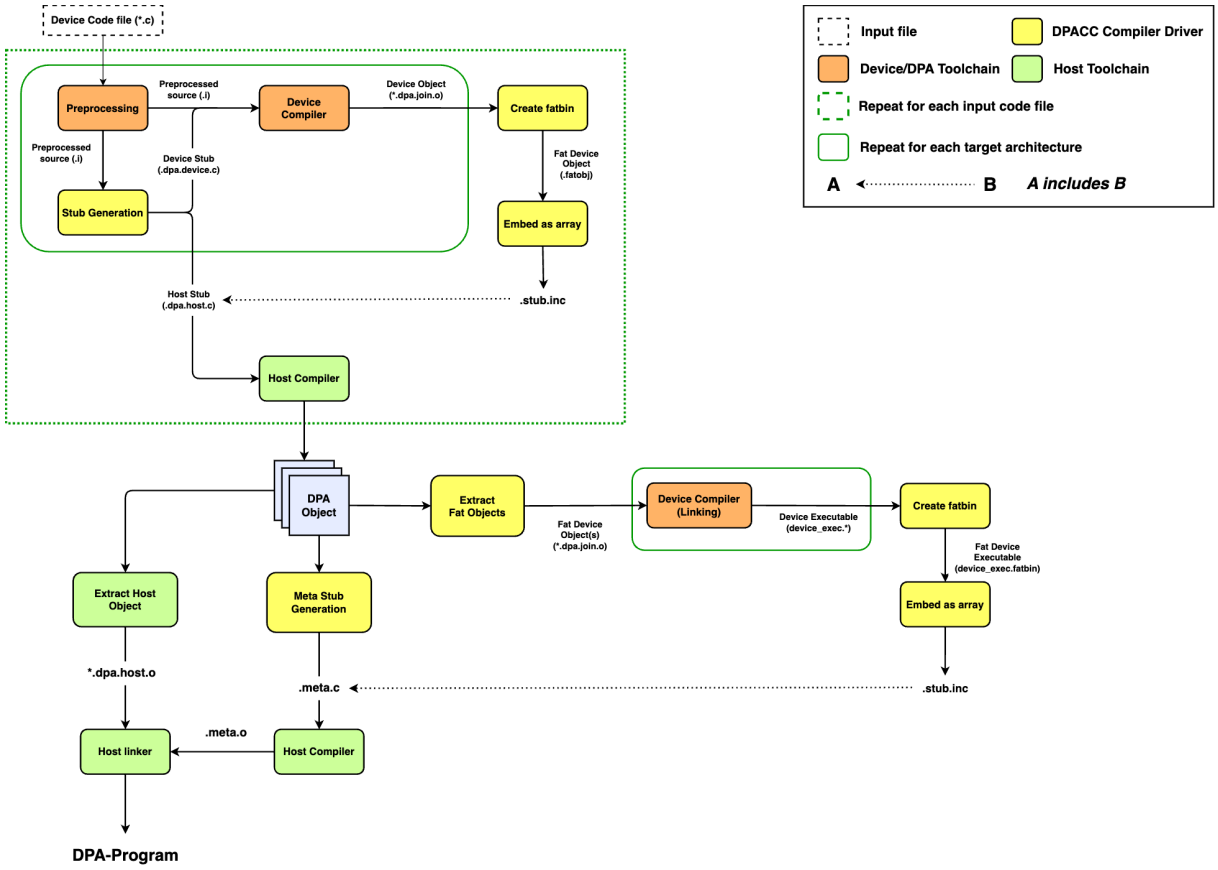
The host library is a static archive. The device library is a file of specialized fatbinary container format type which contains archives of device objects built for different targets.



The 'Device Archive' box in the preceding figure indicates the fatbinary container. The fatbinary container should be treated as an opaque object by the end-user and should not be manipulated in any way.

7.6.3.3.2 DPACC Trajectory

The following diagram illustrates DPACC compile-and-link mode trajectory.



7.6.3.3.3 Modes of Operation

In each of the below modes, DPACC accepts single or multiple target names through the `mcpu` option and builds the output such that all the mentioned targets are supported.

7.6.3.3.3.1 Compile-and-link Mode

This is a one-step mode that accepts C source files or DPA object files and produces the DPA program. Specifying the output library name is mandatory in this mode.

Example commands:

```
$ dpacc in1.c in2.c -o libapp1.a -hostcc=gcc -mcpu=nv-dpa-bf3                                  # Takes C sources to
produce libapp1.a library which supports a single target - nv-dpa-bf3
$ dpacc in3.dpa.o in4.dpa.o -o libapp2.a -hostcc=gcc -mcpu=nv-dpa-bf3,nv-dpa-cx8              # Takes DPA object files
to produce libapp2.a library which supports multiple targets - nv-dpa-bf3 and nv-dpa-cx8
$ dpacc in1.c in3.dpa.o -o libapp3.a -hostcc=gcc -mcpu=nv-dpa-bf3,nv-dpa-cx7,nv-dpa-cx8       # Takes C source and DPA
object to produce libapp3.a library which supports multiple targets - nv-dpa-bf3, nv-dpa-cx7 and nv-dpa-cx8
```

7.6.3.3.3.2 Compile-only Mode

This mode accepts C source code and produces `.dpa.o` object files. These files can be given to DPACC to produce the DPA program. The mode is invoked by the `--compile` or `-c` option.

To display the object file name, use the `--output-file` or `-o` option.

Example commands:

```
$ dpacc -c input1.c -hostcc=gcc -mcpu=nv-dpa-cx7                                    # Produces input1.dpa.o which
supports a single target - nv-dpa-cx7
$ dpacc -c input2.c -o in2.dpa.o -hostcc=gcc -mcpu=nv-dpa-cx8,nv-dpa-cx7            # Produces in2.dpa.o which
supports multiple targets - nv-dpa-cx7 and nv-dpa-cx8
$ dpacc -c input3.c input4.c -hostcc=gcc -mcpu=nv-dpa-bf3,nv-dpa-cx7,nv-dpa-cx8    # Produces input3.dpa.o and
input4.dpa.o which support multiple targets - nv-dpa-bf3, nv-dpa-cx7 and nv-dpa-cx8
```

7.6.3.3.3.3 Library Generation Mode

This mode accepts C source files or DPA object files and produces the DPA program. Specifying the output DPA library name is mandatory in this mode.

Example commands:

```
$ dpacc in1.c in2.c -o libdummy1 -hostcc=gcc -mcpu=nv-dpa-cx8 -gen-libs                                  # Takes
C sources to produce a DPA-Library (libdummy1_host.a and libdummy_device.a archives) which supports a single target
- nv-dpa-cx8
$ dpacc in3.dpa.o in4.dpa.o -o libdummy2 -hostcc=gcc -mcpu=nv-dpa-cx8,nv-dpa-bf3 -gen-libs               # Takes
DPA object files to produce a DPA-Library (libdummy2_host.a and libdummy2_device.a archives) which supports
multiple targets - nv-dpa-bf3 and nv-dpa-cx8
$ dpacc in1.c in3.dpa.o -o outdir/libdummy3 -hostcc=gcc -mcpu=nv-dpa-bf3,nv-dpa-cx7,nv-dpa-cx8 -gen-libs   # Takes
C source and DPA object to produce a DPA-Library (outdir/libdummy3_host.a and outdir/libdummy3_device.a archives)
which supports multiple targets - nv-dpa-bf3, nv-dpa-cx7 and nv-dpa-cx8
```

7.6.3.4 Execution

To execute DOCA DPACC compiler:

```
Usage: dpacc <list-of-input-files> -hostcc=<path> -mcpu=<targets> [other options]
Helper Flags:
  -h, --help                          Print help information about DPACC
  -V, --version                       Print DPACC version information
  -v, --verbose                       List the compilation commands generated by this invocation while also
executing every command in verbose mode
  -dryrun, --dryrun                   Only list the compilation commands generated by DPACC, without executing them
  -keep, --keep                       Keep all intermediate files that are generated during internal compilation
steps in the current directory
  -keep-dir, --keep-dir               Keep all intermediate files that are generated during internal compilation
steps in the given directory
  -optf, --options-file <file>,...    Include command line options from the specified file
```

7.6.3.4.1 Mandatory Arguments

Flag	DPACC Mode	Description
List of one or more input files	All	List of C source files or DPA object file names. Specifying at least one input file is mandatory. A file with an unknown extension is treated as a DPA object file.
`-mcpu`, `--mcpu <targets>`	All	Specify the list of target DPA hardwares for code generation. (See DPA Hardware Architectures for more details) Multiple target names can be specified through this option. Supported values: `nv-dpa-bf3, nv-dpa-cx7, nv-dpa-cx8, nv-dpa-cx9`

Flag	DPACC Mode	Description
`-hostcc`, `--hostcc <path>`	All	Specify the host compiler. This is typically the native compiler present on the host system. ⚠ The host compiler used to link the host application with the DPA program must be link-compatible with the `hostcc` compiler provided here.
`-o`, `--output-file <file>`	Compile-and-link/ library generation	Specify name and location of the output file.

7.6.3.4.2 Commonly Used Arguments

✅ Use the `--help` option to display a list of all supported options.

Flag	Description
`-app-name`, `--app-name <name>`	Specify DPA application name for the DPA program. This option is required if multiple DPA programs are part of a host application because each DPA application must have a unique name. Default name is `__dpa_a_out`.
`-flto`, `--flto`	Enable link-time optimization (LTO) for device code. Specify this option during compilation along with an optimization level in `devicecc-options`.
`-devicecc-options`, `--devicecc-options <options>`,...	Specify the list of options to pass to the device compiler.
`-devicelink-options`, `--devicelink-options <options>`,...	Specify the list of options to pass during device linking stage.
`-device-libs`, `--device-libs '-L<path> -l<name>'`,...	Specify the list of device libraries including their names (in `-l`) and their paths (in `-L`). FlexIO libraries are linked by default.
`-I`, `--common-include-path <path>`,...	Specify include search paths common to host and device code compilation. FlexIO headers paths are included by DPACC by default.
`-o`, `--output-file <file>`	Specify name and location of the output file. • Compile-only mode: name of the output DPA object file. If not specified, `.dpa.o` is generated for each `.c` file. • Compiler-and-link mode: name of the output DPA program. This is a mandatory option in compiler-and-link mode. • Library generation mode: name of the output library. This is a mandatory option for this mode. Output files `<name>_device.a` and `<name>_host.a` are generated.

Flag	Description
`-hostcc-options`, `--hostcc-options <options>`,...	Specify the list of options to pass to the host compiler.
`-gen-libs`, `--gen-libs`	Generate a DPA library from input files
`-ldoca_dpa`, `--ldoca_dpa`	Link with DOCA-DPA libraries

⚠ Using machine-dependent options through `-devicecc-options` to influence compiler code generation is not supported. Examples of unsupported options through `-devicecc-options` are `-mcpu, -march, -mabi`, etc.

⚠ The `devicecc-options` option allows passing any option to the device compiler. However, passing options that prevent compilation of the input file may lead to unexpected behavior (for example, `-devicecc-options="-version"` makes the device compiler print the version and not process input files).

⚠ Incompatible options that affect DPA global function argument sizes during DPACC invocation and host application compilation may lead to undefined behavior during execution (for example, passing `-hostcc-options="-fshort-enums"` to DPACC and missing this option when building the host application).

7.6.3.4.3 DPA Hardware Architectures

The following table indicates the DPA architectures, the associated values supported in the compiler through the `-mcpu` option, and the macros defined by the compiler to identify these architectures.

Hardware Name	Value	Macro
ConnectX-7	`nv-dpa-cx7`	`__NV_DPA_CX7`
BlueField-3	`nv-dpa-bf3`	`__NV_DPA_BF3`
ConnectX-8	`nv-dpa-cx8`	`__NV_DPA_CX8`
ConnextX-9	`nv-dpa-cx9`	`__NV_DPA_CX9`

Because ConnectX-7 and BlueField-3 share the same DPA hardware, the compiler treats `nv-dpa-cx7` as an alias of `nv-dpa-bf3`.

7.6.3.4.3.1 Link Compatibility

Only link-compatible relocatable objects can be linked together; attempting to link incompatible objects will result in an error. Additionally, the toolchain version of the linker must match the toolchain version of the compiler used to produce the objects.

Forward compatibility is generally supported: If architecture B is newer than A and they are link-compatible, objects built for target A can be linked to build an application for target B. However, the inverse (i.e., linking objects built for target B into an application for target A) is not valid.

For example, BlueField-3/ConnectX-7 and ConnectX-8 are link-compatible. This means objects built for BlueField-3/ConnectX-7 can be linked together to build an application for ConnectX-8.

Executable Target → / Object Target ↓	nv-dpa-bf3 / nv-dpa-cx7	nv-dpa-cx8	nv-dpa-cx9
nv-dpa-bf3 / nv-dpa-cx7	Compatible	Compatible	Compatible
nv-dpa-cx8	Incompatible	Compatible	Compatible
nv-dpa-cx9	Incompatible	Incompatible	Compatible

7.6.3.4.4 Architecture Macros

The compiler defines identifier macros for each version of DPA hardware, as listed in the DPA Hardware Architectures table. Each identifier macro has a unique integer value strictly greater than those of older DPA CPU models. Known aliases, such as BlueField-3 DPA and ConnectX-7 DPA, share the same integer value.

The macro `__NV_DPA` is defined as the value of the current compilation target. This can be used to write device code specific to a DPA hardware generation:

```
#if __NV_DPA == __NV_DPA_BF3
// Code for BlueField-3 here
#elif __NV_DPA > __NV_DPA_BF3
```

```
// Code for devices after BlueField-3 here
#endif
```

⚠ The ordering established by the hardware version macros does not imply an ordering of features supported by the hardware. It is the user's responsibility to ensure that features used in code specific to a DPA version are actually supported by that hardware.

7.6.3.4.5 LTO Usage Guidelines

7.6.3.4.5.1 Restrictions

- Only the default linker script is supported with LTO
- Using options `-fPIC` / `-fpic` / `-shared` / `-mcmodel=large` through `-devicecc-options` is not supported when LTO is enabled
- Fat bitcode objects containing both LLVM bitcode and ELF representation are not supported
- Thin LTO is not supported

7.6.3.4.5.2 Compatibility

During compilation, LLVM generates the object as bitcode intermediate representation (IR) when LTO is enabled instead of ELF representation. The bitcode IR generated by the DPA compiler is only guaranteed to be compatible within the same version. The toolchain version of the compiler which builds the objects involved in link-time optimization (enabled with `-flto`) and the toolchain version of the linker which performs LTO must be the same.

7.6.3.4.6 Experimental Features

7.6.3.4.6.1 `__dpa_memcpy` Builtin

DPACC supports the `__dpa_memcpy` builtin, an inline implementation of the standard `memcpy` operation. It is designed to minimize memory operations when the copy size is known at compile time. Unlike the current inline `memcpy` implementation, `__dpa_memcpy` accounts for the alignment of both source and destination base pointers, producing optimized code even when the source and destination have mismatched alignments.

The builtin signature is the same as the standard library `memcpy` function.

Usage Notes

To achieve optimal code generation, developers should provide alignment information for the source and destination buffers using one of the following methods:

- `aligned` attribute: Use when declaring buffers or variables.
- `assume_aligned` attribute: Use if a function returns an aligned buffer.
- `__builtin_assume_aligned()` builtin: Use if the underlying buffer of a pointer is known to be aligned.

Usage Example

The following example demonstrates using `__builtin_assume_aligned()` to inform the compiler of 8-byte alignment, even when accessing offsets:

```
#define LENGTH 24

void aligned_parameters(uint8_t* dst, uint8_t* src) {
    // Inform compiler that dst and src base pointers are 8-byte aligned
    dst = __builtin_assume_aligned(dst, 8);
    src = __builtin_assume_aligned(src, 8);

    // Copy with offsets (even if offsets result in mismatched alignment)
    __dpa_memcpy(dst + 50, src + 60, LENGTH);
}
```

This feature is currently experimental. If your project maintains a custom `memcpy()` implementation to optimize load/store sequences, we invite you to evaluate `__dpa_memcpy` as an alternative. We welcome feedback regarding its efficiency and integration in real-world use cases.

7.6.3.4.7 Deprecated Features

- The `-ldpa` option which links with DOCA-DPA libraries is deprecated and will be removed in future releases. Use the `-ldoca_dpa` option instead.

7.6.3.4.8 Examples

This section provides some common use cases of DPACC and showcases the `dpacc` command.

7.6.3.4.8.1 Building Libraries

This example shows how to build DPA libraries using DPACC. Libraries for DPA typically contain two archives, one for the host and one for the device.

```
dpacc input.c -hostcc=gcc -mcpu=nv-dpa-bf3 -o lib<name> -gen-libs -hostcc-options="-fPIC"
```

This command generates the output files `lib<name>_host.a` and `lib<name>_device.a`.

The host stub archive can be linked with other host code to generate a shared/static host library.

- Generating a static host library:

```
ar x lib<name>_host.a                  # Extract objects to generate *.o
ar cr lib<name>.a <*src.host.o> *.o    # Generate final static archive with all objects
```

- Generating a shared host library:

```
gcc -shared -o lib<name>.so <*src.host.o> -Wl,-whole-archive -l<name>_host -Wl,-no-whole-archive       #
Link the generated archive to build a shared library
```

7.6.3.4.8.2 Linking with DPA Device Library

The DPA device library generated by DPACC using `-gen-libs` as part of a DPA library can be consumed by DPACC using the `-device-libs` option. All such libraries are only linked statically.

```
dpacc input.c -hostcc=gcc -mcpu=nv-dpa-bf3 -o libInput.a -device-libs="-L <path-to-library> -l<libName>"
```

7.6.3.4.8.3 Enabling Link-time Optimizations

Link-time optimizations can be enabled using `-flto` along with an optimization level specified for device compilation.

```
dpacc input1.c -hostcc=gcc -mcpu=nv-dpa-bf3 -c -flto -devicecc-options="-O2"
dpacc input2.c -hostcc=gcc -mcpu=nv-dpa-bf3 -c -flto -devicecc-options="-O2"
dpacc -mcpu=nv-dpa-bf3 input1.dpa.o input2.dpa.o -hostcc=gcc -o libInput.a
```

7.6.3.4.8.4 Including Headers

This example includes headers for device compilation using `devicecc-options` and host compilation using `hostcc-options`. You may also specify headers for any compilation on both the host and device side using the `-I` option.

```
dpacc input.c -hostcc=gcc -mcpu=nv-dpa-bf3 -o libInput.a -I <common-headers-path> -devicecc-options="-I <device-
headers-path>" -hostcc-options="-I <host-headers-path>"
```

7.6.3.4.8.5 Providing Non-default Security Attributes Blob

By default, the `dpacc` compiler embeds a security attributes blob provided by FlexIO. To override this behavior, `dpacc` provides the `--dpa-proc-attr` option.

This flag allows you to specify the path to a custom, user-provided attributes blob. When used, this blob will be embedded into the compiled application instead of the default one.

For detailed instructions on creating the attributes file and converting it into a blob, please refer to the "DPA Application Attributes to Blob" documentation.

The following command demonstrates the use of this flag to specify a custom attributes blob:

```
dpacc dev_code.c -hostcc=gcc -mcpu=nv-dpa-bf3 -o libapp.a --dpa-proc-attr /path/to/attributes/blob
```

7.6.3.4.8.6 Linking FlexIO Libraries Dynamically

DPACC provides options that control how the `libflexio-al` and `libflexio-al-cp` libraries are linked during device linking.

Default behavior:

- `libflexio-al`: Linked statically
- `libflexio-al-cp`: Linked dynamically

This behavior can be controlled using the `--link-flexio-al` and `--link-flexio-al-cp` options.

To override the default and link the `libflexio-al-cp` library statically, use the following:

```
dpacc dev_code.c -hostcc=gcc -mcpu=nv-dpa-bf3 -o libapp.a --link-flexio-al-cp=static
```

7.6.3.4.8.7 Dump Targets Supported by a Fatbinary File

The targets supported by a fatbinary file can be dumped using `dpa-fatbin`. This tool can also dump the targets supported by a DPA library from the device archive.

```
dpa-fatbin --list libfoo_device.a
dpa-fatbin --list device_exec.fatbin
```

7.6.3.4.8.8 Dump Target of Device ELF file

The target for which a device ELF file is built can be dumped using `dpa-objdump`.

```
dpa-objdump --file-headers foo.o
```

7.6.3.4.8.9 Generating Output as Source Code

DPACC provides the option `-src-output` to generate output as host-source code. This source can be compiled by the host compiler to generate functionally equivalent output which DPACC would have generated directly.

This example shows how to build various outputs of DPACC as source using this option and how to compile the generated source.

DPA Program Source

Generate DPA program source to DPACC:

```
dpacc input.c -hostcc=gcc -mcpu=nv-dpa-bf3 -o libfoo.c -src-output
```

Compile the generated source using the host compiler to generate an object and build an archive with this object. The macro `__DPACC_SRC_TARGET__` must be defined when building this object to remove unnecessary code when building from source.

```
$ gcc libfoo.c -c -I /opt/mellanox/flexio/include -Wno-attributes -Wno-pedantic -Wno-unused-parameter -Wno-return-
type -Wno-implicit-function-declaration -D__DPACC_SRC_TARGET__
$ ar cr libfoo.a libfoo.o
```

DPA Library Source

Generate DPA library source passing this option to DPACC

```
dpacc input.c -hostcc=gcc -mcpu=nv-dpa-bf3 -o libfoo -gen-libs -src-output
```

This generates the device archive `libfoo_device.a` and host code files `libfoo.lib.c`, `input.dpa.c`. The host archive of DPA library is generated by compiling these sources and building an archive. The `__DPACC_SRC_TARGET__` macro needs to be defined in this case to remove unnecessary code.

```
$ gcc libfoo.lib.c input.dpa.c -c -I /opt/mellanox/flexio/include -Wno-attributes -Wno-pedantic -Wno-unused-
parameter -Wno-return-type -Wno-implicit-function-declaration -D__DPACC_SRC_TARGET__
$ ar cr libfoo_host.a libfoo.lib.o input.dpa.o
```

DPA Object Source

Generate DPA object source passing this option to DPACC:

```
dpacc input.c -hostcc=gcc -mcpu=nv-dpa-bf3 -c -src-output
```

This generates a single file, `input.dpa.c`. Compile the host file to generate an object.

```
gcc input.dpa.c -c -I /opt/mellanox/flexio/include -Wno-attributes -Wno-pedantic -Wno-unused-parameter -Wno-return-
type -Wno-implicit-function-declaration
```

7.6.3.4.9 DPA Compiler Usage

The **DPA-Compiler** is an LLVM-based compiler used internally by DPACC to compile and link device code.

7.6.3.4.9.1 Passing Options

User-specified options can be passed to the underlying compiler and linker using the following DPACC flags:

- `--devicecc-options`: Passes options to the compiler.
- `--devicelink-options`: Passes options to the linker.

7.6.3.4.9.2 Inlining Control

The compiler supports the `-finline-level=<n>` option to control inlining aggressiveness, where `<n>` is an integer between 0 and 100. This option is supported even during Link Time Optimization (LTO).

- Value 100 – Maximizes inlining. All "viable" functions (e.g., those without `noinline` attributes) are inlined.
- Value 0 – Minimizes inlining. The compiler inlines only functions marked with the `always_inline` attribute or those where inlining is unconditionally beneficial under the current cost model.

7.6.3.4.9.3 Additional Resources

Refer to the following resources for additional options:

- Clang Compiler User Manual
- Clang Command Line Argument Reference
- Target-dependent Compilation Options
- LLD Command Line Reference

> ⚠ **Important Notes**
>
> - Invoking the compiler, assembler, or linker directly (bypassing DPACC) may lead to unexpected errors
> - Linker options are processed through the compiler driver (`dpa-clang`).
> - Unlike GNU `ld` (which replaces the configuration), the LLD linker script is additive (i.e., it is honored in addition to the default configuration). You may need specific options to override default behaviors.
> - Enabling optional standard library extensions by defining the `__STDC_WANT_LIB_EXT1__` macro is not supported.

7.6.3.4.9.4 dpacc-extract Command Line Options

`dpacc-extract` extracts a device executable out of a DPA program or a host executable containing DPA program(s).

To execute `dpacc-extract`:

```
Usage  : dpacc-extract <input-file> -o=<output-file> [other options]
Options
=======

--app-name                (-app-name)
        Specify name of the DPA application to extract.
        This option is mandatory if more than one application is present in the input file.

--dpa-proc-attr           (-pa)
        Extract DPA process attributes blob.

--help                    (-h)
        Print this help information on this tool.

--info                    (-i)
        List apps and supported targets.

--mcpu                    (-mcpu)
        Specify name of the device for which the application is to be extracted.
        This option is mandatory if the application is built for multiple devices.

--options-file <file>,...  (-optf)
        Include command line options from specified file.

--output-file             (-o)
        Specify name of the output file.

--version                 (-V)
        Print version information on this tool.
```

Mandatory arguments:

Flag	Description
Input file	DPA program or host executable containing DPA program. Specifying one input file is mandatory.
`-o`, `--output-file <file>`	Specify name and location of the output device executable.
`-app-name`, `--app-name <name>`	Specify name of the DPA application to extract. Mandatory if input file has multiple DPA apps.
`-mcpu`, `--mcpu <target>`	Specify name of the device for which the application is to be extracted. Mandatory if there are multiple target variants for an app.

7.6.3.4.9.5 Objdump Command Line Options

The `dpa-objdump` utility prints the contents of object files and final linked images named on the command line.

For more information, refer to the Objdump command line reference.

7.6.3.4.9.6 Archiver Command Line Options

`dpa-ar` is a Unix ar-compatible archiver.

For more information, refer to the Archiver command line reference.

7.6.3.4.9.7 NM Tool Command Line Options

The `dpa-nm` utility lists the names of symbols from object files and archives.

For more information, refer to the NM tool command line reference.

7.6.3.4.9.8 Miscellaneous Notes

- Objects produced by LLD are not compatible with those generated by any other linker.
- Ensure that there is at least one reference to the device entry point function in the DPA program from the host application so that during linking, the DPA program is not silently discarded by the host linker because it is not referenced.

7.6.3.5 Release Notes

7.6.3.5.1 New Features

Title	Description
Inlining Control	Introduced the `-finline-level` option to control the aggressiveness of function inlining.
Optimized Memcpy	Added the `__dpa_memcpy` builtin, an optimized inline implementation of the standard `memcpy` operation.
Kernel Diagnostics	Added the `strict-dpa-thread-existence` option to enable diagnostics for kernel registration failures.

7.6.3.5.2 Changes and Bug Fixes

Title	Description
Naming Convention	Removed the file name substring from the generated unpack function names.
`__extract_fields`	Resolved limitations and issues associated with the `__extract_fields` builtin.

7.6.4 Single Point of Resource Distribution

This document describes the Single Point of Resource Distribution (SPRD) system, including the `dpa-resource-mgmt` tool, new Flex IO SDK APIs for consuming SPRD outputs, and the DPA Execution Unit (EU) management tool, `dpaeumgmt`.

⚠ Execution Unit partitioning is planned for support in a future release.

7.6.4.1 Introduction

DPA Flex IO applications may run simultaneously across multiple VHCAs, with multiple applications per VHCA. This can lead to contention for shared resources—such as Execution Units (EUs). Historically, applications independently allocated EUs based on general recommendations, which could result in performance degradation or even application crashes due to over-commitment.

To address this, the SPRD system provides a centralized infrastructure to orchestrate DPA resource allocation across applications. It is designed primarily for administrators managing DPUs in scalable environments and is managed using the `dpa-resource-mgmt` tool.

SPRD enables consistent resource planning at scale, for example, deploying the same configuration across a cluster of DPUs.

7.6.4.1.1 Key Characteristics

- Centralized EU resource management via `dpa-resource-mgmt`.
- Supports BlueField-3 and newer platforms.
- Operates over the `dpaeumgmt` EU management infrastructure.
- Host applications can reside on:
  - The BlueField Arm core (BF-ARM)
  - One or more external hosts (e.g., multi-host server configurations)
- Supports multiple instances of the same application running across different hosts.
- Non-SPRD-aware applications continue to run unaffected.

7.6.4.1.2 Integration Requirements

To fully adopt SPRD, the following updates are required:

- New APIs must be added to the FlexIO SDK.
- Existing tests and applications that use EU resources must be updated to consume allocations provided via the SPRD tool and APIs.

7.6.4.1.3 Glossary

This table introduces important terms necessary to understand this document:

Term	Definition
DPA	Data-path accelerator; an auxiliary processor designed to accelerate data-path operations.
DPA partition manager	PCIe device function capable of controlling the system's EUs. On NVIDIA® BlueField®-3, this is the ECPF. It is associated with the default partition. The application is named `dpaeumgmt`.
DOCA	SDK for DPU.
EU (Execution Unit)	Hardware execution unit; a logical DPA processing unit.
EU group	A collection/subset of EUs created using `dpaeumgmt`. EU groups belong to an EU partition and can only consist of EUs from that partition.
EU object	Refers to either an EU partition or an EU group.
EU partition	An isolated pool of EUs created using `dpaeumgmt`. A vHCA must be associated with a partition to use DPA resources and execute software threads.
EU affinity	Method for pairing a DPA thread with a DPA EU. Supported types: • none – use any available EU • strict – use a specific EU by ID • group – use an EU from a specified group
MFT	NVIDIA Firmware Tools.
SPRD	Single Point of Resource Distribution (`dpa-resource-mgmt`).
vHCA	Virtual Host Channel Adapter; a virtualized representation of a physical network interface.

7.6.4.2 Preparation and Description

To work with SPRD, ensure the following prerequisites are met:

7.6.4.2.1 System Requirements

To work with SPRD, the following requirements must be met:

- A functioning system with DOCA installed
- Python 3.6 or higher
- An NVIDIA® BlueField®-3 or newer device
- MFT package installed and running, version 4.32.0-94 or higher
- Firmware (FW) version XX.45.0322 or higher
- `dpa-resource-mgmt` package installed and running, version 25.04.160 or higher

7.6.4.2.2 EUs and Cores

The hardware consists of several cores, each containing a set number of EUs. Some EUs or entire cores may be reserved by the firmware and are therefore unavailable to both `dpa-resource-mgmt` and user applications.

7.6.4.2.3 Partition Concept

A partition is a logical, continuous array of EUs starting at index zero, with a fixed size. Partitions are assigned to one or more vHCAs, and only applications on those vHCAs can use the EUs in the assigned partition.

Partition types:

- Default partition (ROOT):
  - Created at boot on root devices (ECPF in DPU mode, PF in NIC mode)
  - Operates over all free EUs initially
  - Uses absolute EU indices
- Sub-partitions:
  - Created and deleted at runtime
  - Pull EUs from the default partition (which then loses access to them)
  - EUs in a sub-partition do not need to be contiguous, but must not overlap with other sub-partitions
  - Use relative EU indices starting from 0

When a sub-partition is deleted, its EUs are returned to the default partition.

7.6.4.2.4 Group Concept

A group is a firmware-managed list of EUs. When EU affinity is set to "group", the firmware selects an EU from the assigned group.

- The maximum number of groups per sub-partition is defined when the partition is created
- The default partition (ROOT) has its limit defined by the `max_num_dpa_groups` capability (currently 15)
- Every partition also has an implicit hidden group, used when EU affinity is set to `none`

The total number of groups allowed on a device must be ≤ `max_num_dpa_groups` (15), and is calculated as:

$$(1) \quad P + RG + \sum_{i=1}^{P} G_i$$

Where:

- P – number of sub-partitions (excluding the default)
- RG – number of groups in the default (ROOT) partition
- G_i – number of groups in each sub-partition `i`

> Example limitation: Even if no groups are defined in any partition, the number of sub-partitions cannot exceed 15, due to the group tracking mechanism.

7.6.4.3 SPRD

7.6.4.3.1 dpa-resource-mgmt Utility

The primary tool provided by SPRD is `dpa-resource-mgmt`, a Python 3-based CLI utility used by system administrators to configure and manage DPA resource allocations. It interfaces with the lower-level `dpaeumgmt` utility to perform hardware-level execution unit (EU) operations.

This utility takes as input:

- The InfiniBand (ibv) device name
- A YAML configuration file describing partition and application layout
- An optional output path where generated application configuration files will be saved (defaults to current working directory)

Each output file corresponds to a defined partition and contains the required configuration for applications that will run within that partition.

7.6.4.3.1.1 Operating Modes

config – Configure Partitions and Generate Application Files

Creates partitions and EU groups as defined in the YAML file, and generates corresponding application configuration files.

Options:

```
-d, --device DEVICE        ibv device name (required)
-f, --filename FILENAME    YAML configuration file (required)
-o, --output OUTPUT        Output directory for generated files (optional; default: current path)
-v, --verbose              Print underlying dpaeumgmt commands (optional)
```

query – Query Resource Status

Displays resource-related information such as chip-level capabilities, vHCA data, or DPA resource allocation. Output can be directed to a file and formatted in YAML or human-readable format.

Options:

```
-d, --device DEVICE        ibv device name (required)
-t, --type {chip,vhca,resources}
                           Type of information to display (required)
-f, --filename FILENAME    Output file (optional; default: stdout)
-y, --yaml-format          Output in YAML format (optional; default: human-readable)
-v, --verbose              Show executed commands (optional)
```

clear – Clean Up Existing Configuration

Destroys all partitions and groups associated with the given device.

Options:

```
-d, --device DEVICE        ibv device name (required)
-v, --verbose              Show executed commands (optional)
```

version – Print Tool Version

Displays the currently installed version of `dpa-resource-mgmt`.

7.6.4.3.1.2 Back-end

The `dpa-resource-mgmt` utility operates by interfacing with the `dpaeumgmt` tool to interact directly with the hardware. It performs the following key functions:

- System discovery – Retrieves detailed hardware and topology information from the chip, including:
  - Number of cores
  - Number of available EUs
  - vHCA identifiers and their parent-child relationships
- Configuration parsing and validation:
  - Reads the YAML configuration file provided via the `--filename` option
  - Validates the structure and content of the file
  - If any issue is detected (e.g., syntax error, invalid partition configuration), the utility exits with a descriptive error message
- Pre-configuration checks:
  - Checks for existing active partitions, running processes, and configured EU groups
  - If such elements are found, the utility prompts the administrator to remove them manually, then exits without making changes
- Partition setup – If no conflicts are found, the utility proceeds to:
  - Create EU partitions
  - Configure EU groups

- Generate partition-specific application configuration files, which are saved in the output directory (one file per partition)

This structured backend workflow ensures consistent and safe allocation of DPA resources across different applications and hosts.

7.6.4.3.1.3 Examples of Running dpa-resource-mgmt

Query VHCA Information

```
$ dpa-resource-mgmt query -t vhca -d mlx5_0
    VHCA_ID = 0x1
    FUNCTION_TYPE = ECPF
    PCI_BDF = 80:00.0
    VPORT_ID = 0x0

            VHCA_ID = 0x2
            FUNCTION_TYPE = PF
            PCI_BDF = 80:00.1
            VPORT_ID = 0x0

            VHCA_ID = 0x3
            FUNCTION_TYPE = PF
            PCI_BDF = 80:00.2
            VPORT_ID = 0x0

            VHCA_ID = 0x4
            FUNCTION_TYPE = PF
            PCI_BDF = 80:00.3
            VPORT_ID = 0x0

...
```

Query DPA Chip Information

```
$ dpa-resource-mgmt query -t chip -d mlx5_0
Maximal number of DPA EU per group (max_num_dpa_eu_per_group): 190
Maximal number of active DPA EU (max_num_dpa_eu): 190
Maximal number of DPA EU partitions (max_num_dpa_eu_partitions): 15
Maximal number of VHCAs associated with a single partition (max_num_partition_vhca_id): 16
Maximal number of EU groups could be created (max_num_dpa_groups): 15
Heap maximal size (heap_max_size): 1073741824
Maximal number of EU groups by FirmWare (max_eu_groups): 16
Maximal number of processes per VHCA (max_process_per_vhca): 64
Maximal number of DPA processes (max_processes): 64
Maximal number of DPA threads (max_threads): 40000
Maximal number of DPA threads per process (max_threads_per_process): 20000
Number of cores (num_cores): 12
DPA thread stack size (thread_stack_size): 16384
Cores:
        Core ID 0
        EUs number 16
        EUs IDs 0-15
        EUs indexes 0-15

        Core ID 1
        EUs number 16
        EUs IDs 16-31
        EUs indexes 0-15

        Core ID 2
        EUs number 16
        EUs IDs 32-47
        EUs indexes 0-15

...
```

Query DPA Resource Information

```
$ dpa-resource-mgmt query -t resources -d mlx5_0
Free EUs in ROOT partition 0-3,9-15,30,31,40-47,67-79,112-159,169
Cores available for use in ROOT partition 0-2,4,7-9,14
Free EUs in ROOT partition with groups 0-3,9-15,30,31,40-47,67-79,112-159,162-189

sudo /opt/mellanox/doca/tools/dpaeumgmt eu_group create --dpa_device mlx5_0 --range 162-168 --name_group RG1
```

7.6.4.3.2 Format of Input YAML File

The input YAML file is divided into two main parts:

1. Partition definitions
2. Application definitions (not covered in this document)

These parts are separated by the standard YAML `---` divider.

7.6.4.3.2.1 Partition Definitions

This section defines how execution units (EUs) are assigned to partitions and groups.

Example:

```
version: 25.04

partitions:
  PARTITION_1:
    vhca_id: 1
    EU_allocation:
      - abs_EUs: 4-8
      - core: 1
        num_EUs: 14
      - core: 2
        num_EUs: 8
    groups:
      - name: EU1
        EUs:
          - abs_EUs: 16,17,20-22
          - core: 2
            num_EUs: 1
      - name: EU1_1
        EUs:
          - abs_EUs: 26-28

  PARTITION_2:
    vhca_id: 2
    EU_allocation:
      - core: 3
        num_EUs: 16
      - core: 4
        num_EUs: 3
    groups:
      - name: EU2
        EUs:
          - core: 3
            num_EUs: 4
          - core: 4
            num_EUs: 1

  PARTITION_3:
    vhca_id: [3, 4, 9, 10-13]
    EU_allocation:
      - core: 5
        num_EUs: 16
      - core: 6
        num_EUs: 16
    groups:
      - name: EU3
        EUs:
          - core: 5
            num_EUs: 16
          - core: 6
            num_EUs: 1

root_partition_groups:
  - name: RG0
    EUs:
      - abs_EUs: 170-188
  - name: RG1
    EUs:
      - core: 10
        num_EUs: 7
```

7.6.4.3.2.2 Partition Configuration Schema (Input YAML Format)

```
version: "string"  # Version identifier (e.g., "25.04")
# REQUIRED: version must be defined

partitions:  # Defines different partitions such as ARM, HOSTx86, etc.
  # Can be an empty dictionary: {}
  "<partition_name>":  # Dynamic key, replace with actual partition names
    vhca_id:  # Virtual Host Channel Adapter (VHCA) ID
      one_of:
        - type: "integer"  # Single VHCA ID (e.g., 1, 2)
        - type: "array"    # Multiple VHCA IDs (e.g., [3, 4, 9, 10-13])
          items: "integer"

    EU_allocation:  # List of Execution Unit (EU) allocations
      # REQUIRED: EU_allocation must be defined
      - abs_EUs: "string"  # Absolute EU range, e.g., "4-8" or "16,17,20-22"
      - core: "integer"    # Core ID to which EUs are allocated
        num_EUs: "integer"  # Number of EUs allocated

    groups:  # Defines groups of EUs within each partition
      - name: "string"  # Name of the EU group (e.g., "EU1", "EU2")
        EUs:  # List of Execution Units assigned to the group. Should be either abs_EUs or core with num_EUs.
          # REQUIRED: EUs must be defined
          - abs_EUs: "string"  # Absolute EU assignments (e.g., "26-28")
          - core: "integer"    # Core ID for EU allocation
            num_EUs: "integer"  # Number of EUs assigned to the core

root_partition_groups:  # Defines global root partition groups
  - name: "string"  # Name of the root partition group (e.g., "RG0")
    # REQUIRED: name must be defined
    EUs:  # List of Execution Units assigned to the group. Should be either abs_EUs or core with num_EUs.
      # REQUIRED: EUs must be defined
      - abs_EUs: "string"  # Absolute EU assignments (e.g., "170-188")
      - core: "integer"    # Core ID for EU allocation
        num_EUs: "integer"  # Number of EUs assigned to the core
```

7.6.4.3.2.3 Schema Description

Field	Description
`version`	Required. Specifies the configuration version (e.g., `"25.04"`).
`partitions`	Defines custom partitions and their associated resources. Can be empty (`{}`).
`partitions.<name>.vhca_id`	Required. Specifies the VHCA ID(s) to associate with the partition. Accepts a single number, list, or range. Example: `2`, `[3, 4]`, or `10-13`.
`partitions.<name>.EU_allocation`	Required. Defines EUs to assign to the partition. Supports: • `abs_EUs` – Comma-separated numbers or ranges (e.g., `7-9,11`) • `core` / `num_EUs` – Allocates a number of EUs from a specified core
`partitions.<name>.groups`	Defines named EU groups within a partition. Each group must include: • `name` – Group name (e.g., `EU1`) • `EUs` – Similar format to `EU_allocation`
`root_partition_groups`	(Optional) Defines EU groups within the ROOT partition. Uses the same format as `groups`. Each must have a unique `name` and valid `EUs`.

7.6.4.3.2.4 Notes on Field Behavior

`abs_EUs` vs. `core` / `num_EUs`

- Use `abs_EUs` for **precise** EU selection.
- Use `core` + `num_EUs` for **abstracted** allocation based on availability.
- Cannot combine both methods within a single mapping item.

Default Partition Behavior

- EUs not explicitly assigned to custom partitions remain in the default **ROOT** partition.
- The default partition is auto-created on boot and operates over unallocated EUs.

Partition Constraints

- Sub-partitions may not overlap in EU assignment.
- On sub-partition deletion, its EUs are returned to the ROOT partition.
- Each partition has its own **relative EU indexing** starting at 0.

Group Constraints

- The number of allowed groups is limited by the `max_num_dpa_groups` capability (currently 15).
- Hidden default groups are internally used for affinity mode `none`.

7.6.4.3.2.5 Application Definitions (YAML: DPA_APPS)

This section describes how applications are mapped to partitions and which execution units (EUs) or groups they use. EU values are defined in absolute terms for clarity but are converted to relative indices in output files.

Example:

```
DPA_APPS:
  APP1:
    - partition: PARTITION_1
      affinity_EUs: [35, 37-39]
      groups: [EU1, EU1_1]
      affinity_core:
        - core: 1
          num_EUs: 4
    - partition: PARTITION_2
      affinity_EUs: [61, 62]
      groups: EU2
    - partition: ROOT
      groups: RG0
      affinity_EUs: [190, 191]
      affinity_core:
        - core: 0
          num_EUs: 2
  APP2:
    - partition: PARTITION_1
      affinity_EUs: [63]
      groups: EU2
  APP3:
    partition: PARTITION_3
    affinity_EUs: [97, 99]
  APP4:
    partition: PARTITION_3
    affinity_EUs: 98
    groups: EU3
```

7.6.4.3.2.6 Application-to-Partition Mapping Schema (Input YAML Format)

```
DPA_APPS:  # List of applications with their partition mappings
  "<app_name>":  # Dynamic key, replace with actual application names (e.g., APP1, APP2)
    one_of:
      - type: array  # If an application has multiple partitions
        items:
          partition: "string"  # Name of the partition (e.g., "PARTITION_1", "PARTITION_2", "ROOT")
          # REQUIRED: partition must be defined

          affinity_cores:  # List of core/num_EUs pairs assigned to this app
            - core: "integer"
              num_EUs: "integer"
```

```
      affinity_EUs:  # List of Execution Units (EUs) assigned to this app
        one_of:
          - type: "array"  # List of EUs (e.g., [35, 37-39])
            items: integer
          - type: "integer"  # Single EU value (e.g., 98)
          - type: "string"  # Absolute EU range, e.g., "4-8" or "16,17,20-22"

      groups:  # Groups assigned to this app
        one_of:
          - type: array  # Multiple groups (e.g., ["EU1", "EU1_1"])
            items: string
          - type: string  # Single group (e.g., "EU2")

  - type: object  # If an application has only one partition
    properties:
      partition: "string"
      affinity_cores:
        - core: "integer"
          num_EUs: "integer"
      affinity_EUs:
        one_of:
          - type: array
            items: integer
          - type: integer
      groups:
        one_of:
          - type: array
            items: string
          - type: string
```

7.6.4.3.2.7 Schema Overview

Field	Description
`DPA_APPS`	Root node for defining applications
`<app_name>`	Application name (e.g., `APP1`, `APP2`)
`partition`	Partition assigned to the application (`PARTITION_1`, `PARTITION_2`, or `ROOT`)
`affinity_EUs`	Absolute EU values assigned to the app. Accepts: single int, list, ranges (e.g., `[35, 37-39]`), string (e.g. `35, 37-39`)
`affinity_core`	Alternative to `affinity_EUs`; assign EUs by number per core (e.g., `core: 1`, `num_EUs: 4`)
`groups`	Named EU groups the app uses. Accepts: single string or list (e.g., `["EU1", "EU2"]`)

7.6.4.3.2.8 Notes

`affinity_EUs` vs `affinity_cores`

Method	Description
`affinity_EUs`	Offers precise control using explicit EU numbers or ranges.
`affinity_cores`	Uses a core ID and number of EUs to assign. Abstracts allocation and balances load.

Using `affinity_cores` is recommended when the partition itself uses `core/num_EUs` style allocation.

Mixing `affinity_EUs` with Groups

Although supported, it's not recommended to mix strict `affinity_EUs` with group-based allocation (`groups`). Doing so may introduce conflicts during EU assignment but is not prohibited.

Using the `ROOT` Partition

Apps may be assigned to the `ROOT` partition. In this case:

- You must reference one of the `root_partition_groups`.
- You may use `affinity_EUs` or `affinity_core` — but only with EUs/cores not already allocated by sub-partitions.

7.6.4.3.2.9 Known Limitation

`dpa-resource-mgmt` does not validate whether a `vhca_id` belongs to a root PF in NIC mode or a VF. Errors will only occur during backend validation (via `dpaeumgmt`).

7.6.4.3.3 Output YAML files

After a successful run of `dpa-resource-mgmt`, the tool generates a YAML file for each partition defined in the input file. Each output file is named after its corresponding partition (e.g., `PARTITION_1.yaml`) and contains the list of applications assigned to that partition, along with their resolved EU and group mappings.

7.6.4.3.3.1 Example Output YAML file

```
version: 25.04
DPA_APPS:
  - name: APP1
    number_of_groups: 2
    # EU1, EU1_1
    groups: [1, 2]
    # absolute EUs: [16, 17, 18, 19, 20, 21, 32, 33, 35, 37, 38, 39]
    number_of_affinity_EUs: 12
    affinity_EUs: [5, 6, 7, 8, 9, 10, 19, 20, 22, 24, 25, 26]

  - name: APP2
    # absolute EUs: [16, 17, 22, 23, 24, 25, 26, 27, 34, 36]
    number_of_affinity_EUs: 10
    affinity_EUs: [5, 6, 11, 12, 13, 14, 15, 16, 21, 23]

  - name: APP3
    # absolute EUs: [16, 18, 19, 20, 21, 28, 29, 32, 33]
    number_of_affinity_EUs: 9
    affinity_EUs: [5, 7, 8, 9, 10, 17, 18, 19, 20]
```

7.6.4.3.3.2 Format Reference

Field	Description
`version`	**Required.** Specifies the YAML schema version (e.g., `"25.04"`).
`DPA_APPS`	**Required.** List of applications assigned to the partition.
`name`	**Required.** Application name (e.g., `APP1`).

Field	Description
`number_of_affinity_EUs`	Optional. Number of affinity EUs assigned to the app.
`affinity_EUs`	Optional. List of **relative EU IDs** (converted from absolute).
`number_of_groups`	Optional. Number of groups assigned to the app.
`groups`	Optional. List of group indices (integer values); original group names are included as comments.

⚠ The affinity_EUs values are relative to the partition in which the app is declared. The tool calculates them based on absolute values provided in the input YAML.

7.6.4.3.3.3 Format of output YAML file

```
version: "string"  # Version identifier (e.g., "25.04")
        # REQUIRED: version must be defined

DPA_APPS:  # List of applications with their attributes
  - name: "string"  # Name of the application (e.g., "APP3", "APP4")
         # REQUIRED: name must be defined

    #  (Optional) Number of affinity Execution Units (EUs) assigned to the application
    number_of_affinity_EUs: "integer"

    #  (Optional) List of affinity EU identifiers
    affinity_EUs:
      type: array
      items: integer  # Example: [17, 19] or [18]

    # (Optional) Number of groups assigned to the application
    number_of_groups: "integer"

    # (Optional) List of group identifiers
    groups:
      type: array
      items: integer  # Example: [1] (corresponds to "EU3" in the comment)
```

7.6.4.3.3.4 Key Behaviors

- Relative EU IDs – EUs are converted to partition-relative indices; this improves portability and compatibility across deployments
- Group Mapping – Group names from the input YAML are mapped to numeric indices; the mapping is shown as comments for traceability
- Partition Isolation – Each output file corresponds to a single partition, containing only the apps assigned to that partition

7.6.4.4 SPRD Configuration and Management Flow

All operations are performed using `dpa-resource-mgmt -d mlx5_X`, where `mlx5_X` is the root device name.

7.6.4.4.1 Gather Application Requirements

The system administrator receives the following details from users and developers:

- A list of applications to be used
- A list of devices on which the applications will run
- Resource requirements for each application (e.g., number of EUs, group needs)

7.6.4.4.2 Map Devices to VHCAs

Run the following command to determine the mapping between devices and VHCAs using the `pci_bdf` field:

```
dpa-resource-mgmt query -d mlx5_X -t vhca
```

You can also run `sudo mst status -v` from the MFT package to obtain device details.

7.6.4.4.3 Inspect Core and EU Layout

Run the following command to retrieve chip-level information such as core counts, EU layout, and absolute EU IDs:

```
dpa-resource-mgmt query -d mlx5_X -t chip
```

7.6.4.4.4 Create Partition Configuration

Using the gathered data, create a YAML configuration file with the following:

- Partition definitions.
- EU allocation (either by core/num_EUs or absolute EU IDs).
- EU groups within partitions (optional).
- Root partition groups (optional).

7.6.4.4.5 Define Application Assignments

Add the application mapping section to the YAML configuration file, based on:

- Application names
- Resource requirements
- Target partitions and group assignments

7.6.4.4.6 Validate Configuration

Run the following command to validate the YAML configuration:

```
dpa-resource-mgmt config -d mlx5_X -f <config.yaml>
```

7.6.4.4.7 Handle Conflicts (If Any)

If the tool returns an error due to existing partitions, groups, or active processes:

1. Clear the existing configuration:

   ```
   dpa-resource-mgmt clear -d mlx5_X
   ```

2. If clearing does not resolve the issue, perform a full chip reset

7.6.4.4.8 Review the Resulting Setup

Once configuration is successful, analyze the resulting setup:

```
dpa-resource-mgmt query -d mlx5_X -t resources
```

Use this step to verify if EU and group allocations are optimal.

7.6.4.4.9 Iterate (Optional)

If changes are required, modify the YAML file and revalidate configuration.

7.6.4.4.10 Distribute Output Files

After finalizing the configuration:

- Retrieve the output YAML files generated by `dpa-resource-mgmt`
- Distribute these files to the respective hosts where applications will run
- Notify users and developers to begin using their assigned resources

7.6.4.4.11 Revise as Needed

If any issues arise or new requirements are introduced, repeat the process from the start.

7.6.4.5 Flex IO SDK API for SPRD Support

To integrate SPRD with a host application, the typical workflow is:

1. Read a binary resource file generated by the `dpa-resource-mgmt` utility.
2. Pass the contents to `flexio_resources_get()` to populate a `flexio_res` structure.
3. Use the accessor functions to obtain execution unit (EU) or execution group (EUG) information.
4. Use this data to configure affinity for creating a `flexio_event_handler`.
5. After use, release the allocated structure using `flexio_resources_destroy()`.

7.6.4.5.1 Core API Functions

7.6.4.5.1.1 Main Functions

- `flexio_resources_get`

```
/**
 * Read resources for a given key from an SPRD resource buffer.
 *
 * @param[in] key      Application name as defined in the SPRD YAML output.
 * @param[in] buf      Binary buffer from dpa-resource-mgmt output.
 * @param[in] buf_len  Buffer size in bytes.
 * @param[out] res     Output pointer to a populated flexio_res structure.
 *
 * @return flexio_status enum value.
 */
flexio_status flexio_resources_get(const char *key, const void *buf, size_t buf_len,
                                   struct flexio_res **res);
```

- `flexio_resources_destroy`

```
/**
 * Free memory allocated for a flexio_res structure.
 *
 * @param[in] res  Pointer to the structure to destroy.
 *
 * @return flexio_status enum value.
 */
flexio_status flexio_resources_destroy(struct flexio_res *res);
```

7.6.4.5.1.2 Accessor Functions

- Get application name:

```
/**
 * @brief Get application name from a Flex IO resources struct.
 *
 * This function gets the application name from a Flex IO resources struct.
 *
 * @param[in] res - A pointer to a Flex IO resources struct.
 *
 * @return application name.
 */
FLEXIO_EXPERIMENTAL char *flexio_resources_get_app_name(struct flexio_resource *res);
```

- Number of execution groups:

```
/**
```

```
 * @brief Get number of execution groups from a Flex IO resources struct.
 *
 * This function gets the number of execution groups from a Flex IO resources struct.
 *
 * @param[in] res - A pointer to a Flex IO resources struct.
 *
 * @return number of execution groups.
 */
FLEXIO_EXPERIMENTAL int flexio_resources_get_eugs_num(struct flexio_res *res);
```

- Execution group list:

```
/**
 * @brief Get execution unit groups list from a Flex IO resources struct.
 *
 * This function gets the execution unit groups list from a Flex IO resources struct.
 *
 * @param[in] res - A pointer to a Flex IO resources struct.
 *
 * @return execution unit groups list.
 */
FLEXIO_EXPERIMENTAL uint32_t *flexio_resources_get_eugs(struct flexio_res *res);
```

- Number of execution units:

```
/**
 * @brief Get execution units number from a Flex IO resources struct.
 *
 * This function gets the execution units number from a Flex IO resources struct.
 *
 * @param[in] res - A pointer to a Flex IO resources struct.
 *
 * @return execution units number.
 */
FLEXIO_EXPERIMENTAL int flexio_resources_get_eus_num(struct flexio_res *res);
```

- Execution unit list:

```
/**
 * @brief Get execution units list from a Flex IO resources struct.
 *
 * This function gets the execution units list from a Flex IO resources struct.
 *
 * @param[in] res - A pointer to a Flex IO resources struct.
 *
 * @return execution units list.
 */
FLEXIO_EXPERIMENTAL uint32_t *flexio_resources_get_eus(struct flexio_res *res);
```

7.6.4.5.2 Example of Using EU Resources

```
file = fopen(filename, "rb");
if (!file) {
        printf("Cannot open file!n");
        return ERROR;
}

fseek(file, 0, SEEK_END);
buf_len = ftell(file);
if (buf_len == 0) {
        printf("Empty file!\n");
        return ERROR;
}
fseek(file, 0, SEEK_SET);

buf = calloc(sizeof(char), buf_len);
if (!buf) {
        printf("Cannot allocate\n");
        return ERROR;
}

if (buf_len != fread(buf, sizeof(char), buf_len, file)) {
        printf("Incorrect read\n");
        return ERROR;
}

fclose(file);

/* ..............  */

ret = flexio_resources_get(key, buf, buf_len, &resourses);

if (ret != FLEXIO_STATUS_SUCCESS) {
        printf("Failed to read resources for key %s\n", key);
```

```
        return ERROR;
}

free(buf);

/* ..............  */

attr.affinity.type = FLEXIO_AFFINITY_GROUP;
attr.affinity.id = flexio_resourses_get_eugs(resourses)[0];
ret = flexio_event_handler_create(process, &attr, &eug_handle_id);
if (ret != FLEXIO_STATUS_SUCCESS) {
        printf("Failed to create event_handler");
        return ERROR;
}

attr.affinity.type = FLEXIO_AFFINITY_STRICT;
attr.affinity.id = flexio_resourses_get_eus(resourses)[0];
ret = flexio_event_handler_create(process, &attr, &eu_handle_id);
if (ret != FLEXIO_STATUS_SUCCESS) {
        printf("Failed to create event_handler");
        return ERROR;
}

/* ..............  */

ret = flexio_resources_destroy(resources);
if (ret != FLEXIO_STATUS_SUCCESS) {
        printf("Failed to free resources");
        return ERROR;
}
```

7.6.4.6 Back-End Tool - dpaeumgmt

The `dpaeumgmt` tool enables management of DPA Execution Units (EUs), the fundamental compute resource of the Data Path Accelerator (DPA). It can run either on the host or on a target DPU and provides control over EU allocation, ensuring optimal resource distribution before using the DOCA FlexIO SDK API.

Without explicit EU allocation, a DPA software thread cannot execute, as it would lack access to pipeline or compute time resources.

Key use cases:

- Strict affinity execution – Run a DPA thread on a specifically assigned EU. `dpaeumgmt` can query the highest allowed EU ID for this purpose.
- Group Affinity Execution – Define EU groups. Once a group is created and assigned a unique ID, DPA threads can use group affinity to select an available EU from within the group.
- EU Partition Management – Manage EU partitions to logically separate compute resources across different virtual host channel adapters (VHCAs).

A DPA thread can only run if a suitable EU (according to its affinity type) is available.

7.6.4.6.1 Execution Unit Objects

At system boot, a default EU partition is automatically created. This partition initially owns all system EUs and is managed exclusively by the DPA partition manager function.

- When a DPA thread runs with `none` affinity, an EU is selected from the default partition's pool—excluding any EUs already allocated to groups.

- If no free EUs remain in the default pool, the thread fails to run.

7.6.4.6.2 dpaeumgmt CLI Reference

7.6.4.6.2.1 General Commands

Command	Description
`dpaeumgmt -h`	Print basic usage information
`dpaeumgmt help`	Show detailed help for all commands
`dpaeumgmt version`	Print the version of the tool

7.6.4.6.2.2 EU Group Commands

Command	Description
`dpaeumgmt eu_group info -d <device>`	Show system limits and max values for EU groups
`dpaeumgmt eu_group create -d <device> -n <name> -r <range>`	Create an EU group with a name and EU range
`dpaeumgmt eu_group destroy -d <device> -g <id>`	Destroy an EU group by ID
`dpaeumgmt eu_group destroy -d <device> -n <name>`	Destroy an EU group by name
`dpaeumgmt eu_group query -d <device>`	Query all EU groups on the device
`dpaeumgmt eu_group query -d <device> -n <name>`	Query a specific EU group by name
`dpaeumgmt eu_group query -d <device> -g <id>`	Query a specific EU group by ID
`dpaeumgmt eu_group apply -d <device> --file_groups <file>`	Replace EU groups with ones specified in the input JSON file

7.6.4.6.2.3 EU Partition Commands

Command	Description
`dpaeumgmt partition info -d <device>`	Show partition-related system limits
`dpaeumgmt partition create -d <device> -v <vhca_list> -r <range> -m <max_groups>`	Create a new partition with specified VHCA IDs and EU range
`dpaeumgmt partition destroy -d <device> -p <partition_id>`	Destroy a partition by ID
`dpaeumgmt partition query -d <device>`	Query all partitions

Command	Description
`dpaeumgmt partition query -d <device> -p <partition_id>`	Query a specific partition

7.6.4.6.2.4 Info Commands

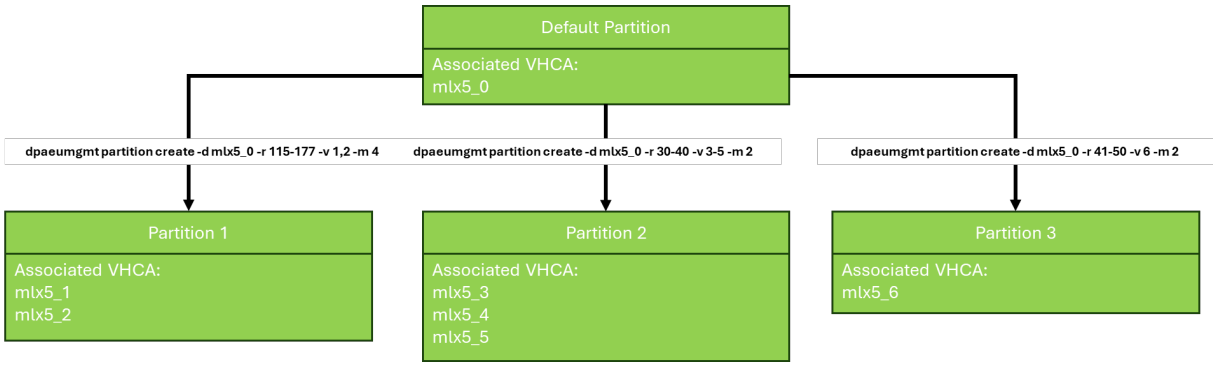
Command	Description
`dpaeumgmt info vhca -d <device>`	Show vHCA mapping and hierarchy
`dpaeumgmt info vhca -d <device> -y <yaml_file>`	Save vHCA info to YAML file
`dpaeumgmt info chip -d <device>`	Show chip-level resource info (cores, EUs, etc.)
`dpaeumgmt info chip -d <device> -y <yaml_file>`	Save chip info to YAML file
`dpaeumgmt info status -d <device>`	Show current state: partitions, root groups, processes
`dpaeumgmt info status -d <device> -y <yaml_file>`	Save status to YAML file

7.6.4.6.2.5 Common Flags and Options

Flag	Description
`-d`, `--dpa_device`	The device interface name (e.g., mlx5_0)
`-r`, `--range_eus`	EU range for allocation (e.g., "4-8,16,22")
`-v`, `--vhca_list`	Comma-separated list or range of VHCA IDs (e.g., "1,2,3", "4-6")
`-m`, `--max_num_eu_group`	Max number of groups in a partition
`-n`, `--name_group`	Group name (string up to 15 characters)
`-g`, `--id_group`	Group ID (integer)
`-p`, `--id_partition`	Partition ID (integer)
`-f`, `--file_groups`	Path to JSON file describing EU groups
`-y`, `--yaml_file`	Path to YAML file to write output

7.6.4.6.3 vHCAs and Partitions

The following diagram illustrates the ownership and control of a partition by a vHCA and also which vHCAs have claim to (i.e., can use) a partition.



7.6.4.6.4 Known Limitations of dpaeumgmt

Limitation	Description
Tool must run before DPA process creation	dpaeumgmt must be executed before any DPA process is started. Fails if run over an active process.
EU group names must be unique	Duplicate group names within the same partition are not allowed.
Partition creation consumes group quota	Each new partition reserves one default group and up to 'max_num' groups specified at creation.
Non-ECPF vHCAs require partitions	vHCAs other than ECPF must have a configured partition before using EU resources.
Only default partition sees real EU IDs	Other partitions use virtual EU numbers starting from 0.
Group IDs are virtual and scoped per partition	Same group ID can exist in multiple partitions with different semantics.
vHCA ID overlap not allowed	A vHCA cannot belong to multiple partitions.
vHCA IDs not discoverable via dpaeumgmt	User must know vHCA IDs in advance, e.g., via 'mst status -v'.
Partition deletion blocked by existing EU objects	All EU groups must be removed before destroying a partition.
EU assignment is opaque	No way to query which EU is selected at runtime.
vHCA scope is isolated	Each vHCA only sees its partition's groups, EUs, and limits.
Group ID assignment is not guaranteed	IDs are dynamically assigned and not persistent.
Default groups are not user-managed	System-created default groups cannot be edited or deleted.
EU ID range bounded	Valid IDs are between 0 and (max EU ID - 1), retrievable via 'info chip'.
No VF support	Virtual Functions are not supported by dpaeumgmt.
Partitions created only from DPA partition manager	Partition creation must be initiated from the manager function (e.g., ECPF).
Max 16 hardware EU groups	System limit of 16 concurrent EU group entities.

7.6.5 DOCA DPA GDB Server Tool

This document describes the DPA GDB Server tool.

> The DPA GDB Server Tool is currently supported at beta level.

7.6.5.1 Introduction

The DPA GDB Server tool (`dpa-gdbserver`) enables debugging FlexIO DEV programs.

DEV programs for debugging are selected using a token (8-byte value) provided by the FlexIO process owner.

> Any GDB, familiar with RISC-V architecture, can be used for the debug. Refer to this page for information how to work with GDB.

7.6.5.1.1 Glossary

Term	Description
PUD	Process under debug. DEV-side processes intended for debug.
EU	Execution unit (similar to hardware CPU core)
DPA	Data path accelerator
RPC	Remote process communication. Mechanism used in FlexIO to run DEV-side code instantly. Runtime is limited to 6 seconds.
HOST	x86 or aarch64 Linux OS which manages dev-side code (i.e., DEV)
DEV	RISC-V code, loaded by HOST into the DPA's device. Triggered to run by different types of interrupts. DEV side is directly connected to ConnectX adapter card.
GDB	GNU Project debugger. Allows users to monitor another program while it executes.
GDBSERVER	Tool for remote debug programs
RTOS	Real-time operation system running on RISC-V core. Manages handling of interrupts and calls to DEV user processes routines.
RSP	Remote serial protocol. Used for interaction between GDB and GDBSERVER.

7.6.5.1.2 Package Contents

The `dpa-gdbserver` package contains the `dpa-gdbserver` executable, which runs on the DPA to facilitate debugging.

This package does not contain the host-side debugger, `gdb-multiarch`, or an equivalent multi-architecture GDB application. Users must obtain and install a GDB version that supports the RISC-V architecture (such as `gdb-multiarch`) for their specific environment to interact with the server.

7.6.5.1.3 Known Limitations

- DPA GDB technology does not catch fatal errors. Therefore, if a fatal error occurs, core dump (created by `flexio_coredump_create()`) should be used.
- DPA GDB technology does not support Outbox access. GDB users cannot write to Doorbell or to Window configuration areas.
- DPA GDB technology does not support Window access. Read/write to Window memory does not work properly.

7.6.5.2 DPA-specific Notes

7.6.5.2.1 Token

The process under debug (PUD) can expose a debugging token. Every external process, using this token, get full access to the process with given token. To not show it constantly (e.g., for security reasons), users can modify their host application temporary. See `flexio_process_udbg_token_get()`.

7.6.5.2.2 Connection on Application Launch

If the code which needs debugging begins to run immediately after launch, the user should modify the host application to stop upon start to give the user time to run `dpa-gdbserver`. One possible way of doing this is to place function `getchar()` immediately after process creation.

7.6.5.2.3 Dummy Thread Concept

Something to consider with DPA debugging is that a PUD does not have a running thread all time (e.g., the process's thread may exist but be waiting for incoming packets). In a regular Linux application, this scenario is not possible and GDB does not support such cases.

Therefore, when no thread is running, `dpa-gdbserver` reports a dummy thread:

gdb

```
(gdb) info thread
  Id   Target Id                                Frame
* 1    Thread 1.805378433 (Dummy Flexio thread) 0x0800000000000000 in ?? ()
(gdb)
```

In this case user can inspect memory, create breakpoints, and give the `continue` command.

Commands like `step`, `next`, and `stepi` can not be executed for the Dummy thread.

7.6.5.2.4 Watchdog Issues

The RTOS has a watchdog timer that limits DEV code interrupt processes to 100 seconds. This timer is stopped when the user connects to DEV with GDB. Therefore users will have no time limitation for debugging.

7.6.5.3 Tool TCP Port and Execution Unit (EU)

By default, `dpa-gdbserver` uses TCP port 1981 and runs on EU 29. If this conflicts with another application (or if other instances of `dpa-gdbserver` are running), users should change the defaults as follows:

Bash

```
$> dpa-gdbserver mlx5_0 -T <token> -s <port> -E <eu_id>
```

7.6.5.4 Debugging

7.6.5.4.1 Preparation for Debug

Modify your FlexIO application if needed. Make sure the HOST code prints `udbg_token` and waits for GDB connection if needed:

C code. Host side. diff

```
+   uint64_t udbg_token;

    flexio_process_create(..., &flexio_process);

+   udbg_token = flexio_process_udbg_token_get(flexio_process);
+   if (udbg_token)
+       printf("Process created. Use token >>> %#lx <<< for debug\n", udbg_token);
```

```
+    printf("Stop point for waiting of GDB connection. Press Enter to continue..."); /* Usually you don't need this
stop point */
+    fflush(stdout);
+    getchar();
```

Extract the DPA application from the FlexIO application. For example:

Bash

```
$> dpacc-extract cc-host/app/host/flexio_app_name -o flexio_app_name.rv5
```

7.6.5.4.2 Start Debugging

1. Run your FlexIO application. It should expose the debug token:

   Bash

   ```
   $> flexio_app_name mlx5_0
   Process created. Use token >>> 0xd6278388ce4e682c <<< for debug
   ```

2. Run `dpa-gdbserver` with the debug token received:

   Bash

   ```
   $> dpa-gdbserver mlx5_0 -T 0xd6278388ce4e682c
   Registered on device mlx5_0
   Listening for GDB connection on port 1981
   ```

3. Run any GDB with RISC-V support. For example, `gdb-multiarch`:

   Bash

   ```
   $> gdb-multiarch -q flexio_app_name.rv5
   Reading symbols from flexio_app_name.rv5...
   (gdb)
   ```

4. Connect to the gdbserver using proper TCP port and hostname, if needed:

   gdb

   ```
   (gdb) target remote :1981
   Remote debugging using :1981
   0x0800000000000000 in ?? ()
   ```

7.6.5.4.3 DPA-specific Debugging Techniques

7.6.5.4.3.1 Easy Example of Transitioning from Dummy to Real Thread

Transitioning between the dummy thread and a real thread is not standard practice for debugging under GDB. In an ideal situation, the user would know exactly the entry points for all their routines and can set breakpoints for all of them. Then the user may run the `continue` command:

gdb

```
(gdb) target remote :1981
Remote debugging using :1981
0x0800000000000000 in ?? ()
(gdb) info threads
  Id   Target Id                                 Frame
* 1    Thread 1.805378433 (Dummy Flexio thread) 0x0800000000000000 in ?? ()
(gdb) b foo
Breakpoint 1 at 0x400000b2: file ../tests/path/hello.c, line 58.
(gdb) b bar
Breakpoint 2 at 0x40000518: file ../tests/path/hallo.c, line 113.
(gdb) continue
Continuing.
```

Initiate interrupts for your DEV program (depends your task), and GDB should catch a breakpoint and now the real thread of the PUD appear instead of the dummy:

gdb

```
(gdb) continue
Continuing.
(gdb) [New Thread 1.2]
[New Thread 1.130]
[New Thread 1.258]
[New Thread 1.386]
[Switching to Thread 1.2]

Thread 2 hit Breakpoint 1, foo(thread_arg=9008)
    at ../tests/path/hello.c:58
58              struct host_data *hdata = NULL;
(gdb) info threads
  Id   Target Id                                    Frame
* 2    Thread 1.2 (Process 0 thread 0x1 GVMI 0 EU 0)     foo (arg=9008) at ../tests/path/hello.c:58
  3    Thread 1.130 (Process 0 thread 0x81 GVMI 0 EU 1)  foo (arg=9264) at ../tests/path/hello.c:58
  4    Thread 1.258 (Process 0 thread 0x101 GVMI 0 EU 2) foo (arg=9648) at ../tests/path/hello.c:58
  5    Thread 1.386 (Process 0 thread 0x181 GVMI 0 EU 3) foo (arg=9904) at ../tests/path/hello.c:58
(gdb)
```

From this point, you may examine memory and trace your code as usual.

7.6.5.4.3.2 Complicated Example of Transitioning from Dummy to Real Thread

In a more complicated situation, the interrupt happens after GDB connection. In this case, the real thread should start running but cannot because the PUD is in HALT state. The user can type the command `info threads`, see new thread instead of the old dummy, and then switch to the new thread manually:

gdb

```
1  (gdb) target remote :1981
2  Remote debugging using :1981
```

```
3  0x0800000000000000 in ?? ()
4  (gdb) info threads
5    Id   Target Id                                  Frame
6  * 1    Thread 1.805378433 (Dummy Flexio thread) 0x0800000000000000 in ?? ()
7  (gdb) info threads
8  [New Thread 1.32769]
9    Id   Target Id                                        Frame
10   2    Thread 1.32769 (Process 0 thread 0x8000 GVMI 0 EU 3) bar (arg=0xc0, len=0)
11     at /path/lib/src/stub.c:167
12
13 The current thread <Thread ID 1> has terminated.  See `help thread'.
14 (gdb) thread 2
15 [Switching to thread 2 (Thread 1.32769)]
16 #0  bar (arg=0xc0, len=0)
17     at /path/lib/src/stub.c:167
18 167     {
19 (gdb) bt
20 #0  bar (arg=0xc0, len=0)
21     at /path/lib/src/stub.c:167
22 #1  0x000000004000017a in foo (thread_arg=3221)
23     at ../path/dev/hello.c:182
24 #2  0x0000000000000000 in ?? ()
25 Backtrace stopped: frame did not save the PC
26 (gdb)
```

The same command `info threads` in lines 4 and 7 gives different results. This happens because the interrupt occurs between the instances and the real code begins to run.

The user must switch to the new thread manually (see line 14). After this, they can trace/debug the flow as usual (i.e., using the commands `step`, `next`, `stepi`).

7.6.5.4.3.3 Finishing Real Thread without Finishing PUD

Every interrupt handler at some point finishes its way and returns the CPU resources to RTOS. The most common way to do this is to call function `flexio_dev_thread_reschedule()`. The command `next` on this function will have the same effect as the command `continue`:

gdb

```
205             __dpa_thread_fence(__DPA_MEMORY, __DPA_W, __DPA_W);
(gdb) next
206             flexio_dev_cq_arm(dtctx, app_ctx.rq_cq_ctx.cq_idx, app_ctx.rq_cq_ctx.cq_number);
(gdb) next
208             if ((dev_errno = flexio_dev_get_and_rst_errno(dtctx))) {
(gdb) next
213             print_sim_str("Nothing to do. Wait for next duar\n", 0);
(gdb) next
214             flexio_dev_thread_reschedule();
(gdb) next
```

GDB waits until the user types `^C` or a breakpoint is reached after the next interrupt occurred.

7.6.5.5 Error Reporting

> The DPA GDB server tool has been validated with `gdb-multiarch` (version 9.2) and with GDB version 12.1 from RISC-V tool chain.

> The GDB server should support all commands described in GDB RSP (remote serial protocol) for GDB stubs. But only the most common GDB commands are supported.

Should a dpa-gdbserver bug occur, please provide the following data:

- Used GDB (name and version)
- Commands sequence to reproduce the issue
- DPA GDB server tool console output
- DPA GDB server tool log directory content (see next part for details)
- Optional – output data printed when `dpa-gdbserver` is run in verbose mode

7.6.5.5.1 Tool Log Directory

For every run, a temporary directory is created with the template `/tmp/flexio_gdbs.XXXXXX`.

To locate the latest one, run the following command:

Bash

```
$> ls -ldtr /tmp/flexio_gdbs.* | tail
```

7.6.5.5.2 Verbosity Level of gdbserver

By default, `dpa-gdbserver` does not print any log information to screen. Adding `-v` option to command line increases verbosity level, printing additional info to `dpa-gdbserver` terminal display. Verbosity level is incremented according to number of 'v' in command line switch (i.e. `-vv`, `-vvv` etc.).

One `-v` shows the RSP exchange. This is a textual protocol, so users can read and understand requests from GDB and answers from the GDB server:

gdbserver.log -v

```
<<<<< "qTStatus"
>>>>> ""
<<<<< "?"
>>>>> "S05"
<<<<< "qfThreadInfo"
>>>>> "mp01.30011981"
<<<<< "qsThreadInfo"
>>>>> "l"
<<<<< "qAttached:1"
>>>>> "1"
<<<<< "Hc-1"
>>>>> "OK"
<<<<< "qC"
>>>>> "QCp01.30011981"
```

In the examples, `<<<<<` and `>>>>>` are used to indicate data received from GDB and transmitted to GDB, respectively.

When running with a higher verbosity level (e.g., run `dpa-gdbserver` with option `-vv` or higher), the exchange with the RTOS module is shown:

gdbserver.log -vv

```
<<<<< "qfThreadInfo"
/  2/dgdbs_handler - cmd 0x5
/  2/dgdbs_handler - retval 0x4
>>>>> "mp01.30011981"
<<<<< "qsThreadInfo"
/  2/dgdbs_handler - cmd 0x5
/  2/dgdbs_handler - retval 0x5
>>>>> "l"
<<<<< "m800000000000000,4"
/  2/dgdbs_handler - cmd 0xc
/  2/dgdbs_handler - retval 0x9
>>>>> "E0a"
<<<<< "m7ffffffffffffc,4"
/  2/dgdbs_handler - cmd 0xc
/  2/dgdbs_handler - retval 0x9
>>>>> "E0a"
<<<<< "qSymbol::"
>>>>> "OK"
```

Lines beginning with `/  #/` provide the number of internal RTOS threads printed from the DEV side.

7.6.5.6 Useful Info Regarding Work with GDB

This section provides useful information about commands and methods which can help users when performing DPA debug. This is not related to the `dpa-gdbserver` itself. But this is about remote debugging and FlexIO sources.

7.6.5.6.1 Command "directory"

GDB can run on a different host from the one where compilation was done. For example, users may have compiled and run their application on `host1` and run their instance of

GDB on `host2`. In this case, users will see the error message `../xxx/yyy/zzz/your_file.c: No such file or directory`. To solve this problem, copy sources to the host running GDB (`host2` in the example). Make sure to save the original code hierarchy. Use GDB command `directory` to inform where the sources are to GDB:

gdb on host2

```
host2~$> gdb-multiarch -q /tmp/my_riscv.elf
Reading symbols from /tmp/my_riscv.elf...
(gdb) b foo
Breakpoint 1 at 0x4000016c: file ../xxx/yyy/zzz/my_file.c, line 182.
(gdb) target remote host1:1981
Remote debugging using host1:1981
0x0800000000000000 in ?? ()
(gdb) c
Continuing.
[New Thread 1.32769]
[Switching to Thread 1.32769]

Thread 2 hit Breakpoint 1, foo (thread_arg=5728) at ../xxx/yyy/zzz/my_file.c:182
182     ../xxx/yyy/zzz/my_file.c: No such file or directory.
(gdb) directory /tmp/apps/
Source directories searched: /tmp/apps:$cdir:$cwd
(gdb) list
179             struct flexio_dev_thread_ctx *dtctx;
180             uint64_t dev_errno;
181
182             print_sim_str("=====> NET event handler started\n", 0);
183
184             flexio_dev_print("Hello GDB user\n");
185
```

Pay attention to the exact path reported by GDB. The argument for the command `directory` should point to the start point for this path. For example, if GDB looks for `../xxx/yyy/zzz` and you placed the sources in local directory `/tmp/copy_of_worktree`, then the command should be `(gdb) directory /tmp/copy_of_worktree/xxx/` and not `(gdb) directory /tmp/copy_of_worktree/`.

Sometimes, the `*.elf` file provides a global path from the root. In this case, use the command `set substitute-path <from> <to>`. For example, if the file `/foo/bar/baz.c` was moved to `/mnt/cross/baz.c`, then the command `(gdb) set substitute-path /foo/bar /mnt/cross` instructs GDB to replace `/foo/bar` with `/mnt/cross`, which allows GDB to find the file `baz.c` even though it was moved.

See this page of GDB documentation for more examples of specifying source directories.

7.6.5.6.2 Core Dump Usage

If the code runs into a fatal error even though the host side of your project is implemented correctly, a core dump is saved which allows analyzing the core. It should point exactly to where the fatal error occurred. The command `backtrace` can be used to examine the memory and its registers. Change the frame to see local variables of every function on the backtrace list:

gdb

```
$> gdb-multiarch -q -c crash_demo.558184.core /tmp/my_riscv.elf
Reading symbols from /tmp/my_riscv.elf...

[New LWP 1]
#0  0x000000004000126e in read_test (line=153, ptr=0x30) at /xxx/yyy/zzz/my_file.c:109

75                      retval = unpack_cb(&data_from_host->func_params.arg_buf,
(gdb) p /x *data_from_host
$2 = {poll_lkey = 0x1ff2b1, window_id = 0x3, poll_haddr = 0x55dc0f40b900, entry_point = 0x400013d8, func_params =
{func_wo_pack = 0x0, dev_func_entry = 0x400000b0, arg_buf = 0xc0008140}}
(gdb)
```

7.6.5.6.3 Debug of Optimized Code

Usually highly optimized code is compiled and run.

Two types of mistakes in code can be considered:

- Logical errors
- Optimization-related errors

Logical errors (e.g., using `&` instead of `&&`) are reproduced on the non-optimized version of the code. Optimization related errors (e.g., forgetting volatile classification, non-usage of memory barriers) only impact optimization. Non-optimized code is much easier for tracing with GDB, because every C instruction is translated directly to assembly code.

It is good practice to check if an issue can be reproduced on non-optimized code. That helps observe the application flow:

Bash

```
$> build.sh -O 0
```

For tracing this code, using GDB commands `next` and `step` should be sufficient.

But if an issue can only be reproduced on on optimized code, you should start debugging it. This would require reading disassembly code and using the GDB command `stepi` because it becomes a challenge to understand exactly which C-code line executed.

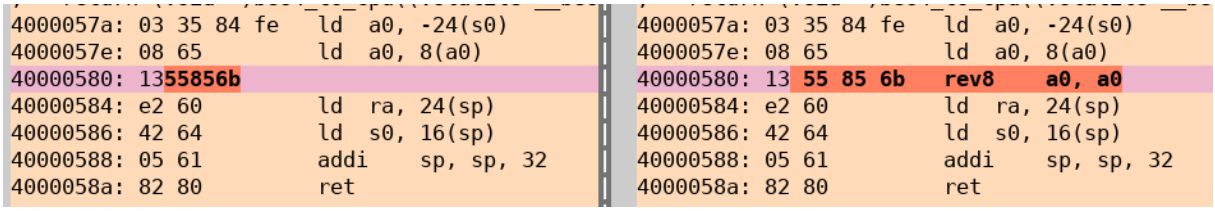
7.6.5.6.4 Disassembly of Advanced RISC-V Commands

DPA core runs on a RISC-V CPU with an extended instruction set. The GDB may not be familiar with some of those instructions. Therefore, `asm` view mode shows numbers instead of disassembly. In this case it is recommended to disassemble your RISC-V binary code manually. Use the `dpa-objdump` utility with the additional option `--mcpu=nv-dpa-bf3`.

bash

```
$> dpa-objdump -sSdxl --mcpu=nv-dpa-bf3 my_riscv.elf > my_riscv.asm
```

The following screenshot shows the difference:



7.6.6 DOCA DPA PS Tool

7.6.6.1 Introduction

DOCA `dpa-ps` is a CLI tool which allows users to monitor running DPA processes and threads. The tool presents sorted lists of the currently running DPA processes and threads.

> The process ID output of the `dpa-ps` tool may be used as the input parameter for the `dpa-statistics` tool.

> This tool is supported for NVIDIA® BlueField®-3 only.

7.6.6.2 Command Flags and Arguments

The following table lists the flags for the `dpa-ps` tool.

Short Option	Long Option	Description
`-h`	`--help`	Help information
`-d`	`--device`	Device interface name (MST/RDMA)
`-p`	`--process-id`	Hexadecimal process ID for filtering
`-t`	`--threads`	Show threads info for each process
`-i`	`--suppress-header-info`	Suppress print header info

Arguments for the flags must be used within quotes (if more than one) and without extra spaces.

7.6.6.3 Example

```
$ sudo ./dpa-ps -d mlx5_0 -t
ProcessID    Process Name
    ThreadID     Thread Name
0            PROCESS_0
    5            EH_0_5_5
    6            EH_0_5_5
1            PROCESS_1
    3            EH_1_3_3
    4            EH_1_4_4
2            PROCESS_2
3            PROCESS_3
    0            EH_3_0_0
    1            EH_3_1_1
    2            EH_3_2_2
4            PROCESS_4
```

7.6.6.4 Known Limitations

- The `dpa-ps` and `dpa-statistics` tools cannot be run at the same time on the same device

7.6.7 DOCA DPA Statistics Tool

7.6.7.1 Introduction

DOCA `dpa-statistics` is a CLI tool which allows users to monitor and obtain statistics on thread execution per running DPA process and thread. The tool is used to expose information about the running DPA processes and threads and to collect statistics on DPA thread performance.

The tool presents performance information for running DPA threads, including the number of cycles and instructions executed in a time period. The tool enables initiating and stopping collection of statistics and displaying the data collected per thread.

> The process ID output of the `dpa-ps` tool may be used as the input parameter for the `dpa-statistics` tool.

> This tool is supported for NVIDIA® BlueField®-3 only.

7.6.7.2 Collecting Performance Statistics Data

The command `collect` works on four mutually exclusive modes:

- Enable mode – start collecting performance data
- Disable mode – stop collecting performance data
- Timeout mode – start collecting, wait with a timeout, stop collect and print info. User could break the wait with Ctrl-C command and then the timeout will be canceled and tool will disable statistics collection and prints the info with the actual time of the collect operation.
- Infinite mode – no special flags. Same as timeout mode but with infinite timeout. The tool awaits the Ctrl-C command to stop.

The following table lists the `collect` command's flags and arguments:

Short Option	Long Option	Description
`-h`	`--help`	Help information
`-d`	`--device`	Device interface name (MST/RDMA)
`-p`	`--process-id`	Hexadecimal process ID for filtering > This flag indicates a specific command for the command to operate on. Otherwise, statistics are collected from all processes.
`-i`	`--suppress-header-info`	Suppress print header info
`-n`	`--enable`	Enable collect info
`-o`	`--disable`	Disable collect info

Short Option	Long Option	Description
`-t`	`--timeout`	Enable collect, wait with timeout, disable collect and print info Timeout value is in milliseconds. Examples for inputting timeout value: • 45 – 45 milliseconds • 45.55 – 45 milliseconds and 550,000 nanoseconds • .0005 – 500 nanoseconds • 45m55n – 45 milliseconds and 55 nanoseconds • 66n – 66 nanoseconds
`-r`	`--reset`	Reset counters before operation starting collect operation

7.6.7.3 Presenting Statistics List

Presenting performance statistics is applicable after initiating data collection.

The following table lists the `show` command's flags and arguments:

Short Option	Long Option	Description
`-h`	`--help`	Help information
`-d`	`--device`	Device interface name (MST/RDMA)
`-p`	`--process-id`	Hexadecimal process ID for filtering
`-i`	`--suppress-header-info`	Suppress print header info

Output example:

```
$ sudo ./dpa-statistics show -d mlx5_0 -p 1
ProcessID    Process Name
    ThreadID    Cycles              Instruction         Time              Executions          Thread Name
1            PROCESS_1
    3           266268              18193               164               41                  EH_1_0_0
    4           411571              32727               252               47                  EH_1_1_1
```

Where:

- `ProcessID` – The `dpa_process_object_id` to which the thread belongs
- `Process Name` – The `dpa_process_name` to which the thread belongs
- `ThreadID` – DPA thread object ID
- `Cycles` – Total EU cycles the thread used
- `Instruction` – Total number of instructions the thread executed
- `Time` – Total time in ticks the thread was active
- `Executions` – Total number of thread invocations
- `Thread Name` – The `dpa_thread_name`

7.6.7.3.1 Examples

- Example of `collect` in infinite mode for process 0 with suppress header info:

```
$ sudo ./dpa-statistics collect -d mlx5_0 -p 0 -i
...^C
Data collected for 4606 milliseconds 0 nanoseconds
0           PROCESS_0
    5           223964            13754             140               31          EH_0_5_5
    6           190130            13754             114               31          EH_0_6_6
```

- Example of `collect` in timeout mode with a timeout of 1 second and half a millisecond.

```
$ sudo ./dpa-statistics collect -d mlx5_0 -t 1000.500
Data collected for 1000 milliseconds 500000 nanoseconds
ProcessID    Process Name
    ThreadID    Cycles            Instruction       Time              Executions        Thread Name
0           PROCESS_0
    5           223964            13754             140               31                EH_0_5_5
    6           190130            13754             114               31                EH_0_6_6
1           PROCESS_1
    3           266268            18193             164               41                EH_1_3_3
    4           411571            32727             252               47                EH_1_4_4
2           PROCESS_2
3           PROCESS_3
    0           223205            13754             137               31                EH_3_0_0
    1           189896            13754             113               31                EH_3_1_1
    2           191796            13754             117               31                EH_3_2_2
4           PROCESS_4
```

- Example of enabling statistics collection with reset of counters.

```
$ sudo ./dpa-statistics collect -d mlx5_0 -n -r
```

- Example of disabling statistics collection.

```
$ sudo ./dpa-statistics collect -d mlx5_0 -o
```

7.6.7.4 Known Limitations

- Reading large statistics counter blocks takes a long time
- The `dpa-ps` and `dpa-statistics` tools cannot be run at the same time on the same device

7.6.8 DPA Application Security Attributes to Blob

7.6.8.1 Overview

`dpa-app-attributes2blob` is a tool for converting between FlexIO attributes YAML files and binary blob files, and vice versa. It is typically used to generate binary configuration

blobs from human-readable YAML attributes, or to reverse the process for inspection and debugging.

7.6.8.2 Features

- Converts attributes YAML files to binary blobs (default mode)
- Converts binary blobs back to attributes YAML files
- Supports a nested `Feature_list` structure
- Validates input files and provides clear error messages
- Sets default values to `false` for unspecified fields
- Provides detailed feature descriptions in generated YAML files
- Supports error modes for blob-to-YAML conversion
- Configurable blob size for YAML-to-binary conversion
- Comprehensive bit validation in binary blobs

7.6.8.3 Usage

```
dpa-app-attributes2blob [--help] [--version] [mode] [error_mode] [blob_size] <input-file> <output-file>
```

Option	Description	Notes
`--yaml2bin`	Convert an attributes YAML file to a binary blob	Default
`--bin2yaml`	Convert a binary blob to an attributes YAML file	N/A
`--restrictive`	Treat invalid bits in a binary blob as errors	• Default • bin2yaml only
`--notification`	Treat invalid bits in a binary blob as warnings	bin2yaml only
`--blob-size <size>`	Specify the output size of the blob in bytes. The size must be a multiple of 4 and less than 1024.	• 8 bytes by default • yaml2bin only

7.6.8.3.1 Examples

- Convert YAML to binary blob:

```
dpa-app-attributes2blob --yaml2bin config.yaml output.bin
```

- Simple convert YAML to binary blob:

```
dpa-app-attributes2blob config.yaml output.bin
```

- Convert YAML to binary blob with custom size:

```
dpa-app-attributes2blob --yaml2bin --blob-size 16 config.yaml output.bin
```

- Convert binary blob to YAML:

```
dpa-app-attributes2blob --bin2yaml output.bin config.yaml
```

- Convert binary blob to YAML with warning mode:

```
dpa-app-attributes2blob --bin2yaml --notification output.bin config.yaml
```

7.6.8.4 Attributes YAML Format

- The attributes must have a top-level mapping containing only a `Feature_list` key.
- The `Feature_list` value must be a mapping containing feature flags.
- Field values must be boolean (`true` / `false` , `yes` / `no` , `on` / `off`).
- Fields not explicitly set default to `false` .
- Supported fields:
  - `Congestion_Control_Flow_Context_Access` : Enables the application to access the Congestion Control Flow Context.
  - `Programmable_Congestion_Control` : Enables the application to serve Programmable Congestion Control events.
  - `Generating_Empty_CQE` : Enables the application to generate an Empty CQE on a given CQ (e.g., for triggering other software entries).
  - `Device_Emulation` : Enables the application to emulate a PCIe device.

7.6.8.4.1 Example Attributes YAML

```yaml
Feature_list:
  Congestion_Control_Flow_Context_Access: true
  Programmable_Congestion_Control: false
  Generating_Empty_CQE: true
  Device_Emulation: true
```

7.6.8.4.2 Generated YAML Output

When converting from binary to YAML, the tool generates descriptive comments:

```
# This file was generated by dpa-app-attributes2blob
```

```
# A dictionary of features enabled/disabled for the application
Feature_list:
  # Enables application to access Congestion Control Flow Context
  Congestion_Control_Flow_Context_Access: true
  # Disables application to serve Programmable Congestion Control events
  Programmable_Congestion_Control: false
  # Enables application to generate Empty CQE on a given CQ, e.g. for triggering other SW entries
  Generating_Empty_CQE: true
  # Enables application to emulate a PCI device
  Device_Emulation: true
```

7.6.8.5 Error Handling

- The tool checks for duplicate fields, unknown fields, invalid boolean values, and malformed YAML structure.
- Only one document and the specified nested structure are allowed in the YAML.
- Sequences and aliases/anchors are not supported.
- In blob-to-YAML mode, the tool validates that only valid feature bits are set in the binary blob.
- Invalid bits can be treated as errors (default) or warnings (using `--notification`).
- The tool provides detailed error messages showing which specific bits are invalid in the binary blob.
- Command-line validation ensures error modes are only used with `--bin2yaml` and size options are only used with `--yaml2bin`.

7.6.8.6 Binary Blob Format

- The binary blob is stored in big-endian byte order.
- Custom blob sizes can be specified using the `--blob-size` option.
- The blob size must be a multiple of 4 bytes and cannot exceed 1024 bytes.
- Only the bits corresponding to defined features are validated; other bits are checked to ensure they are not set to `1`.

7.7 DOCA Flow Tune Tool

DOCA Flow Tune is a powerful, one-stop-shop solution, providing visibility and analysis capabilities for DOCA Flow programs.

7.7.1 Introduction

> DOCA Flow Tune is supported at alpha level.

DOCA Flow Tune is a one-stop-shop solution which allows developers to visualize their traffic steering pipelines, have a live monitor of software Key Performance Indicators (KPIs) as well as hardware counters, and gain valuable performance insights about their DOCA-Flow-based program.

DOCA Flow Tune is especially useful for the following scenarios:

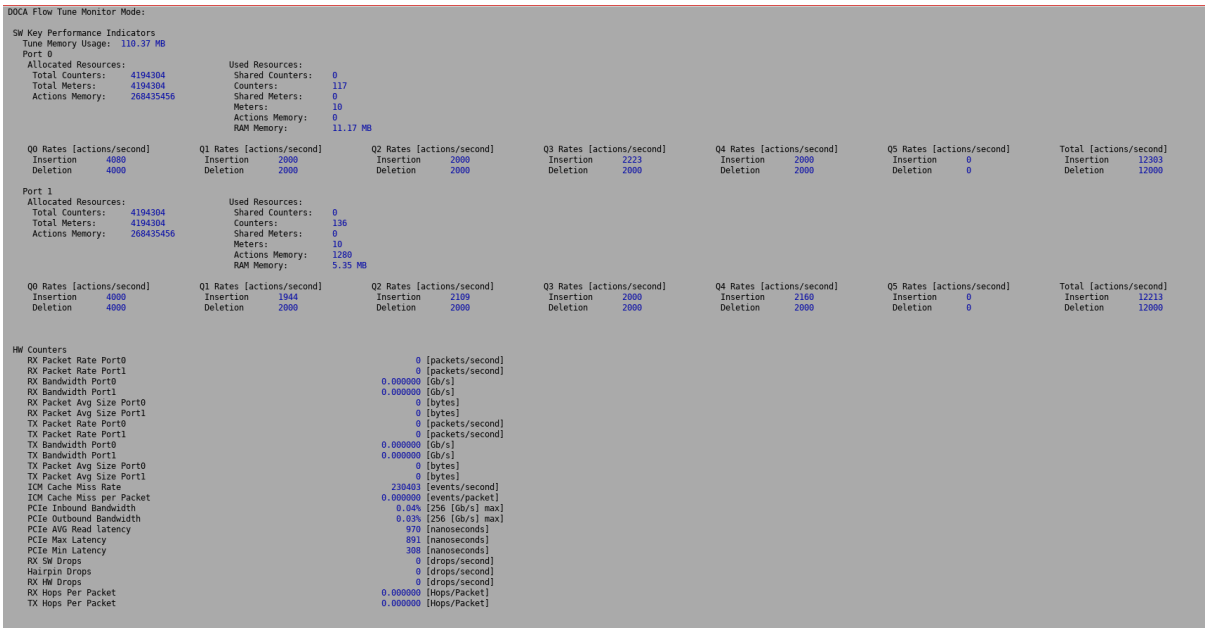
- Aiding developers during the development of their traffic steering pipeline by providing visualization of the pipeline, and later also performance insights about the designed pipeline
- Aiding developers in pre-production environments by providing live monitoring of the performance indicators of the program on both software and hardware levels, and helping detect possible bottlenecks/critical paths so they are addressed before deployment to production environments
- Aiding administrators monitor the program in production by providing live monitoring as well as high-rate hardware counters to be used when analyzing a possible deployment/setup issue

The tool operates in three distinct modes, Monitor, Analyze, and Visualize, which are presented in the following subsections.

Collecting, analyzing, and displaying information from the analyzed DOCA-Flow-based program requires the explicit activation of the DOCA Flow Tune server by the target program. For more information about that, refer to the DOCA Flow Tune Server programming guide.

7.7.1.1 Monitor Mode Overview

This mode collects and displays both hardware counters and software KPIs in real time (as extracted from the running DOCA Flow program and the underlying setup), providing a comprehensive view of the system's performance:



This information can also be exported to a CSV/JSON file for further analysis.

For more information about this mode, please refer to section "Monitor Mode".

For information about running DOCA Flow Tune in this mode, please refer to section "Monitor Command".

7.7.1.2 Analyze Mode Overview

The analyze mode supports the ability to dump the internal steering pipeline state to be used by Visualize mode.

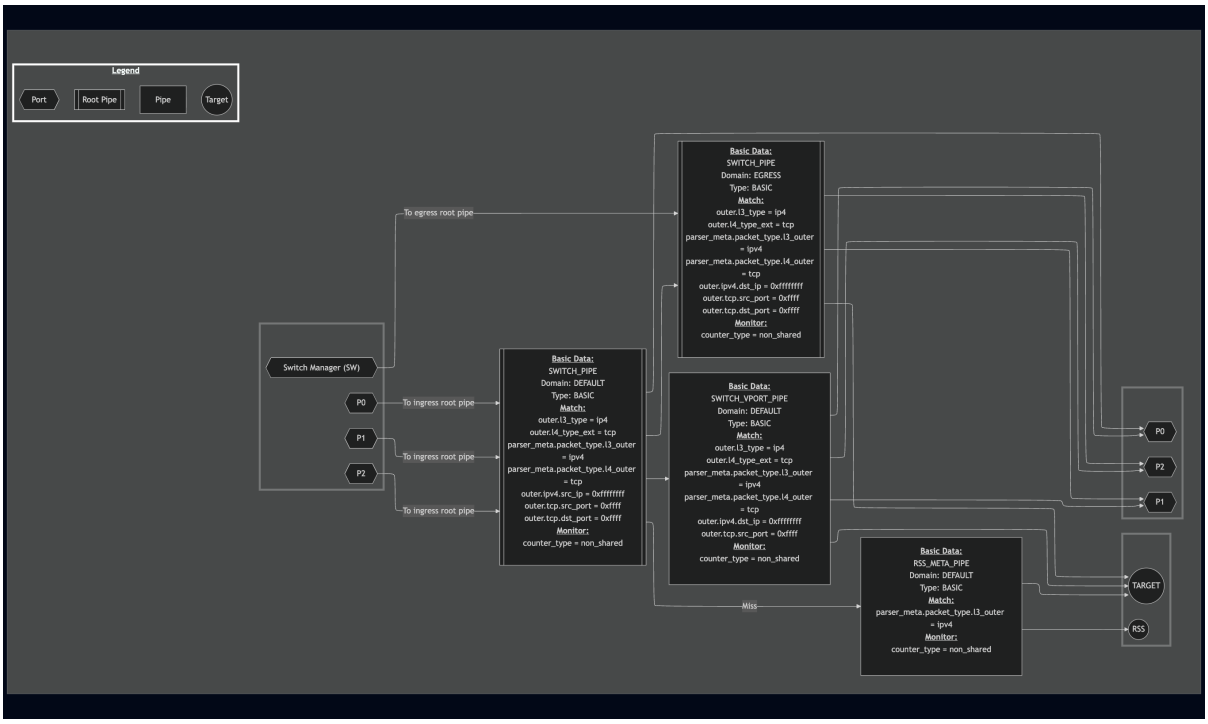
For more information about this mode, please refer to section "Analyze Mode".

For more information about running DOCA Flow Tune in this mode, please refer to section "Analyze Command".

7.7.1.3 Visualize Mode Overview

This mode allows users to produce a graphical representation of their steering pipeline (as built using the DOCA Flow API), allowing developers to quickly understand their program's pipeline, and compare it with their intended architecture.

The following diagram represents DOCA Flow Switch to Wire sample:



7.7.1.3.1 Mermaid Graph

The DOCA Flow Tune Mermaid graph visually represents the pipeline structure and metadata. It uses the following conventions:

- Shapes:
  - Square: Represents a pipe (root pipes denote with two additional lines inside the figure).
  - Hexagon: Represents a port.
  - Circle: Represent a pipeline target (drop, RSS, Kernel, etc).
  - Arrow: Indicates a possible connection between pipes and ports.
- Pipe Data Layers:
  Pipe metadata is organized into multiple visual layers. Layers can be stacked and selectively displayed when analyzing the pipeline.
  - Base Layer (default):
    - Includes general pipe attributes:
      - Name, label, type, domain, port id, hash algorithm
    - Match fields, action data and monitor configuration
    - Mask fields if provided.
  - Cost Layer:
    - Displays the minimum and maximum cost a packet can incur while traversing the pipe.
    - Overlays on top of the base layer.
  - Critical Path Layer:
    - Highlights the pipeline path with the highest total processing cost.

        - If multiple paths have the same cost, a single one is arbitrarily highlighted.
    - Resources Layer:
        - Shows resource utilization per pipe, including:
            - Number of counters
            - Number of meters
            - Action memory usage
            - RAM consumption
        - This layer is an overlay on the base layer.

> For more information about this mode, refer to section "Visualize Mode".

> For more information on running DOCA Flow Tune in this mode, refer to section "Visualize Command".

7.7.2 Dependencies

DOCA Flow Tune depends on the following DOCA SDK libraries:

- DOCA Flow
- DOCA Telemetry

7.7.3 Prerequisites

- DOCA 3.0.0 and higher.
- For optimal experience, it is recommended to comply with the prerequisites of all the listed dependencies, and especially with their recommended firmware versions.

7.7.4 Execution

To execute DOCA Flow Tune tool:

```
Usage: doca_flow_tune [Program Commands] [DOCA Flags] [Program Flags]

Program Commands:
  analyze                         Run Flow Tune in Analyze mode
  monitor                         Run Flow Tune in Monitor mode
  visualize                       Run Flow Tune in Visualize mode

DOCA Flags:
  -h, --help                      Print a help synopsis
  -v, --version                   Print program version information
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
```

```
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file
```

This usage printout can be printed to the command line interface (CLI) using the `-h` (or `--help`) option:

```
doca_flow_tune -h
```

The same applies for each of the tool's commands (and subcommands). For instance:

```
doca_flow_tune monitor -h
```

7.7.4.1 Monitor Command

The `monitor` command presents software KPIs and hardware counters. Each component offers various options, which can be specified in the configuration file under the `monitor` section, or through the CLI.

```
Usage: doca_flow_tune monitor [Program Commands] [DOCA Flags] [Program Flags]

Program Commands:
  background                        Collect SW key performance indicators and HW counters on the background

DOCA Flags:
  -h, --help                        Print a help synopsis
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma

Program Flags:
  --enable-dump                     Enable counters data dumping to file
  --disable-dump                    Disable counters data dumping to file
  --dump-file-name                  Counters dump file name to create
  --dump-file-format                Counters dump file format {json, csv}
  --hw-profile                      Register hardware profile {basic, full}
  --sw-profile                      Register software profile
  -f, --cfg-file                    JSON configuration file
```

Supported sub-commands:

- `background` – This subcommand allows performing file dumping without displaying the output on the screen. This is useful for scenarios where one wants to log counters without cluttering the terminal. It also supports high-rate dumping for hardware counters which may be activated using the `--high-rate` flag.

  ```
  Usage: doca_flow_tune monitor background [DOCA Flags] [Program Flags]

  DOCA Flags:
    -h, --help                      Print a help synopsis
    -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
  30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
    --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE,
  20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
    --log-filter                    Filter logs from specific modules, separated by comma

  Program Flags:
    --high-rate                     Enable dumping HW counters data to file in high rate
  ```

```
  --hw-profile                    Register hardware profile {basic, full}
  --sw-profile                    Register software profile
```

7.7.4.1.1 CLI Examples

- To launch the `monitor` command with a given configuration file:

```
doca_flow_tune monitor -f /tmp/flow_tune_cfg.json
```

- To launch the `monitor` command with both a given configuration file and a CLI parameter for specifying the desired hardware counters profile:

```
doca_flow_tune monitor -f /tmp/flow_tune_cfg.json --hw-profile basic
```

- To launch the `monitor` command with the `background` subcommand and the request to perform a high-rate collection and export for the hardware counters:

```
doca_flow_tune monitor -f /tmp/flow_tune_cfg.json background --high-rate
```

The tool silently creates and updates the `flow_tune{.csv, .json}` file.

7.7.4.2 Analyze Command

The `analyze` command runs a specified set of analysis methods over the target DOCA Flow program. The analysis supports the ability to export a JSON description of the steering pipeline, as is used by the `visualize` command, and could later be used for future analysis methods (both online or offline).

```
Usage: doca_flow_tune analyze export [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                      Print a help synopsis
  -l, --log-level                 Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                 Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                    Filter logs from specific modules, separated by comma
  -j, --json <path>               Parse command line flags from an input json file

Program Flags:
  --file-name                     File name on which the pipeline information will be saved
  -f, --cfg-file                  JSON configuration file
```

Supported subcommands:

- `export` – This command allows the tool to export a running DOCA Flow program's pipeline into a JSON file. This file is the main input for other features of the tool, such as the graphical visualization.

> The `export` subcommand is currently mandatory.

7.7.4.2.1 CLI Examples

- To launch the `analyze` command without a configuration file:

```
doca_flow_tune analyze export
```

  The JSON file is stored into its default path.
- To launch the `analyze` command with a given configuration file that specifies the desired values for all configurations necessary:

```
doca_flow_tune analyze export -f /tmp/flow_tune_cfg.json
```

- To launch the `analyze` command with a configuration file while also configuring the output path for the exported JSON file through the CLI:

```
doca_flow_tune analyze export -f /tmp/flow_tune_cfg.json --file-name my_program_pipeline_desc.json
```

  The exported pipeline is stored as `my_program_pipeline_desc.json` into the chosen/default output directory.

7.7.4.3 Visualize Command

The `visualize` command visualizes the steering pipeline of a given DOCA Flow program. The command works on a given JSON file as input. This file can either be generated by the `analyze export` command or queried dynamically from a running program, in which case the command would dump the pipeline from the program and then generate the visualization output file.

> The visualization output file is a Mermaid markdown format.

> This file can be fed to any of the widely available Mermaid visualization tools, as explained in depth in the corresponding section "Visualize Mode".

```
Usage: doca_flow_tune visualize [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                        Print a help synopsis
  -l, --log-level                   Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level                   Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL,
30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter                      Filter logs from specific modules, separated by comma
  -j, --json <path>                 Parse command line flags from an input json file
```

```
Program Flags:
  --pipeline-desc                 Input JSON file that represents the Flow application pipeline
  --file-name                     File name on which the visualization information will be saved
  -f, --cfg-file                  JSON configuration file
  --cost                          Show cost
  --critical-path                 Show critical path
  --resources                     Show resources
  --distribution                  Show distribution
  --tag                           Add mermaid tag (```mermaid) to the .md file
  --enhanced                      Enable enhanced graph coloring
```

7.7.4.3.1 CLI Examples

- Launching the `visualize` command without a configuration file triggers a live query of the pipeline from the currently running DOCA Flow program. In the absence of an input JSON file, the tool automatically generates and dumps a JSON representation of the active pipeline to be used for Mermaid diagram generation.

  ```
  doca_flow_tune visualize
  ```

  Example output:

  ```
  2025-04-09 15:06:44 - flow_tune - INFO - Pipeline description file not provided or doesn't exist, dumping
  pipeline description to /tmp/tmp_pipeline_desc.json
  2025-04-09 15:06:44 - flow_tune - INFO - Flow program pipeline information was exported to "/tmp/
  tmp_pipeline_desc.json"
  2025-04-09 15:06:44 - flow_tune - INFO - Mermaid graph exported to /tmp/flow_tune/flow_tune_pipeline_vis.md
  2025-04-09 15:06:44 - flow_tune - INFO - DOCA Flow Tune finished successfully
  ```

- Launching the `visualize` command with a given configuration file that specifies the desired values for all needed configurations:

  ```
  doca_flow_tune visualize -f /tmp/flow_tune_cfg.json
  ```

- To launch the `visualize` command with a configuration file while configuring the output path for the Mermaid file through the CLI and providing an offline pipeline file:

  ```
  doca_flow_tune visualize -f /tmp/flow_tune_cfg.json --file-name my_program_pipeline_viz.md --pipeline-desc
  my_program_pipeline_desc.json
  ```

  The exported Mermaid file is stored as `my_program_pipeline_viz.md` into the chosen/default output directory. Because the pipeline description file is explicitly provided, this command could be used offline, as it would not need connection with the DOCA Flow program to visualize.

  > ⚠ To launch the `visualize` command with the `--critical-path` or `--cost` flags, the `low_level_info` setting must be enabled (`true`):
  >
  > - When using a configuration file, the `low_level_info` field must be set to `true` in the `analyze` section of the provided configuration file. For example:

```
doca_flow_tune visualize --cost -f /tmp/flow_tune_cfg.json
# flow_tune_cfg.json must include: "low_level_info": true
```

- When using an offline pipeline JSON file, the file must have been generated with `low_level_info` enabled at the time of the dump:

```
doca_flow_tune visualize --cost --pipeline-desc my_program_pipeline_desc.json
# my_program_pipeline_desc.json must have been dumped with "low_level_info": true
```

7.7.5 Configuration

DOCA Flow Tune has a configuration file which allows customizing various settings.

> The configuration file is divided into sections to simplify its usage.

7.7.5.1 Config File Default Values

If a configuration file is not provided, DOCA Flow Tune uses its default values for fields which are mandatory.

> A list of all default values can be seen in the appendix.

In Monitor mode, if a software KPIs or hardware counters query is not needed, removing the `hardware` or `software` fields from the configuration file disables the respective feature.

7.7.5.2 Custom Config File

Instead of using default configuration values, users can create a file of their own and provide a file path when running DOCA Flow Tune (`-f` / `--cfg-file`).

Once used, DOCA Flow Tune loads all provided values directly from the file, while the rest of the fields (if any) use their respective default values.

7.7.5.3 Overriding Config Values from CLI

Setting some of the fields in the configuration file is supported through CLI using the `--file-name` flag. If used, the values provided from the CLI would override the values of the fields from the configuration file. This allows for easier configuration of common

values without the need to create a new custom file or to modify an existing configuration file.

7.7.5.4 Common Configuration Values

Some sections of the configuration file are shared between multiple runtime modes of DOCA Flow Tune (i.e., Monitor, Analyze, Visualize) and generally have to do with the output/input file paths and interaction with the live DOCA Flow program.

flow_tune_cfg.json

```
{
...
    "outputs_directory": "/tmp/flow_tune/",
...
    "network": {
        "server_uds": "/tmp/tune_server.sock",
        "uds_directory": "/var/run/doca/flow_tune/"
    },
...
}
```

7.7.5.4.1 Output Directory

`outputs_directory` defines the main directory on which all output products are saved. This field does not have a default value. If no value is provided, DOCA Flow Tune files are saved at the following directories:

- Counters dump file {.json, .csv} – `/tmp/flow_tune/`
- Analyze export pipeline description file – `/tmp/flow_tune/`
- Pipeline visualization file – `/tmp/flow_tune/`

7.7.5.4.2 Connection to DOCA Flow Tune Server

Some features of DOCA Flow Tune work by interacting with a live DOCA Flow based program. This is enabled through a server that is running in the background as part of the DOCA Flow library, and requires all the following to be applied:

1. DOCA Flow based program should explicitly enable the server.

   > More information is available in the relevant DOCA Flow Tune Server programming guide.

2. The DOCA-Flow-based program should run using the trace-enabled DOCA Flow library.

> More information is available in the "Debug and Trace Features" section of the DOCA Flow programming guide.

DOCA Flow Tune should be configured in a way to allow it to connect to the matching server. This can be done by modifying the following variables under the `network` section of the configuration file:

- `server_uds` – DOCA Tune Server Unix Domain Socket (UDS) path. Default value is `/tmp/tune_server.sock`.
- `uds_directory` – Directory on which all local UDSs are created. Default value is `/var/run/doca/flow_tune/`.

7.7.6 Monitor Mode

7.7.6.1 Hardware Counters

This table provides the supported hardware counters and their associated profiles.

Counter Name	Description	Unit	Profile Basic	Profile Full
RX Packet Rate	The number of received packets per second	pkt/sec	✓	✓
RX Bandwidth	The data transfer rate based on the number of packets received per second	Gb/s	✓	✓
RX Packet Average Size	The average size of received data packets	Bytes	✓	✓
TX Packet Rate	The number of packets transmitted per second	pkt/sec	✓	✓
TX Bandwidth	The data transfer rate based on the number of packets transmitted per second	Gb/s	✓	✓
TX Packet Average Size	The average size of transmitted data packets	Bytes	✓	✓
RX SW Drops [1] [2]	The number of packets dropped due to a lack of WQE for the associated QPs/RQs (excluding hairpin QPs/RQs)	drops/sec	✓	✓
Hairpin Drops [3] [2]	The number of packets dropped due to a lack of WQE for the associated hairpin QPs/RQs	drops/sec	✓	✓
RX HW Drops [4]	The number of packets discarded due to no available data or descriptor buffers in the RX buffer	drops/sec	✓	✓
ICM Cache Miss Rate	The rate of data requests that miss in the ICM (interconnect context memory) cache	events/sec	✗	✓

Counter Name	Description	Unit	Profile Basic	Profile Full
ICM Cache Miss per Packet	The number of data requests that miss per packet	events /pkt	✗	✓
PCIe Inbound Bandwidth [5]	The number of bits received from the PCIe toward the device per second.	Gb/s	✗	✓
PCIe Outbound Bandwidth [5]	The number of bits transmitted from the device toward the PCIe per second	Gb/s	✗	✓
PCIe AVG Read latency [5]	The average PCIe read latency for all read data	nsec	✗	✓
PCIe Max Latency [5]	The maximum latency (in nanoseconds) for a single PCIe read from the device	nsec	✗	✓
PCIe Min Latency [5]	The minimum latency (in nanoseconds) for a single PCIe read from the device	nsec	✗	✓
RX Hops Per Packet	The number of hops per packet in RX domain	hops/ pkt	✗	✓
TX Hops Per Packet	The number of hops per packet in TX domain	hops/ pkt	✗	✓

1. If drops are observed, this may be because the software was unable to process all received packets. Consider reducing CPU processing time or increasing the number of utilized cores and queues.
2. Supported only on NVIDIA® ConnectX®-7 and above.
3. If drops are observed, the Tx packet processing is probably causing a bottleneck. Consider simplifying the process or adjusting the number or size of hairpin queues or implementing locking mechanisms.
4. If drops are observed, the Rx packet processing is probably causing a bottleneck. Consider simplifying it.
5. PCIe counters are supported only on the host side.

7.7.6.2 Software Key Performance Indicators

The following table lists the supported software Key Performance Indicators (KPIs) and their associated profiling categories:

Key Performance Indicator	Description	Units	Profile
Insertion rate	Number of successful table entry insertions per queue per second	actions/ sec	`entries_ops_rates`
Deletion rate	Number of successful table entry deletions per queue per second	actions/ sec	`entries_ops_rates`

Key Performance Indicator	Description	Units	Profile
Action resources	Number of resources utilized by the program for all user-defined actions	N/A	`action_resources`

7.7.6.2.1 Action Resources Counters

The `action_resources` section displays the following per-port counters, including both the total allocated and currently used amounts:

- Resource counters:
  - Number of Shared Counters
  - Number of Counters
  - Number of Shared Meters
  - Number of Meters
  - Actions Memory
- Used memory resources:
  - RAM

7.7.6.3 Configuration

7.7.6.3.1 Counters Dumper

7.7.6.3.1.1 Hardware Counters

Counter Name	Units
Rate of RX packets on port 0	Packets per second
Rate of RX packets on port 1	Packets per second
RX bandwidth on port 0	Gb/s
RX bandwidth on port 1	Gb/s
Average RX packet size on port 0	Bytes
Average RX packet size on port 1	Bytes
Rate of TX packets on port 0	Packets per second
Rate of TX packets on port 1	Packets per second
TX bandwidth on port 0	Gb/s
TX bandwidth on port 1	Gb/s
Average TX packet size on port 0	Bytes
Average TX packet size on port 1	Bytes

Counter Name	Units
ICMC misses rate	Events per second
ICMC misses per packet	Events per packet
The bandwidth of bytes received from PCIe toward the device	Gb/s
The bandwidth of bytes transmitted from the device toward PCIe	Gb/s
The average PCIe read latency	Nanoseconds
The total latency for all PCIe read from the device	Nanoseconds
The total number of PCIe packets	Events
The maximum latency for a single PCIe read from the device	Nanoseconds
The minimum latency for a single PCIe read from the device	Nanoseconds
RX software drops	Drops per second
Hairpin drops	Drops per second
RX hardware drops	Drops per second
RX Hops Per Packet	[Hops/Packet]
TX Hops Per Packet	[Hops/Packet]

7.7.6.3.1.2 Software KPI Counters

Counter Name	Units
Queue <i> Insertion Rate	Deletions per second
Queue <i> Deletion Rate	Insertions per second
Total Insertion Rate	Insertions per second
Total Deletion Rate	Insertions per second
Total Allocated Counters	
Total Used Counters	
Total Used Shared Counters	
Total Allocated Meters	
Total Used Meters	
Total Used Shared Meters	
Total Allocated Actions memory	Bytes
Total Used Actions memory	Bytes
Used RAM Memory	Bytes

7.7.6.3.1.3 CSV Format

The CSV format stores two types of rows, specific to each counter module:

- ***Hardware Counter Rows***

Module Name	HW Counter Name	Counter Value	Timestamp
HW	Hairpin drops	8	142623139459
HW	TX Hops Per Packet	197503959728	142623139459

- Module Name – Hardware module name
- HW CounterName – Hardware counter name
- Counter Value – Counter value
- Timestamp – Hardware timestamp

- ***Software KPI Rows***

Module Name	Port ID	SW Counter Name	Counter Value	Timestamp
SW	0	Queue 0 Insertion Rate	34511	1727345744137828
SW	1	Queue 2 Insertion Rate	37050	1727345755137828
SW	0	Allocated Counters	4	1727345755137828
SW	0	Total Allocated Counters	3	1727345755137828

- Module Name – Software module name
- Port ID – Software port ID
- SW KPI Name – KPI name
- KPI Value – KPI value
- Timestamp – Software timestamp

7.7.6.3.1.4 JSON Format

The JSON output consists of a root object where each key represents a timestamp. The value associated with each timestamp is a nested JSON object containing the performance counters and metrics recorded at that specific point in time.

JSON output example:

```
{
  "171106550167": {
    "Hairpin Drops Rate": 0.0,
    "ICMC Miss Rate": 0.0,
    "ICMC Miss per Packet": 18.944444444444443,
    "PCIe AVG Read Latency": 6028.0,
    "PCIe Inbound BW": 0.0,
    "PCIe Max Read Latency": 396.0,
    "PCIe Min Read Latency": 346.0,
    "PCIe Outbound BW": 0.0,
    "RX Bandwidth Port0": 0.0,
    "RX Bandwidth Port1": 0.0,
    "RX HW Drops Rate": 0.0,
    "RX Hops Per Packet": 0.0,
    "RX Packet Avg Size Port0": 0.0,
    "RX Packet Avg Size Port1": 0.0,
    "RX Packet Rate Port0": 0.0,
    "RX Packet Rate Port1": 0.0,
    "SW Drops Rate": 0.0,
    "TX Bandwidth Port0": 0.0,
    "TX Bandwidth Port1": 0.0,
    "TX Hops Per Packet": 0.0,
    "TX Packet Avg Size Port0": 0.0,
    "TX Packet Avg Size Port1": 0.0,
    "TX Packet Rate Port0": 0.0,
    "TX Packet Rate Port1": 0.0
  },
  ...
}
```

7.7.6.3.2 Configuration File

DOCA Flow Tune's configuration file consists of two main parts of relevance for Monitor mode:

- `dumper` dump object
- `monitor` configuration object

The following is an example for both sections:

flow_tune_cfg.json

```
{
...
     "dumper": {
        "enable": true,
        "high-rate": false,
        "file_name": "flow_tune.json",
        "stats_time": 1,
        "format_type": "json", // types: {csv, json}
        "max_files": 3,
        "max_size_bytes": 1000000
    },

...

     "monitor": {
        "screen_mode": "dark",  // modes: {light, dark}
        "hardware": {
            "pci_addresses": [
                "b1:00.0",
                "b1:00.1"
            ],
            "profile": "full"  // profiles: {basic, full}
        },
        "software": [
            {
                "flow_port_id": 0,
                "profiles": [
                    "entries_ops_rates"  // profiles: {entries_ops_rates, action_resources}
                ]
            },
            {
                "flow_port_id": 1,
                "profiles": [
                    "entries_ops_rates"
                ]
            }
        ]
    }
...
}
```

7.7.6.3.2.1 Dumper Configuration Section

The dumper allows exporting the hardware and software counters collected by the tool into a output file for further analysis or record keeping. This is particularly useful for logging performance metrics over time.

How to Enable Counters Dumper

To enable CSV dumping, modify the configuration in the JSON file as follows:

```
{
  "dumper": {
        "enable": true,
        "file_name": "flow_tune.csv",
        "format_type": "csv",
    },
}
```

To enable JSON dumping, modify the configuration in the JSON file as follows:

```
{
  "dumper": {
        "enable": true,
        "file_name": "flow_tune.json",
        "format_type": "json",
    },
}
```

The supported fields are:

- `enable` – Set to `true` to enable counters dumping or `false` to disable it. Default value is `false`.
- `file_name` – The name of the dump file where the data will be saved. By default when enabling the dumper, format type is `Json`.
- `format_type` – The dump file format `CSV` or `Json`.
- `max_size_bytes` – The maximum size (in bytes) of the dump file. Once this limit is reached, a new file is created based on the `max_files` setting.
- `max_files` – The maximum number of CSV files to keep. When this limit is reached, the oldest files are deleted.

The counters dumping can also be enabled or disabled from the CLI using the `--enable-dump` or `--disable-dump` flags, respectively. For example:

```
doca_flow_tune monitor -f /tmp/flow_tune_cfg.json --enable-dump
```

Additionally, the format type and filename can be updated by using the `--dump-file-name` and `--dump-file-format` flags, for example:

```
doca_flow_tune monitor -f /tmp/flow_tune_cfg.json --dump-file-name "counters_dump.csv" --dump-file-format "csv"
```

7.7.6.3.2.2 Monitor Configuration Section

Screen Mode

The Monitor module supports two screen modes: `dark` and `light`.

Hardware

The `hardware` section includes the `pci_addresses` and `profile` fields:

- The `pci_addresses` field expects an array of PCIe addresses for NIC ports. The tool uses these addresses to retrieve the corresponding NIC device and the desired port IDs.

  > ⚠ PCIe addresses must belong to the same device.

  > ℹ The tool supports up to two ports per device.

- The `profile` field expects to receive either a `basic` or `full` profile.
  - `basic` profile – includes packet- and port-related counters (i.e., Bandwidth, Packets Per Second, Average Packet Size, Packet Drops)
  - `full` profile – includes all the `basic` counters and adds additional debug counters (e.g., ICMC and PCIe counters)

    > For more information about the counters please refer to section "Hardware Counters".

The hardware counters profile can be set from the CLI by adding `--hw-profile`. For example:

```
doca_flow_tune monitor -f /tmp/flow_tune_cfg.json --hw-profile basic
```

Software

The `software` section includes the `flow_port_id` and `profiles` fields:

- `flow_port_id` field – expects a single DOCA Flow port identification number. Flow port ID should be set by the DOCA Flow program, by calling the `doca_flow_port_cfg_set_devargs()` API call with a proper port ID string.
- `profiles` field – accepts one or more of the supported profiling categories.
  - `entries_ops_rates` profile – includes both insertion and deletion rates KPIs
  - `action_resources` profile – provides data on allocated and in-use resources, including counters, meters, and actions memory.

The software profile can be set from the CLI by adding `--sw-profile`, for example:

```
doca_flow_tune monitor -f /tmp/flow_tune_cfg.json --sw-profile entries_ops_rates
```

7.7.7 Analyze Mode

Analyze mode gathers (and later analyzes) information in order to assist users to better understand and debug their DOCA-Flow-based program.

7.7.7.1 Pipeline Export

This tool export an internal state of the DOCA-Flow-based program in a proprietary JSON format. This allows the tool to provide offline information about a given program

which can be later be analyzed. One such example is the ability to visualize the pipeline of the target program without having said program run on real hardware.

While the pipeline export operation is meant to encode all relevant information for future analysis, the format itself is proprietary and is only meant to be consumed by other DOCA tools.

7.7.8 Visualize Mode

The `doca_flow_tune visualize` command generates a visual representation of a DOCA Flow pipeline using the Mermaid diagram format.

7.7.8.1 Supported Pipe Types

The following pipe types are supported in visualization mode:

- Basic
- Control
- Hash
- CT – Fully supported in the Base and Resources layers. For other layers, the visualization results may be inaccurate.
- Ordered List – Fully supported in the Base and Resources layers. For other layers, the visualization results may be inaccurate.

7.7.8.2 Viewing the Pipeline

Running the `visualize` command produces a Mermaid-format file representing the pipeline structure. Mermaid is a text-based diagramming language supported by many documentation tools and editors. One commonly used online editor is Mermaid Live, which can be used to render and inspect the generated pipeline diagram.

To view the pipeline:

1. Open Mermaid Live.
2. Copy the contents of the generated `.mmd` file.
3. Paste the contents into the editor to visualize the pipeline.

7.7.8.3 Visualization Layers

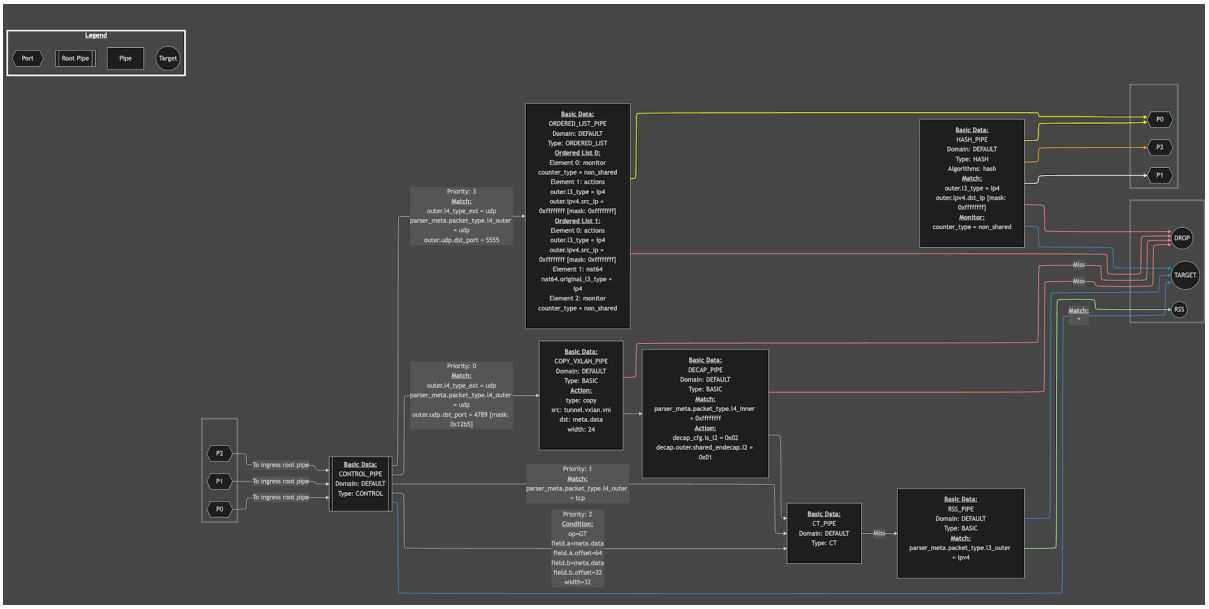
Each Mermaid diagram can include multiple layers, each offering a distinct view into pipeline characteristics. If no specific layer is selected, the base layer is used by default.

7.7.8.3.1 Base Layer

This layer visualizes the static configuration of the DOCA Flow pipeline, including:

- Pipe node data:
  - Name
  - Label
  - Port ID
  - Domain
  - Type
  - Mask configuration
  - Defined actions
  - Monitor attributes
- Pipe link (arrow) data:
  - For Control pipes: Priority, condition and matching values (e.g., `*` indicates match-all).
  - For other pipes: Miss links are marked accordingly.

Using `--enhanced`, pipe links going into DROP/TARGET/RSS/PORT will be colored to ease the paths identification.

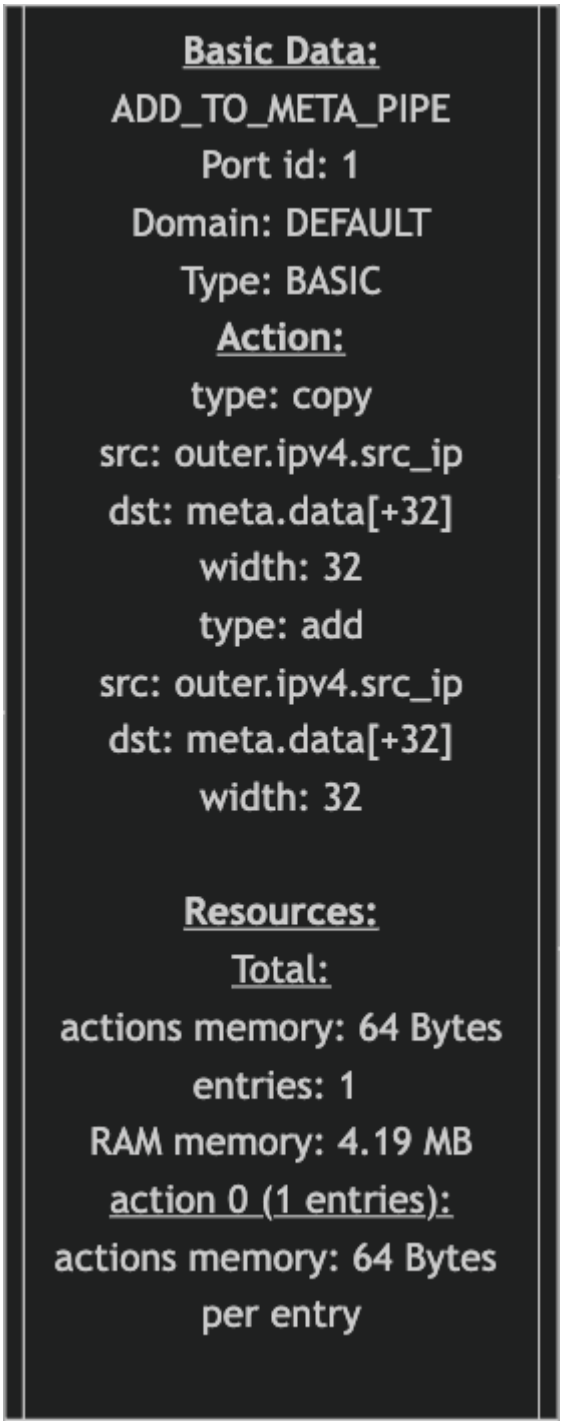


7.7.8.3.2 Resources Layer

Enabled via the `--resources` flag, this layer adds information about resource utilization:

- Pipe node data:
  - Total number of actions in use by entries (all pipe types)
  - Resource breakdown per action (non-Control pipes only)

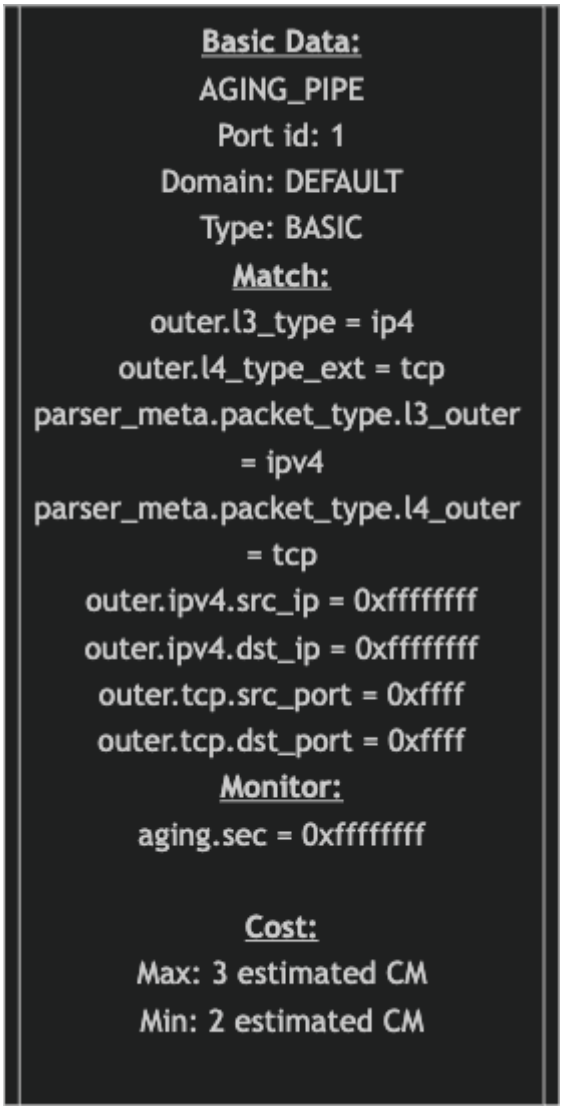
- Resources visualized:
    - Counters
    - Meters
    - Actions memory
    - Entry count
    - RAM usage



7.7.8.3.3 Cost Layer

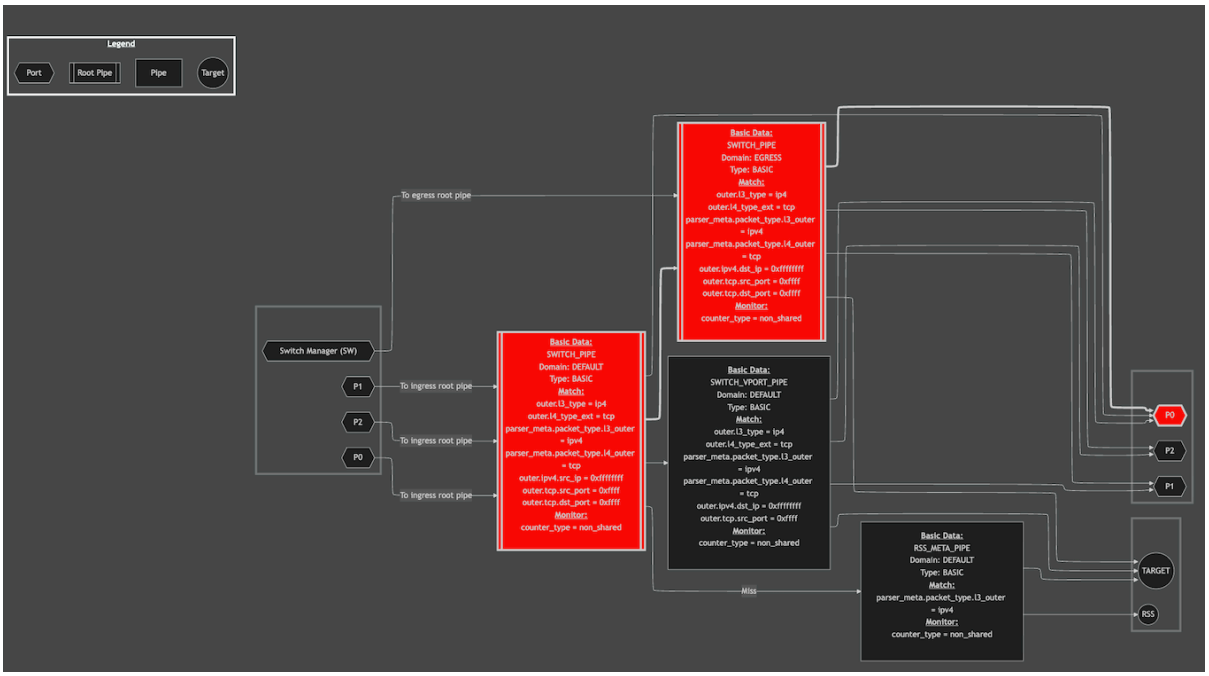
Enabled via the `--cost` flag, this layer estimates the cache impact of processing packets through the pipeline:

- Minimum and maximum estimated cache misses per pipe
- Helps identify high-cost areas in the pipeline



7.7.8.3.4 Critical Path Layer

Enabled via the `--critical-path` flag, this layer highlights the pipeline path with the highest estimated processing cost (i.e., the path with the most cache misses). If multiple paths are tied, one is selected arbitrarily.



7.7.8.3.5 Distribution Layer

Enabled via the `--distribution` flag, this layer simulates traffic flow through the pipeline using a PCAP input file.

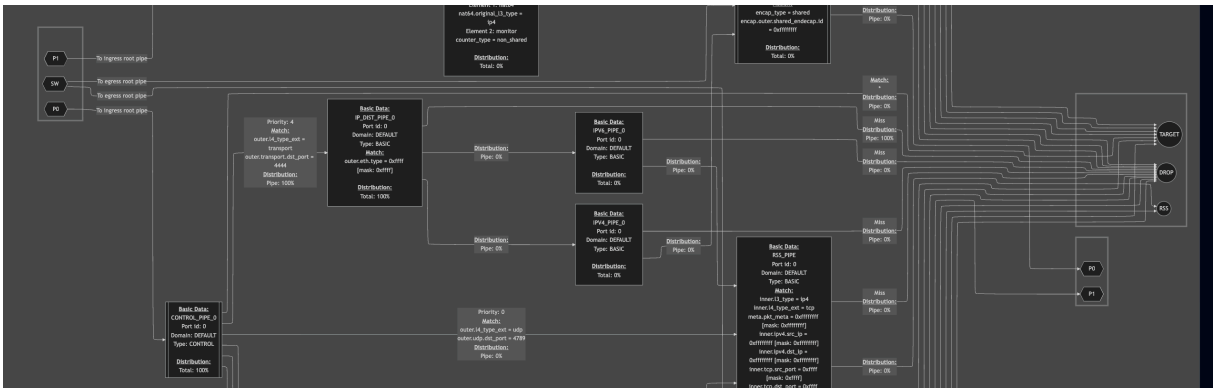
> ⚠ This layer does not support all pipe types. Consequently, results may be inaccurate for pipelines containing unsupported types.

Requirements:

- A PCAP file must be provided via the `--pcap-file` flag or in the configuration file.
- The `low_level_info` parameter must be set to `true` in the configuration when performing offline analysis.

Output data:

- Pipe node data:
  - `Distribution`: Displays the percentage of *total* packets that passed through this specific pipe.
    - Example: `Total: 62%`
- Pipe link data:
  - `Distribution`: Displays the percentage of packets from the *source* pipe that traversed this specific link.
    - Example: `Pipe: 78%`



In the partial diagram above, packets can be observed flowing along the following path: Port 0 → `CONTROL_PIPE_0` → `IP_DIST_PIPE_0` → DROP.

7.7.9 Known Issues

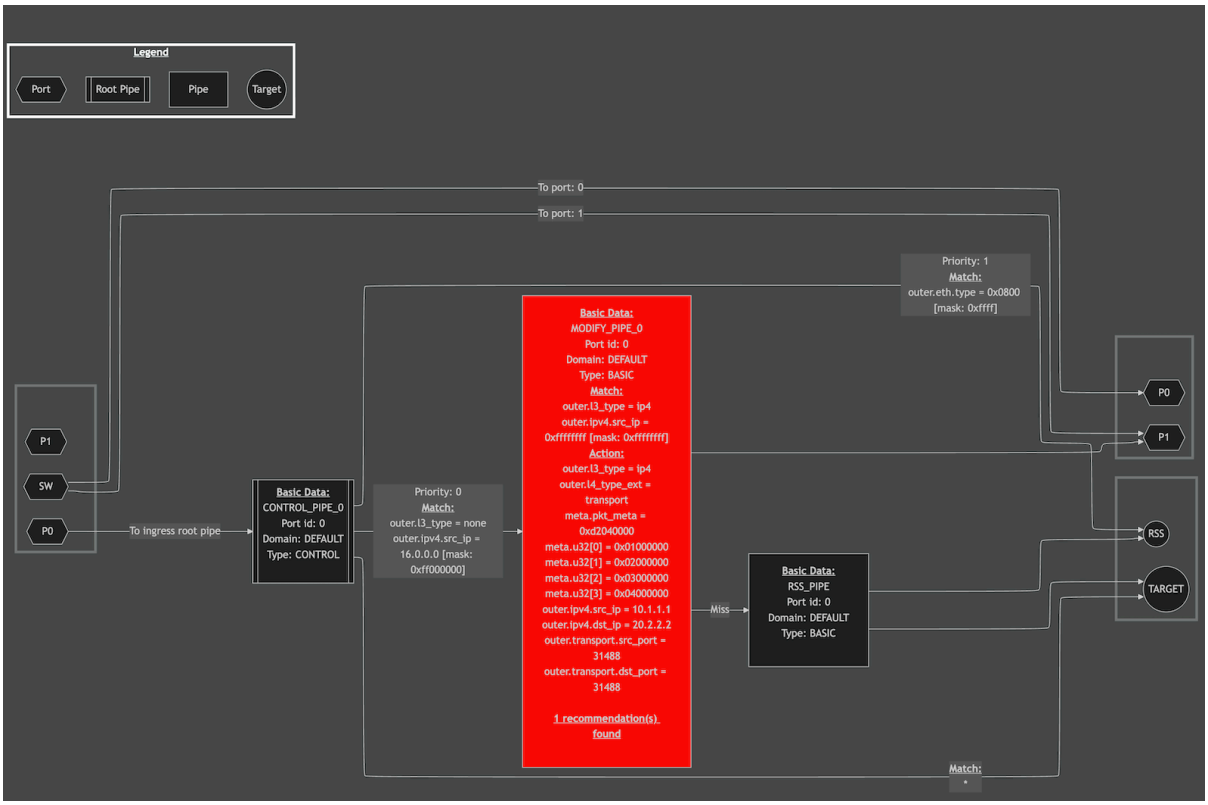
- Match values for the following fields are not supported:
  - `outer.l2_type`
  - `outer_l3_type`
  - `outer_l4_type`
  - `tun.gre.protocol`
  - `tun.key_present`
- The Distribution layer functions only when using supported match fields. Unsupported fields may result in inaccurate or incomplete packet flow analysis.

7.7.9.1 Recommendations Layer

When enabled using the `--recommendations` flag, this layer identifies and highlights pipeline components that can be optimized for better performance.

Supported insights:

- Action and action description split recommendations. This insight enables the tune tool to suggest splitting pipes that contain actions which can benefit from separation. By dividing these pipes into two, the system optimizes the steering processing path, improving overall performance.



7.7.10 Use Cases

7.7.10.1 Actions Memory Calculation

The DOCA Flow API requires the application to configure the maximum actions memory using the `doca_flow_port_cfg_set_actions_mem_size()` function. There are two strategies for determining the optimal value:

7.7.10.1.1 Measured Strategy

- Configure the application with the maximum supported actions memory.
- Run the application under expected load.
- Execute the Flow Tune tool in Monitor mode.
- Use the reported memory usage from the tool to determine the optimal actions memory size.
- Update the application configuration to match the measured usage, ensuring compliance with the DOCA Flow API.

```
Port 1
 Allocated Resources:                  Used Resources:
  Shared Counters:    0                 Shared Counters:    0
  Counters:           8388608           Counters:           1306
  Shared Meters:      0                 Shared Meters:      0
  Meters:             8388608           Meters:             100
  Actions Memory:     536870912         Actions Memory:     12800
```

7.7.10.1.2 Calculated Strategy

- Start with a minimal actions memory size in the application configuration.
- After pipe creation (but before adding entries), run the Flow Tune tool in Visualization mode with the Resources Layer enabled.
- For each pipe:
  - Multiply the expected number of entries by the reported actions memory per entry.
- Sum the memory requirements across all pipes to obtain the total actions memory needed.
- Set this value in the application using the appropriate DOCA Flow API.

7.7.10.2 Counter Observation

Use the tool in Monitor mode to observe hardware and software counters in real time. The tool provides per-second updates on:

- Entry insertion and deletion rates
- Memory and resource utilization
- Other performance metrics

This helps identify performance bottlenecks and track system behavior under load.

7.7.10.3 Program Pipeline Visualization

By running the tool in Visualization mode, the developer can:

- Generate a graphical representation of the DOCA Flow program pipeline
- Understand the packet processing path and logic
- Debug and validate flow construction
- Optimize the pipeline for performance and correctness

7.7.10.4 Identifying Bottle Neck Pipes

Running the tool in Visualization mode with the `--cost` and `--critical-path` flags enables detection of performance-critical paths:

- Highlights pipes with the highest cache miss estimates
- Marks the most critical path (i.e., the slowest or most resource-intensive)
- Helps developers focus optimization efforts on the slowest segments of the pipeline

7.7.11 Troubleshooting

7.7.11.1 Telemetry fwctl driver is not loaded

7.7.11.1.1 Error

When running the DOCA Flow Tune in Monitor mode, the following log messages are encountered at startup:

```
[DOCA][WRN][priv_doca_telemetry_fwctl.cpp:121][priv_doca_telemetry_fwctl_find_device_by_pci] Failed finding fwctl
device: Opening directory /sys/class/fwctl/ failed. Make sure you have the fwctl driver loaded
[DOCA][ERR][priv_doca_telemetry_fwctl.cpp:201][priv_doca_telemetry_fwctl_open_by_devinfo] devinfo 0x55c572286520:
Failed to open fwctl device: Failed to find matching fwctl device
```

7.7.11.1.2 Solution

The DOCA Telemetry SDK uses the `fwctl` driver to query the hardware counters, so it is essential to have it installed and loaded.

7.7.11.1.2.1 Step 1: Verify the Driver Installation

First, check if the driver is installed as follow:

- Debian/Ubuntu:

  ```
  $ sudo apt list --installed | grep fwctl
  ```

- RHEL:

  ```
  $ sudo yum list installed | grep fwctl
  ```

If the driver is not installed, install it by running the following commands:

- Debian/Ubuntu:

```
$ sudo apt search fwctl
>> <fwctl-package-name>/....

$ sudo apt install -y <fwctl-package-name>
```

- RHEL:

```
$ sudo yum search fwctl
>> <fwctl-package-name>/....

$ apt/yum install -y <fwctl-package-name>
```

7.7.11.1.2.2 Step 2: Check if the Driver is Loaded

After installing the driver, verify that it is loaded by executing:

```
$ sudo lsmod | grep fwctl
```

You should see output similar to:

```
> mlx5_fwctl 20480 0
> fwctl 16384 1 mlx5_fwctl
> mlx5_core 2134016 2 mlx5_fwctl,mlx5_ib
> mlx_compat 69632 14
 rdma_cm,ib_ipoib,mlxdevm,mlxfw,mlx5_fwctl,iw_cm,ib_umad,fwctl,ib_core,rdma_ucm,ib_uverbs,mlx5_ib,ib_cm,mlx5_core
```

If the driver is not loaded, load it by running:

```
$ sudo modprobe mlx5_fwctl
```

7.7.11.2 Mermaid visualization in Visual Studio Code

Visual Studio Code provides extensions to view Mermaid markdown format, these extensions can be used to view the Mermaid output from DOCA Flow Tune tool.

However, for these extension to work, DOCA Flow Tune tool should run with `--tag`.

7.7.11.3 Limited Feature Set – Could Not Detect Running DOCA Flow Program

7.7.11.3.1 Error

When running DOCA Flow Tune, the following log message is encountered at startup, followed by some features failing to work/load:

```
[DOCA][WRN][flow_tune.cpp:195][get_flow_app_data] Could not detect a running DOCA Flow program, some features will
be impacted
```

7.7.11.3.2 Solution

Some features of DOCA Flow Tune work by interacting with a live DOCA-Flow-based program. This is enabled through a server running in the background as part of the DOCA Flow library, and requires all of the following to be applied:

- DOCA-Flow-based program should explicitly enable the server. More information is available in the DOCA Flow Tune Server programming guide.
- DOCA-Flow-based program should run using the "trace enabled" DOCA Flow library. More information is available in the "Debug and Trace Features" section of the DOCA Flow programming guide.\

7.7.11.4 visualize --cost or --critical-path Not Working

7.7.11.4.1 Error

When running DOCA Flow Tune in `visualize` mode with the `--cost` or `--critical-path` flags, the following error may occur:

```
2025-04-14 12:24:20 - flow_tune - ERROR - Low level info need to be enabled to visualize cost or critical path
2025-04-14 12:24:20 - flow_tune - ERROR - Failed to export mermaid graph
2025-04-14 12:24:20 - flow_tune - ERROR - DOCA Flow Tune failed during "visualize" command: Invalid input
2025-04-14 12:24:20 - flow_tune - ERROR - DOCA Flow Tune finished with errors
```

7.7.11.4.2 Solution

The `--cost` and `--critical-path` options require low-level pipeline information, which is not enabled by default.

To resolve this issue, ensure that `"low_level_info": true` is specified in one of the following ways:

1. Option 1 – configuration file:

   ```
   doca_flow_tune visualize --cost -f /tmp/flow_tune_cfg.json
   ```

   Make sure the config file (`flow_tune_cfg.json`) includes:

   ```
   "analyze": {
     "low_level_info": true
   }
   ```

2. Option 2 – offline pipeline description:

```
doca_flow_tune visualize --cost --pipeline-desc my_program_pipeline_desc.json
```

Ensure that `my_program_pipeline_desc.json` was originally exported with `"low_level_info": true` enabled during analysis or dump.

7.7.12 Appendix – Configuration File Example

flow_tune_cfg.json

```
{
    "outputs_directory": "/tmp/flow_tune/",
    "logging": {
        "developer_log": "/var/log/doca/flow_tune/flow_tune_dev.log",
        "operational_log": "/var/log/doca/flow_tune/flow_tune.log"
    },
    "network": {
        "server_uds": "/tmp/tune_server.sock",
        "uds_directory": "/var/run/doca/flow_tune/"
    },
    "dumper": {
        "enable": false,
        "file_name": "flow_tune.csv",
        "format_type": "csv",
        "max_size_bytes": 1000000000,
        "max_files": 1
    },
    "analyze": {
        "file_name": "flow_tune_pipeline_desc.json",
        "low_level_info": false
    },
    "visualize": {
        "pipeline_desc_file": "/tmp/flow_tune/flow_tune_pipeline_desc.json",  // Non-mandatory field
        "file_name": "flow_tune_pipeline_vis.md",
        "pcap_file": "sample_pcap.pcap"
    },
    "monitor": {
        "screen_mode": "light",
        "hardware": {
            "pci_addresses": [
                "08:00.0",
                "08:00.1"
            ],
            "profile": "full"
        },
        "software": [
            {
                "flow_port_id": 0,
                "profiles": [
                    "entries_ops_rates",
                    "action_resources"
                ]
            },
            {
                "flow_port_id": 1,
                "profiles": [
                    "entries_ops_rates",
                    "action_resources"
                ]
            }
        ]
    }
}
```

Where:

- `outputs_directory` – Main directory on which all output products are saved. This field does not have a default value. If no value is provided, DOCA Flow Tune files are saved at the following directories:
  - Dumper file – `/tmp/flow_tune/`
  - Analyze export pipeline description file – `/tmp/flow_tune/`
  - Pipeline visualization file – `/tmp/flow_tune/`

- `logging` - Log files directory.
  - `developer_log` – developer level log file.
  - `operational_log` – user level log file.
- `network`
  - `server_uds` – DOCA Tune Server Unix Domain Socket (UDS) path. Default value is `/tmp/tune_server.sock`.
  - `uds_directory` – Directory on which all local UDS is created. Default value is `/var/run/doca/flow_tune/`.
- `dumper`
  - `enable` – true if information should be saved into a dump file. Default value is `false`.
  - `file_name` – Dump filename. Default value is `flow_tune.json`.
  - `format_type` – The dump file format `CSV` or `Json`. Default value is `Json`.
  - `max_size_bytes` – The file maximum size in bytes. When the limit is reached, a new file is created. Default value is `1Gb`..
  - `max_files` – Maximum CSV files to create. Default value is `1`.
- `analyze`
  - `file_name` – Flow program pipeline description filename. File is created under `outputs_directory` path. Default value is `flow_tune_pipeline_desc.json`.
  - `low_level_info` – Pipeline description JSON file to include low level information.
- `visualize`
  - `pipeline_desc_file` – Flow program pipeline description input file path. This file is the product of the `analyze export` command. If not provided, then the `visualize` command triggers a creation of it (a run of `analyze export`).
  - `file_name` – Flow program pipeline visualization filename. File is created under the `outputs_directory` path. Default value is `flow_tune_pipeline_vis.md`.
  - `pcap_file` – PCAP file to use when running distribution algorithm.
- `monitor`
  - `screen_mode` – Monitor command theme to be used. Default value is `light`.
  - `hardware`
    - `pci_addresses` – List of PCIe addresses which DOCA Flow Tune should inspect.

- `profile` – Hardware profile to be used for each PCIe address given. Default value is `full`.

- `software`
  - `flow_port_id` – Flow program port identification number which DOCA Flow Tune should inspect.
  - `profiles` – List of software profiles to be used for the specific port identification number given. Default value is `[entries_ops_rates]`.

7.8 DOCA Ngauge

This document provides instructions on the usage of the `ngauge` tool.

7.8.1 Introduction

`ngauge` tool is used to analyze, visualize, and debug network performance on a single node. The tool is designed for probing NIC hardware counters and storing the collected data in HDF5 format, along with relevant metadata, for subsequent processing. Additionally, the tool provides graphical progress updates and a measurement summary directly on the CLI, offering real-time insights into the measurement process.

Supported hardware: NVIDIA® BlueField®-3, NVIDIA® ConnectX®-7, and above.

`ngauge` relies on the `fwctl` driver and, therefore, cannot be run simultaneously with other tools or services that also utilize this driver.

7.8.2 Prerequisites

- BlueField-3 or ConnectX-7 and above with firmware version xx.43.1000 or higher
- `fwctl` driver installed on the host:

  On hosts running Linux kernel version 6.15 and above, there is no need to install `fwctl` manually as it is available by default, unless it was explicitly disabled during kernel configuration.

OS	Commands

Deb-based [1]	a. Search for the package:
	`apt-cache search fwctl`
	b. Install the package:
	`sudo apt install <package-name>`

RPM-based	a. Search for the package:
	`dnf search fwctl`
	b. Install the package:
	`sudo dnf install <package-name>`

1. On Ubuntu 20.04, the `fwctl` driver is not loaded automatically upon system startup. To load it, run the command `modprobe mlx5_fwctl` after every reboot. ↩

7.8.2.1 Installing Ngauge

Install `ngauge` by running `sudo apt-get install ngauge` or `sudo dnf install ngauge` (on x86 or Arm 64 hosts).

> On the DPU, the `ngauge` package is pre-installed, so the above step is not necessary.

7.8.3 Description

All the configurations for `ngauge` are defined in an input YAML file.

1. Copy a sample configuration file from `/usr/share/doc/ngauge/examples/settings`.

   > Use the one which best fits your scenario single/dual port, etc.

2. Specify the device to run on using its PCIe address. For example:

   ```
   device: "0000:03:00.0"
   ```

3. Configure the output path and file prefix (both are mandatory):

```
output:
  path: /path/to/output/directory
  prefix: "ngauge_data_"
  silent: false
```

- The output file is saved in the format `/path/to/output/directory/<prefix>_<DATE>_<TIME>.h5`.
- The exact file name is printed after each run.
- If the `silent` option is set to `true`, progress indications on the command line are suppressed (default: `false`).

4. Configure parameters for the application's runtime behavior:

```
params:
  mode: repetitive  # [repetitive, single]
  period_us: 1e2    # Sampling period in microseconds (e.g., "1e2" = 100 µs)
```

> Numbers in decimal or scientific notation are accepted. In the example, `1e2` means 100 µs.

5. Define the counters to measure. The `id` (data ID) is the only mandatory field. Additional fields are optional:

```
counters:
  - id: 0x1020000100000000  # Data ID (mandatory)
    desc: RX bytes port 0   # Description (optional)
    unit: RX port           # Unit type (optional)
    accumulating: false     # Whether the counter accumulates values (optional)
    normalizer: time        # Normalizer, if present, must be either 'time', or a non-zero number, or one
of the configured Data IDs with an 'id/' prefix (optional)
    cutoff_min: 1           # Cutoff minimum: data below this value will not be recorded (optional)
    cutoff_max: 3e10        # Cutoff maximum: data above this value will not be recorded (optional)
```

> All supported performance counters may be found under section "Supported Data IDs".

7.8.3.1 Parsing Output

A sample plugin named `simple-plot` is provided and installed under `/usr/share/doc/ngauge/examples/plugins`.

This plugin demonstrates how to open the output HDF5 file generated by `ngauge` and plot the data. While it focuses on plotting, the data can also be used for various types of analysis. This plugin is a basic demonstration and is not intended for advanced use.

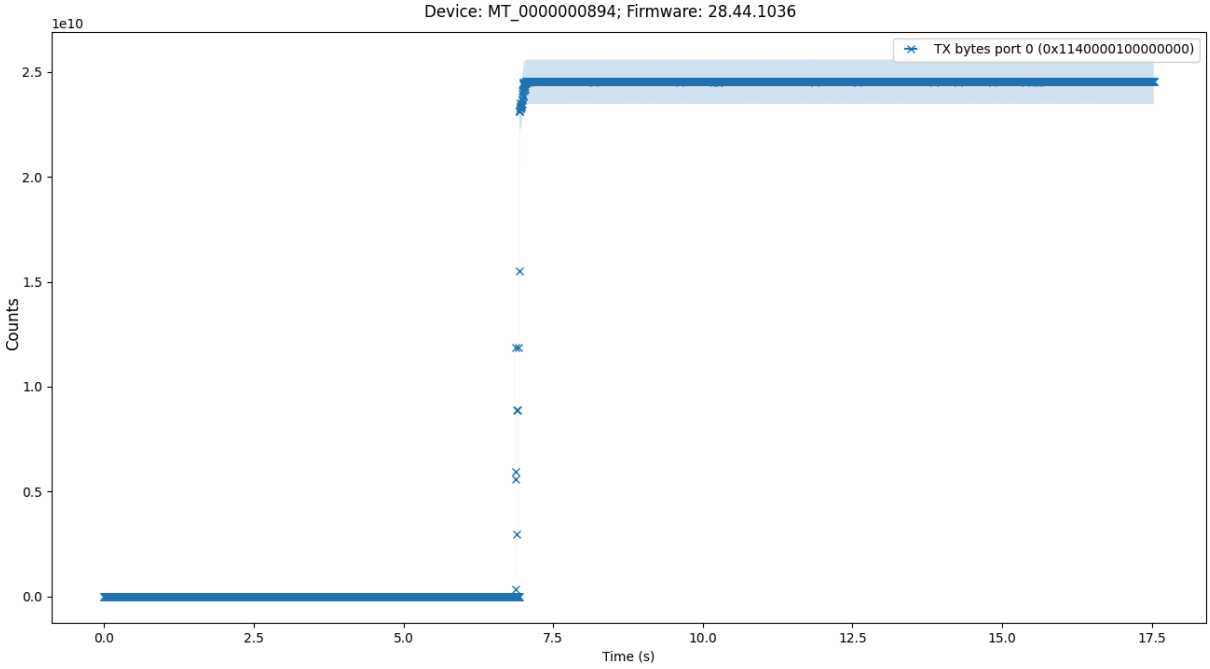
To plot the data from an `ngauge` output file, use the following command:

```
/usr/share/doc/ngauge/examples/plugins/simple_plot.py <ngauge output .h5 file> <counter ID> [<counter ID> ...]
```

Use the `-h` flag to view additional options, including plotting on a logarithmic scale and in the frequency domain.

If your output directory is `/tmp` (the default), you can always reference the most recent results without manually copying the file name by using the expression `"$(ls -1 /tmp/ngauge_data_*.h5 | tail -n1)"`.

The following is a simple plot example. The lighter area around the samples represents the worst-case measurement error.



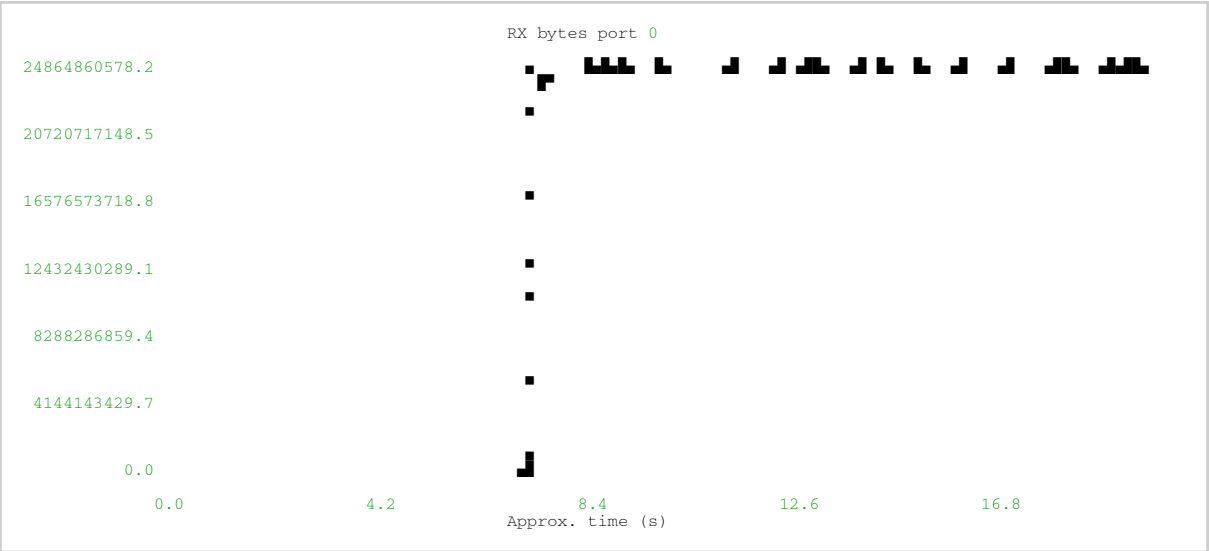
The GUI includes a zoom-in function that allows you to drill down for higher resolution.

An alternative plugin, `simple_text_plot.py`, generates text-based plots directly in the terminal. Although its resolution is significantly lower, it supports zooming into specific regions and proves especially useful when graphical output is unavailable or when network connectivity to the server is limited.

The usage syntax is similar to that of the graphical plotting plugin. Use the `-h` flag to view additional options, such as plotting in the frequency domain, specifying the start, end, or duration of the plotted interval, and more.

```
/usr/share/doc/ngauge/examples/plugins/simple_text_plot.py <ngauge output .h5 file> <counter ID> [<counter ID> ...]
```

Simple text plot example:



The sample plugins are provided as examples and are not integral parts of the `ngauge` tool. Dependencies such as NumPy, H5py, Matplotlib, plotext, and others may need to be installed separately to run these plugins.

7.8.4 Execution

To run `ngauge`:

```
ngauge <configuration YAML file>
```

The output is saved as an HDF5 file (`.h5`) in the path specified in the configuration YAML.

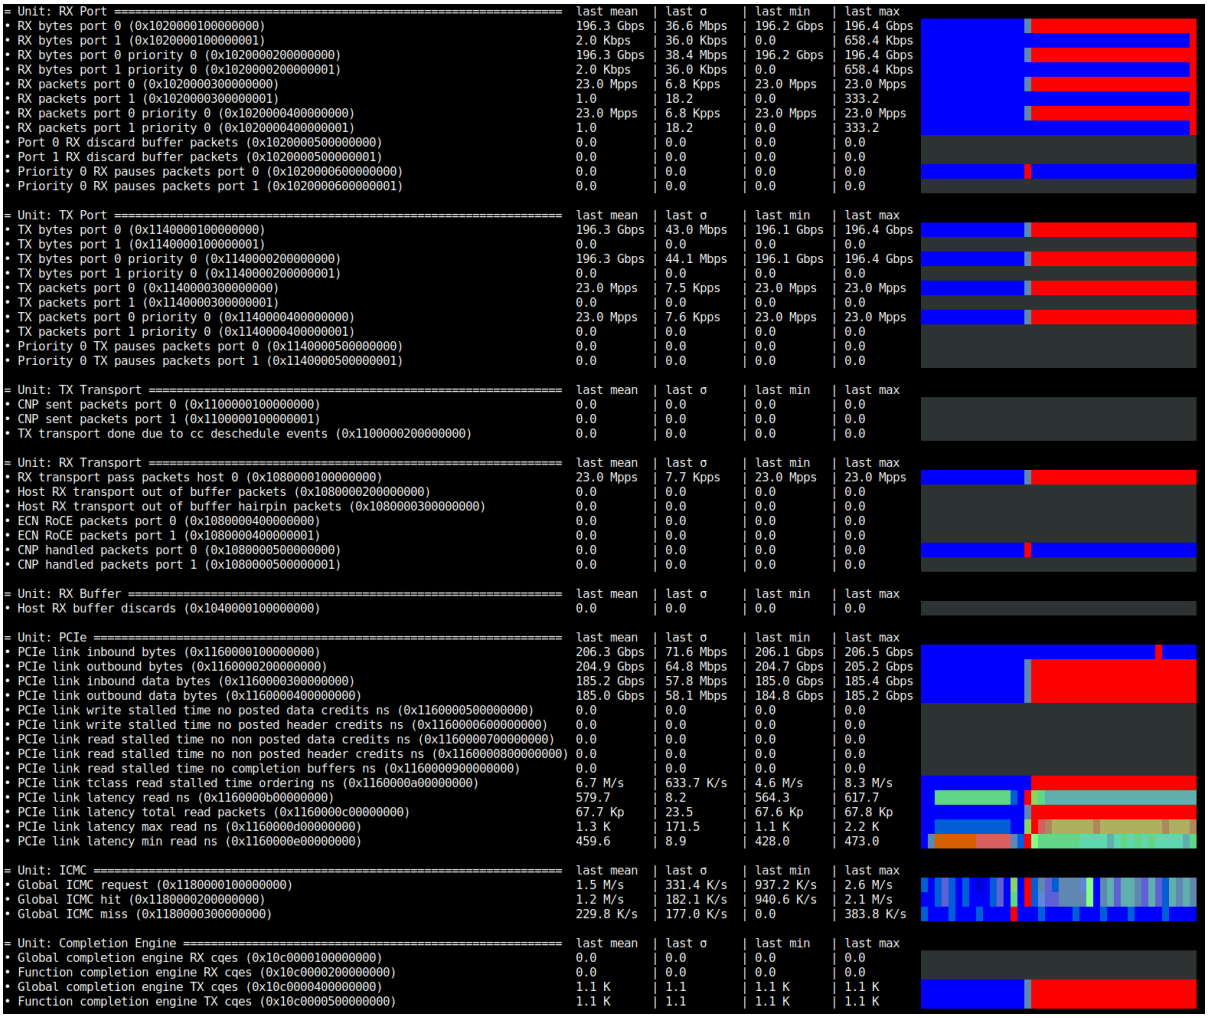
To end a run before the full dataset is collected `Ctrl+C` (SIGINT) can be used. This is a normal and supported way to end the run, and all results collected up to that point will be saved as usual.

During the run, progress bars for each counter will be displayed. These bars provide visual feedback on the counter activity, with color coding to indicate value levels:

- Blue – Represents low values relative to other values of the same counter
- Red – Represents high values relative to other values of the same counter
- Intermediate colors (gradient) – Values between low and high, transitioning from blue to red
- Solid gray bars – Indicate no changes in the values of this counter during the run

Data is updated once per second, showing the mean, standard deviation (σ), minimum, and maximum values observed during the last second.

This visual representation helps track counter activity in real time, offering immediate insights into system behavior.



7.9 DOCA Perftest

This guide describes DOCA Perftest, an RDMA benchmarking tool designed for compute clusters that enables fine-tuned evaluation of bandwidth, message rate, and latency across various RDMA operations and complex multi-node scenarios.

7.9.1 Introduction

NVIDIA® doca-perftest is an RDMA benchmarking utility designed to evaluate performance across a wide range of compute and networking environments—from simple client-server tests to complex, distributed cluster scenarios.

It provides fine-grained benchmarking of bandwidth, message rate, and latency, while supporting diverse RDMA operations and configurations.

Key features:

- Comprehensive RDMA Benchmarks – Supports bandwidth, message rate, and latency testing.
- Unified RDMA Testing Tool – A single executable for all RDMA verbs, with rich configuration options and CUDA/GPUDirect RDMA integration.
- Cluster-Wide Benchmarking – Run distributed tests across multiple nodes, initiated from a single host, with aggregated performance results.
- Flexible Scenario Definition – Define complex multi-node, multi-test configurations via a JSON input file.
- Command-Line Simplicity – Quickly run local or point-to-point benchmarks directly from the CLI.
- Synchronized Execution – Ensures all benchmarks begin and end simultaneously for consistent results.

The `doca-perftest` utility simplifies evaluation and comparison of RDMA performance across applications and environments.

7.9.2 Comparison with Legacy Perftest

Unlike legacy RDMA benchmarking tools (e.g., `ib_write_bw`, `ib_send_lat`), `doca-perftest` is a native implementation designed for modern data centers. As opposed to a wrapper, it is a standalone product that replaces both the legacy tools and the custom orchestration scripts often required to run them at scale.

Architectural differences:

Feature	Legacy Perftest	DOCA Perftest
Scope	Point-to-Point (P2P) only	Single-node to Cluster-wide
Orchestration	Manual or third-party wrappers	Built-in (Single-host initiation)
Concurrency	Single-process per execution	Native multi-process/multi-core
Synchronization	Loose (Serial start)	Hardware-aligned (Synchronized start/stop)
Result Handling	Per-process manual extraction	Automatic cluster-wide aggregation

Benefits of migration to `doca-perftest`:

- Standard RDMA benchmarks require complex external scripts (Ansible, Bash, Python) to manage remote process launching, NUMA pinning, GPU selection and result parsing.
  `doca-perftest` handles these natively via the CLI or JSON scenario files.
- In large-scale clusters, measuring fabric congestion or incast/outcast scenarios requires all nodes to hit the network simultaneously.
  `doca-perftest` utilizes a centralized sync engine to ensure all processes begin and end traffic in a coordinated window, providing accuracy that is impossible to achieve with asynchronous legacy wrappers.
- While legacy tools require running multiple instances to saturate high-speed links (e.g., 200G/400G+), `doca-perftest` scales linearly across cores within a single execution using the `-N` or `-C` flags.
- Rather than collecting individual output files from dozens of servers, `doca-perftest` provides a unified report. This includes the full scenario definition, all raw results, and calculated aggregations per-device, per-node, and per-test.

7.9.3 Simple Point-To-Point Benchmarks

For simple benchmarks, `doca-perftest` can be run directly from the command line.

When invoked on the client, the utility automatically launches the corresponding server process (requires passwordless SSH) and selects optimal CPU cores on both systems based on NUMA affinity.

Example command:

```
# Run on client
doca_perftest -d mlx5_0 -n <server-host-name>
```

This is equivalent to running:

```
# On server
doca_perftest -d mlx5_0 -N 1 -c RC -v write -m bw -s 65536 -D 10

# On client
doca_perftest -d mlx5_0 -N 1 -c RC -v write -m bw -s 65536 -D 10 -n <server-host-name>
```

Parameter breakdown:

Parameter	Description
`-d mlx5_0`	Uses the device `mlx5_0`.
`-N 1`	Runs one process, automatically selecting an optimal core. (Use `-C <core>` to specify manually.)
`-c RC`	Uses a Reliable Connection (RC) transport.

Parameter	Description
`-v write`	Selects the Write verb for transmission.
`-m bw`	Measures bandwidth.
`-s 65536`	Sets message size to 65,536 bytes.
`-D 10`	Runs for 10 seconds.
`-n <server-host-name>`	(Client only) Specifies the remote target host.

For a full list of CLI arguments, run `doca_perftest -h` or `man doca_perftest`.

If passwordless SSH is not configured, you must manually run `doca-perftest` on both client and server, ensuring parameters match.

7.9.4 Complex Multi-Node Scenarios

For large-scale or multi-benchmark configurations, `doca-perftest` accepts a JSON input file defining all participating nodes, benchmarks, and parameters.

Example invocation:

```
doca_perftest -f path_to_scenario_file.json
```

JSON mode advantages:

- Can be initiated from any node in the cluster (even non-participating ones).
- Synchronizes benchmark start and stop across all nodes.
- Aggregates all metrics on the initiating host.
- Supports predefined traffic patterns such as `ALL_TO_ALL`, `MANY_TO_ONE`, `ONE_TO_MANY`, and `BISECTION`.
- Fully compatible with all CLI parameters — JSON parameters inherit the same defaults.

Example JSON configuration files are provided under: `/usr/share/doc/doca-perftest/examples/`. It is recommended to start by copying and modifying an existing example file.

7.9.5 Benchmark Results

7.9.5.1 Bandwidth

Bandwidth tests measure the aggregate data transfer rate and message-handling efficiency across all participating processes.

Metrics collected:

- Message Rate (Mpps): Number of Completion Queue Entries (CQEs) processed per second.
- Bandwidth (Gb/s): Total throughput (`bandwidth = message_rate × message_size`).

Measurement notes:

- Results are aggregated across all active test processes.
- Concurrency is controlled via `-co` (CLI) or the `cores` field (JSON).
- Test duration is averaged across processes for consistent sampling.

Interpretation tips:

Observation	Possible Cause
High message rate, low bandwidth	Small message sizes
High bandwidth, moderate message rate	Larger messages or fewer CQEs

These results help optimize network saturation, queue depth, and core allocation strategies.

7.9.5.2 Latency

Latency tests measure the delay between message transmission and acknowledgment. The measured direction depends on the RDMA verb used.

RDMA verb modes:

Verb	Measurement Type
Send/Receive	One-way latency (Client → Server)
Write	Round-trip latency (Client → Server → Client)

Metrics collected:

- Minimum latency – Fastest observed transaction
- Maximum latency – Longest observed transaction

- Mean latency – Average across all iterations
- Median latency – Midpoint value (less influenced by outliers)
- Standard deviation – Variability indicator
- 99% tail latency – 99% of messages completed within this time
- 99.9% tail latency – Outlier detection for extreme cases

Measurement notes:

- Latency measured using tight RDMA verb loops.
- Timing collected on the sender side for accuracy.
- Aggregated across processes for final reporting.

Interpretation tips:

Pattern	Insight
Low mean/median, high max/tail	Indicates jitter or queue buildup
Low standard deviation	Indicates stable and predictable performance
High 99%/99.9% tail	Indicates possible SLA breaches in real-time workloads

`doca-perftest` provides improved write latency accuracy over legacy `perftest` tools.

Differences in latency measurement methodologies exist; compare tools carefully when validating results.

7.9.6 Common Arguments and Use-Cases

This section highlights some of the most commonly used parameters and use-cases.

7.9.6.1 Unidirectional vs Bidirectional Traffic

`doca-perftest` supports two traffic-flow modes that fundamentally change how data moves between nodes and how resources are allocated.

7.9.6.1.1 Unidirectional Traffic (Default)

- In unidirectional mode, traffic flows in one direction only.
- The client (requestor) initiates operations, and the server (responder) receives them.

- This is the default mode and provides clear, predictable performance metrics.

7.9.6.1.2 Bidirectional Traffic

In bidirectional mode, traffic flows in both directions simultaneously. Each side acts as both requestor and responder, creating full-duplex communication.

Bidirectional tests use two traffic runners (requestor + responder) sharing resources. It may show different aggregate bandwidth than 2× unidirectional.

Run bi-directional traffic from the command line:sa

```
# Enable bidirectional traffic
doca_perftest -d mlx5_0 -n <server-name> -b
```

For JSON mode, use the `"TrafficDirection"` field and set it to `"BIDIR"` or `"UNIDIR"`.

7.9.6.2 Traffic Patterns

Traffic patterns provide built-in shortcuts for complex multi-node communication scenarios.

While these configurations were always possible through detailed JSON definitions, traffic patterns dramatically simplify setup for common topologies.

Example JSONs using traffic patterns are available under `/usr/share/doc/doca-perftest/examples`.

Available patterns:

- `ONE_TO_ONE`
- `ONE_TO_MANY`
- `MANY_TO_ONE`
- `ALL_TO_ALL`
- `BISECTION`

> ⚠ Multicast is not supported. Each connection is point-to-point, synchronized to start simultaneously.

They collapse complex multi-node wiring into a few lines of JSON. Instead of manually listing dozens of connections, you specify a regex-like host list and a pattern (e.g., `ALL_TO_ALL`) and `doca-perftest` generates and synchronizes all connections for you.

7.9.6.2.1 One-to-One (O2O)

Simple point-to-point between two nodes; useful for baseline performance testing.

```
"testNodes": [ {"hostname": "node01", "deviceName": "mlx5_0"},
               {"hostname": "node02", "deviceName": "mlx5_0"} ],
"trafficPattern": "ONE_TO_ONE"
```

7.9.6.2.2 One-to-Many (O2M)

Single sender to multiple receivers; the first node sends to all others.

```
"testNodes": [ {"hostname": "sender", "deviceName": "mlx5_0"},
               {"hostname": "receiver[1-10]", "deviceName": "mlx5_0"} ],
"trafficPattern": "ONE_TO_MANY"
```

This creates 10 connections: sender → receiver1, sender → receiver2, ..., sender → receiver10.

7.9.6.2.3 Many-to-One (M2O)

Multiple senders to one receiver; all nodes send to the first node.

```
"testNodes": [  {"hostname": "aggregator", "deviceName": "mlx5_0"},
                {"hostname": "client[01-20]", "deviceName": "mlx5_0"}  ],
"trafficPattern": "MANY_TO_ONE"
```

This creates 20 connections: client1 → aggregator, client2 → aggregator, ..., client20 → aggregator.

7.9.6.2.4 All-to-All (A2A)

Full-mesh connectivity; every node connects to every other node.

```
"testNodes": [  {"hostname": "compute[01-16]", "deviceName": "mlx5_0"} ],
"trafficPattern": "ALL_TO_ALL",
"trafficDirection": "UNIDIR"
```

This creates 240 connections (16×15) for unidirectional, or 120 bidirectional pairs.

7.9.6.2.5 Bisection (B)

Divides nodes into two equal halves; the first half connects to the second half. Requires an even number of nodes.

```
"testNodes": [  {"hostname": "rack1-[01-10]", "deviceName": "mlx5_0"},
                {"hostname": "rack2-[01-10]", "deviceName": "mlx5_0"} ],
"trafficPattern": "BISECTION"
```

This creates 10 connections: rack1-01 ↔ rack2-01, rack1-02 ↔ rack2-02, ..., rack1-10 ↔ rack2-10.

7.9.6.3 Per-iteration-sync Flow (Lock-step Benchmarking)

Designed to mimic AI workloads, this flow ensures data transfer occurs in distinct, synchronized steps. By forcing every process to wait for all peers to complete an iteration before proceeding, it enables granular data validation and allows for QP parameter modification between steps.

Configuration constraints:

- Must be triggered via JSON; CLI execution is not supported
- Requires `ALL_2_ALL` pattern with `BIDIR` traffic
- Must be defined by specific iterations (time-based duration is not supported).

7.9.6.3.1 Logic and Implementation

The flow utilizes a bidirectional `ALL_TO_ALL` pattern. Each iteration consists of four distinct phases:

1. Data phase:
    a. Every process sends a data message to all peers.
    b. The total `msgSize` is split across available QPs. Each QP writes to a specific offset to utilize the full buffer.
2. Sync phase:
    - Once data transfer completes, each process sends a Sync Message to all peers.
    - The Sync Message is a zero-length RDMA Write with Immediate Data.
3. Barrier phase:
    - A process completes the iteration only after it has received confirmation for its own Sync Send *and* received Sync Messages from all peers.
4. Post-iteration (management) phase:
    - Occurs after synchronization but before the next iteration begins.
    - Performs non-timed management tasks, such as modifying QPs, checking data validation results, or updating pointers.

7.9.6.3.2 Configuration

This flow is supported only in JSON mode (CLI is not supported). Add the following fields to your configuration file:

Field	Value	Notes
`iterationSync`	`"true"`	Activates the flow logic.
`trafficPattern`	`"ALL_2_ALL"`	Required. Must be used even for 1:1 node connections.
`trafficDirection`	`"BIDIR"`	Required. Flow requires bidirectional exchange.
`iterations`	(Integer)	Required. Defines the run duration. Time-based "Duration" mode is not supported.
`verb`	`"write"` / `"writeImm"`	Determines the verb used in the Data Phase.
`metric`	`"bw"`	Calculates both Bandwidth and Latency.

7.9.6.3.3 Data Validation Integration

When `dataValidation` is set to `true`, the flow performs a bit-exact verification of all received data at the end of every iteration.

- Highly effective for catching transient data corruption in complex A2A patterns.
- Validation occurs during the "post-iteration" management phase, outside of the timed performance interval.

7.9.6.3.4 Limitations

- Due to the heavy synchronization barrier, the measured "streaming" bandwidth will be lower than a standard continuous A2A test.
- A single scenario file cannot mix synchronization types. All tests must be either "Iteration-Sync" (`"iterationSyncType": "write_imm"`) or standard (`"iterationSyncType": "none"`).

7.9.6.4 Hostname and Device Name Ranged Selection

To streamline configuration for multi-node and multi-device scenarios, `doca-perftest` supports bracket-based range expansion in JSON mode. This allows you to define large-scale clusters concisely.

7.9.6.4.1 Supported Syntax

Feature	Syntax Example	Expansion Result
Numeric Range	`perf-host[0-3]`	`perf-host0`, `perf-host1`, `perf-host2`, `perf-host3`
Comma List	`perf-host[0,2,4]`	`perf-host0`, `perf-host2`, `perf-host4`
Zero Padding	`node[01-03]`	`node01`, `node02`, `node03` (Padding is preserved)

7.9.6.4.2 Expansion Logic

When ranges are defined for both hostnames and device names, the tool generates all possible combinations (Cartesian product).

For example:

- Input: `hostname=host[1-2]`, `devicename=mlx5_[0-1]`
- Result (4 Connections):
  a. `host1` ↔ `mlx5_0`
  b. `host1` ↔ `mlx5_1`
  c. `host2` ↔ `mlx5_0`
  d. `host2` ↔ `mlx5_1`

7.9.6.5 Multiprocess (Cores)

`doca-perftest` can run synchronized multi-process tests, ensuring traffic starts simultaneously across all cores.

By default, it runs a single process on one automatically selected core.

Process and core selection:

Option	Description
`-N` / `"num_processes"`	Number of processes; cores auto-selected.
`-C` / `"cores"`	Explicitly specify core IDs or ranges.

Examples:

```
# Run on 3 synchronized processes (cores auto-selected)
doca_perftest -d mlx5_0 -n <server> -N 3

# Run on specific cores
doca_perftest -d mlx5_0 -n <server> -C 5
doca_perftest -d mlx5_0 -n <server> -C 5,7
doca_perftest -d mlx5_0 -n <server> -C 5-9
```

7.9.6.6 Working with GPUs – Device Selection

`doca-perftest` can automatically select the most suitable GPU for each network device based on PCIe topology proximity. The ranking follows NVIDIA's `nvidia-smi topo` hierarchy: **NV > PIX > PXB > PHB > NODE > SYS**.

This ensures that the GPU closest to the NIC is chosen, minimizing latency and maximizing throughput.

Although auto-selection is the default behavior, users can still manually specify a GPU device using the `-G` argument in CLI mode, or the `"cuda_dev"` field in JSON mode.

```
# Manually choose a specific GPU
doca_perftest -d mlx5_0 -n server-name -G 0

# Automatically select both GPU and memory type (recommended)
doca_perftest -d mlx5_0 -n server-name -M cuda

# Deprecated syntax (still supported, equivalent to cuda_auto_detect)
doca_perftest -d mlx5_0 -n server-name --cuda 0
```

7.9.6.7 Working with GPUs – Memory Types

RDMA operations can leverage GPU memory directly, bypassing CPU involvement for maximum throughput and minimal latency.

`doca-perftest` supports several CUDA memory modes optimized for different hardware and driver configurations.

7.9.6.7.1 Auto-Detection Mode (cuda_auto_detect)

Automatically selects the best available CUDA memory type in this order:

1. Data Direct
2. DMA-BUF
3. Peermem

This is the recommended mode for most users.

Automatically selects the optimal CUDA memory strategy:

```
# Auto-detect best GPU memory type (recommended)
doca_perftest -d mlx5_0 -n server-name -M cuda -G 0

# With custom CUDA library path
doca_perftest -d mlx5_0 -n server-name -M cuda -G 0 --cuda_lib_path /usr/local/cuda-12/lib64

# Deprecated but equivalent syntax
doca_perftest -d mlx5_0 -n server-name --cuda 0
```

Fallback behavior: With `-M cuda_auto_detect`, `doca_perftest` automatically tries `cuda_data_direct` → `cuda_dmabuf` → `cuda_peermem` in this order.

7.9.6.7.2 Standard CUDA Memory (cuda_peermem)

Traditional CUDA peer-memory allocation.

Supported on all CUDA-capable systems, though with slightly higher overhead compared to newer methods.

```
# Explicitly force peermem (bypasses auto-detect)
doca_perftest -d mlx5_0 -n server-name -M cuda_peermem -G 0

# Auto-detect fallback order (when using -M cuda_auto_detect):
#   1) cuda_data_direct (fastest, requires HW/driver support)
#   2) cuda_dmabuf
#   3) cuda_peermem (universal fallback)
```

7.9.6.7.3 DMA-BUF Memory (cuda_dmabuf)

Uses the Linux DMA-BUF framework for zero-copy GPU–NIC transfers. Requires CUDA 11.7+ and kernel support.

```
doca_perftest -d mlx5_0 -n server-name -M cuda_dmabuf-G 0
```

7.9.6.7.4 Data Direct Memory (cuda_data_direct)

Most efficient GPU memory access method using direct PCIe mappings. Requires specific hardware and driver support; provides the lowest latency and highest throughput.

```
doca_perftest -d mlx5_0 -n server-name -M cuda_data_direct-G 0
```

7.9.6.8 Memory Types

Beyond GPU memory types, `doca-perftest` supports several memory allocation strategies for RDMA operations.

7.9.6.8.1 Host Memory (host)

Default mode using standard system RAM.

```
# Default host memory usage
doca_perftest -d mlx5_0 -n <server-name>

# Explicitly specify host memory
doca_perftest -d mlx5_0 -n <server-name> -M host
```

7.9.6.8.2 Null Memory Region (nullmr)

Does not allocate real memory; useful for ultra-low-latency synthetic tests.

```
# Null memory region for bandwidth testing
doca_perftest -d mlx5_0 -n <server-name> -M nullmr
```

7.9.6.8.3 Device Memory (device)

Allocates memory directly on the adapter hardware (limited by on-board capacity).

```
# Null memory region for bandwidth testing
doca_perftest -d mlx5_0 -n <server-name> -M device
```

7.9.6.9 RDMA Drivers

Two RDMA driver backends are supported:

> ⚠ The available drivers depend on your installed packages and hardware.

Driver	Prerequisites	Usage
IBV (libibverbs)	The standard RDMA Verbs delivered as part of DOCA-OFED (and standard inbox drivers). Recommended for general compatibility across all IB/RoCE adapters.	`-r ibv` (default)
DV (doca_verbs)	The specialized DOCA RDMA Verbs backend. This provides a high-performance alternative to standard verbs and is optimized for the DOCA SDK ecosystem.	`-r dv`

7.9.6.10 Auto-Launching Remote Server

`doca-perftest` can automatically launch the remote server via SSH (CLI-only).

Requires passwordless SSH and identical versions on both sides.

```
# Auto-launch server (default)
doca_perftest -d mlx5_0 -n server-name

# Disable auto-launch
doca_perftest -d mlx5_0 -n server-name --launch_server disable
```

Server override examples:

```
# Server uses different device than client
doca_perftest -d mlx5_0 -n server-name --server_device mlx5_1

# Server uses different memory type
doca_perftest -d mlx5_0 -n server-name -M host --server_mem_type cuda_auto_detect

# Server runs on specific cores
doca_perftest -d mlx5_0 -n server-name -C 0-3 --server_cores 4-7

# Alternate server executable path
doca_perftest -d mlx5_0 -n server-name --server_exe /tmp/other_doca_perftest_version

# Different SSH username, supported by passwordless-ssh
doca_perftest -d mlx5_0 -n server-name --server_username testuser
```

7.9.6.11 QP Histogram

The QP histogram provides visibility into how work is distributed across multiple queue pairs during a test. This is useful for identifying load balancing issues, scheduling inefficiencies, or hardware limitations when using multiple QPs.

Enabling QP histogram:

```
# Enable QP histogram with multiple queue pairs
doca_perftest -d mlx5_0 -n server-name -q 8 -H
```

Example output:

```
---------------------- QP WORK DISTRIBUTION ----------------------
Qp num 0:                                          45.23 Gbit/sec  |  Relative deviation: -2.1%
Qp num 1:                                          46.89 Gbit/sec  |  Relative deviation: 1.5%
Qp num 2:                                          45.67 Gbit/sec  |  Relative deviation: -1.2%
Qp num 3:                                          48.21 Gbit/sec  |  Relative deviation: 4.3%
```

7.9.6.12 Start Packet Sequence Number

Start PSN Controls the initial Packet Sequence Number for each Queue Pair (QP) at connection initialization. If unspecified, a random value is generated.

This feature is essential for debugging sequence-sensitive behavior, ensuring reproducibility, and interoperability testing.

Interface	Configuration	Requirement
CLI	`--start-psn <val1>,<val2>...`	The number of values must exactly match the number of QPs.
JSON	`"startPsn": { "qp0": 1000, "qp1": 1001 }`	Keys must be contiguous (e.g., `qp0`, `qp1`) and start at `qp0`.

7.9.6.13 Data Validation

Data validation verifies the integrity of RDMA traffic during bandwidth tests. When enabled, the requestor generates a deterministic payload for each message, and the responder compares the received data against the expected pattern.

To enable validation, set the `dataValidation` field to `true` in your test configuration.

> ⚠ No other specific JSON changes are required, provided the test meets the constraints listed below.

> ⚠ Validation introduces CPU and memory overhead, reducing measured bandwidth. `iteration-sync` mode, however, performs validation during the inter-iteration gap, preserving performance accuracy.

7.9.6.13.1 Prerequisites and Constraints

- Test type: Supported only for bandwidth tests (latency testing is not supported).
- Supported modes:
  - Standard `send` verb tests.
  - Tests running in `iteration-sync` mode.
- Buffer configuration: `rxDepth` must be greater than or equal to `txDepth`.
- Warmup: Warmup time must be explicitly disabled.
- Enhanced Reliability (ER): If "ER Auto Mode" is set, it will be automatically disabled when validation is active.

7.9.6.13.2 Output and Reporting

When validation is enabled, the JSON output includes a `validationResults` section.

- Key metric: `invalidDataSampleCount` (the total number of messages that failed validation).
- Logging: Individual failure logs are capped at the first 5,000 invalid samples. Additional failures are counted in the metric but not logged individually.

> ⚠ If validation is disabled, this section is omitted entirely.

7.9.6.14 Enhanced Connection Establishment

ECE is an optional RDMA setup phase that aligns connection capabilities between the client and server before traffic begins.

When enabled, `doca-perftest` exchanges ECE parameters for each connection, leveraging the hardware-firmware negotiation that occurs during the Queue Pair (QP) transition from RESET to INIT.

7.9.6.14.1 High-Level Flow

The ECE process ensures both sides agree on supported features before establishing the connection.

1. The client queries its local ECE capabilities and sends them to the server via the control channel.
2. The server applies the client's proposal, transitions its QP to INIT, and queries the device for the final accepted ECE configuration.
3. The server sends the finalized ECE configuration back to the client.
4. The client applies the finalized configuration, transitions its QP to INIT, and validates the negotiated result.
5. Standard QP data exchange and RTR/RTS transitions proceed as usual.

7.9.6.14.2 ECE Configuration

Interface	Instruction
CLI	Add the `--use_ece` flag.
JSON	Set `"useEce": true` in the test configuration.

7.9.6.14.3 Limitations and Constraints

Driver Support	Currently supported only with the libibverbs driver (`ibv`)
Connection Type	Supported only on RC QPs

7.9.6.15 QP Hints

DOCA RDMA Verbs supports attaching opaque Congestion Control (CC) hints to Queue Pairs (QPs) for use by the Programmable Congestion Control (PCC) algorithm.

`doca-perftest` allows users to provide a binary hints file along with specific metadata (file size, vendor ID, and format ID). These parameters are passed directly to the PCC via the DOCA RDMA Verbs driver.

This feature is available only when using the DOCA RDMA Verbs driver (`-r dv`).

7.9.6.15.1 Configuring QP Hints

You can configure QP hints via CLI or JSON.

- CLI – Pass a comma-separated list containing the file path and metadata using the `--cc_group_hints` flag.
- JSON input – Add the `ccGroupHints` object to your test configuration:

```
"ccGroupHints": {
    "filePath": "/path/to/hints.bin",
    "fileSize": 1024,
    "vendorId": 1,
    "formatId": 1
}
```

7.9.6.16 TPH

PCIe optimization providing hints to CPUs for cache management and reduced memory-access latency.

Requires ConnectX-6 + hardware and a TPH-enabled kernel.

Parameters:

Option	Meaning
`--ph`	Processing hint: 0 = Bidirectional (default), 1 = Requester, 2 = Completer, 3 = High-priority completer
`--tph_core_id`	Target CPU core for TPH handling
`--tph_mem`	Memory type: `pm` = Persistent, `vm` = Volatile

Examples:

```
# Invalid: Core ID without memory type
doca_perftest -d mlx5_0 -n server-name --tph_core_id 0  # ERROR

# Invalid: Memory type without core ID
doca_perftest -d mlx5_0 -n server-name --tph_mem pm  # ERROR

# Valid: Both or neither
doca_perftest -d mlx5_0 -n server-name --ph 1  # OK (hints only)
doca_perftest -d mlx5_0 -n server-name --ph 1 --tph_core_id 0 --tph_mem pm  # OK (full config)
```

7.9.7 Running doca-perftest on BlueField-3 Devices

`doca-perftest` is capable of generating traffic from either the x86 host or the BlueField Arm cores, determined entirely by the input JSON configuration.

7.9.7.1 MPI Network Configuration

When launching `doca-perftest` from the server (regardless of whether the traffic originates from the x86 host or the BlueField), it is recommended to explicitly specify the MPI TCP network interface.

Add the subnet that connects the management server and the BlueField devices to the `mpiTcpNetworkInterfaces` field in your JSON input (e.g., `"mpiTcpNetworkInterfaces": "10.7.8.0/24"`).

7.9.7.2 Traffic Originating from x86 Host (Server)

In this mode, traffic is generated by the x86 server. The RDMA device on the host (e.g., `mlx5_0`) performs DMA operations directly to/from host DRAM via PCIe.

Data path:

- Path: NIC ↔ PCIe ↔ Host Memory
- Bottlenecks: Performance is influenced by PCIe bandwidth and host CPU behavior, in addition to the network link and NIC capabilities.

JSON configuration:

- `hostName`: Set to the x86 server hostname.
- `deviceName`: Set to the RDMA device on the server (e.g., `mlx5_0`).

7.9.7.3 Traffic Originating from BlueField (Arm Cores)

In this mode, traffic is generated by the BlueField Arm cores, even if the test is launched from the x86 server. The RDMA device on the BlueField (e.g., `p0`, `p1`, `mlx5_2`) performs DMA operations to/from the BlueField's on-board DDR.

Data path:

- Path: NIC ↔ DPU DDR (No PCIe hop)
- Bottlenecks: Performance is typically limited by the network link, NIC, and DPU DDR bandwidth. The PCIe bus is not involved in the data path.

JSON Configuration:

- `hostName` : Set to the BlueField hostname.
- `deviceName` : Set to the RDMA device on the BlueField (e.g., `p0` , `mlx5_2`).

  > ⚠ Device naming conventions may vary depending on the BlueField operating mode.

7.9.8 SLURM

`doca-perftest` integrates seamlessly with SLURM job schedulers, leveraging MPI for multi-node orchestration within SLURM allocations.

The following is a basic usage example with `salloc` :

1. Allocate nodes via SLURM (e.g., `salloc -N8`).
2. Update the JSON to include the allocated nodes. Simple bisection example:

```
"testNodes": [  {"hostname": "rack1-[01-03]", "deviceName": "mlx5_0"},
                {"hostname": "rack2-[04-07]", "deviceName": "mlx5_0"} ],
"trafficPattern": "BISECTION"
```

3. Run the `doca-perftest` with the updated json

```
# Invalid: Core ID without memory type
doca_perftest -f <updated-json>
```

7.10 DOCA Pipeline Language Developer Tools

These pages describe the NVIDIA DOCA Pipeline Language (DPL) Developer Tools, which are used to inspect and debug DPL programs on NVIDIA® BlueField® DPUs.

> ℹ For instructions on creating, compiling, and deploying DPL programs, refer to the DOCA Pipeline Language Service Guide.

7.10.1 Introduction

NVIDIA provides a suite of developer tools to assist with the validation and debugging of DPL applications:

Tool	Description
DPL Compiler	Converts DPL source code into a binary format that can be loaded by the DPL Runtime Daemon (`dpl_rtd`).
P4 Runtime Shell	Open-source control plane manager implementing the P4Runtime API.
DPL Nspect	Command-line interface (CLI) for inspecting DPL runtime state, including tables, keys, counters, and more.
DPL Debugger	Graphical interface for visualizing and debugging packet flow through the DPL program.
DPL Admin	CLI tool for dynamically modifying configuration items in the DPL Runtime Daemon.
DPL Runtime Controller SDK	SDK for building custom P4Runtime applications or integrating with DPL shared memory APIs.

All tools interact with the DPL Runtime Daemon (`dpl_rtd`) running on the BlueField DPU.

7.10.2 Prerequisites

To use the DPL developer tools, the following components must be set up:

1. DPL Runtime Service
    a. The DPL Runtime Service container must be deployed and running on the DPU. This service manages the DPL Runtime daemon.
    b. Ensure the `dpl_rtd` process is active and the DPU is configured to operate in DPU mode.
2. Starting a debug session requires the DPL program to be compiled for debugging:
    a. Compile the DPL program using the DPL Compiler with the debug flag `-g` enabled.
    b. Load the compiled binary into `dpl_rtd` using the P4Runtime controller.

> For further details, refer to Compiling DPL Applications.

7.10.3 Setup

The developer tools are included in the DPL Development Container, which is publicly available on NGC. For installation instructions, refer to the DPL Installation Guide.

7.10.4 Support and Feedback

To ask questions or provide feedback regarding DPL Developer Tools, visit the NVIDIA DOCA Enterprise Networking Forum.

You must register with the NVIDIA Developer Program to post on the forums. Registration is not required to view existing discussions. For help with registration, please refer to the FAQ.

7.10.5 DPL Nspect

This page describes the DPL Nspect tool, which is used to inspect DPL programs loaded onto the NVIDIA® BlueField® DPU.

7.10.5.1 Introduction

The DOCA Dependency Compatibility Policy is designed to provide customers with high velocity and flexibility during updates, enabling them to update specific layers of their system without requiring a full stack overhaul.

The primary objectives of this policy are to support decoupled updates for teams managing separate firmware and software stacks, allow for targeted upgrades on specific devices, minimize maintenance downtime by updating only necessary components, and guarantee investment protection by ensuring application continuity across platform releases.

This policy applies to all NVIDIA network device products and their associated software and firmware stacks.

7.10.5.2 DPL Nspect Execution

To view basic usage information, run the `dpl nspect` without arguments. For a detailed usage guide, use the `-h` or `--help` flags. You can also view command-specific help by running `dpl nspect [command] -h`.

7.10.5.2.1 Prerequisites and Configuration

- Server Connection: DPL Nspect requires a connection to a host (local or remote) where the DPL Nspect Server is running as part of the DPL Runtime Service.
- Address Configuration: The host address and port can be configured in two ways:
    a. Directly using the `-a` / `--address` argument.

b. By setting the `DPL_NSPECT_SERVER_ADDRESS` environment variable (e.g., `DPL_NSPECT_SERVER_ADDRESS=127.0.0.1:9560`).

> ⚠ Hostnames are resolved at runtime (e.g., `localhost` resolves to `127.0.0.1`).

- Data Directory: Configuration and logs are stored in the Data directory.

7.10.5.2.2 Command Usage

```
usage: dpl_nspect [-h] [-v] [-ll] [-nh] -a ADDRESS [-t TIMEOUT] [--cacert PATH_TO_CA_CERT] [--cert PATH_TO_CERT]
[--private-key PATH_TO_KEY]
                  {system-info,devices,tables,query,graph,config,counters,meters,hw-steering,debug,perf} ...

options:
  -h, --help            show this help message and exit
  -v, --version         show program's version number and exit
  -ll, --low-level      Display low level internal information. (default: False)
  -nh, --no-hints       Disable hints for further information.
                        You may set the DPL_NSPECT_DISABLE_HINTS environment variable instead of using this flag:
                        "export DPL_NSPECT_DISABLE_HINTS=1" (default: False)
  -a ADDRESS, --address ADDRESS
                        The dpl_nspect server socket address of the form IPv4/IPv6* [address][:port]
                        IPv6*: To use with a port the address must be enclosed in literal square brackets.
                        Example: ipv6:[2607:f8b0:400e:c00::ef]:443 or ipv6:[::]:1234
                        The address/port can be assigned to and read from the environment variable:
DPL_NSPECT_SERVER_ADDRESS. (default: None)
  -t TIMEOUT, --timeout TIMEOUT
                        [Optional] gRPC channel connectivity timeout. (default: 0)

commands:
  For further info run dpl_nspect <command> -h

  {system-info,devices,tables,query,graph,config,counters,meters,hw-steering,debug,perf}
    system-info         Display system information, e.g. HW Model, OS, OFED.
    devices             List the configured virtual devices.
    tables              List tables of programs loaded on the DPU.
    query               List table entries, keys and actions.
    externs             List externs details and values.
    graph               Display a graph of the Pipeline, using DOT language.
                        This graph can be graphically rendered using DOT renderers, such as online DOT graphics
visualizer websites
    config              Get/Set the device configuration.
    hw-steering         Display HW Steering rules dump.
    debug               Start a debug recording session.
    perf                Display live performance monitor statistics.

Authentication:
  Mutually inclusive arguments for secure connection using SSL authentication

  --cacert PATH_TO_CA_CERT
                        CA certificate path for secure connections (default: None)
  --cert PATH_TO_CERT   Client certificate path for mutual authentication (default: None)
  --private-key PATH_TO_KEY
                        Client private key path for mutual authentication (default: None)

Data directory: /root/.local/share/dpl_devtools
```

7.10.5.3 DPL Nspect Commands and Flags

The following sections describe specific commands and their outputs.

> ⚠ The DPL program `hello_packet.p4` (referenced at the end of this section) was used to generate the examples below.

Most commands support the `--json` argument to output data in JSON format, facilitating integration with automated scripts.

7.10.5.3.1 system-info

```
dpl nspect system-info
```

Displays system information.

Example output:

System Information

Key	Value
DOCA version	3.1.0105-1
DPL Runtime daemon version	1.2.0-1.rel-1.2.0
Debug Schema Version	Device ID: 1000, doctype: /nvp4c/devtools/base/v9, target_doctype: /nvp4c/devtools/doca/v3
Linux OS version	"Ubuntu 22.04.5 LTS"
OFED Version	OFED-internal-25.07-0.9.7:
RDMA Core Version	2507mlnx58-1.2507097

7.10.5.3.2 devices

```
dpl nspect devices
```

Lists all configured DPL devices, displaying a table for each device.

- Title: Contains program details only if a program is loaded.
- Interface: The interface name as defined in the DP device configuration file.
- ID: The port ID as defined in the DPL device configuration file.
- IB: The physical InfiniBand port ID used for the DPL port ID.

Example output:

Device 1000
Program: hello_packet, Loaded At: 2025-10-22 12:29:36, Load Duration: 0.174s

Ports					Configuration	
Interface	ID	IB	REG_C0	MAC	Key	Value
ens6f0np0	0	50	0x10000/0xffff0000	00:00:00:00:00:00	P4 Controller Port ID	9876
ens6f0r0	1	2	0x30000/0xffff0000	00:00:00:00:00:00		
ens6f0r1	2	3	0x40000/0xffff0000	00:00:00:00:00:00		
ens6f0r2	3	4	0x50000/0xffff0000	00:00:00:00:00:00	FW Version	32.47.0218
ens6f0r3	4	5	0x60000/0xffff0000	00:00:00:00:00:00		
ens6f0r4	5	6	0x70000/0xffff0000	00:00:00:00:00:00	HW Model	BlueField-3
ens6f0r5	6	7	0x80000/0xffff0000	00:00:00:00:00:00		
ens6f0r6	7	8	0x90000/0xffff0000	00:00:00:00:00:00	Multiport eSwitch	Disabled
ens6f0r7	8	9	0xa0000/0xffff0000	00:00:00:00:00:00		

7.10.5.3.3 tables

```
dpl nspect tables [--json]
```

Lists all tables defined in the DPL program.

- ID: The P4 runtime ID of the object as defined in the `p4info.txt` file.
- Direct Externs: Lists the names of all direct extern instances defined for the table (e.g., direct counter, direct meter).

Output example:

hello_packet.forward_table - 50144908

Keys			Actions			Direct Externs	Entries Count	Source Location	Supports Timeout
ID	Name	Type	ID	Name	Params				
1	headers.ethernet.src_addr	exact	19510525	hello_packet.drop		hello_packet.hello_direct_counter hello_packet.hello_direct_meter	6	hello_packet.p4:46	False
			19237259	hello_packet.forward	ID: 1, Name: port, Size: 32				
			21257015	NoAction					

The `--json` flag provides the output in JSON format. For example:

```
[
  {
    "title": {
      "Table ID": 40048916,
      "Table Name": "tbl_drop"
    },
    "rows": [
      {
        "Keys": {
          "title": {},
          "rows": []
        },
        "Actions": {
          "title": {},
          "rows": [
            {
              "ID": "19510525",
              "Name": "hello_packet.drop",
              "Params": ""
            }
          ]
        },
        "Direct Externs": [],
        "Entries Count": "1",
```

```
        "Source Location": "None",
        "Supports Timeout": "False"
      }
    ]
  },
  {
    "title": {
      "Table ID": 50144908,
      "Table Name": "hello_packet.forward_table"
    },
    "rows": [
      {
        "Keys": {
          "title": {},
          "rows": [
            {
              "ID": "1",
              "Name": "headers.ethernet.src_addr",
              "Type": "exact"
            }
          ]
        },
        "Actions": {
          "title": {},
          "rows": [
            {
              "ID": "19510525",
              "Name": "hello_packet.drop",
              "Params": ""
            },
            {
              "ID": "19237259",
              "Name": "hello_packet.forward",
              "Params": {
                "title": {},
                "rows": [
                  {
                    "ID": "1",
                    "Name": "port",
                    "Size": "32"
                  }
                ]
              }
            },
            {
              "ID": "21257015",
              "Name": "NoAction",
              "Params": ""
            }
          ]
        },
        "Direct Externs": [
          "hello_packet.hello_direct_counter",
          "hello_packet.hello_direct_meter"
        ],
        "Entries Count": "6",
        "Source Location": "hello_packet.p4:46",
        "Supports Timeout": "False"
      }
    ]
  }
]
```

7.10.5.3.4 query

```
dpl nspect query
```

Lists all entries currently contained in each table.

- Entry ID: The runtime ID assigned to the entry at creation time (not a P4 context ID).
- Keys: If no key is displayed, it indicates a default entry.
- Extern entries: Displays data for extern entries associated with the table entry (result of an explicit extern call within the Action).

Example output:

hello_packet.forward_table - 50144908

Entry ID [Priority]	Keys	Action	Extern Entries
5[0]	headers.ethernet.src_addr == 0xbbbbbbbbbb (exact)	NoAction()	
4[0]	headers.ethernet.src_addr == 0xaaaaaaaaaa (exact)	NoAction()	
3[0]	headers.ethernet.src_addr == 0xdddddddddd (exact)	hello_packet.drop()	hello_packet.hello_counter[1] = (packets=0, bytes=0)
2[0]	headers.ethernet.src_addr == 0x2222222222 (exact)	hello_packet.forward(port=0x2)	hello_packet.hello_direct_counter[2] = (packets=0, bytes=0)
1[0]	headers.ethernet.src_addr == 0x1111111111 (exact)	hello_packet.forward(port=0x1)	hello_packet.hello_direct_counter[1] = (packets=0, bytes=0)
0[0]		hello_packet.forward(port=0x3)	hello_packet.hello_direct_counter[0] = (packets=0, bytes=0)

7.10.5.3.5 externs

```
dpl nspect externs
```

Lists all externs in the DPL program (one table per extern instance???).

- Indirect Externs: First column shows Index.
- Direct Externs: First column shows Table Entry ID (corresponds to the ID seen in the `query` command).

NvDirectCounter(Pkts/Bts) hello_packet.hello_direct_counter - 320479669

Table Entry ID	Packets	Bytes
5	0	0
4	0	0
3	0	0
2	0	0
1	0	0
0	0	0

NvCounter(4, Pkts/Bts) hello_packet.hello_counter - 307179965

Index	Packets	Bytes
0	0	0
1	0	0
2	0	0
3	0	0

NvDirectMeterPeakTrTCM(Pkts) hello_packet.hello_direct_meter - 359616562

Table Entry ID	CIR	CBS	PIR	PBS
5	1	2	3	4
4	1	2	3	4
3	1	2	3	4
2	1	2	3	4
1	1	2	3	4
0	1	2	3	4

NvTcpState(4) hello_packet.hello_tcp - 2319426381

Index	Last Direction	Last ACK Number	Last SEQ Number
0	ORIGINAL	0	0
1	ORIGINAL	0	0
2	ORIGINAL	0	0
3	ORIGINAL	0	0

NvMemory(4) hello_packet.hello_memory - 2360326091

Index	Bytes

The `--types` argument allows querying specific extern categories (counter, meter, tcp_state, memory) and/or scope (direct for table-bound, indirect for standalone).

```
dpl nspect externs --types counter,meter,direct
```

NvDirectCounter(Pkts/Bts) hello_packet.hello_direct_counter - 320479669

Table Entry ID	Packets	Bytes
5	0	0
4	0	0
3	0	0
2	0	0
1	0	0
0	0	0

NvDirectMeterPeakTrTCM(Pkts) hello_packet.hello_direct_meter - 359616562

Table Entry ID	CIR	CBS	PIR	PBS
5	1	2	3	4
4	1	2	3	4
3	1	2	3	4
2	1	2	3	4
1	1	2	3	4
0	1	2	3	4

7.10.5.3.6 graph

```
dpl nspect --low-level graph
```

Generates a DOT graph representing all potential packet paths within the pipeline.

Example output:

```
digraph hello_packet_pipeline {
    graph [compound=true nodesep=0.1]
    node [height=0 width=0]
    // Legend
    subgraph cluster_legend {
        graph [fontsize="6pt" label=Legend]
```

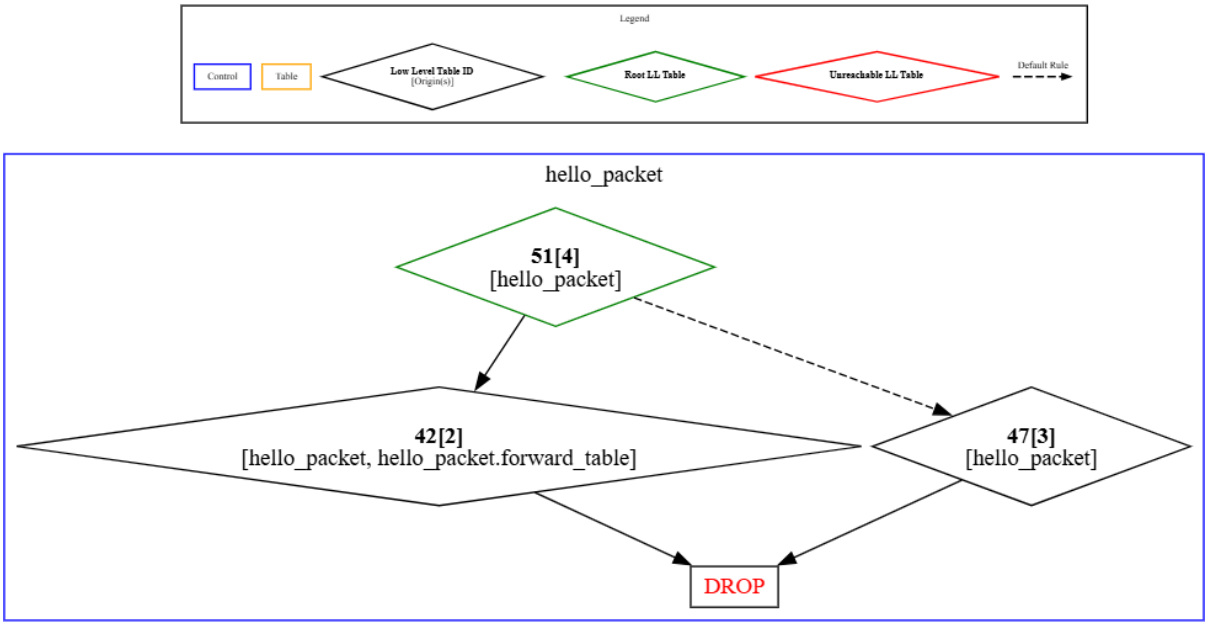
```
        control [label=Control color=blue fontsize="6pt" id=control shape=rectangle]
        table [label=Table color=orange fontsize="6pt" id=table shape=rectangle]
        ll_table [label=<<B>Low Level Table ID</B><BR/>[Origin(s)]> fontsize="6pt" id=ll_table shape=diamond]
        legend_invis [height=0 id=legend_invis shape=point style=invis width=0]
        ll_root_table [label=<<B>Root LL Table</B>> color=green fontsize="6pt" id=ll_root_table shape=diamond]
        ll_unreachable_table [label=<<B>Unreachable LL Table</B>> color=red fontsize="6pt" id=ll_unreachable_table
shape=diamond]
        default_rule_invis_tail [fontsize="6pt" height=0 id=default_rule_invis_tail shape=point style=invis
width=0]
        default_rule_invis_head [fontsize="6pt" height=0 id=default_rule_invis_head shape=point style=invis
width=0]
        default_rule_invis_tail -> default_rule_invis_head [label="Default Rule" arrowsize="0.5px" fontsize="6pt"
id="default_rule_invis_tail-default_rule_invis_head" style=dashed]
        subgraph rank_0 {
            rank=same
            control [id=control]
            default_rule_invis_head [id=default_rule_invis_head]
            default_rule_invis_tail [id=default_rule_invis_tail]
            ll_root_table [id=ll_root_table]
            ll_table [id=ll_table]
            ll_unreachable_table [id=ll_unreachable_table]
            table [id=table]
        }
    }
    // Pipeline Stage: main
    subgraph cluster_hello_packet {
        graph [color=blue label=hello_packet shape=rectangle]
        legend_invis [height=0 id=legend_invis shape=point style=invis width=0]
        "51[4]" [label=<<B>51[4]</B><BR/>[hello_packet]> color=green id="51[4]" shape=diamond]
        "42[2]" [label=<<B>42[2]</B><BR/>[hello_packet, hello_packet.forward_table]> id="42[2]" shape=diamond]
        DROP [fontcolor=red id=DROP shape=box]
        "47[3]" [label=<<B>47[3]</B><BR/>[hello_packet]> id="47[3]" shape=diamond]
        legend_invis -> "51[4]" [id="legend_invis-51[4]" style=invis]
        "51[4]" -> "42[2]" [id="51[4]-42[2]"]
        "42[2]" -> DROP [id="42[2]-DROP"]
        "51[4]" -> "47[3]" [id="51[4]-47[3]" style=dashed]
        "47[3]" -> DROP [id="47[3]-DROP"]
        subgraph rank_0 {
            rank=same
            "51[4]" [id="51[4]"]
        }
        subgraph rank_1 {
            rank=same
            "42[2]" [id="42[2]"]
            "47[3]" [id="47[3]"]
        }
        subgraph rank_2 {
            rank=same
            DROP [id=DROP]
        }
    }
}
```

```
dpl nspect --low-level graph --url
```

The `--url` flag generates an HTTP URL link to render the graph using GraphvizOnline.

Legend:

- Low Level Table (LL Table): Refers to the internal HWS Table object created from loading the DPL program.
- Root LL Table: The starting point of the generated pipeline.



7.10.5.3.7 debug

Starts a debug session. Packets sent during this session are traced and recorded to an output archive, which can be inspected using the DPL Debugger.

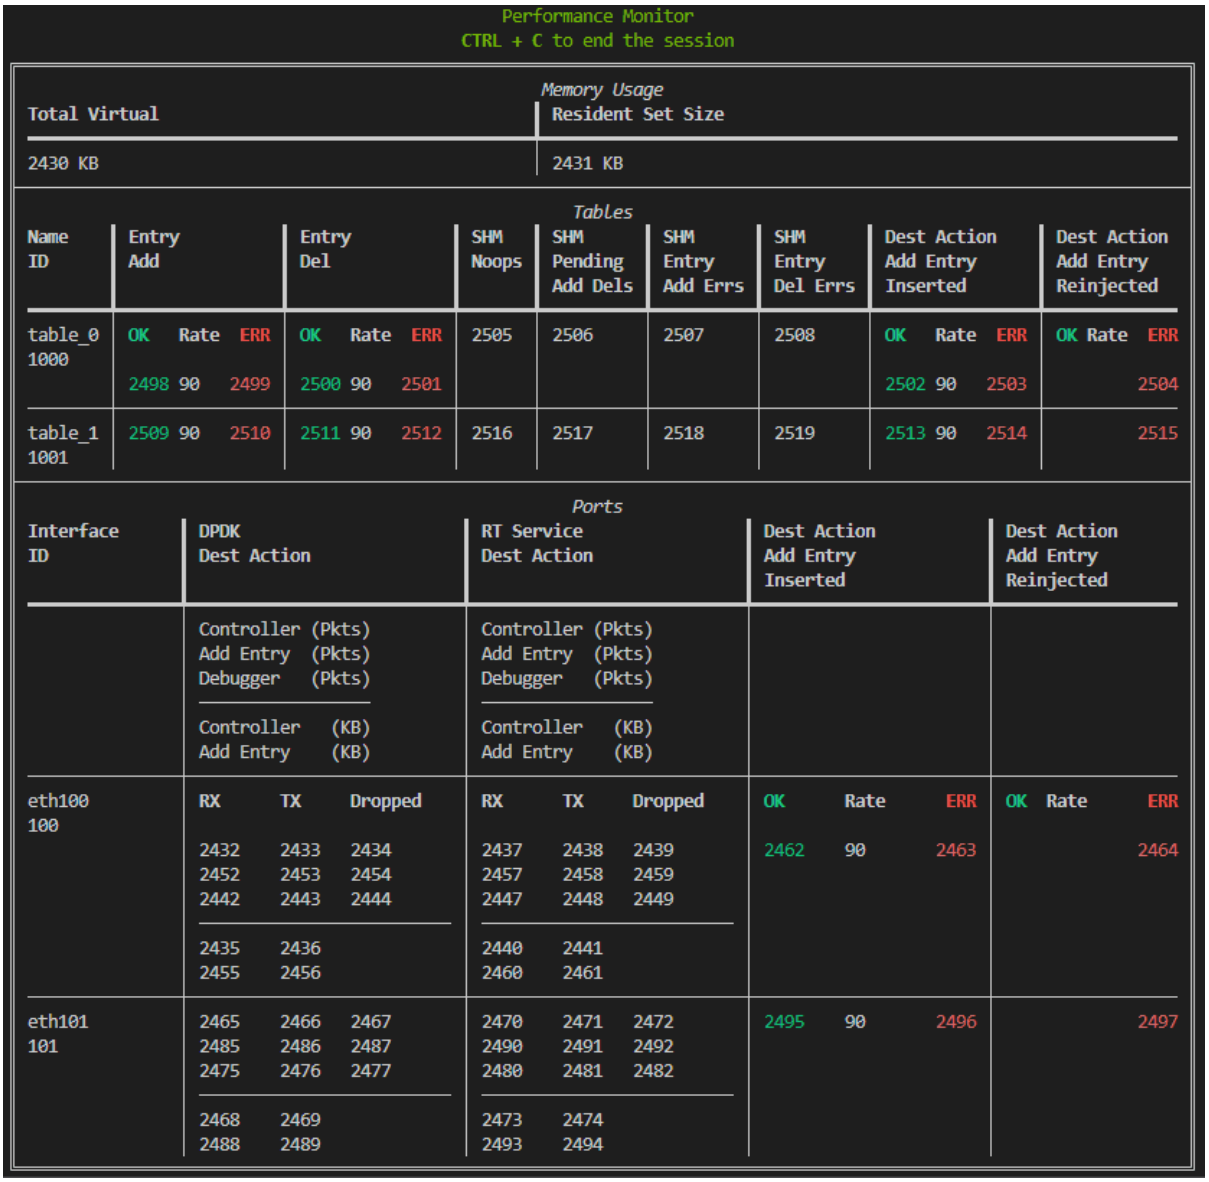
```
dpl nspect debug -o hello_packet.tar.gz
```

7.10.5.3.8 perf

```
dpl nspect perf
```

Displays real-time performance statistics.

Example output:



The following sections breakdown the statistics provided in the example output.

7.10.5.3.8.1 Memory Usage Statistics

Displays the real-time memory consumption of the DPL Runtime Service.

Metric	Description
Total Virtual Memory	The total amount of virtual memory used by the service.
Resident Set Size	The amount of physical memory (RAM) currently being used (in KB).

7.10.5.3.8.2 Table Entry Operations Statistics

Tracks operations for each DPL table (one row per table).

Category	Column	Description	Notes
Entry Add/ Del	OK	Total number of successful additions or deletions	Tracks *all* table entry operations.
	ERR	Total number of failed additions or deletions	
	Rate	The difference in successful operations between the current and previous sample	
SHM	Noops	Count of entries where a delete was requested before the addition was fully processed	**Verbose mode only.** Tracks *entries*. Only for SHM-enabled tables
	Pending Add Dels	Count of delete operations received for entries that are still pending hardware confirmation	**Verbose mode only.** Tracks *operations*
	Entry Add/Del Errs	Total number of failed SHM entry additions or deletions	**Verbose mode only.** Tracks *operations*
Dest Action Add Entry	Inserted	Successful table entry additions triggered specifically by the *Add Entry* action	**Verbose mode only.** Tracks *table entries*
	Reinjected	Total number of *failed* reinjection attempts (ERR column).	**Verbose mode only.** Tracks *packets*. The OK/Rate columns are always empty

7.10.5.3.8.3 Port Statistics Statistics

Tracks packet flow through destination actions (one row per Port Interface ID).

Layer	Row/ Action	Description	Notes
DPDK Dest Action	N/A	Packet flow statistics at the hardware (DPDK) layer	
RT Service Dest Action	N/A	Packet flow statistics at the application (RT Service) layer	
Action Types	Controller	Flow statistics for packets destined for the Controller	
	Add Entry	Flow statistics for packets destined for the Add Entry action	Same metrics as the *Tables* section, but tracked per port
	Debugger	Flow statistics for packets destined for the Debugger	Only displays Packet Counts (no KB)
Flow Direction	RX / TX	Packets received or transmitted in this layer/ action	Displays both Packet Counts and KB
	Dropped	Packets dropped in this layer/action	Only displays Packet Counts (no KB)

) main;
```

7.10.6 DPL Debugger

This section describes the DPL Debugger Tools, used to debug pipeline packets that DPL programs are processing in NVIDIA® BlueField®.

> ⚠ The debugger works only with DPL programs that compiled in one of the available debug modes.

7.10.6.1 Introduction

The DPL Debugger is a GUI application that can run a debug session or open a pre-recorded (through `nspect debug`) debug session file.
Debug session shows the flow of network packets throughout a DPL program's pipeline and lets the developer trace the details of each packet's course. See the documentation on the extern function nv_send_debug_pkt.

Running `dpl debugger` with no additional arguments will open the GUI application.

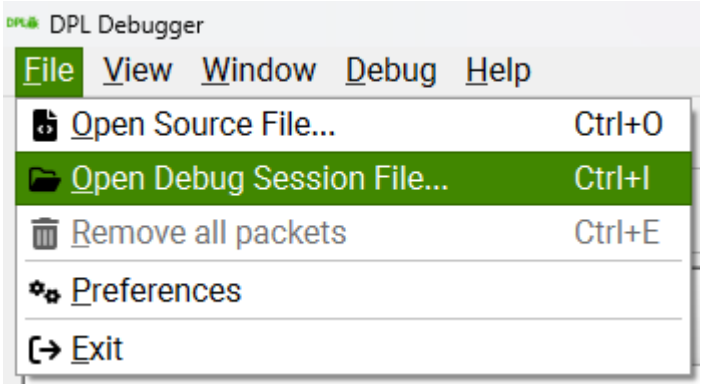
7.10.6.2 Opening Pre-recorded Debug Session File

The pre-recorded debug session file is a `tar.gz` archive and is the output of a recorded debug session created with the `nspect debug` command.

Option 1: Specify the file to open when running the debugger from the command line.

```
dpl debugger hello_packet.tar.gz
```

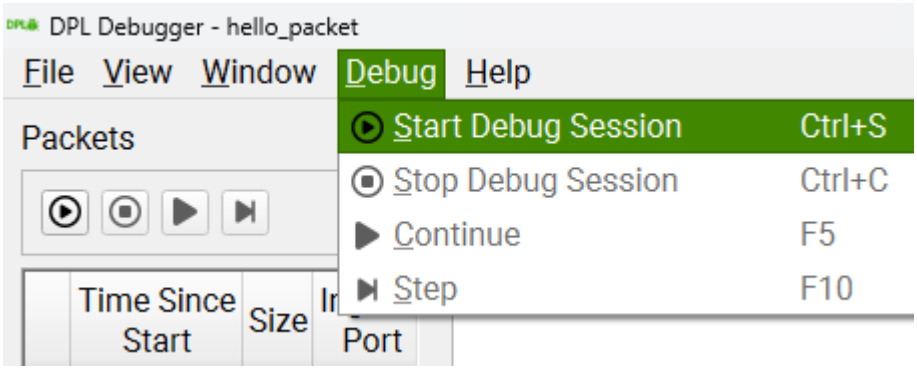
Option 2: Click **File** → **Open Debug Session File** and select your file.



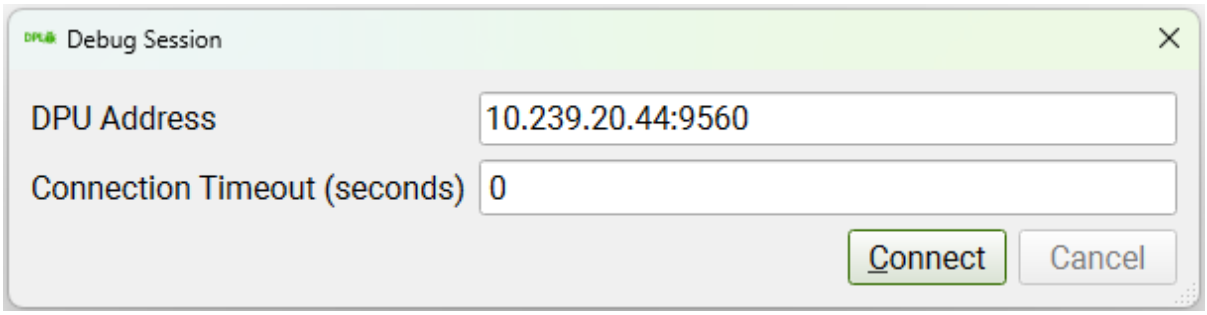
7.10.6.3 Starting Debug Session

Running a debug session from the debugger is possible and has the advantage of processing and inspecting the packets at runtime.

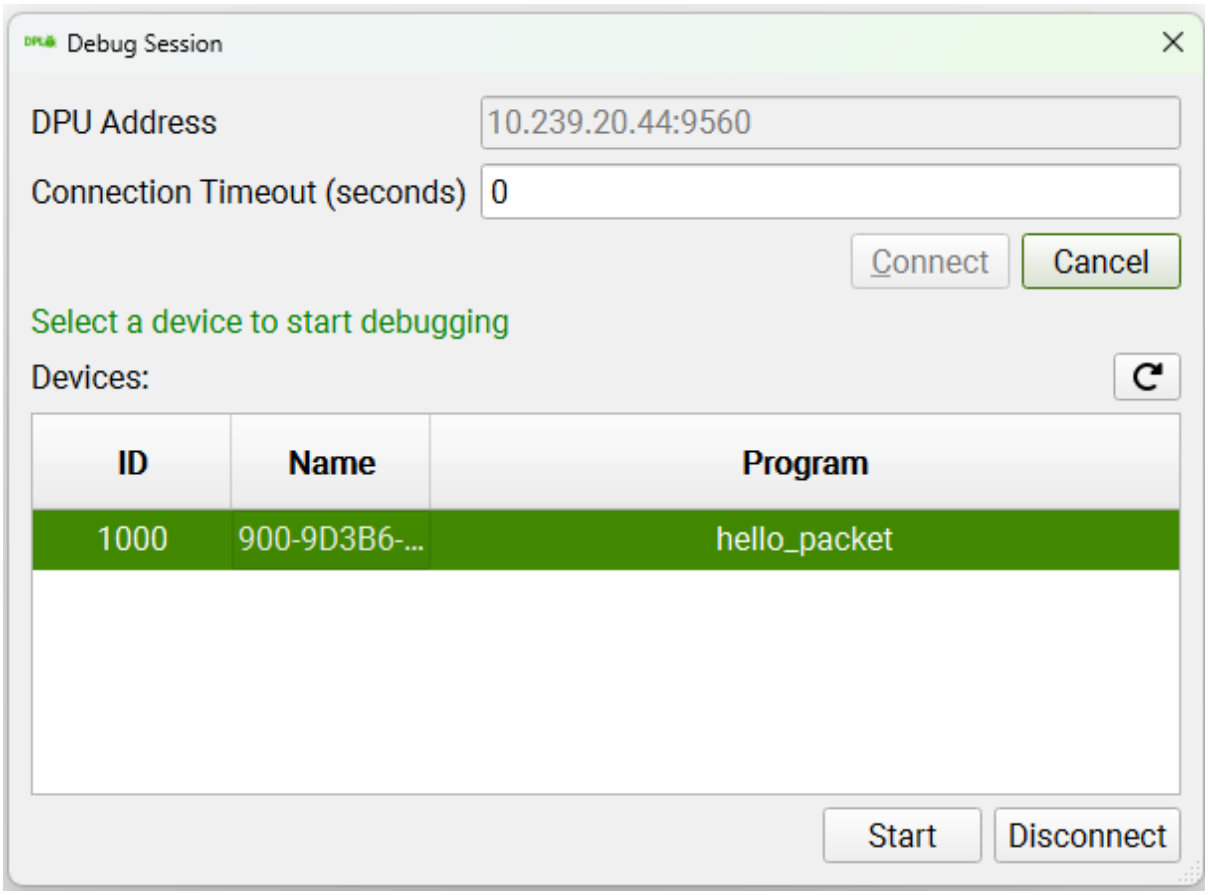
You can click on the Start Debug Session button, click Ctrl+S, or click **Debug** → **Start Debug Session**



Set the DPU address and port (the default port is 9560), and the connection timeout if required (0 = no timeout), and click **Connect**.



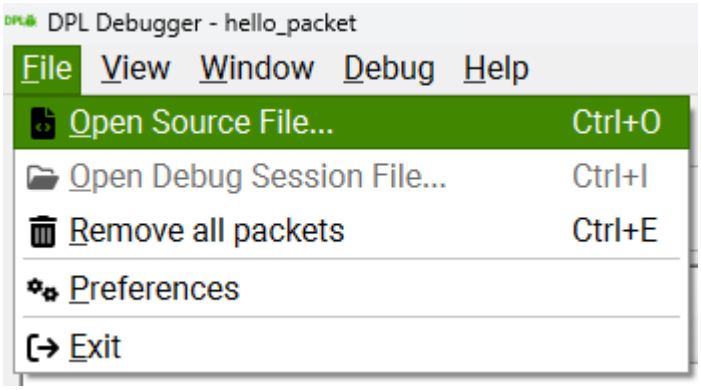
Select the desired device to debug and click Start



7.10.6.4 Enabling Debug Points

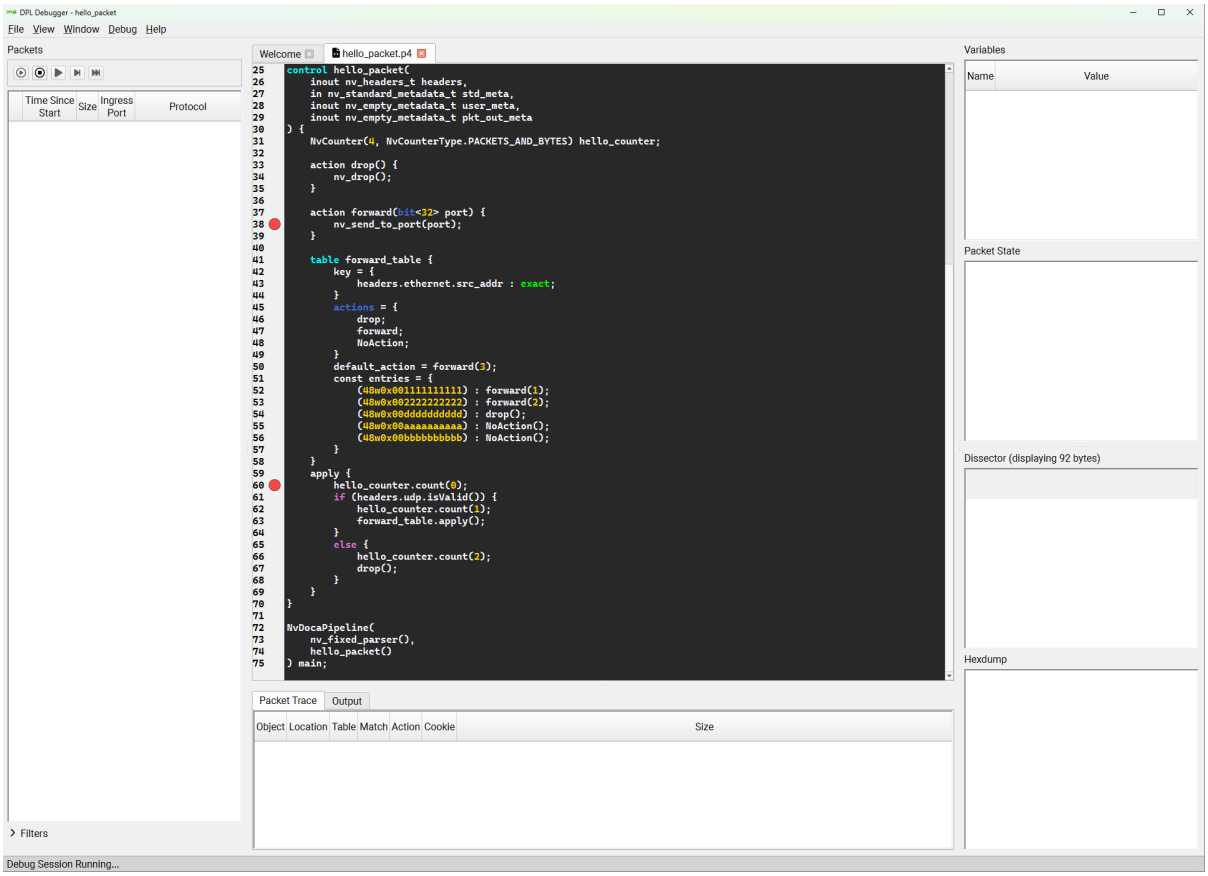
First, remember that to enable debug points, you must compile your program in one of the available debug modes (see more details here). After a debug session is started from the debugger GUI application, all the debug points in the program are DISABLED by default and don't affect the pipeline of the packet. When a packet hits an enabled debug point, it is sent to the debugger, displayed, and can be injected back to the same point in the pipeline on user demand.

Enabling and disabling debug points is done the same as in traditional debugger GUI applications - open the source file of the program and click on the left margin next to the requested line. Additionally, pressing F9 will toggle a breakpoint on the line where the caret currently stands, similar to how a mouse press on the margin would.



⚠ The available debug points to enable depend on which debug mode you compiled the program with.

Similar to traditional debugger GUI applications, if the line doesn't have a debug point associated with it, the next available debug point will be enabled instead.



7.10.6.5 Debugging the Program Pipeline

hello_packet.p4

The following program was used for the screen captures in this section. The program was compiled with the debug-mode=auto flag.

```

 */

control hello_packet(
    inout nv_headers_t headers,
    in nv_standard_metadata_t std_meta,
    inout nv_empty_metadata_t user_meta,
    inout nv_empty_metadata_t pkt_out_meta
) {
    NvCounter(4, NvCounterType.PACKETS_AND_BYTES) hello_counter;

    action drop() {
```

```
        nv_drop();
    }

    action forward(bit<32> port) {
        nv_send_to_port(port);
    }

    table forward_table {
        key = {
            headers.ethernet.src_addr : exact;
        }
        actions = {
            drop;
            forward;
            NoAction;
        }
        default_action = forward(3);
        const entries = {
            (48w0x001111111111) : forward(1);
            (48w0x002222222222) : forward(2);
            (48w0x00dddddddddd) : drop();
            (48w0x00aaaaaaaaaa) : NoAction();
            (48w0x00bbbbbbbbbb) : NoAction();
        }
    }
    apply {
        hello_counter.count(0);
        if (headers.udp.isValid()) {
            hello_counter.count(1);
            forward_table.apply();
        }
        else {
            hello_counter.count(2);
            drop();
        }
    }
}

NvDocaPipeline(
    nv_fixed_parser(),
    hello_packet()
) main;
```

send_hello_packet

The following script was used for sending traffic
Assume port "p1" is connected via loopback to port "p0".

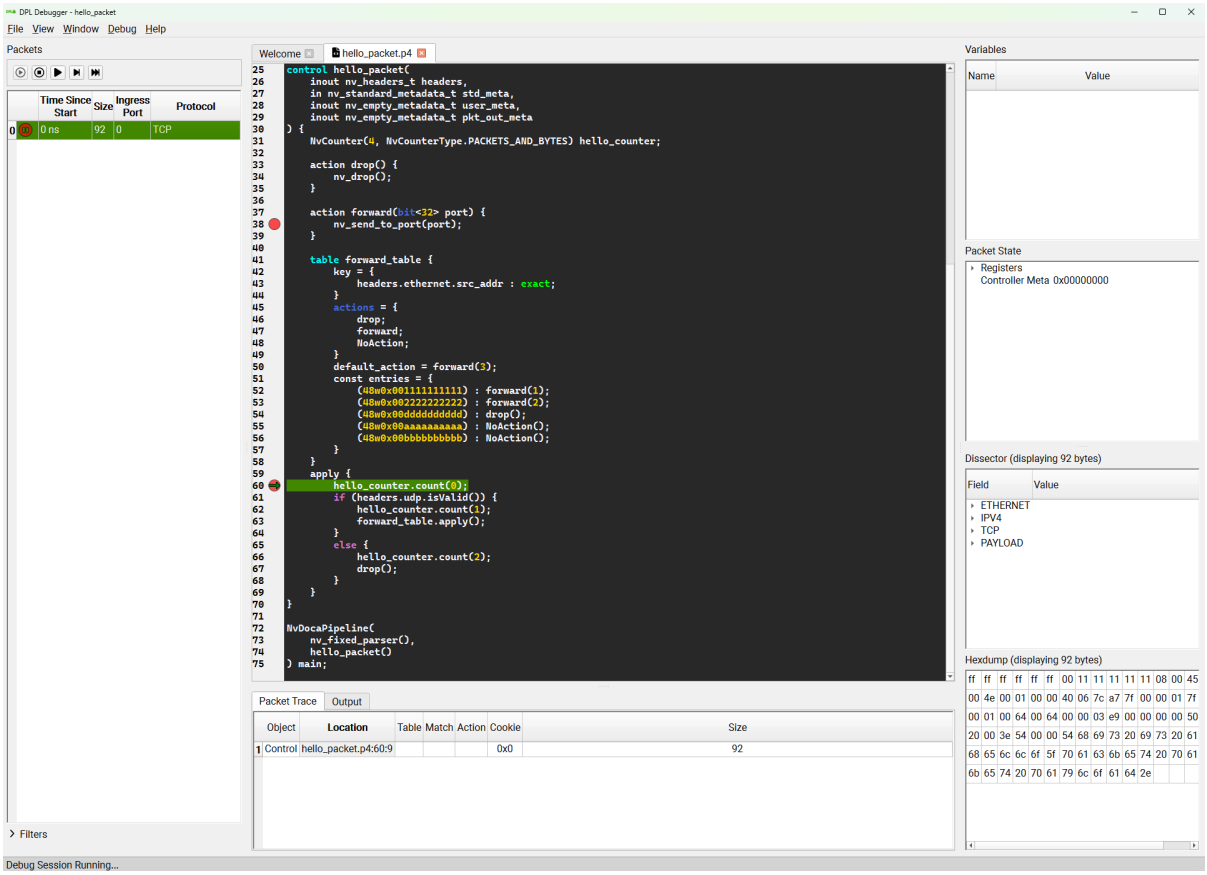
```
from scapy.all import IP, TCP, Ether, Packet, Raw, sendp

packet = (Ether(src='00:11:11:11:11:11', dst='ff:ff:ff:ff:ff:ff') /
          IP() /
          TCP(sport=100, dport=100, seq=1001, flags='P') /
          Raw(load=b'This is a hello_packet packet payload.'))

sendp(packet, "p1", count=1)
```

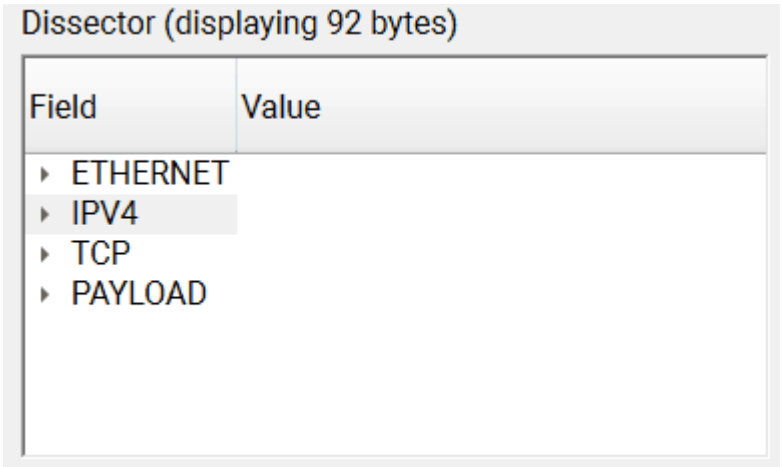
When a packet hits an enabled debug point, it is sent to the debugger and displayed. A red icon is shown to indicate that the packet is paused by the debugger. Clicking the packet reveals the packet data and state. A green arrow is shown to indicate the current debug-point the packet is paused on.

Note: The packet in the **Packets** list correlates directly to the **first row** in the **Packet Trace** list, any change that the packet will undergo (for example its size or protocol) after reinjection will only be reflected in the **next row** of the **Packet Trace** list.



Once the packet is paused, it is possible to edit its content through either the Dissector or the Hexdump.

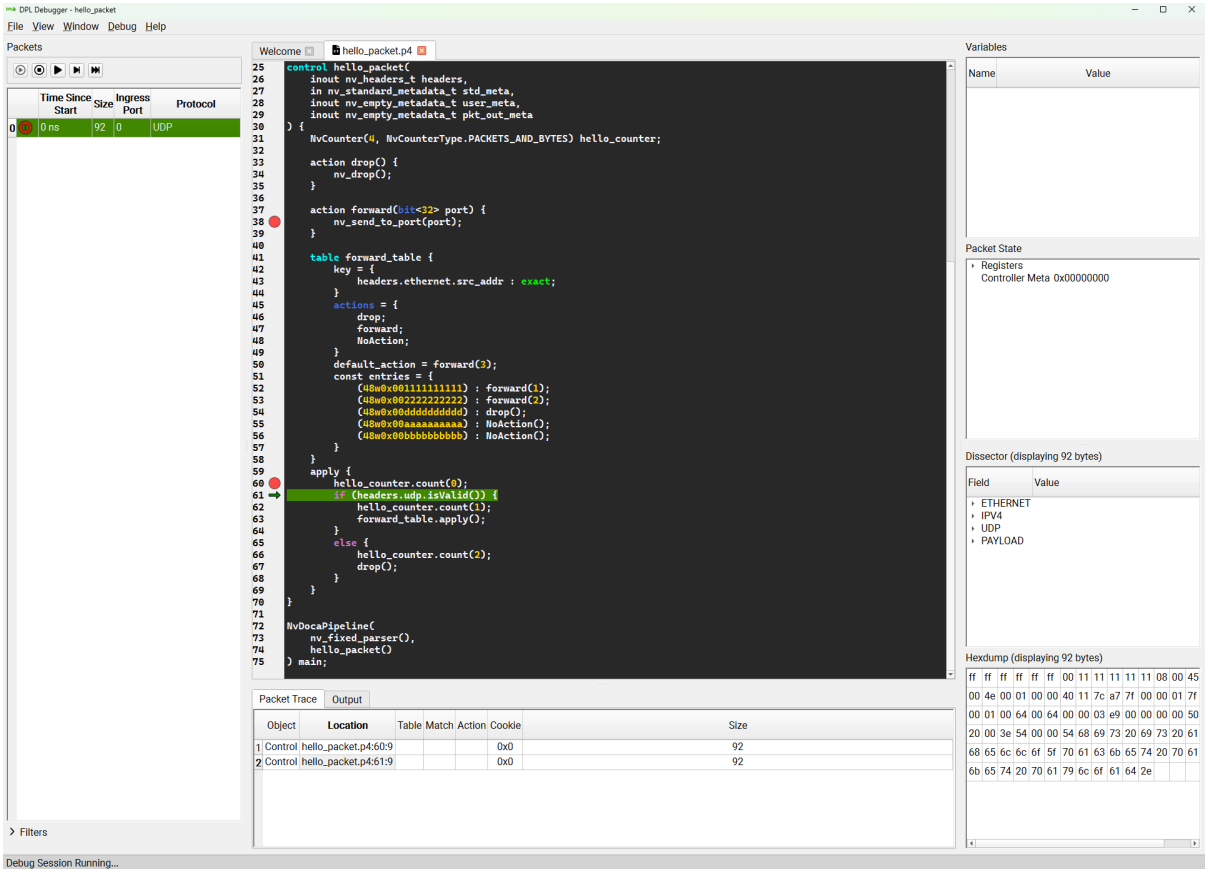
For example, we can edit the packet's protocol from TCP to UDP using the dissector.



We now inject the packet back to the same point at the pipeline, by clicking either **Debug** → **Continue**, **Debug** → **Step** or **Debug** → **Continue with Trace**.

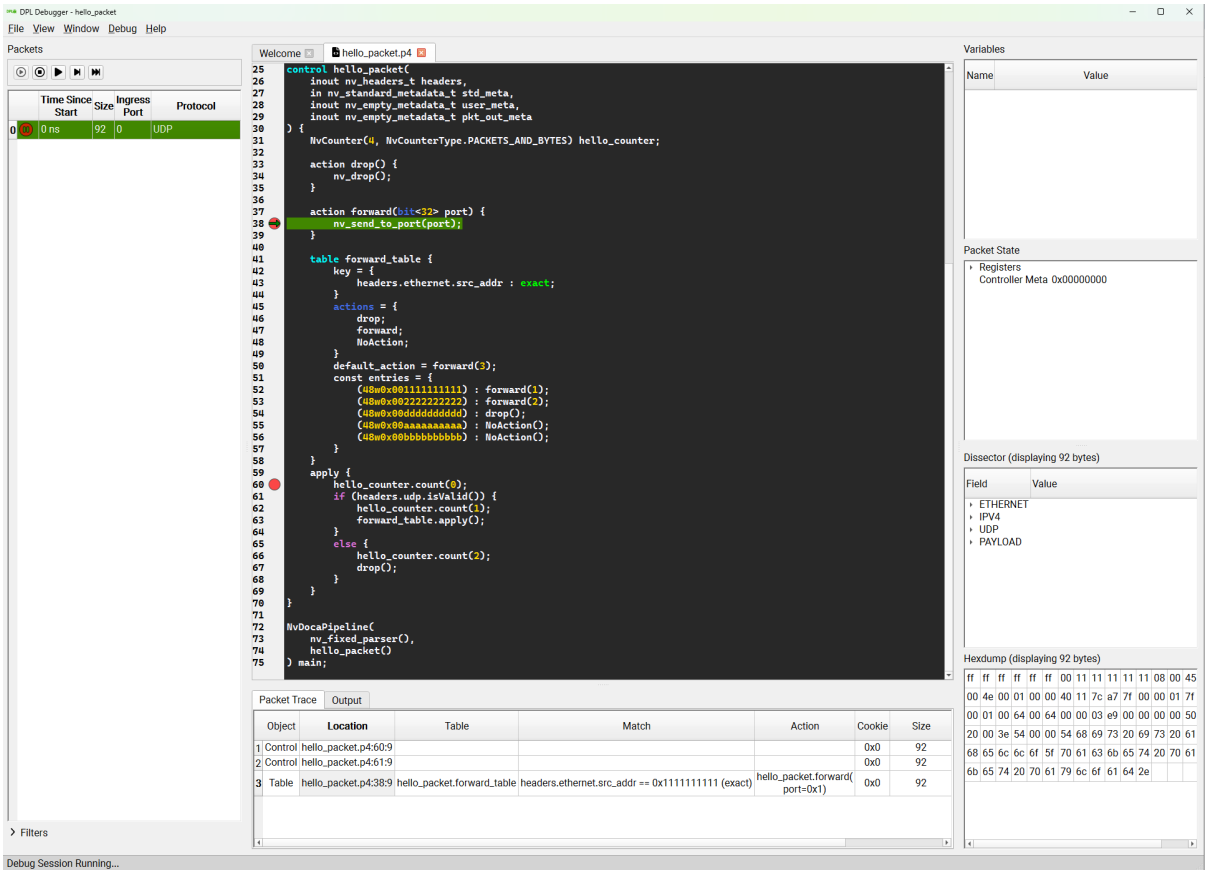
> ⚠ All three debug operations apply for all currently paused packets.

By clicking **Step**, the packet pauses in the next line, even though there is no breakpoint enabled. In addition, a new row in the "Packet Trace" widget is displayed, which represents a single debug point hit.



We click **Continue**, and the packet pauses only at the next enabled breakpoint. Moreover, we observe that the packet's path diverged as a result of our edit - we changed its protocol from TCP to UDP, and therefore the condition of the if statement was satisfied.

> ⚠ Clicking **Continue with Trace** advances the packet the same as clicking continue, but it additionally shows the trace of the packet in all debug points it passes along the way.



Continuing the packet once again causes the "Pause" icon to disappear, as there are no more breakpoints in the rest of the packet's pipeline.

7.10.6.6 Widgets

7.10.6.6.1 Packet List

Displays the packets that were sent to the debugger. Selecting a packet in the list reveals the packet trace of the packet.

The list can be cleared by clicking **File** → **Remove all packets**.

		Time Since Start	Size	Ingress Port	Protocol
0		0 ns	92	0	TCP
1		2.6 ms	92	0	TCP
2		9.88 secs	80	0	UDP
3		9.88 secs	80	0	UDP
4		9.89 secs	80	0	UDP
5		29.7 secs	80	0	UDP
6		35.4 secs	92	0	TCP

7.10.6.6.2 Packet Trace

Each row represents a single debug point hit. Selecting a debug point reveals the packet data, state, and pipeline at the time the packet hit the debug point.

	Object	Location	Table	Match	Action	Cookie	Size
1	Control	hello_packet.p4:60:9				0x0	92
2	Control	hello_packet.p4:61:9				0x0	92
3	Table	hello_packet.p4:38:9	hello_packet.forward_table	headers.ethernet.src_addr == 0x1111111111 (exact)	hello_packet.forward(port=0x1)	0x0	92

7.10.6.6.3 Filter

Packets can be filtered by:

- Table name
- Action
- Match Field
- Match Type
- Match Value
- Ingress port
- Packet Size
- Protocol

Toggle the Filters view, click the '**+**' button to add a filter, and the **Apply** button to apply the filters.

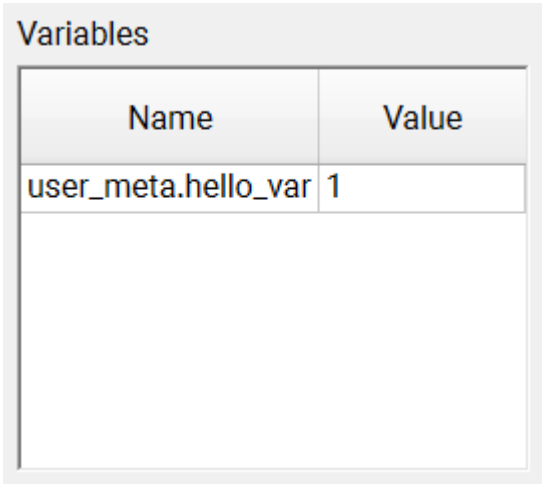
Showing 3 out of 7 packets

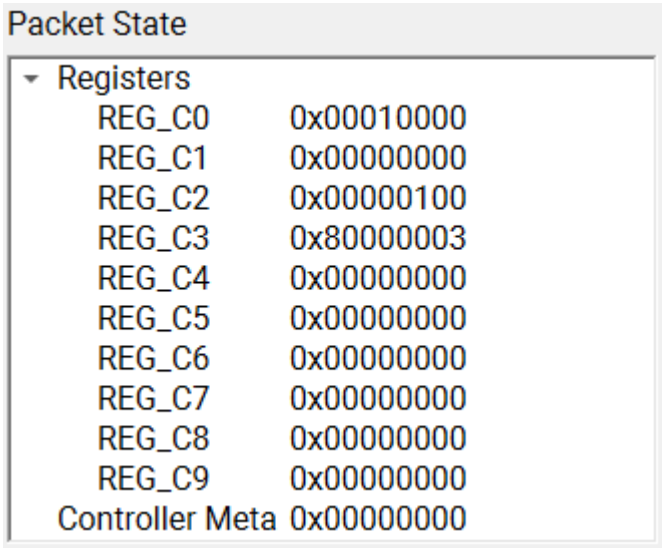
7.10.6.6.4 Variables

Shows the variables defined in the program, and their respective values at the time the selected debug-point was hit.



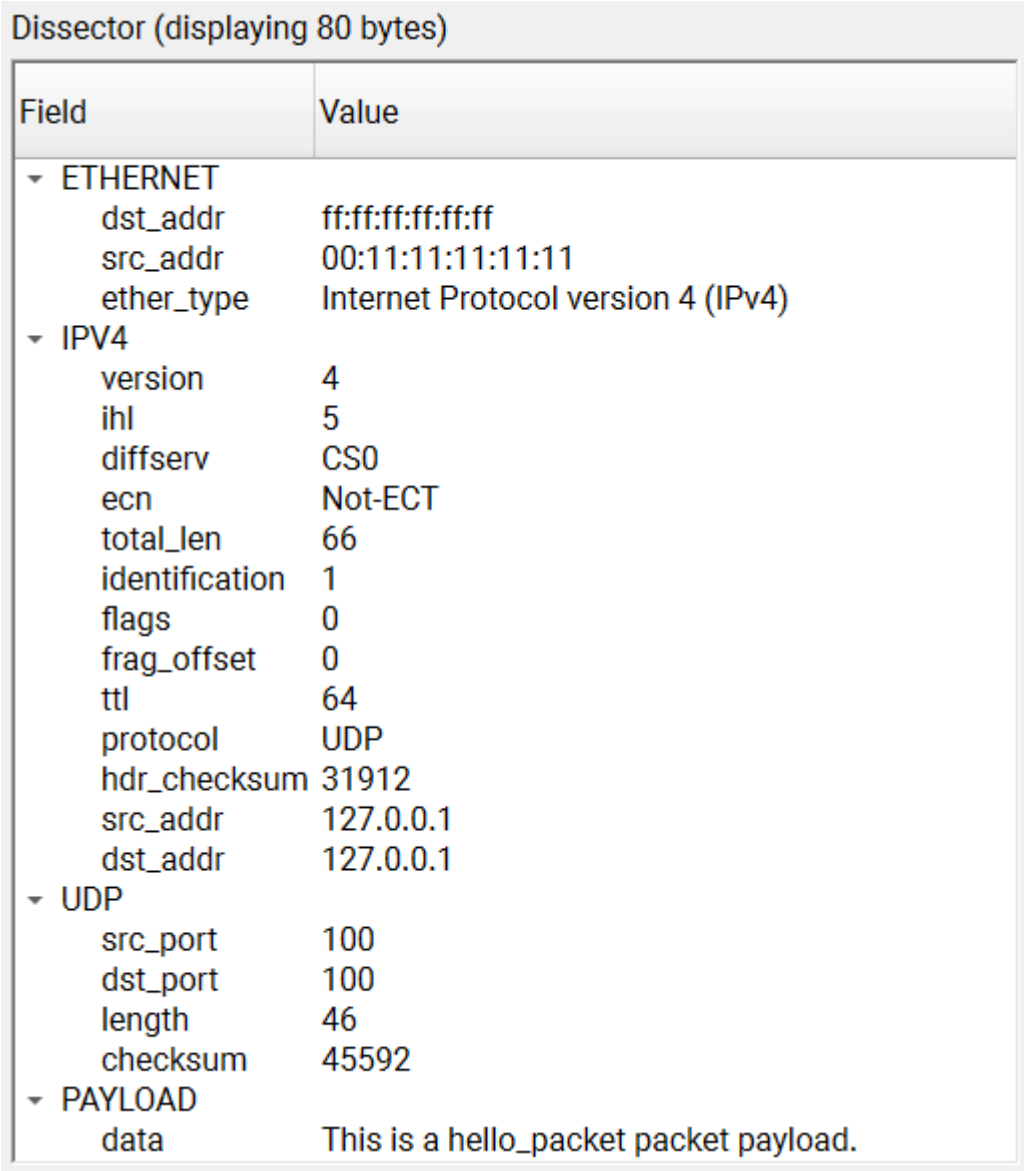
7.10.6.6.5 Packet State

Shows low level variables such as registers and controller meta.



7.10.6.6.6 Packet Dissector

Shows the parsed packet. Any paused packet can be edited by double-clicking any of the view's values (or using F2). Note that the editable values are always shown in decimal format, and are translated to the expected format upon saving.



7.10.6.6.7 Hex Dump

Shows a raw hex dump of the packet. Any paused packet can be edited by double-clicking the hexdump values (or using F2).

Hexdump (displaying 80 bytes)

ff	ff	ff	ff	ff	ff	00	11	11	11	11	11	08	00	45	00
00	42	00	01	00	00	40	11	7c	a8	7f	00	00	01	7f	00
00	01	00	64	00	64	00	2e	b2	18	54	68	69	73	20	69
73	20	61	20	68	65	6c	6c	6f	5f	70	61	63	6b	65	74
20	70	61	63	6b	65	74	20	70	61	79	6c	6f	61	64	2e

7.10.6.6.8 Source Code

Source files can be opened by clicking **File** → **Open Source File**. Additionally, sources are displayed when clicking objects that have a correlation to a source location (e.g., debug points, tables, actions, etc...).

The debugger seeks the DPL source file using the search paths defined in the Settings, or by browsing manually for the file.

44          }
45          actions = {
46              drop;
47              forward;
48              NoAction;
49          }
50          default_action = forward(3);
51          const entries = {
52              (48w0x001111111111) : forward(1);
53              (48w0x002222222222) : forward(2);
54              (48w0x00dddddddddd) : drop();
55              (48w0x00aaaaaaaaaa) : NoAction();
56              (48w0x00bbbbbbbbbb) : NoAction();
57          }
58      }
59      apply {
60          hello_counter.count(0);
61          if (headers.udp.isValid()) {
62              hello_counter.count(1);
63              forward_table.apply();
```

Packet Trace | Output

	Object	Location	Table	Match	Action	Cookie	Size
1	Control	hello_packet.p4:60:9				0x0	92
2	Control	hello_packet.p4:61:9				0x0	92
3	Table	hello_packet.p4:38:9	hello_packet.forward_table	headers.ethernet.src_addr == 0x1111111111 (exact)	hello_packet.forward(port=0x1)	0x0	92

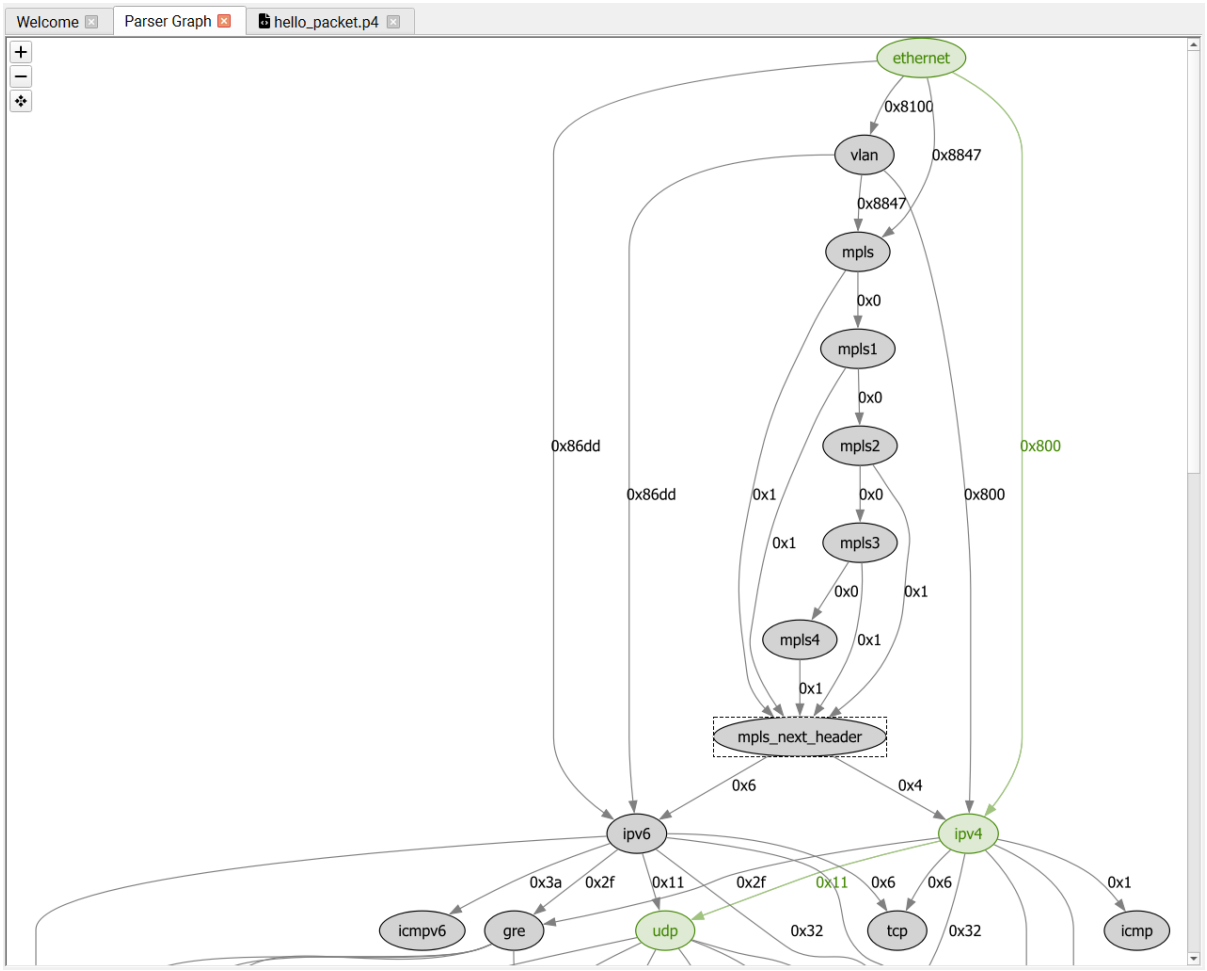
7.10.6.6.9 Pipeline

The pipeline graph can be opened by clicking **View** → **Pipeline Graph**. It shows the pipeline of the currently selected packet. Clicking on a row in the packet trace highlights (with a dashed outline) the respective debug point in the pipeline.

	Object	Location	Table	Match	Action	Cookie	Size
1	Control	hello_packet.p4:60:9				0x0	92
2	Control	hello_packet.p4:61:9				0x0	92
3	Table	hello_packet.p4:38:9	hello_packet.forward_table	headers.ethernet.src_addr == 0x1111111111 (exact)	hello_packet.forward(port=0x1)	0x0	92

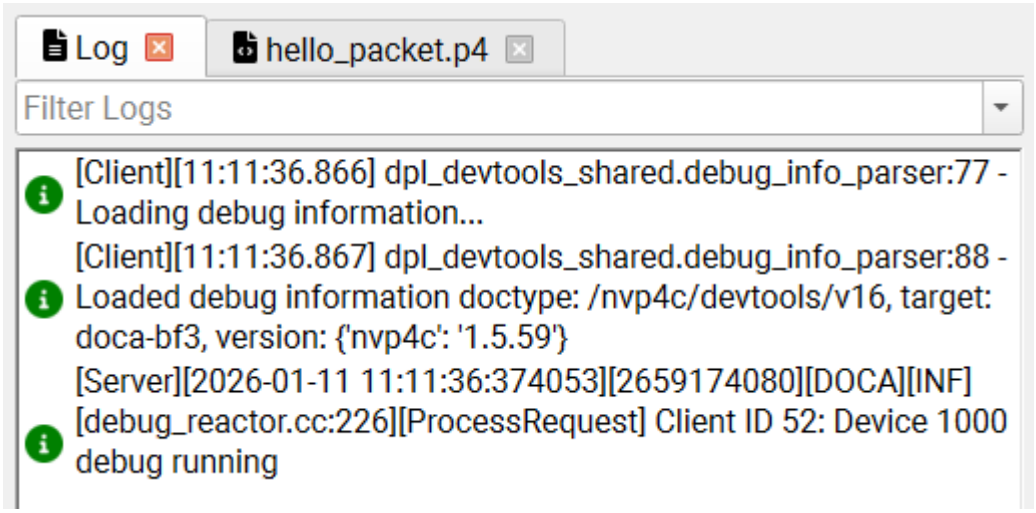
7.10.6.6.10 Parser

The parser graph can be opened by clicking **View** → **Parser Graph**. It shows the complete parser graph of the program, and outlines how the currently selected packet is parsed. The graph consists of both flex nodes which the DPL programmer instigated and static (fixed) nodes which are inherent part of the hardware.



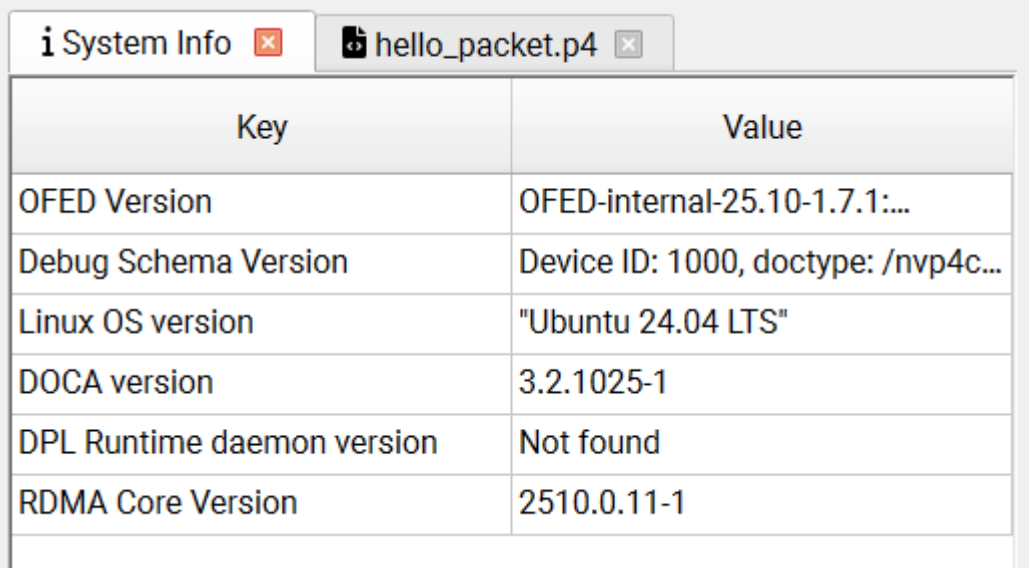
7.10.6.6.11 Log

The Log view can be opened by clicking **View** → **Log**. It shows the internal logs of the DPL Runtime daemon. The logs can be filtered by severity levels.



7.10.6.6.12 System Info

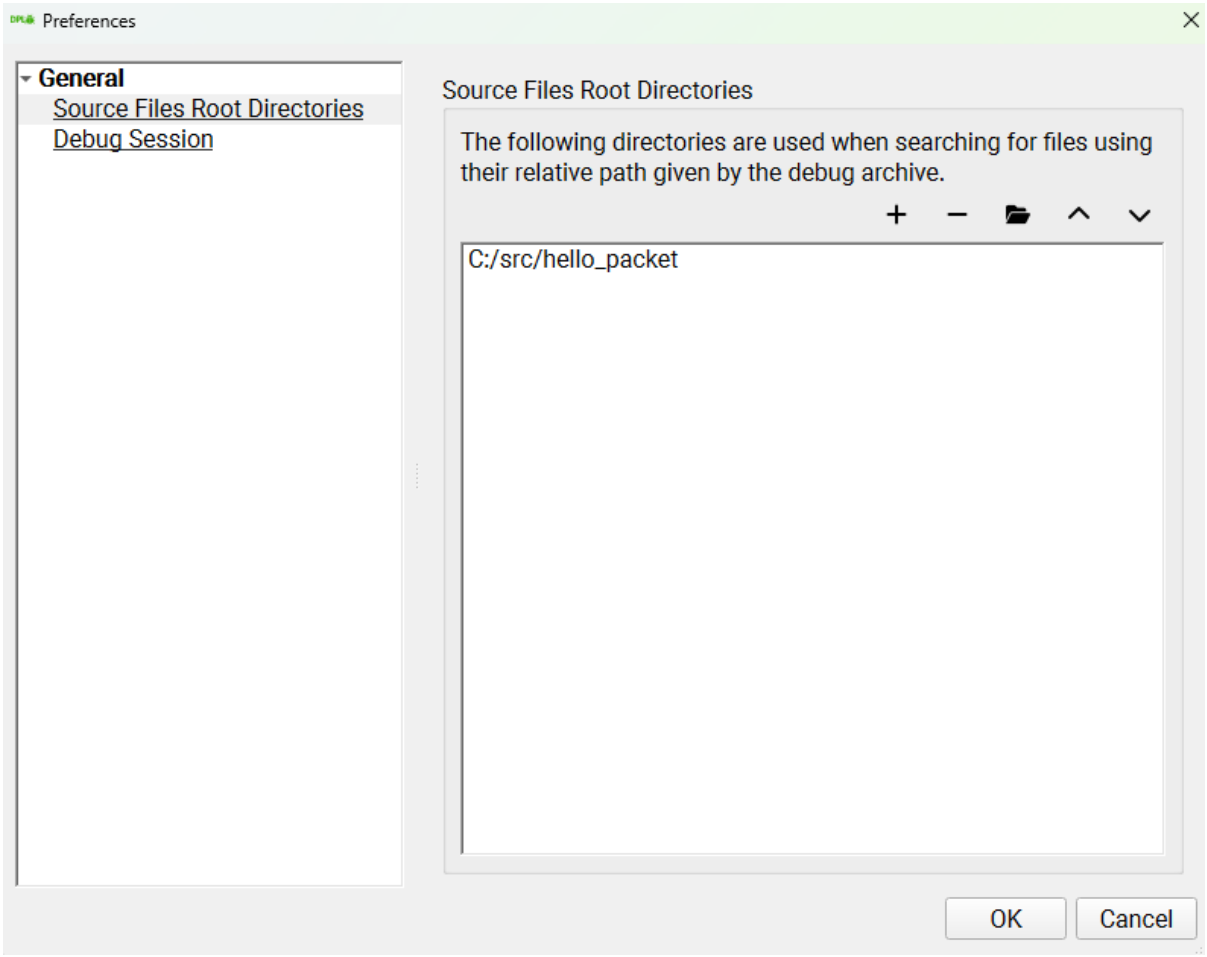
The System Info view can be opened by clicking **View→ System Info.**



7.10.6.7 Setting Source Directories

When an object with a correlation to a source location is clicked, the debugger searches in the source directories for the source file and display it.

Click **File** → **Preferences** menu and set the location of the DPL program sources.



7.10.7 DPL Admin

7.10.7.1 Introduction

DPL Admin is a CLI tool used for managing and inspecting the DPL Runtime daemon. It provides the following functionalities:

- Viewing the current configuration of the DPL Runtime daemon
- Reading the DPL Runtime Service logs
- Setting the log level for the DPL Runtime Service
- Retrieving the hardware steering dump, capabilities, and NVConfig of the DPL Runtime Service

> The DPL Admin tool is accessed and managed through the `dpl_dev` container. For detailed execution steps, refer to the Usage Guide.

7.10.7.2 Options and Commands

Usage:

```
dpl_admin.sh help
```

```
usage: dpl admin [--help] [-a <host:port>] ... <dpl_admin command> [args...]
```

Options:

Flag / Option	Description
`-h`, `--help`	Show help message and exit
`-V`, `--version`	Display the program's version number and exit
`-v`, `--verbose`	Increase output verbosity (default: `False`)
`-a HOST:PORT`, `--address HOST:PORT`	Set the `dpl_admin` server socket address in the format `[ipv4/6]:[address]:[port]` IPv6 addresses with ports must be enclosed in square brackets. Examples: `ipv6:[2607:f8b0:400e:c00::ef]:443` `ipv6:[::]:1234` `10.1.1.1:9600` If not specified, defaults to `localhost:9600`
`-t [SEC]`, `--timeout [SEC]`	Set gRPC channel connectivity timeout in seconds (default: `60`)

Authentication options (mutually inclusive for secure connection):

Flag / Option	Description
`--cacert PATH_TO_CA_CERT`	Path to CA certificate for secure connections
`--cert PATH_TO_CERT`	Path to client certificate for mutual authentication
`--private_key PATH_TO_KEY`	Path to client private key for mutual authentication

Available commands:

> Use `dpl admin <command> -h` for more details on each.

Command	Description
`config`	Retrieve device configurations
`set-counter-cache-timeout`	Set counter cache timeout for the device
`set-log-level`	Configure the logging level
`get-log-full`	Fetch the full device log
`get-log-recent`	Retrieve recent log entries

Command	Description
`hws-dump`	Dump hardware steering data
`hca-capabilities`	Show HCA capabilities
`nv-config`	Access non-volatile configuration settings
`set-idle-timeout-polling-interval`	Set the idle timeout polling interval

> ⚠ The `-a` flag is only required if the address and port are not set in the environment variable `DPL_ADMIN_DEFAULT_ARGS`, as documented under section "Configuring Launch Scripts". The examples below assume `DPL_ADMIN_DEFAULT_ARGS` has already been configured.

7.10.7.2.1 config

Displays the DPL Runtime Service configuration information, including servers, logging, devices and HAL configurations.

- Usage:

```
dpl_admin -a <host:port> config
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit
- Example:

```
dpl_admin config
```

- Output:

```

                                                                          number of queues:      1
                                                                             queue size:         1024
                                                                             burst size:         32
```

7.10.7.2.2 set-counter-cache-timeout

Sets counter cache timeout for device.

- Usage:

```
dpl admin -a <host:port> set-counter-cache-timeout --device_id/-d <DEVICE_ID> --timeout_value/-t
<TIMEOUT_VALUE>
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit.
  - `--device_id`, `-d` – Required; specifies device ID.
  - `--timeout_value`, `-t` – Required; specifies new counter cache time-out value.
- Example:

```
dpl admin set-counter-cache-timeout --device_id 1000 --timeout_value 3
```

- Output:

```
Device ID: 1000, new timeout: 3 msec
```

7.10.7.2.3 set-log-level

Sets DPL Runtime Service's log level.

- Usage:

```
dpl admin -a <host:port> set-log-level --level <LOG_LEVEL>
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit.
  - `--level`, `-l` – Required; new log level out of `{DISABLE, CRITICAL, ERROR, WARNING, INFO, DEBUG, TRACE}`
- Example:

```
dpl admin set-log-level --level DEBUG
```

- Output:

```
dpl_rtd log level set to: 'DEBUG'
```

> Setting log level is not persistent. DPL Admin restarts with log level according to config file.

7.10.7.2.4 get-log-full

Reads DPL Runtime Service's log into a file.

- Usage:

```
dpl admin -a <host:port> get-log-full
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit.
  - `--outpath`, `-o` – Optional; specifies output log file path. Defaults to current directory.
- Example:

```
dpl_admin get-log-full --outpath '/tmp/dpl_agent.log'
```

- Output:

```
Find Log file at: '/tmp/dpl_agent.log'
```

7.10.7.2.5 get-log-recent

Displays recent DPL Runtime Service's log lines.

- Usage:

```
dpl admin -a <host:port> get-log-recent
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit.
  - `--number_of_lines`, `-n` – Optional; specifies number of recent log lines to read. Defaults to 10.
- Example:

```
dpl admin get-log-recent --number_of_lines 6
```

- Output:

```
[12:45:09:480451][73079][DOCA][INF][OnReadDone] New client connected to device 1000
[12:45:09:481295][73078][DOCA][INF] A program was previously loaded, clearing it before applying new one...

[12:45:09:522419][73078][DOCA][INF] [DPL Device 1000] DPL program was loaded successfully.
```

7.10.7.2.6 hws-dump

Dumps DPL Runtime Service's hardware steering rules into a file.

- Usage:

```
dpl admin -a <host:port> hws-dump --device_id/-d <DEVICE_ID>
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit.
  - `--device_id`, `-d` – Required; specifies device ID.
  - `--parser_args`, `-a` – Optional; specifies arguments to pass to HWS dump tool.
  - `--outpath`, `-o` – Optional; specifies output file path. Defaults to current directory.
- Example:

```
dpl admin hws-dump --device_id 1000 --parser_args '-vvv' --outpath '/tmp/dpl_hws_dump.txt'
```

- Output:

```
Find HWS dump file at: '/tmp/dpl_hws_dump.txt'
```

Intended as a debugging aid for developers.

Passing multiple options for the `--parser_args` flag requires wrapping them with back-slash escaped quotation marks or apostrophe. For example:

```
dpl admin hws-dump --device_id 1000 --parser_args \'-vvv --extra_hw_res all\' --outpath '/tmp/
dpl_hws_dump.txt'
```

7.10.7.2.7 hca-capabilities

Dumps NIC HCA capabilities into a file.

- Usage:

```
dpl admin -a <host:port> hca-capabilities --device_id/-d <DEVICE_ID>
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit.
  - `--device_id`, `-d` – Required; specifies device ID.
  - `--outpath, -o` – Optional; specifies output file path. Defaults to current directory.
- Example:

```
dpl admin hca-capabilities --device_id 1000 --outpath '/tmp/dpl_hca_capabilities.json'
```

- Output:

```
Find HCA capabilities file at: '/tmp/dpl_hca_capabilities.json'
```

7.10.7.2.8 nv-config

Dumps DPL Runtime Service's NV config into a file.

- Usage:

```
dpl admin -a <host:port> nv-config --device_id/-d <DEVICE_ID>
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit.
  - `--device_id`, `-d` – Required; specifies device ID.

- `--outpath, -o` – Optional; specifies output file path. Defaults to current directory.

- Example:

```
dpl admin nv-config --device_id 1000 --outpath '/tmp/dpl_nv_config.txt'
```

- Output:

```
Find NV config file at: '/tmp/dpl_nv_config.txt'
```

7.10.7.2.9 set-idle-timeout-polling-interval

Sets idle timeout polling interval [in seconds]

- Usage:

```
dpl admin -a <host:port> set-idle-timeout-polling-interval --device_id/-d <DEVICE_ID> --interval/-i
<NEW_INTERVAL>
```

- Options:
  - `-h`, `- help` – Displays command's help message and exit.
  - `--device_id`, `-d` – Required; specifies device ID.
  - `--interval`, `-i` – Required; New polling interval to be set [seconds].
- Example:

```
dpl admin set-idle-timeout-polling-interval --device_id 1000 --interval 3
```

- Output:

```
Device ID: 1000, new polling interval: 3 seconds
```

7.10.8 P4 Runtime Controller

DPL applications are deployed to the NVIDIA® BlueField® networking platform (DPU or SuperNIC) via the P4Runtime API. Since DPL is derived from the P4-16 language, it is compatible with the P4Runtime specification, enabling standard runtime interaction with the compiled DPL pipeline

7.10.8.1 Introduction

The P4 Runtime shell (`p4runtime_sh`) is a Python-based CLI tool used to interact with this API. It is primarily used for loading DPL programs, testing match-action tables, and debugging pipeline behavior.

- Loading simple DPL programs
- Testing match-action tables
- Debugging pipeline behavior

The shell can be invoked using the launch script provided in the DPL Development container.

> For detailed instructions, refer to "Loading DPL Applications" documentation.

7.10.8.2 Basic Information and Inspection

These commands allow you to view the high-level structure of your loaded P4 program.

- Retrieves the content of `p4info.txt` for the currently loaded DPL program:

```
p4info
```

- Lists all available tables:

```
tables
```

- Displays information about a specific table:

```
tables["<P4_TABLE_NAME>"]
```

- Lists all defined actions:

```
actions
```

- Shows parameters and sizes for a specific action:

```
actions["<P4_ACTION_NAME>"]
```

7.10.8.3 Working with P4 Table Entries

7.10.8.3.1 Specifying Match Keys

When creating or modifying entries, you must define the match keys. The syntax depends on the match type defined in your DPL program.

Match Method	Syntax for Specifying Match Key Value	Note
Exact	`te.match["<KEY_NAME>"] = "<VALUE>"`	Exact value match.
Ternary	`te.match["<KEY_NAME>"] = "<VALUE>&&&<MASK>"` `te.priority = <PRIORITY_VALUE>`	The mask is provided in the match line, separated by `&&&`. If the mask is not specified, a full match mask will be used.
LPM	`te.match["<KEY_NAME>"] = "<VALUE>/<PREFIX_LEN>"`	The prefix length is provided in the match line, separated by `/`. If the prefix length is not specified, the full field bitwidth is used.
Range	`te.match["<KEY_NAME>"] = "<MIN_VALUE>..<MAX_VALUE>"`	The values are are separated by `..`, both values must be present.

7.10.8.3.2 Adding Entries

To add a standard entry, you must define the table, the action, the match keys, and the action parameters.

- Regular entry:

```
te = table_entry["<P4_TABLE_NAME>"](action="<P4_ACTION_NAME>")
te.match["<MATCH_KEY_NAME>"] = "<MATCH_VALUE>"
te.action["<PARAMETER_NAME>"] = "<PARAMETER_VALUE>"
te.insert()
```

- Entry with idle timeout:

```
te = table_entry["<P4_TABLE_NAME>"](action="<P4_ACTION_NAME>")
te.match["<MATCH_KEY_NAME>"] = "<MATCH_VALUE>"
te.action["<PARAMETER_NAME>"] = "<PARAMETER_VALUE>"
te.idle_timeout_ns = 3000000000 # Example: 3 seconds
te.insert()
```

7.10.8.3.3 Reading Entries

- Read a specific entry:

```
te = table_entry["<P4_TABLE_NAME>"]
te.match["<MATCH_KEY_NAME>"] = "<MATCH_VALUE>"
te.read(lambda te: print(te))
```

- Read all entries in a table:

```
te = table_entry["<P4_TABLE_NAME>"]
te.is_default = False
te.read(lambda te: print(te))
```

- Read time since last hit**:**

⚠ Only for tables with `idle-timeout` enabled.

```
te = table_entry["<P4_TABLE_NAME>"]
te.time_since_last_hit.elapsed_ns = 0 # Enable reading timestamp
te.match["<MATCH_KEY_NAME>"] = "<MATCH_VALUE>"
te.read(lambda te: print(te))
```

7.10.8.3.4 Deleting Entries

- Delete a specific entry:

```
te = table_entry["<P4_TABLE_NAME>"]
te.match["<MATCH_KEY_NAME>"] = "<MATCH_VALUE>"
te.delete()
```

- Delete all entries in a table:

```
te = table_entry["<P4_TABLE_NAME>"]
te.read(lambda te: te.delete())
```

7.10.8.3.5 Modifying Entries

You can modify specific action parameters of an existing table entry without removing it, provided those parameters are explicitly marked as modifiable in the P4 program.

⚠ Modification is supported only for action parameters annotated with `@nv_modifiable`. Refer to DOCA Target Architecture for more details.

⚠ Match keys, Action IDs, and non-annotated parameters cannot be changed in place. To modify these fields, you must delete the existing entry and insert a new one.

The following example demonstrates how to update a modifiable parameter:

```
# Select the table and action
te = table_entry["<P4_TABLE_NAME>"](action="<P4_ACTION_NAME>")

# Define the match keys to identify the specific entry
te.match["<MATCH_KEY_NAME>"] = "<MATCH_VALUE>"

# Update the specific parameter (Must be annotated with @nv_modifiable)
te.action["<PARAMETER_NAME>"] = "<NEW_VALUE>"

# Commit the modification
te.modify()
```

7.10.8.3.6 Managing Default Entries

> ⚠ Default entries are implicit. They cannot be inserted or deleted, only modified or read.

- Reading a default entry:

```
te = table_entry["<P4_TABLE_NAME>"]
te.is_default = True
te.read(lambda te: print(te))
```

- Reading with counter:

```
te = table_entry["<P4_TABLE_NAME>"]
te.is_default = True
te.counter_data.byte_count = 0  # Request counter data
te.read(lambda te: print(te))
```

- Modifying a default entry: Modification follows the same rules as standard entries. You can only update action parameters annotated with `@nv_modifiable`.

```
te = table_entry["<P4_TABLE_NAME>"](action="<P4_ACTION_NAME>")
te.is_default = True
te.action["<@nv_modifiable PARAMETER_NAME>"] = "<PARAMETER_VALUE>"
te.modify()
```

7.10.8.4 Working with Counters

7.10.8.4.1 Direct Counters

Direct counters are attached to specific table entries.

- List counters: `direct_counters`
- Read specific entry counter:

```
ce = DirectCounterEntry("<P4_DIRECT_COUNTER_NAME>")
ce.table_entry.match["<KEY_NAME>"] = "<VALUE>"
ce.read(lambda ce: print(ce))
```

- Read default entry counter: Set `ce.table_entry.is_default = True` before reading.
- Clear specific counter: Set `ce.packet_count = 0` and call `ce.modify()`.
- Clear all counters:

```
for dc in direct_counters:
    ce = DirectCounterEntry(dc.name)
    ce.packet_count = 0
    ce.modify()
```

7.10.8.4.2 Indirect Counters

Indirect counters are accessed by index.

- List counters: `counters`
- Read specific index:

```
ce = counter_entry["<P4_INDIRECT_COUNTER_NAME>"]
ce.index = <INDEX>
ce.read(lambda ce: print(ce))
```

- Clear specific index: Set `ce.byte_count = 0` and `ce.packet_count = 0`, then call `ce.modify()`.

7.10.8.5 Working with Meters

7.10.8.5.1 Direct Meters

- List meters: `direct_meters`
- Read specific meter:

```
me = DirectMeterEntry("<P4_DIRECT_METER_NAME>")
me.table_entry.match["<KEY>"] = "<VALUE>"
me.read(lambda me: print(me))
```

- Configure meter: Set config values (`cir`, `cburst`, `pir`, `pburst`) and call `me.modify()`.

7.10.8.5.2 Indirect Meters

- List meters: `meters`
- Read specific index:

```
me = meter_entry["<P4_INDIRECT_METER_NAME>"]
me.index = <INDEX>
me.read(lambda me: print(me))
```

- Clear meter: Set `me.cir = 0` (and other rates) and call `me.modify()`.

7.10.8.6 Packet I/O and Notifications

7.10.8.6.1 Packet In (Sniffing)

To capture packets sent from the DPL Runtime to the Controller:

```
packet_in.sniff(lambda m: print(m), timeout=10)
```

> ⚠ For detailed parsing, you can import `impacket` and decode the payload

7.10.8.6.2 Packet Out (Sending)

To send packets from the Controller to the DPL Runtime. You typically use `scapy` to build the packet first.

```
# 1. Build packet string (using Scapy or raw bytes)
my_pkt = b'<PACKET_BYTE_STRING>'

# 2. Send packet with metadata
# Repeat metadata args for every metadata defined in P4
packet_out(payload=my_pkt, <METADATA_NAME>="<VALUE>").send()
```

7.10.8.6.3 Idle Timeout Notifications

To receive notifications for entry timeouts (requires `nv_support_timeout` in DPL source):

```
idle_timeout_notification.sniff(lambda m: print(m), timeout=10)
```

7.10.9 DPL Runtime Controller SDK

DPL applications are deployed to the NVIDIA® BlueField® networking platform (DPU or SuperNIC) using the P4Runtime API. However, tables annotated with `nv_high_update_rate=true` are managed exclusively through the `dpl_rt_controller` SDK.

7.10.9.1 Introduction

7.10.9.1.1 Control Protocols

The DPL runtime service implements two control plane protocols for managing data plane elements:

- P4Runtime – Based on the open, gRPC-based standard (P4Runtime Spec)
- NVIDIA Proprietary Protocol – Optimized for High Update Rate tables, this protocol operates over shared memory.

> ⚠ P4Runtime controllers can run remotely on systems with TCP/IP access to the DPU where the `dpl_rt_service` container is active. The proprietary `dpl_rt_controller` must run locally on the DPU, as it attaches to shared memory created by the `dpl_rt_service` container.

The proprietary `dpl_rt_controller` SDK provides two controller interfaces:

- `dpl_p4rt_controller` (gRPC-based) – Used to manage all data plane elements:
  - Configure pipeline (load P4 program)
  - Manage table entries (add/delete/modify, read counters, read entries)
  - Perform packet I/O (send/receive packets from the P4Runtime server)
  - Receive idle timeout notifications (for tables supporting timeouts)
- `dpl_rt_controller` (Shared Memory-based) – Used to control *High Update Rate* (HUR) table entries:
  - Add/delete/modify operations
  - Counter updates
  - Receive idle timeout notifications (for tables supporting timeouts)
  - Limited to tables marked with `nv_high_update_rate=true`

The `dpl_rt_controller` can be optionally integrated with a P4Runtime controller to offer unified table management across both regular and high-update-rate tables.

7.10.9.1.2 Table Types

The DOCA Pipeline Language (DPL) supports two categories of tables:

7.10.9.1.2.1 Regular P4 Table

- Defined per standard P4Runtime specifications.
- Managed via the gRPC-based P4Runtime controller.
- Supports all match types supported by the DPL compiler.

7.10.9.1.2.2 High Update Rate Table

- Declared like a regular table, with the `nv_high_update_rate = true` attribute. See High Update Rate Tables in the DOCA Target Architecture.
- Managed via the proprietary `dpl_rt_controller` SDK.
- Designed for optimized performance:
  - Eliminates gRPC overhead.
  - Avoids protobuf encoding.
  - Uses rule handles instead of hash-table lookups.
- Restrictions:
  - Only exact match is supported; this is enforced by the DPL Compiler.
  - Inserting duplicate entries is not rejected by `dpl_rtd`. It is the responsibility of the user's controller application to avoid inserting duplicates.
    - Each duplicate entry will receive a distinct `dpl_rt_controller_entry` handle. However, previously existing handles will be invalidated.
    - Deleting an invalidated handle will trigger a completion error. This error is silently ignored by `dpl_rtd` but is tracked in the `dpl_rt_controller_table_statistics.deletion_errors` counter for debugging purposes.
  - Attempting to modify a non-modifiable or unsupported action parameter will be silently ignored. However, this may corrupt or invalidate the output of `dpl_nspect` queries.
  - HUR tables cannot have constant entries defined in the DPL program.
  - HUR tables are only manageable via the proprietary `dpl_rt_controller` SDK:
    - No API for entry lookup. The user controller application must maintain its own map between rules and their `dpl_rt_controller_entry` handles.
    - HUR tables do not support the use of gRPC-based P4Runtime controllers for adding, deleting, modifying or reading entries.
    - Non-HUR tables can continue to use P4Runtime for management.

7.10.9.1.3 SDK Libraries Overview

The DPL SDK includes the following components:

7.10.9.1.3.1 Header Files

Path	Purpose
`/usr/include/dpl_p4rt_controller.hpp`	gRPC-based P4Runtime controller
`/usr/include/dpl_rt_controller.h`	Proprietary controller for High Update Rate tables

7.10.9.1.3.2 Shared Libraries

Library	Description
`libdpl_p4rt_proto.so`	Auto-generated P4Runtime `.proto` bindings
`libdpl_p4rt_controller.so`	gRPC implementation for P4Runtime
`libdpl_rt_controller.so`	API implementation for shared-memory-based High Update Rate tables

7.10.9.1.3.3 API Summary

dpl_p4rt_controller

Controller Class

The main interface for managing the P4 Runtime connection and state.

Method	Description
`Controller`	Constructs a new Controller object.
`~Controller`	Destructor. Cleans up the Controller object.
`ConnectUnsecured`	Establishes an unsecured connection to `dpl_rtd`.
`ConnectSecured`	Establishes a secured TLS connection to `dpl_rtd`.
`GetChannelStub`	Returns the Channel Stub object used for gRPC communication.
`GetClientReaderWriter`	Returns the `ClientReaderWriter` object for bidirectional streaming.
`LoadProgram`	Loads a P4 program onto the `dpl_rtd`.
`GetP4Info`	Retrieves the `p4::config::v1::P4Info` metadata of the currently loaded program.
`GetGrpcOps`	Retrieves gRPC callback operations for manipulating regular tables via generic `dpl_rt_controller` APIs.
`GetElectionId`	Returns the currently defined Election ID.
`GetDeviceId`	Returns the defined Device ID.

Helper Functions

Utility functions for data type conversion and formatting.

Method	Description
`GetBeByteString`	Template function that converts a value into a big-endian (network byte-order) string.
`ByteStringToHexString`	Converts a byte string into its hexadecimal string representation.

dpl_rt_controller

Context Management

Functions for initializing, connecting, and cleaning up the controller context.

Method	Description	Notes
`dpl_rt_controller_attach`	Attach to `dpl_rtd` Shared Memory (SHM).	Must be called first, once per process. If `dpl_rtd` crashes, the controller process must be restarted.
`dpl_rt_controller_detach`	Detach from `dpl_rtd` shared memory.	
`dpl_rt_controller_connect`	Creates a device context.	
`dpl_rt_controller_disconnect`	Cleanup and disconnect a device.	Disconnecting deletes all remaining High Update Rate table entries.

Entry Allocation

Functions to allocate handles for table entries before they are added.

Method	Description	Notes
`dpl_rt_controller_table_entry_alloc_shm`	Allocate a High Update Rate table entry handle from shared memory.	Supported only for tables defined with `nv_high_update_rate=true`.
`dpl_rt_controller_table_entry_alloc_grpc`	Allocate a Regular P4Runtime table entry handle using defined gRPC callbacks.	Not supported for High Update Rate tables. `dpl_rt_controller_grpc_ops_set()` must be called before using this.
`dpl_rt_controller_table_entry_free`	Free the backing memory of an entry handle.	Used only in error flows (e.g., cleaning up after a failure to add an entry).

Entry Management

Core functions for adding, modifying, and deleting table entries.

Method	Description	Notes
`dpl_rt_controller_table_entry_add`	Add a table entry.	The `dpl_rtd` does not reject duplicate insertions to High Update Rate tables. The user app must prevent duplicates and maintain a map between rules and handles (no lookup API exists).
`dpl_rt_controller_table_entry_modify`	Modify a table entry.	• Only parameters annotated with `@nv_modifiable` can be changed. • Modifying non-annotated parameters is silently ignored and may corrupt `dpl_nspect` output. • Use compiler-generated wrapper APIs instead.
`dpl_rt_controller_table_entry_delete`	Delete a table entry.	Deleting an entry invalidates its handle. If duplicates exist, deleting one invalidates the handles for all. Subsequent operations on invalidated handles trigger errors that are silently ignored but counted in `deletion_errors` stats.

Method	Description	Notes
`dpl_rt_controller_table_entry_get_shm`	Get the opaque pointer to the C table entry structure.	Supported only for entries allocated using `alloc_shm`.
`dpl_rt_controller_table_entry_get_grpc`	Get the opaque pointer to the `p4::v1::TableEntry`.	Supported only for entries allocated using `alloc_shm`.
`dpl_rt_controller_table_entry_get_table_id`	Get the table ID of the entry.	Supported only for entries allocated using `alloc_grpc`.

gRPC Integration

Callbacks for managing standard P4Runtime tables.

Method	Description
`dpl_rt_controller_grpc_ops_set`	Sets P4Runtime controller gRPC callbacks to allow management of regular table entries.
`dpl_rt_controller_grpc_ops_clear`	Clears the currently set gRPC callbacks.

TCP State Management

Functions for managing TCP state indices.

Method	Description	Notes
`dpl_rt_controller_tcp_state_get_entries`	Get available indexes in a TCP state object for adding new entries.	Do not reuse indexes for multiple entries with the same direction. When adding new entries, call this again to get fresh indexes.
`dpl_rt_controller_tcp_state_query`	Query the TCP state for a given index.	

Utility & Statistics

Method	Description	Notes
`dpl_rt_controller_table_statistics`	Get table statistics.	• Supported only for tables with `nv_high_update_rate=true`. • The `insertions` counter starts at 1 due to the default entry inserted at load time.
`dpl_rt_controller_event_type_to_str`	Get string representation of an event type.	

Idle Timeout

Method	Description
`dpl_rt_controller_table_entry_modify_idle_timeout`	Modify the idle timeout of a table entry.
`dpl_rt_controller_idle_timeout_query`	Get all entries with expired idle timeout on the device.

PSP (Security & Encryption)

Functions for managing PSP Data Encryption Keys (DEK).

Method	Description	Notes
`dpl_rt_controller_psp_dek_modify`	Modify the DEK of a PSP object at a specific index.	
`dpl_rt_controller_psp_dek_modify_all`	Modify all DEKs of a PSP object.	
`dpl_rt_controller_psp_dek_query`	Query the DEK of a PSP object at a specific index.	User application must free the `key.bytes` array after use.
`dpl_rt_controller_psp_dek_query_all`	Query all DEKs of a PSP object.	User application must free the `key.bytes` array after use.
`dpl_rt_controller_generate_psp_keys`	Generate PSP keys.	User application must free the `key.bytes` array after use.

7.10.9.1.3.4 Sample Applications

Controller sample applications can be found under:

```
/opt/dpl_rt_controller/samples/
```

7.10.9.2 Installation and System Setup

7.10.9.2.1 SDK Packages and Requirements

The DPL Runtime Controller SDK consists of the following packages:

- `dpl-rt-controller`
- `dpl-rt-controller-dev`
- `dpl-p4rt-controller`

- `dpl-p4rt-controller-dev`
- `dpl-rt-controller-samples`

> ⚠ Currently, the DPL Runtime Controller SDK supports only Ubuntu 24.04 operating system.

7.10.9.2.2 Installation Methods

The installation process depends on your hardware deployment mode.

7.10.9.2.2.1 BlueField DPU Mode

Method	Pre-installed
Details	The SDK packages are included in the BlueField Bootstream (BFB) image. No manual installation is required after installing the BFB.

7.10.9.2.2.2 Host Mode (e.g., ConnectX-9)

Method	Manual installation
Details	Packages must be installed from the DOCA-host repository: `sudo apt install dpl-rt-controller dpl-rt-controller-dev dpl-p4rt-controller dpl-p4rt-controller-dev dpl-rt-controller-samples`

7.10.9.2.3 Hugepages Configuration

When loading DPL programs containing High Update Rate (HUR) tables, the system uses hugepages to pre-allocate entry buffers. The required buffer size depends on table properties, specifically the number of keys and total table size.

7.10.9.2.3.1 Default Behavior and Troubleshooting

The `dpl_system_setup.sh` script (see *DPL Container Deployment* under section "Pulling the Container Resources and Scripts from NGC") allocates 2048 hugepages by default.

If this allocation is insufficient for your program, `dpl_rtd` will fail to load and log an error suggesting: `(Try increasing hugepages number)`.

7.10.9.2.3.2 Adjusting the Allocation

To resolve this, run the setup script with the `--hugepages-num` flag set to a value appropriate for your workload.

For example, to load a HUR table with 16 million entries on a DPU, increase the allocation to 4096:

```
sudo <PATH_TO>/dpl_system_setup.sh --hugepages-num 4096
```

7.10.9.2.3.3 Large Allocations (>4GB)

If your configuration requires more than 4GB of hugepages (e.g., `hugepages-num > 2048` on standard 2MB hugepages), you must also update the container resource limits.

1. Open `dpl_rt_service.yaml`.
2. Locate the section `spec` → `resources` → `limits`.
3. Increase the limit for `hugepages-2Mi` to match your new allocation.

7.10.9.3 DPL P4Runtime Controller Library

```
namespace DPL_P4RT_Controller {

/* ------------------------------------------------------------------------
 * Controller class for connecting to dpl_rtd over gRPC.
 * ------------------------------------------------------------------------ */
class Controller {
public:
    /*
     * ------------------------------------------------------------------------
     * gRPC APIs
     * ------------------------------------------------------------------------
     */

    /**
     * @brief Construct a new Controller object.
     *
     * Assigns default election IDs of (high = 0, low = 1).
     *
     * @param [in] device_id
     * The Device ID to connect to in the dpl_rtd.
     * @param [in] ipaddr
     * The address for connecting to dpl_rtd
     */
    DOCA_EXPERIMENTAL
    Controller(uint32_t device_id, const char *ipaddr);

    /**
     * @brief Construct a new Controller object with custom election IDs.
     *
     * @param [in] device_id
     * The Device ID to connect to in the dpl_rtd.
     * @param [in] ipaddr
     * The address for connecting to dpl_rtd
     * @param [in] election_id_high
     * High part of the 128bit election ID used to determine the primary controller.
     * @param [in] election_id_low
     * Low part of the 128bit election ID used to determine the primary controller.
     */
    DOCA_EXPERIMENTAL
    Controller(uint32_t device_id, const char *ipaddr, uint64_t election_id_high, uint64_t
election_id_low);

    /**
     * @brief Destroy the Controller object
     *
     */
    DOCA_EXPERIMENTAL
    ~Controller();

    /**
     * @brief Create an unsecured connection to dpl_rtd.
     *
     * This requires that TLS authentication was not enabled on dpl_rtd P4RT_RPC_SERVER.
     *
     * Uses grpc::InsecureChannelCredentials().
     *
     * @return doca_error_t :
     * DOCA_SUCCESS - in case of success.
     * Error code - in case of failure.
     */
    DOCA_EXPERIMENTAL
    doca_error_t ConnectUnsecured(void);

```

```
63      /**
64       * @brief Create a secured TLS connection to dpl_rtd.
65       *
66       * This requires that TLS authentication was properly enabled and configured on dpl_rtd
    P4RT_RPC_SERVER.
67       *
68       * Uses grpc::SslCredentials().
69       *
70       * @param [in] ca_crt_path
71       * Path to ca.crt (cacert).
72       * @param [in] client_key_path
73       * Path to client.key (cert).
74       * @param [in] client_crt_path
75       * Path to client.crt (private-key).
76       * @return doca_error_t :
77       * DOCA_SUCCESS - in case of success.
78       * Error code - in case of failure.
79       */
80      DOCA_EXPERIMENTAL
81      doca_error_t ConnectSecured(const char *ca_crt_path, const char *client_key_path, const char
     *client_crt_path);
82
83      /**
84       * @brief Get the Channel Stub object for communicating with the dpl_rtd.
85       *

7.10.9.5 Idle Timeout Entries

Efficient management of network device tables is essential for maintaining optimal performance and resource utilization. In dynamic environments, table entries may become stale or unused over time. To address this, *idle timeout* provides a proactive mechanism for table hygiene. This feature continuously monitors the activity of each table entry. If an entry is not accessed (or "hit") within a specified duration (the idle timeout period) it is marked as `stale`.

7.10.9.5.1 Limitations

Idle timeout support applies only to:

- Tables that explicitly support idle timeout
- Non-default entries

7.10.9.5.2 Usage

> See sections "DPL P4Runtime Controller Library" and "DPL Runtime Controller Library" for full details.

- Creating an entry with idle timeout: Use the same flow as for entries without idle timeout, but set the `idle_timeout_ns` field in the `dpl_rt_controller_add_entry_attr` struct, and pass it to the entry addition function.
- Modifying idle timeout: Use the `dpl_rt_controller_table_entry_modify_idle_timeout` API.
- Receiving stale entry notifications:
  - For gRPC-based (regular) tables – stale entry notifications are sent via the gRPC interface.
  - For High Update Rate (HUR) tables – use `dpl_rt_controller_idle_timeout_query` to retrieve stale entries.

7.10.9.5.3 Handling of Stale Entries

It is the controller implementer's responsibility to manage stale entries. System-specific constraints often require tailored solutions. Consider the following caveats:

- When using timeouts to delete entries, deletions should occur only within the timeout handling routine. Otherwise, the implementer must ensure protection against multiple deletions of the same entry.
- In systems where timeout scanning and entry deletion/insertion occur in different threads, pointers returned by the timeout scanning function may point to invalid or different entries by the time they are processed. The implementer must address this.
  - A basic solution is to use a mutex to block deletions while scanning and handling timeouts.
- The idle timeout query function does not cause process crashes, regardless of whether it is called from single-threaded or multi-threaded environments.

7.10.9.6 DPL Runtime Controller Samples

Sample controller applications for a given DPL programs are installed by the `dpl-rt-controller-samples` package at the `/opt/dpl_rt_controller/samples/` directory.

7.10.9.6.1 Running the Sample

> Building the sample applications requires meson utility. Make sure it is available on your system. To install meson on Ubuntu, run:
>
> ```
> sudo apt update
> sudo apt install meson
> ```

Follow these steps to build and run a sample application:

1. Connect to the DPU.
2. Make sure the DPL Runtime Service is up and running. See DPL Container Deployment for more details.
3. Navigate to the desired sample application directory (one of the folders under `/opt/dpl_rt_controller/samples/` on the DPU).
4. Compile the provided DPL program (e.g., `hello_world.p4`) found at the sample's directory. See Compiling DPL Applications for more details.
5. Copy the DPL program compilation output directory (`_out`) to a local path on the DPU.

   > The compilation output directory contains the required C header files (`<program name>_dpl_shm.h and <program name>_dpl_shm_id.h`) for compiling the sample controller application.

6. Compile the C sample application:

   ```
   cd /opt/dpl_rt_controller/samples/<sample_name>
   meson /tmp/build -Dsample_programs_out=<PATH_TO_DPL_PROGRAM_COMPILATION_OUT_FOLDER>
   ninja -C /tmp/build
   ```

   > Replace the `<PATH_TO_DPL_PROGRAM_COMPILATION_OUT_FOLDER>` with the path to the local directory containing the DPL program compilation output folder (where the required C header files (`<program name>_dpl_shm.h and <program name>_dpl_shm_id.h`) are found).

   > The binary `dpl_sample_<sample_name>` is created under `/tmp/build/`.

7. Run the sample application using a privileged user. For example:

   ```
   sudo /tmp/build/dpl_sample_basic 1000 <path-to-p4info.txt> <path-to-dplconfig>
   ```

7.10.9.6.2 Samples

7.10.9.6.2.1 Basic

This sample demonstrates how to manage entries on a High Update Rate table as well as a regular table.

The sample logic includes:

1. Connecting to `dpl_rtd` over gRPC.
2. Loading a DPL program.
3. Connecting to `dpl_rtd` over SHM (Shared Memory).
4. Adding entry to a regular table.
5. Adding entry to a High Update Rate table.
6. Reading entries counter.
7. Deleting entries.
8. Displaying statistics.
9. Disconnecting and destroying all structures.

References:

- `/opt/dpl_rt_controller/samples/basic/basic_sample.cc`
- `/opt/dpl_rt_controller/samples/basic/basic_main.cc`
- `/opt/dpl_rt_controller/samples/basic/hello_world.p4`
- `/opt/dpl_rt_controller/samples/basic/meson_options.txt`
- `/opt/dpl_rt_controller/samples/basic/meson.build`

7.10.9.6.2.2 gRPC Only

This sample demonstrates how to use the generic `dpl_rt_controller` APIs to manage regular P4Runtime tables when High Update Rate tables are neither required nor defined in the DPL program.

The sample logic includes:

1. Connecting to `dpl_rtd` over gRPC.
2. Loading a DPL program.
3. Creating `dpl_rt_controller` device without SHM support.
4. Adding entry to a regular table.
5. Reading entries counter.
6. Deleting entries.
7. Disconnecting and destroying all structures.

References:

- `/opt/dpl_rt_controller/samples/grpc_only/grpc_only_sample.cc`

- `/opt/dpl_rt_controller/samples/grpc_only/grpc_only_main.cc`
- `/opt/dpl_rt_controller/samples/grpc_only/grpc_only.p4`
- `/opt/dpl_rt_controller/samples/grpc_only/meson_options.txt`
- `/opt/dpl_rt_controller/samples/grpc_only/meson.build`

7.10.9.6.2.3 Idle Timeout Sample

The sample logic includes:

1. Connecting to `dpl_rtd` over gRPC.
2. Loading a DPL program.
3. Connecting to `dpl_rtd` over SHM (SHared Memory).
4. Adding 2 entries to a regular table (gRPC) with very long timeout.
5. Adding 2 entries to a High Update Rate table (SHM) very long timeout.
6. Waiting for couple of seconds to see if entries expire (shouldn't).
7. Querying for stale entries (should find any).
8. Modifying idle timeout for one gRPC entry and one SHM entry.
9. Querying for stale entries (should find two).
10. Deleting all entries.
11. Displaying statistics.
12. Disconnecting and destroying all structures.

References:

- `/opt/dpl_rt_controller/samples/idle_timeout/idle_timeout_sample.cc`
- `/opt/dpl_rt_controller/samples/idle_timeout/idle_timeout_main.cc`
- `/opt/dpl_rt_controller/samples/idle_timeout/idle_timeout.p4`
- `/opt/dpl_rt_controller/samples/idle_timeout/meson_options.txt`
- `/opt/dpl_rt_controller/samples/idle_timeout/meson.build`

7.10.9.6.2.4 TCP state (Connection Tracking) Sample

This sample demonstrates how to manage a TCP connection state, including adding entries to track connections and retrieving the connection's acknowledgement (ACK) number and sequence (SEQ) number of the last packet that hit the TCP state object.

The sample logic includes:

1. Connecting to `dpl_rtd` over gRPC.
2. Loading a DPL program.
3. Connecting to `dpl_rtd` over SHM (SHared Memory).
4. Setting up DPDK for packet processing and table entry management (addition/deletion).
5. Printing statistics and current TCP state object info.
6. Disconnecting and destroying all structures.

References:

- `/opt/dpl_rt_controller/samples/tcp_state/tcp_state.p4`
- `/opt/dpl_rt_controller/samples/tcp_state/tcp_state_sample.cc`
- `/opt/dpl_rt_controller/samples/tcp_state/tcp_state_main.cc`
- `/opt/dpl_rt_controller/samples/tcp_state/meson_options.txt`
- `/opt/dpl_rt_controller/samples/tcp_state/meson.build`

7.10.9.6.2.5 PSP Sample

This sample demonstrates a basic client-server PSP (PSP Security Protocol) implementation, featuring key exchange and encrypted traffic forwarding.

> Since the PSP key exchange is outside the scope of the DOCA Pipeline Language (DPL) itself, this sample implements a gRPC-based mechanism.

The application uses `dpl_rt_controller` to generate keys and program the DEK tables. Combined with the provided `psp.p4` program, it enables a complete end-to-end encrypted workflow.

The sample runs on two connected NICs. Both run the DPL Runtime Service and share the `psp.p4` program, acting as Client (Sender) and Server (Receiver).

> The application exchanges keys using an unencrypted gRPC channel.

> In its current implementation, the PSP Sample application enables one-way communication from the client (sender) to the server (receiver).

Sample Logic

The following sequence describes the interaction between the Client and Server components.

- Server side:
  a. Connects to `dpl_rtd` via gRPC.
  b. Loads the DPL program (`psp.p4`).
  c. Listens for key-exchange requests.
  d. On Request:
    i. Generates PSP keys and assigns a SPI (Security Parameter Index).
    ii. Inserts an entry into the `decap_table` using the SPI.
    iii. Sends the generated keys back to the Client.
  e. Ready to decrypt incoming traffic.
- Client side:
  a. Connects to `dpl_rtd` via gRPC.

b. Loads the DPL program (`psp.p4`).
c. Requests key exchange from the Server (one key per entry).
d. Programs the DEK using the received keys.
e. Inserts an entry into the `encap_table` using the corresponding SPI.
f. Ready to encrypt and send traffic.

References

- `/opt/dpl_rt_controller/samples/psp/psp.p4`
- `/opt/dpl_rt_controller/samples/psp/psp_main.cc`
- `/opt/dpl_rt_controller/samples/psp/psp_sample.cc`
- `/opt/dpl_rt_controller/samples/psp/psp_gateway_service.cc`
- `/opt/dpl_rt_controller/samples/psp/psp_gateway_service.hpp`
- `/opt/dpl_rt_controller/samples/psp/meson_options.txt`
- `/opt/dpl_rt_controller/samples/psp/meson.build`

Usage

```
./dpl_sample_psp <device_id> <p4info_path> <program_path> <mode (client|server)> <address (ip:port|port)>
<number_of_entries (optional)>

Positional Arguments:
    device_id: DPL device ID
    p4info_path: Path to P4Info file
    program_path: Path to DPL program file
    mode: Operation mode (client or server)
    address: Remote PSP gateway address in format <ip:port> for client mode (required) or <port> for server mode
(optional). Default is 50051 for server mode.
    number_of_entries: Number of entries to insert into the encap_table and decap_table. For client mode only.
Default is 5.
```

Workflow

1. Run the application in server mode on the first NIC.

```
./dpl_sample_psp 1000 <path-to-p4info.txt> <path-to-dplconfig> server
```

2. Run the application in client mode on the second NIC.

```
./dpl_sample_psp 1000 <path-to-p4info.txt> <path-to-dplconfig> client "<server_ip>:50051"
```

3. Send test traffic: On the client side, inject packets to a virtual function (VF). The sample configures default entries for the range `1.1.1.1` to `1.1.1.X` .
    - Match keys:
        - `IPv4_dst_address` : "2.2.2.2"
        - `IPv4_src_address` : "1.1.1.1" $\rightarrow$ "1.1.1.<count>"
    - Scapy command:

```
sendp(Ether(src="00:11:11:11:11:11", dst="00:22:22:22:22:22") /
      IP(src="1.1.1.1", dst="2.2.2.2") /
      Raw(load=b'\xCA\xFE\x12\x34'), iface='eth8')
```

- Run `tcpdump` on the Server's VF interface. You should see the decrypted packet `0xCAFE1234`.

7.10.9.6.2.6 Gateway SHM Sample

This sample demonstrates how to control a VXLAN gateway program using HUR tables via SHM.

> This sample requires the `json-c` package. To install it on Ubuntu, run:
>
> ```
> sudo apt install libjson-c-dev
> ```

Sample Logic

The controller interacts with `dpl_rtd` through two distinct channels: gRPC for configuration and SHM for high-speed table updates.

1. Connect to `dpl_rtd` via gRPC.
2. Load the DPL program.
3. Connect to `dpl_rtd` via SHM.
4. Parse `gateway.entries.json` and add entries to the High Update Rate tables via SHM.
5. Print counters and entry details upon user key press.
6. Disconnect and clean up resources.

References

- `/opt/dpl_rt_controller/samples/gateway_shm/gateway_shm.p4`
- `/opt/dpl_rt_controller/samples/gateway_shm/gateway.entries.json`

- `/opt/dpl_rt_controller/samples/gateway_shm/meson.build`

7.10.9.6.2.7 Modify Entry Sample (Atomic Updates)

This sample demonstrates the dynamic modification of table entry action parameters in a DPL-defined data plane.

It utilizes the SDK API to update specific action data (e.g., Source Port, ECN, DSCP) atomically. Unlike standard operations that require deleting and re-inserting the flow, this method modifies the existing entry in place, ensuring efficient control plane updates and minimizing packet processing disruption.

Sample Logic

The sample logic includes:

1. Connect to `dpl_rtd` via gRPC and SHM.
2. Load the DPL program.
3. Add initial entries via both gRPC and SHM.
4. Test 1: Send packets to hit these entries (verify via `tcpdump`).
5. Update specific parameters of the existing entries via gRPC and SHM.
6. Test 2: Send the same packets again to observe the updated behavior (e.g., changed DSCP or Port).
7. Clean up and exit.

7.11 DOCA PCC Counter Tool

This document provides instruction on the usage of the PCC Counter tool.

> This tool is not supported on NVIDIA® ConnectX®-8 and cannot run in parallel with DOCA Nguage or DOCA Telemetry.

7.11.1 Introduction

The PCC Counter tool is used to print PCC-related hardware counters. The output counters help debug the PCC user algorithm embedded in the DOCA PCC application.

7.11.2 Prerequisites

DOCA 2.2.0 and higher.

7.11.3 Description

If NVIDIA® BlueField®-3 is operating in DPU mode, the script must be executed on the Arm side. If BlueField-3 is operating in NIC mode, the script must be executed on the host side.

> Refer to BlueField Modes of Operation for more information on the DPU's modes of operation.

The following performance counters are supported for PCC:

- `MAD_RTT_PERF_CONT_REQ` – the number of RTT requests received in total
- `MAD_RTT_PERF_CONT_RES` – the number of RTT responses received in total
- `SX_EVENT_WRED_DROP` – the number of TX events dropped due to the CC event queue being full
- `SX_RTT_EVENT_WRED_DROP` – the number of "TX event with RTT request sent indication" dropped due to the CC event queue being full
- `ACK_EVENT_WRED_DROP` – the number of Ack events dropped due to the CC event queue being full
- `NACK_EVENT_WRED_DROP` – the number of Nack events dropped due to the CC event queue being full
- `CNP_EVENT_WRED_DROP` – the number of CNP events dropped due to the CC event queue being full
- `RTT_EVENT_WRED_DROP` – the number of RTT events dropped due to the CC event queue being full
- `HANDLED_SXW_EVENTS` – the number of handled CC events related to SXW
- `HANDLED_RXT_EVENTS` – the number of handled CC events related to RXT
- `DROP_RTT_PORT0_REQ` – the number of RTT requests dropped in total from port 0
- `DROP_RTT_PORT1_REQ` – the number of RTT requests dropped in total from port 1
- `DROP_RTT_PORT0_RES` – the number of RTT responses dropped in total from port 0
- `DROP_RTT_PORT1_RES` – the number of RTT responses dropped in total from port 1
- `RTT_GEN_PORT0_REQ` – the number of RTT requests sent in total from port 0
- `RTT_GEN_PORT1_REQ` – the number of RTT requests sent in total from port 1
- `RTT_GEN_PORT0_RES` – the number of RTT responses sent in total from port 0
- `RTT_GEN_PORT1_RES` – the number of RTT responses sent in total from port 1
- `PCC_CNP_COUNT` – the number of CNP received in total, regardless of whether it is handled or ignored

7.11.4 Execution

To use the PCC Counter:

1. Initialize all supported hardware counters. Run:

```
sudo ./pcc_counters.sh set /dev/mst/mt41692_pciconf0
```

> Counters are zeroed after each `set` command.

2. Query all supported hardware counters. Run:

```
sudo ./pcc_counters.sh query /dev/mst/mt41692_pciconf0
```

> The output counters are counted from the time the `set` command is executed to the time when the `query` command is issued.

Example output:

```
sudo ./pcc_counters.sh query /dev/mst/mt41692_pciconf0
-----------------PCC Counters-----------------
Counter: MAD_RTT_PERF_CONT_REQ  Value: 000000000028b85b
Counter: MAD_RTT_PERF_CONT_RES  Value: 000000000028b85a
Counter: SX_EVENT_WRED_DROP     Value: 0000000000000000
Counter: SX_RTT_EVENT_WRED_DROP Value: 0000000000000000
Counter: ACK_EVENT_WRED_DROP    Value: 0000000000ccdf4f
Counter: NACK_EVENT_WRED_DROP   Value: 0000000000000000
Counter: CNP_EVENT_WRED_DROP    Value: 0000000000000000
Counter: RTT_EVENT_WRED_DROP    Value: 0000000000000000
Counter: HANDLED_SXW_EVENTS     Value: 000000000932543a
Counter: HANDLED_RXT_EVENTS     Value: 000000000028b85c
Counter: DROP_RTT_PORT0_REQ     Value: 0000000000000000
Counter: DROP_RTT_PORT1_REQ     Value: 0000000000000000
Counter: DROP_RTT_PORT0_RES     Value: 0000000000000000
Counter: DROP_RTT_PORT1_RES     Value: 0000000000000000
Counter: RTT_GEN_PORT0_REQ      Value: 0000000000000000
Counter: RTT_GEN_PORT1_REQ      Value: 000000000028b85c
Counter: RTT_GEN_PORT0_RES      Value: 0000000000000000
Counter: RTT_GEN_PORT1_RES      Value: 000000000028b85d
Counter: PCC_CNP_COUNT          Value: 0000000000000000
```

7.12 DOCA Socket Relay

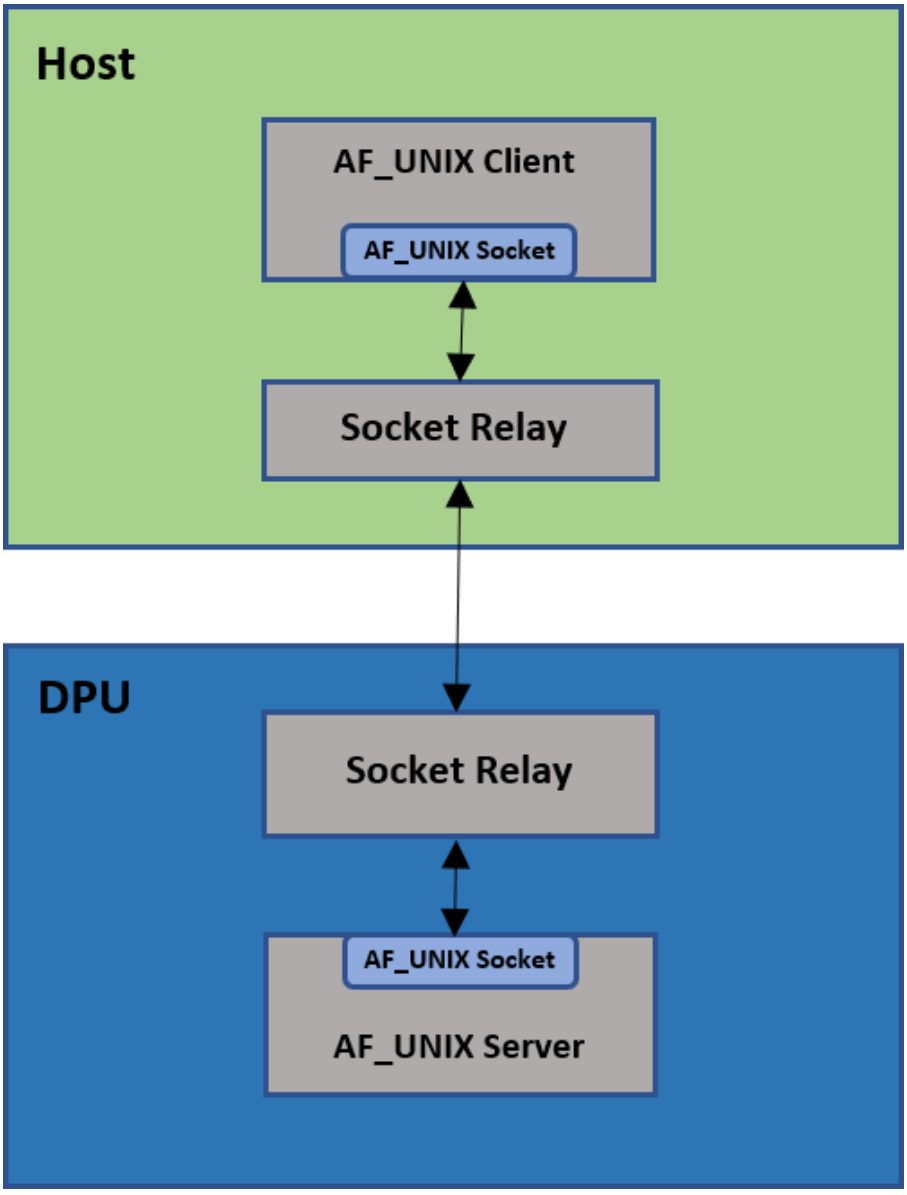
This document describes DOCA Socket Relay architecture, usage, etc.

7.12.1 Introduction

DOCA Socket Relay allows Unix Domain Socket (AF_UNIX family) server applications to be offloaded to the DPU while communication between the two sides is proxied by DOCA Comch.

Socket relay only supports SOCK_STREAM communication with a limit of 512 AF_UNIX application clients.

The tool is coupled to the client AF_UNIX server application. That is, a socket relay instance should be initiated per AF_UNIX server application.



Socket relay is transparent to the application except for the following TCP flows:

- Connection termination must be done by the host side application only
- Once a FIN packet (shutdown system call has been made) is sent by the host side application, data cannot be transferred between the DPU and the host, and the connection must be closed.

The following details the communication flow between the client and server:

- The AF_UNIX client application connects to the socket relay AF_UNIX server in the same way as in the original flow

- The AF_UNIX client application sends SOCK_STREAM packets
- The socket relay (host) AF_UNIX server receives the client application packets, and the Comm Channel client sends them on the channel
- The socket relay (DPU) Comm Channel server receives the client application packets and the AF_UNIX client sends them to the user's AF_UNIX server application

7.12.2 Prerequisites

Windows 10 build 17063 is the minimal Windows version to run DOCA Socket Relay on a Windows host.

7.12.3 Dependencies

NVIDIA® BlueField®-2 firmware version 24.35.1012 or higher.

7.12.4 Execution

To execute DOCA Socket Relay:

```
Usage: doca_socket_relay [DOCA Flags] [Program Flags]

DOCA Flags:
  -h, --help                Print a help synopsis
  -v, --version             Print program version information
  -l, --log-level           Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --sdk-log-level           Set the SDK (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR,
40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  --log-filter              Filter logs from specific modules, separated by comma
  -j, --json <path>         Parse command line flags from an input json file

Program Flags:
  -s, --socket              Unix domain socket path, host side will bind to and DPU connect to
  -n, --cc-name             Comm Channel service name
  -p, --pci-addr            DOCA Comm Channel device PCI address
  -r, --rep-pci             DOCA Comm Channel device representor PCI address (needed only on DPU)
```

For example (DPU side):

```
doca_socket_relay -s /tmp/sr_server.socket -n cc_channel -p 03:00.0 -r b1:00.0
```

7.12.5 Arg Parser DOCA Flags

Refer to the DOCA Arg Parser for more information.

7.12.5.1 General Flags

Short Flag	Long Flag	Description
`h`	`help`	Print a help synopsis
`v`	`version`	Print program version information
`l`	`log-level`	Set the log level for the application: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70 (requires compilation with `TRACE` log level support)
N/A	`sdk-log-level`	Set the log level for the program: • DISABLE=10 • CRITICAL=20 • ERROR=30 • WARNING=40 • INFO=50 • DEBUG=60 • TRACE=70
N/A	`log-filter`	Filter logs from specific modules, separated by comma
`j`	`json`	Parse command line flags from an input JSON file as well as from the CLI (if provided)

Refer to DOCA Arg Parser for more information regarding the supported flags and execution modes.

7.12.5.2 Program Flags

Short Flag	Long Flag	Description
`s`	`socket`	AF_UNIX (`SOCK_STREAM`) path. On the host, this is the path of the socket relay AF_UNIX server for the client's application to connect to. On the DPU, this is the path of the client AF_UNIX server application. ⚠ This flag is mandatory.
`n`	`cc-name`	Comm Channel service name ⚠ This flag is mandatory.

Short Flag	Long Flag	Description
`p`	`pci-addr`	DOCA Comm Channel device PCIe address ⚠ This flag is mandatory.
`r`	`rep-pci`	DOCA Comm Channel device representor PCIe address ⚠ This flag is available and mandatory only on the DPU.

7.13 DOCA Telemetry Utils

This page provides instructions on the usage of the `doca_telemetry_utils` tool.

ℹ Supported hardware is NVIDIA® BlueField®-3, NVIDIA® ConnectX®-7, and above.

7.13.1 Introduction

The `doca_telemetry_utils` tool can be used to display all the available counters, and to generate counter IDs which can be used in other DOCA Tools. It also can get the counter type and settings from a given counter ID, and to inform whether this counter is available on the required hardware.

This tool simplifies counter management, making it easier to identify, configure, and verify counter support for specific devices.

ℹ `doca_telemetry_utils` relies on the `fwctl` driver and, therefore, probing hardware support will fail if run simultaneously with other tools or services that also utilize this driver.

7.13.2 Prerequisites

The `fwctl` driver must be installed on the host:

OS	Commands

Deb-based [1]	1. Search for the package:
	`apt-cache search fwctl`
	2. Install the package:
	`sudo apt install <package-name>`

RPM-based	1. Search for the package:
	`dnf search fwctl`
	2. Install the package:
	`sudo dnf install <package-name>`

1. On Ubuntu 20.04, the `fwctl` driver is not loaded automatically upon system startup. To load it, run the command `modprobe mlx5_fwctl` after every reboot.

7.13.2.1 Installing DOCA Telemetry Utils

To install `doca_telemetry_utils`:

- On deb-based distros, run:

```
sudo apt-get install doca-telemetry-utils
```

- On RPM-based distros, run:

```
sudo dnf install doca-telemetry-utils
```

7.13.3 Description

The `doca_telemetry_utils` tool can be used with either a counter name or a counter data ID.

7.13.3.1 Usage with Counter Name

When providing a counter name, `doca_telemetry_utils` displays the associated data ID and additional details:

The following is an example of running with the counter named `global_icmc_hit`:

```
$ doca_telemetry_utils global_icmc_hit
Data ID: 0x1180000200000000
Name: global_icmc_hit
Unit: ICMC
```

For counters requiring arguments, running the tool with only the counter name displays the options needed.

Running with `port_rx_bytes`:

```
[fill_data_id] Per-port counter 0x10200001 (port_rx_bytes) needs exactly 1 argument (local_port), 0
given.
```

In this case, you must provide the required argument(s) and re-run the command.

Example of specifying the argument `local_port`:

```
$ doca_telemetry_utils port_rx_bytes 0
Data ID: 0x1020000100000000
Name: port_rx_bytes
Unit: RX_PORT
local_port: 0
```

7.13.3.2 Usage with Data ID

When providing a data ID, `doca_telemetry_utils` displays the counter name and other details:

Example of running with data ID `0x1180000200000000`:

```
$ doca_telemetry_utils 0x1180000200000000
Data ID: 0x1180000200000000
Name: global_icmc_hit
Unit: ICMC
```

7.13.3.3 Checking Counter Support on a Device

To check whether a specific counter is supported by a particular device using the device's PCIe address.

To check if the `global_icmc_hit` counter is supported on device `08:00.0`:

```
$ doca_telemetry_utils 08:00.0 0x1180000200000000
Data ID: 0x1180000200000000
Name: global_icmc_hit
Unit: ICMC
Data ID 0x1180000200000000 is supported on device 08:00.0
```

7.13.4 Execution

To run `doca_telemetry_utils`:

```
$ doca_telemetry_utils -h
Usage:
Name to Data ID:
     doca_telemetry_utils [<device PCI>] <name> [relevant properties]
    • To get the options for 'relevant properties' run with 'name' alone.
Data ID to name:
     doca_telemetry_utils [<device PCI>] <DATA_ID>

• If the optional argument <device PCI> is provided, this device will be tested for support of this counter.
• Run with option 'get-counters' to get all the available names.

-h, --help:  Show this help message.
```

Examples:

- Show all available counters:

  ```
  doca_telemetry_utils get-counters
  ```

- Name to data ID with relevant options:

  ```
  doca_telemetry_utils port_rx_bytes 0
  ```

- Name to Data ID with device PCIe:

  ```
  doca_telemetry_utils 08:00.0 port_rx_bytes 0
  ```

- Data ID to name:

  ```
  doca_telemetry_utils 0x1020000100000000
  ```

- Data ID to Name with device PCIe:

  ```
  doca_telemetry_utils 08:00.0 0x1020000100000000
  ```

7.14 DOCA doca-hugepages Tool

This guide provides an overview of the `doca-hugepages` tool, including its purpose, usage instructions, command syntax, and integration guidelines for managing hugepage allocations in NVIDIA DOCA environments.

7.14.1 Introduction

The `doca-hugepages` tool manages hugepages configurations for various applications. It enables users to configure, reload, remove, and display hugepages settings efficiently. The tool is located at `/usr/sbin/doca-hugepages`.

All `doca-hugepages` commands begin with `doca-hugepages` and fall into the following categories:

- `config` – Adds or updates an application's configuration in the database. This command does not apply changes immediately; use the `reload` command to allocate hugepages based on the updated configuration.
- `reload` – Reloads the hugepages configuration for all applications according to the current database.
- `remove` – Removes an application's configuration from the database.
- `show` – Displays the current hugepages configuration for all applications.
- `original-config` – Manages and displays the original system configuration saved by the tool.

7.14.2 Execution

7.14.2.1 config

Adds or updates an application's configuration in the database.

```
doca-hugepages config [-h] --app APP --size SIZE --num NUM [--force]

doca-hugepages config Flags:
    --force (optional)      Forces updating the configuration without prompting.
    --app                   Name of the application.
    --size                  Hugepage size in kB.
    --num                   Number of hugepages to allocate.
```

For example:

```
doca-hugepages config --app myApp --size 2048 --num 10
```

7.14.2.2 reload

Reloads the hugepages configuration for all applications.

```
doca-hugepages reload
```

7.14.2.3 remove

Removes an application's configuration from the database.

```
doca-hugepages remove <app>

doca-hugepages remove Flags:
    --all:      Removes all configurations for the app without prompting.
```

7.14.2.4 show

Displays the current hugepages configuration for all applications.

```
doca-hugepages show
```

7.14.2.5 original-config

Manages the original system configuration captured by the tool on its first run. This snapshot serves as a reference for restoring or comparing configurations.

```
doca-hugepages original-config {update,show}

doca-hugepages original-config Flags:
    show:       Display the original system configuration.
    update:     Override the original system configuration.
```

7.14.2.6 Important Notes

- Always run `doca-hugepages reload` after updating configurations to apply changes.
- Use `--force` with caution to avoid unintended updates.
- Periodically use `show` to verify the active configuration.

7.14.3 Incompatibility with GRUB-Based Hugepages Management

The `doca-hugepages` tool is not supported on systems where hugepages are configured through GRUB (e.g., via `/etc/default/grub`). These two methods are mutually exclusive. Attempting to use both may result in unpredictable behavior or configuration conflicts.

To use `doca-hugepages`, ensure that all hugepages-related GRUB parameters are removed. Conversely, when using GRUB-based configuration, do not invoke `doca-hugepages`.

7.14.4 Integration with Packages

Custom per-application hugepages configurations can be integrated into packages by placing a configuration file in the `/etc/mellanox/hugepages.d/` directory.

Example:

APP.json

```
/etc/mellanox/hugepages.d/APP.json

{
  "2048": {
    "num": 1024,
    "is_active": "inactive"
  }
}
```

In this example:

- `"2048"` – Hugepage size in kilobytes
- `"num"` – Number of hugepages to allocate
- `"is_active"` – Marks the configuration as `"active"` or `"inactive"`

  NVIDIA recommends setting `"is_active": "inactive"` and using the `doca-hugepages` tool to activate the configuration during driver load or system boot. This workflow is supported only on Ubuntu 22.04 systems running on BlueField platforms.

8 DOCA Services

This section provides an overview of the various services provided by DOCA.

8.1 Introduction

DOCA services are DOCA-based products, wrapped in a container for fast and easy deployment on top of the NVIDIA BlueField DPU. DOCA services leverage DPU capabilities to offer telemetry, time synchronization, networking solutions, and more.

Services containers can be found in the NGC catalog, labeled "DOCA" and "DPU", as well as the built-in NVIDIA platform option ("DOCA") in the container catalog.

The following services are not available in the NGC catalog:

- DOCA Management Service
- NVIDIA OpenvSwitch Acceleration (OVS in DOCA)

For information on the deployment of the services, refer to the DOCA Container Deployment Guide.

8.1.1 DOCA Services Quality Level

DOCA Service	Quality Level
DOCA Argus	Beta
DOCA Blueman	GA
DOCA Firefly	GA
DOCA Flow Inspector	GA
DOCA HBN	GA
DMS	Alpha
DPL Service	Beta
SNAP Virtio-FS	Beta
SNAP-4	GA
SNAP-3	GA
DOCA Telemetry	GA
DOCA UROM	GA

DOCA Service	Quality Level
DOCA Virtio-net	GA
OVS-DOCA	GA

8.2 Development Lifecycle

DOCA-based containers consist of two main categories:

- DOCA Base Images: containerized DOCA environments for both runtime and development. Used either by developers for their development environment or in the process of containerizing a DOCA-based solution.
- DOCA Services: containerized DOCA-based products

8.2.1 Development

Before containerizing a product, users must first design and develop it using the same process for a bare-metal deployment on the BlueField DPU.

This process consists of the following steps:

1. Identify the requirements for the DOCA-based solution.
2. Review the feature set offered by the DOCA SDK libraries, as shown in their respective programming guides.
3. Start the development process by following the best practices detailed in the Developer Guide.
4. Test the developed solution.

After development and testing, the product can be containerized.

8.2.2 Containerization

For this process, NVIDIA recommends using DOCA's base images, available on DOCA's NGC page.

There are three image varieties:

- `base-rt` – includes the DOCA runtime, using the most basic runtime environment required by DOCA's SDK
- `full-rt` – builds on the previous image and includes the full list of runtime packages, which are all user-mode components that can be found under the `doca-runtime` package

- `devel` – builds on the previous image and adds headers and development tools for developing and debugging DOCA applications. This image is particularly useful for multi-stage builds.

All images are preconfigured to use to the DOCA repository of the matching DOCA version. This means that installing an additional DOCA package as part of a Docker file or within the development container can be done using the following commands:

```
apt update
apt install <package name>,
```

For DOCA and CUDA environments, the images follow a similar pattern, and are combined with CUDA's images:

- `base-rt` (DOCA) + `base` (CUDA)
- `full-rt` (DOCA) + `runtime` (CUDA)
- `devel` (DOCA) + `devel` (CUDA)

After development and testing, users can start profiling the containerized product in preparation for a production-grade deployment.

> ⚠ DOCA provides base images for both the DPU and the host. For host-related DOCA base images, refer to the image tag suffixed with "-host".

8.2.3 Profiling

As mentioned in the DOCA Container Deployment Guide, the current deployment model of containers on top of the DPU is based on kubelet-standalone. This Kubernetes-based deployment makes use of YAML files to describe the resources required by the pod such as:

- CPU
- RAM
- Huge pages

NVIDIA recommends profiling your product to estimate the resources it requires (under regular deployments, as well as under stress testing) so that the YAML file includes an accurate "resources" section. This allows administrators to better understand the requirements for deploying your service, and also enables the Kubernetes infrastructure to ensure that the service is not malfunctioning after deployment.

After the profiling is complete, the containerized DOCA-based product is ready for the final testing and deployment in production environments.

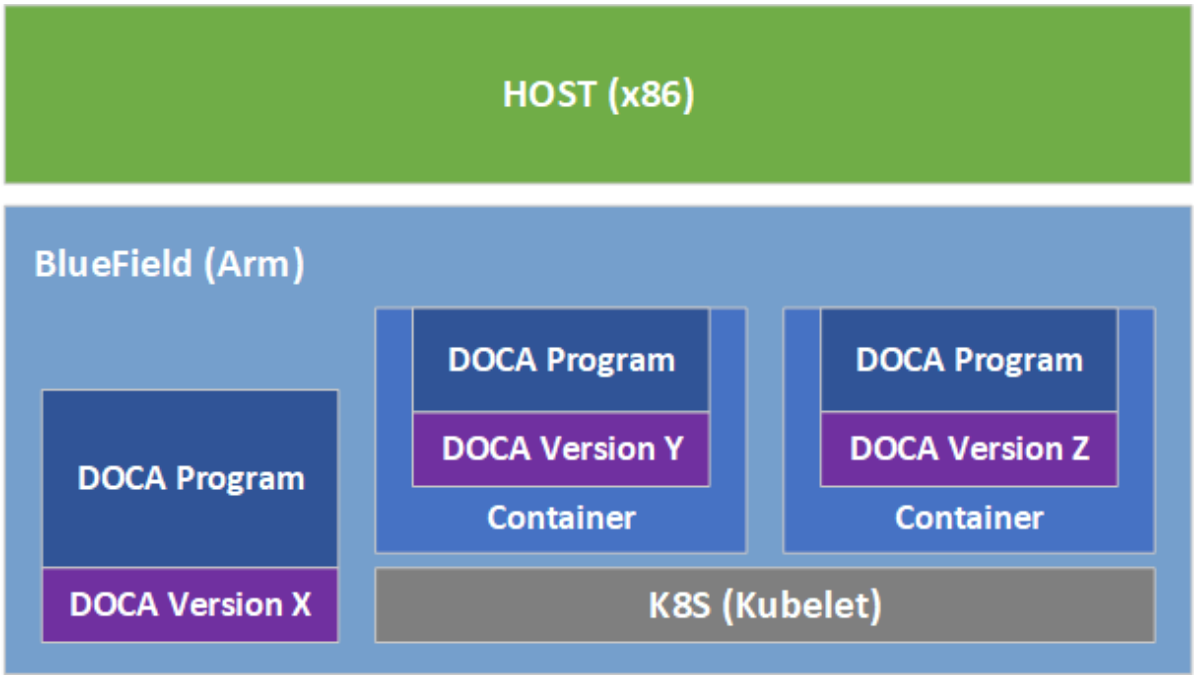
8.3 DOCA Container Deployment Guide

This guide provides an overview and deployment configuration of DOCA containers for NVIDIA® BlueField® DPU.

8.3.1 Introduction

DOCA containers allow for easy deployment of ready-made DOCA environments to the DPU, whether it is a DOCA service bundled inside a container and ready to be deployed, or a development environment already containing the desired DOCA version.

Containerized environments enable the users to decouple DOCA programs from the underlying BlueField software. Each container is pre-built with all needed libraries and configurations to match the specific DOCA version of the program at hand. One only needs to pick the desired version of the service and pull the ready-made container of that version from NVIDIA's container catalog.



The different DOCA containers are listed on NGC, NVIDIA's container catalog, and can be found under both the "DOCA" and "DPU" labels.

8.3.2 Prerequisites

- Refer to the DOCA Installation Guide for Linux for details on how to install BlueField related software

- BlueField image version required is 3.9.0 and higher

> ⚠ Container deployment based on **standalone** Kubelet, as presented in this guide, is currently in **alpha version** and is subject to change in future releases.

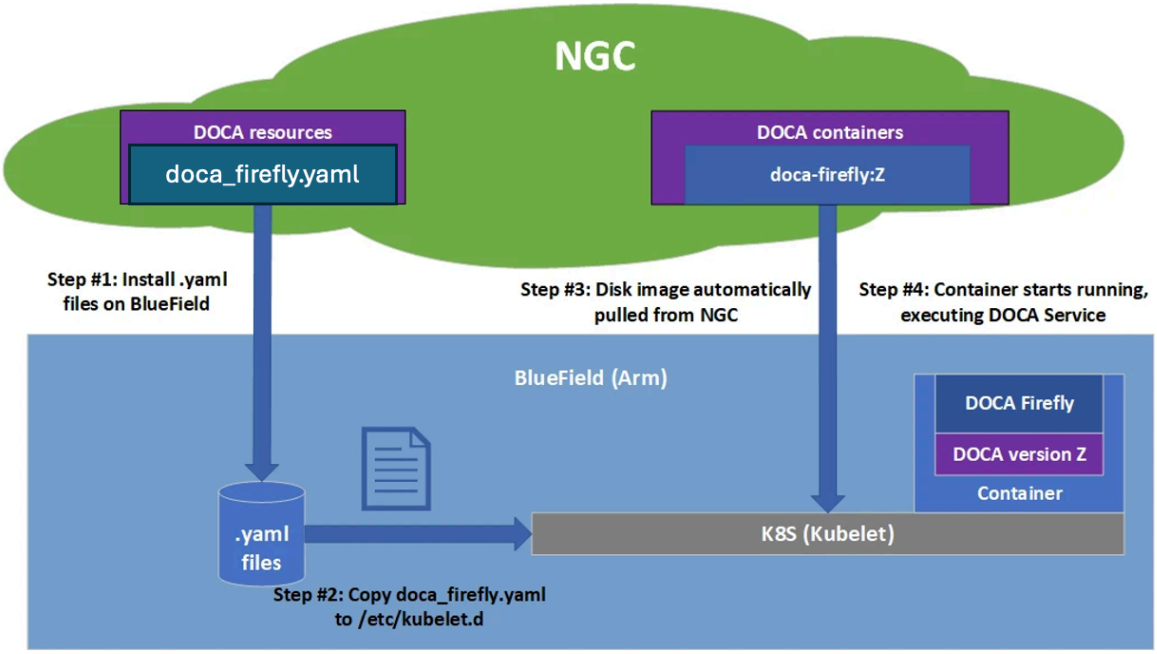
8.3.3 Container Deployment

Deploying containers on top of the BlueField DPU requires the following setup sequence:

1. Pull the container `.yaml` configuration files.
2. Modify the container's `.yaml` configuration file.
3. Deploy the container. The image is automatically pulled from NGC.

Some of the steps must only be performed once, while others are required before the deployment of each container.

What follows is an example of the overall setup sequence using the DOCA Firefly container as an example.



8.3.3.1 Pull Container YAML Configurations

This step pulls the `.yaml` configurations from NGC.

To pull the latest resource version, download the NVIDIA NGC CLI.

For more information regarding the NGC CLI, please refer to the NGC Catalog User Guide.

8.3.3.2 Container-specific Instructions

Some containers require specific configuration steps for the resources used by the application running inside the container and modifications for the `.yaml` configuration file of the container itself.

Refer to the container-specific instructions listed under the container's relevant page on NGC.

8.3.3.3 Structure of NGC Resource

Each DOCA service has a corresponding NGC resources page, referenced in the "Pull Container YAML Configurations" section. This resource contains a `configs` directory, which includes a dedicated subdirectory for each DOCA service version. The latest version contains all available `.yaml` configuration files and scripts.

DOCA Firefly example:

```
doca_firefly_1.6.13
    configs
        1.6.0
        ...
        1.7.1
          doca_firefly.yaml
```

In addition, the resource may contain a `scripts` directory, where services can provide helper scripts and additional configuration files.

Example folder structure for `scripts` directory:

```
+ doca_firefly_1.6.13
+-+ configs
| +--  ...
+-+ scripts
  | +-+ 1.6.0
  | | +-- ...
  | +-+ 1.7.0
  | | +-- ...
```

Users can deploy older DOCA service versions by accessing the relevant YAML file under `configs` and the associated scripts under the matching version directory in `scripts`.

8.3.3.4 Spawn Container

Once the desired `.yaml` file is updated, copy it to Kubelet's input folder. The following example uses `doca_firefly.yaml`, which corresponds to the DOCA Firefly service:

```
cp doca_firefly.yaml /etc/kubelet.d
```

Kubelet automatically pulls the container image from NGC and spawns a pod that runs the container. In this example, the DOCA Firefly service begins execution immediately, and its output can be viewed in the container logs.

8.3.3.5 Review Container Deployment

Follow the following steps to verify a new container deployment and troubleshoot any issues.

1. View currently active pods and their IDs:

   ```
   sudo crictl pods
   ```

   > It may take up to 20 seconds for the pod to start.

   Look for a line matching your container, for example:

   ```
   POD ID              CREATED             STATE   NAME                    NAMESPACE   ATTEMPT   RUNTIME
   06bd84c07537e       4 seconds ago       Ready   doca-firefly-my-dpu     default     0         (default)
   ```

2. If no matching pod appears, view Kubelet logs for errors:

   ```
   sudo journalctl -u kubelet --since -5m
   ```

   Once the issue is resolved, proceed to the next steps.

   > For more troubleshooting tips, refer to the *NVIDIA BlueField Platform Software Troubleshooting Guide*.

3. Verify the container image was downloaded from NGC:

   ```
   sudo crictl images
   ```

   Example output:

   ```
   IMAGE                           TAG                 IMAGE ID            SIZE
   ```

```
k8s.gcr.io/pause                    3.9                 829e9de338bd5       268kB
nvcr.io/nvidia/doca/doca_firefly    1.1.0-doca2.0.2     134cb22f34611       87.4MB
```

4. List active containers:

```
sudo crictl ps
```

Look for a line matching your deployed container (boot time varies by image size):

```
CONTAINER           IMAGE               CREATED             STATE               NAME
ATTEMPT             POD ID              POD
b505a05b7dc23       134cb22f34611       4 minutes ago       Running             doca-firefly
0                   06bd84c07537e       doca-firefly-my-dpu
```

5. If the container is not running, list all recent container deployments:

```
sudo crictl ps -a
```

You may find that the container exited immediately due to an error:

```
CONTAINER           IMAGE               CREATED             STATE               NAME
ATTEMPT             POD ID              POD
de2361ec15b61       134cb22f34611       1 second ago        Exited              doca-firefly
1                   4aea5f5adc91d       doca-firefly-my-dpu
```

6. View container logs. Logs are available during the container's lifetime and for a short time after it exits:

```
sudo crictl logs <container-id>
```

Example:

```
$ sudo crictl logs de2361ec15b61
Starting DOCA Firefly - Version 1.1.0
...
Requested the following PTP interface: p10
Failed to find interface "p10". Aborting
```

For more information on `crictl`, refer to the Kubernetes documentation.

8.3.3.6 Stop Container

The recommended way to stop a pod and its containers is as follows:

1. Delete the YAML configuration file to instruct Kubelet to stop the pod:

```
rm /etc/kubelet.d/<file name>.yaml
```

2. Stop the pod directly (only if it still shows `Ready`)

```
sudo crictl stopp <pod-id>
```

3. Once the pod has stopped, it may also be necessary to stop the container itself:

```
sudo crictl stop <container-id>
```

8.3.4 Troubleshooting Common Errors

This section provides a list of common errors that may be encountered when spawning a container. These account for the vast majority of deployment errors and are easy to verify first before trying to parse the Kubelet journal log.

> For more troubleshooting tips, refer to the *NVIDIA BlueField Platform Software Troubleshooting Guide*.

8.3.4.1 Yaml Syntax

The syntax of the `.yaml` file is extremely sensitive and minor indentation changes may cause it to stop working. The file uses spaces (' ') for indentations (two per indent). Using any other number of spaces causes an undefined behavior.

8.3.4.2 Huge Pages

The container only spawns once all the required system resources are allocated on the DPU and can be reserved for the container. The most notable resource is huge pages.

1. Before deploying the container, make sure that:
    a. Huge pages are allocated as required per container.
    b. Both the amount and size of pages match the requirements precisely.
2. Once huge pages are allocated, it is recommended to restart the container service to apply the change:

```
sudo systemctl restart kubelet.service
sudo systemctl restart containerd.service
```

3. Once the above operations are completed successfully, the container could be deployed (YAML can be copied to `/etc/kubelet.d`).

8.3.5 Advanced Troubleshooting

8.3.5.1 Manual Execution from Within Container - Debugging

> ⚠ The deployment described in this section requires an in-depth knowledge of the container's structure. As this structure might change from version to version, it is only recommended to use this deployment for debugging, and only after other debugging steps have been attempted.

Although most containers define the `entrypoint.sh` script as the container's ENTRYPOINT, this option is only valid for interaction-less sessions. In some debugging scenarios, it is useful to have better control of the programs executed within the container via an interactive shell session. Hence, the `.yaml` file supports an additional execution option.

Uncommenting (i.e., removing `#` from) the following 2 lines in the `.yaml` file causes the container to boot without spawning the container's entrypoint script.

```
# command: ["sleep"]
# args: ["infinity"]
```

In this execution mode, users can attach a shell to the spawned container:

```
crictl exec -it <container-id> /bin/bash
```

Once attached, users get a full shell session enabling them to execute internal programs directly at the scope of the container.

8.3.6 Air-gapped Container Deployment

Container deployment on the BlueField DPU can be done in air-gapped networks and does not require an Internet connection. As explained previously, per DOCA service container, there are 2 required components for successful deployment:

- Container image – hosted on NVIDIA's NGC catalog
- YAML file for the container

From an infrastructure perspective, one additional module is required:

- `k8s.gcr.io/pause` container image

8.3.6.1 Pulling Container for Offline Deployment

When preparing an air-gapped environment, users must pull the required container images in advance so they could be imported locally to the target machine:

```
docker pull <container-image:tag>
docker save <container-image:tag> > <name>.tar
```

The following example pulls DOCA Firefly `1.1.0-doca2.0.2`:

```
docker pull nvcr.io/nvidia/doca/doca_firefly:1.1.0-doca2.0.2
docker save nvcr.io/nvidia/doca/doca_firefly:1.1.0-doca2.0.2 > firefly_v1.1.0.tar
```

Some of DOCA's container images support multiple architectures, causing the `docker pull` command to pull the image according to the architecture of the machine on which it is invoked. Users may force the operation to pull an Arm image by passing the `--platform` flag:

```
docker pull --platform=linux/arm64 <container-image:tag>
```

8.3.6.2 Importing Container Image

After exporting the image from the container catalog, users must place the created `*.tar` files on the target machine on which to deploy them. The import command is as follows:

```
ctr --namespace k8s.io image import <name>.tar
```

For example, to import the firefly `.tar` file pulled in the previous section:

```
ctr --namespace k8s.io image import firefly_v1.1.0.tar
```

Examining the status of the operation can be done using the image inspection command:

```
crictl images
```

8.3.6.3 Built-in Infrastructure Support

The DOCA image comes pre-shipped with the `k8s.gcr.io/pause` image:

```
/opt/mellanox/doca/services/infrastructure/
    docker_pause_3_9.tar
    enable_offline_containers.sh
```

This image is imported by default during boot as part of the automatic activation of DOCA Telemetry Service (DTS).

> ⚠ Importing the image independently of DTS can be done using the `enable_offline_container.sh` script located under the same directory as the image's `*.tar` file.

This image can also be pulled and imported manually, using the following instructions:

- To export the image:

```
docker pull k8s.gcr.io/pause:3.9
docker save k8s.gcr.io/pause:3.9 > docker_pause_3_9.tar
```

- To import the image:

```
ctr --namespace k8s.io image import docker_pause_3_9.tar
crictl images
IMAGE                                 TAG                 IMAGE ID            SIZE
k8s.gcr.io/pause                      3.9                 829e9de338bd5       268kB
```

8.3.7 DOCA Services for Host

A subset of the DOCA services is available for host-based deployment as well. This is indicated in those services' deployment and can also be identified by having container tags on NGC with the `*-host` suffix.

In contrast to the managed DPU environment, the deployment of DOCA services on the host is based on docker. This deployment can be extended further based on the user's own container runtime solution.

8.3.7.1 Docker Deployment

DOCA services for the host are deployed directly using Docker.

1. Make sure Docker is installed on your host. Run:

```
docker version
```

   If it is not installed, visit the official Install Docker Engine webpage for installation instructions.

2. Make sure the Docker service is started. Run:

```
sudo systemctl daemon-reload
```

```
sudo systemctl start docker
```

3. Pull the container image directly from NGC (can also be done using the `docker run` command):
    a. Visit the NGC page of the desired container.
    b. Under the "Tags" menu, select the desired tag and click the paste icon so it is copied to the clipboard.
    c. The docker pull command will be as follows:

    ```
    sudo docker pull <NGC container tag here>
    ```

    For example:

    ```
    sudo docker pull nvcr.io/nvidia/doca/doca_firefly:1.1.0-doca2.0.2-host
    ```

    > For DOCA services with deployments on both DPU and host, make sure to select the tag ending with `-host`.

4. Deploy the DOCA service using Docker:
    a. The deployment is performed using the following command:

    ```
    sudo docker run --privileged --net=host -v <host directory>:<container directory> -e <env variables> -it <container tag> /entrypoint.sh
    ```

    > For more information, refer to Docker's official documentation.

    b. The specific deployment command for each DOCA service is listed in their respective deployment guide.

8.4 DOCA Argus Service Guide

This page provides installation, configuration, and usage instructions for the DOCA Argus Service.

8.4.1 Introduction

DOCA Argus is a DOCA service running on NVIDIA® BlueField® networking platforms, designed to immediately detect and enable response to attacks, minimizing their potential impact and risk.

The DOCA Argus framework provides real-time situational awareness and runtime threat detection by inspecting host memory using advanced memory forensics. Live machine introspection is performed at the hardware level, analyzing specific snippets of

volatile host memory to monitor threats in real time without impacting system performance. DOCA Argus does not violate privacy, as information is extracted only from kernel structures.

Unlike conventional tools, Argus runs independently of the host, requiring no agents, integration, or reliance on host-based resources. This agentless, zero-overhead design enhances system efficiency and ensures resilient security in any compute environment, including bare-metal, virtualized, containerized, and multi-tenant infrastructures. By operating outside the host, isolated in its own trust domain, DOCA Argus remains invisible to attackers—even if the system is compromised.

Cybersecurity professionals can integrate DOCA Argus with SIEM, SOAR, and XDR platforms for continuous monitoring, incident response, and automated threat mitigation, extending existing capabilities into AI infrastructure environments.

NVIDIA BlueField provides built-in, data-centric protection for AI workloads at scale. Combining BlueField's acceleration capabilities with DOCA Argus' proactive threat detection enables cloud service providers and enterprises to secure AI factories without compromising performance or efficiency.

A single BlueField card with DOCA Argus can monitor an entire node.

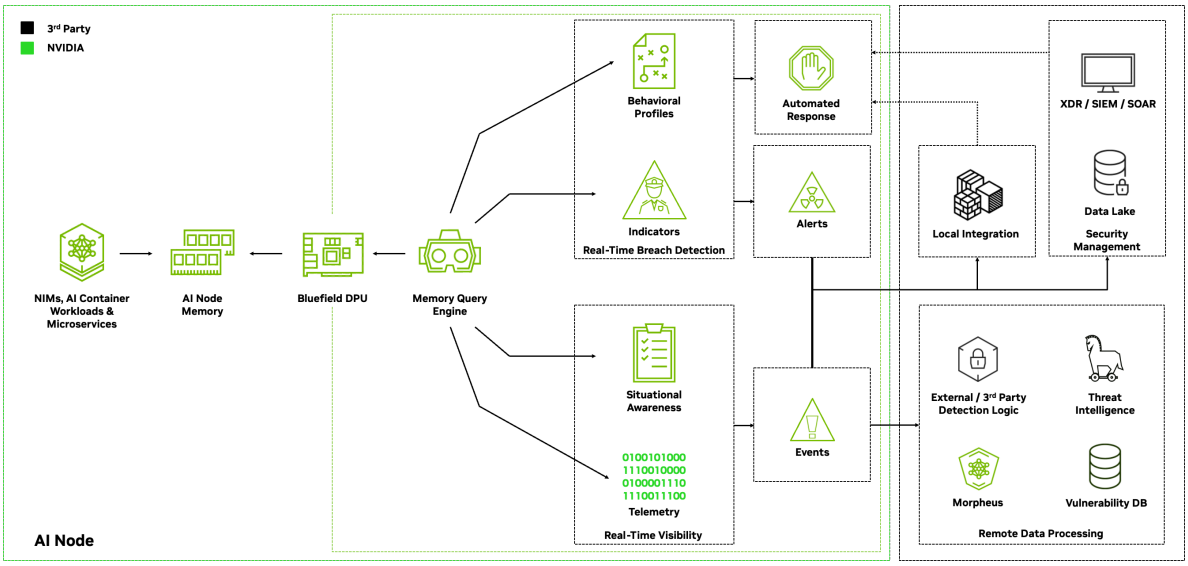
8.4.2 Operation

Raw activities are collected from host memory and used to outline the operational state of a workload. DOCA Argus uses DOCA DMA to access and inspect host memory. Accessed memory is decoded into logical information (e.g., process and thread data). A policy engine processes these activities, filtering irrelevant content and reporting only meaningful data.

Key concepts:

- Event – One or more meaningful activities that represent the current recorded state. Provides situational awareness.
- Alert – One or more meaningful activities that indicate an immediate threat or impact requiring investigation or response.

Events, alerts, and system activity messages are formatted in JSON and syslog, and logged locally. Data can be exported via Fluent Bit integration for delivery to security platforms and data lakes.



8.4.3 Requirements

- Operates only on DPU targets (BlueField-2 or later).
- Requires DPU mode (see BlueField Modes of Operation).
- Requires firmware version 24.35.0388 or later.
- Supported BlueField image versions: 4.11.0 or later.
- Argus service container must run in privileged mode to enable full-system DMA reads.

8.4.4 Limitations

- Tested only on KVM hypervisors.
- Supports Linux-based OSs (bare-metal, virtualization, containers). Windows OS support planned.
- Kata Containers are supported only if NVIDIA-DPU support is enabled.
- Supports only x86 64-bit architectures. AARCH64 support planned.

Prerequisites8.4.5

1. Configure BlueField firmware. On BlueField, configure the PF BAR register:

   ```
   dpu> mlxconfig -d /dev/mst/<mst_device> s PF_BAR2_SIZE=2 PF_BAR2_ENABLE=1
   ```

   Replace `<mst_device>` with:

   - `mt41686_pciconf0` for BlueField-2
   - `mt41692_pciconf0` for BlueField-3

2. Enable IOMMU passthrough (only if not already enabled).

   ⚠ Skip unless DMA fails with messages similar to the following in `dmesg`:

   ```
   mlx5_core 0000:81:00.0: AMD-Vi: Event logged [IO_PAGE_FAULT ...]
   ```

   a. Edit GRUB config:

   ```
   host> sudo vim /etc/default/grub
   ```

   b. Update `GRUB_CMDLINE_LINUX_DEFAULT` with :

   ```
   iommu=pt <intel/amd>_iommu=on
   ```

   c. Apply changes:

   - For Ubuntu:

     ```
     sudo update-grub
     ```

   - For CentOS/RHEL:

     ```
     sudo grub2-mkconfig -o /boot/grub2/grub.cfg
     ```

   d. Reboot.

3. Prepare the target system. Argus should auto-detect target config files. If not, configure it manually:

   a. Download OS debug symbols.

   - For Ubuntu:

     ```
     sudo tee /etc/apt/sources.list.d/ddebs.list << EOF
     deb http://ddebs.ubuntu.com/ $(lsb_release -cs) main restricted universe multiverse
     deb http://ddebs.ubuntu.com/ $(lsb_release -cs)-updates main restricted universe multiverse
     deb http://ddebs.ubuntu.com/ $(lsb_release -cs)-proposed main restricted universe
     multiverse
     EOF
     sudo apt install ubuntu-dbgsym-keyring
     sudo apt-get update
     sudo apt-get install linux-image-$(uname -r)-dbgsym
     ```

   - For CentOS/RHEL:

     ```
     sudo yum install --enablerepo=base-debuginfo \
       kernel-devel-$(uname -r) \
       kernel-debuginfo-$(uname -r) \
       kernel-debuginfo-common-$(uname -m)-$(uname -r)
     ```

   b. Install DOCA on target or copy `doca_apsh_config.py` from BlueField.

   c. Create JSON files:

   ```
   cd /opt/mellanox/doca/tools/
   pip3 install psutil pdbparse
   python3 doca_apsh_config.py --files memregions symbols --os <windows/linux> --path <path to
   dwarf2json>
   cp /opt/mellanox/doca/tools/*.* <shared-folder>
   dpu> scp <shared-folder>/* <path-to-app-shield-binary>
   ```

⚠ `dwarf2json` must be installed separately from GitHub. Repeat this step after kernel updates.

8.4.6 Service Deployment

- For DPU container deployment, see DOCA Container Deployment Guide.
- For Argus-specific deployment, refer to the service container's page.
- For offline deployment (no Internet access), see the *Offline Deployment* section in DOCA Container Deployment Guide..

8.4.7 Service Configuration

Argus configuration is managed via `SERVICE_CONFIG_FILE` in the container YAML.

8.4.7.1 Service

- Immediate shutdown – Terminate immediately on SIGINT/SIGTERM (skip graceful shutdown).
- Service log level – DOCA logging verbosity (default `50` = INFO). Options: `10=DISABLE`, `20=CRITICAL`, `30=ERROR`, `40=WARNING`, `50=INFO`, `60=DEBUG`, `70=TRACE`.
- System scanner sleep time – Delay between scans (`s` = seconds, `m` = minutes, `ms` = milliseconds).

8.4.7.2 DOCA Argus Configuration

- Auto Scan – Scan all available systems unless `systems` section is defined.
- Default – Default configs applied if not overridden in `systems`.
- Systems – List of monitored systems with overrides.

8.4.7.3 Per-System Configurations

- Representor ID – VU ID of VF/PF to track.
    - PF –

```
host> lspci -vv -s <PF_pci_address> | grep VU | cut -d " " -f 4
```

  - VF – Append `VF<x>` to PF's VU ID. Example: `MT2333XZ06YAMLNXS0D0F0VF1`
- Memory regions path – JSON file path (or `auto`) for host OS memory map.
- OS symbol path – JSON file path or directory (or `auto`).
- OS type – `Linux` or `Windows`.
- DMA device name – Matches representor ID. List devices:

```
dpu> ibv_devinfo | grep 'hca_id' | awk '{print $2}'
```

- Service log level – Overrides service log verbosity.
- SDK log level – Sets SDK logging verbosity.
- Limits – Set max values for string length, processes, file descriptors, threads, VMAs.
- Events
  - Container filter – Include/exclude containerized processes.
  - SBOM – List SHA signatures of approved executables/libraries.

8.4.7.4 Collection

- Events – Enable/disable per event type.

8.4.7.5 Output

- Log events to stdout – Enable standard output logging.
- Log folder path – Directory for file logs.
- Log threshold size – Rotate logs at this size.
- Log max files count – Max number of rotated logs.
- Telemetry address – Aggregator address.
- Telemetry tag – Tag for Fluent Bit integration.
- Telemetry format – `JSON` or `syslog`.
- Telemetry user data – Custom user-defined metadata.

8.4.8 Log Types

8.4.8.1 Standard Output

Displays only important service logs, such as version information, successful startups, and error messages on failures.

8.4.8.2 Debug Log Output

Provides a complete log output for debugging, including partial event data, trace logs, collection failures, and more. These logs are stored in the `/var/log/doca_argus/` directory.

8.4.8.3 Event Log Output

Stores a complete event log in JSON format in the log folder path specified in the service configuration file. For local log storage, log rotation is handled by Linux `logrotate`. You can override the default configuration in `/etc/cron.d/logrotate` and `/etc/logrotate.d/argus`.

8.4.8.4 Telemetry Output

The Argus service can produce telemetry records in JSON or syslog formats.

By default, telemetry is disabled. To enable it, set the `telemetry_address` parameter in the service configuration file and ensure `telemetry_tag` matches the tag used in your Fluent Bit configuration.

Telemetry has been tested with Fluent Bit integration, which should run independently from the Argus service.

For example, running Fluent Bit locally on the DPU alongside the Argus service can be configured with the following input section:

```
[INPUT]
    Name                tcp
    Tag                 <your preferred tag>
    Listen              0.0.0.0
    Port                24224
    Format              json
```

If you are using Splunk, add the following encapsulation filter to the Fluent Bit configuration file:

```
[FILTER]
    Name                nest
    Match               *
    Operation           nest
    Wildcard            *
    Nest_under          event
```

Fluent Bit is flexible and can integrate with many output destinations.

The following is a basic example that forwards telemetry data to Elasticsearch:

```
[INPUT]
    Name                tcp
    Tag                 elastic_forward_input
    Listen              0.0.0.0
    Port                24224
    Format              json

[SERVICE]
    Log_Level           info

[OUTPUT]
    Name                es
    Match               *
    Host                <elasticsearch_ip>
    Port                <elasticsearch_port>
    Index               argus
    Suppress_Type_Name  On
    Log_Level           info
```

To run Fluent Bit with this configuration:

```
docker run --rm --net=host -v <path_to_fluentbit_conf_file>:/fluent-bit/etc/fluent-bit.conf --name fluent_bit -it
fluent/fluent-bit
```

Refer to the Fluent Bit manual for details on additional output plugins and configurations.

8.4.9 Output

The DOCA Argus service generates structured output messages containing detailed metadata, system information, and activity data.

The following table describes the fields included in each message:

Parameter	Data Type	Parent Object	Description
`message_header`	object	—	Root-level object containing the message metadata.
`vendor_name`	enum	`message_header`	Name of the vendor. Value: `NVIDIA`.
`product_name`	enum	`message_header`	Name of the product. Value: `DOCA_ARGUS`.
`product_version`	string	`message_header`	Product version.
`message_type`	enum	`message_header`	Can be `EVENT`, `ALERT`, or `SYSTEM_ACTIVITY`.
`severity`	enum	`message_header`	Severity of the event/alert/system activity (`INFO`, `ERROR`, `WARNING`, `MEDIUM`, `HIGH`, `CRITICAL`).
`schema_version`	string	`message_header`	Schema format version used by the message.
`message_id`	string	`message_header`	Unique message identifier.

Parameter	Data Type	Parent Object	Description
`occurred_message_time_iso_8601_ns`	string	`message_header`	ISO_8601 timestamp when the message occurred.
`message_timezone`	string	`message_header`	Time zone of the message origin.
`user_data`	string	`message_header`	Configured user data.
`bluefield_system_information`	object	`message_header`	Information about the BlueField system.
`bluefield_networking_interfaces`	array	`bluefield_system_information`	List of all configured BlueField interfaces, including their names, IP addresses, and MAC addresses.
`bluefield_network_interface_name`	string	`bluefield_networking_interfaces`	Interface name.
`bluefield_network_interface_mac_address`	string	`bluefield_networking_interfaces`	MAC address of the interface.
`bluefield_network_interface_ipv4_address`	string/ array	`bluefield_networking_interfaces`	IPv4 addresses associated with the interface.
`bluefield_network_interface_ipv6_address`	string/ array	`bluefield_networking_interfaces`	IPv6 addresses associated with the interface.
`workload_information`	object	`message_header`	Information about the monitored workload system.
`unique_identifier`	string	`workload_information`	Unique ID of the target system (system name in configuration or VUID for auto-scanned systems).
`os_version`	string	`workload_information`	OS version of the workload (`Linux Kernel x.y` or `Microsoft Windows major.minor.build`).
`workload_networking_interfaces`	array	`workload_information`	List of all workload interfaces, including their names, IP addresses, and MAC addresses.
`workload_network_interface_name`	string	`workload_networking_interfaces`	Interface name.
`workload_network_interface_mac_address`	string	`workload_networking_interfaces`	MAC address of the interface.

Parameter	Data Type	Parent Object	Description
`workload_network_interface_ipv4_addresses`	string/ array	`workload_networking_interfaces`	IPv4 addresses associated with the interface.
`workload_network_interface_ipv6_addresses`	string/ array	`workload_networking_interfaces`	IPv6 addresses associated with the interface.
`activity_data`	object	`message_header`	Details about the activity reported.
`name`	string	`activity_data`	Name of the event/alert/system activity.
`<activity>_details`	object	`activity_data`	Detailed information about the collector that triggered the event or alert.
`<parent_activity>_details`	object	`activity_data`	Details about parent activities that triggered the current activity.

The following example is a JSON message that describes the data that produced for each event and alert:

```
{
    "vendor_name": "NVIDIA",
    "product_name": "DOCA_ARGUS",
    "product_version": "<version>",
    "message_type": "<EVENT | ALERT | SYSTEM_ACTIVITY>",
    "severity": "<INFO | ERROR | WARNING | MEDIUM | HIGH | CRITICAL>",
    "schema_version": "1.0",
    "message_id": "<unique_message_id>",
    "occurred_message_time_iso_8601_ns": "2025-10-22T07:31:46.905224659+00:00",
    "message_timezone": "UTC",
    "user_data": "NONE",
    "bluefield_system_information": {
        "bluefield_networking_interfaces": {
            "0": {
                "bluefield_network_interface_name": "<>",
                "bluefield_network_interface_mac_address": "<>",
                "bluefield_network_interface_ipv4_address": "<>"
                "bluefield_network_interface_ipv6_address": "<>"
            },
             "1": {
                "bluefield_network_interface_name": "<>",
                "bluefield_network_interface_mac_address": "<>",
                "bluefield_network_interface_ipv4_address": "<>"
                "bluefield_network_interface_ipv6_address": "<>"
            },
            "..."
        }
    },
    "workload_information": {
        "unique_identifier": "<>",
        "os_version": "<>",
        "workload_networking_interfaces": {
            "0": {

                "network_interface_ipv4_address": "<>",
                "network_interface_ipv6_address": "<>",
            },
             "1": {
                "network_interface_name": "<>",
                "network_interface_mac_address": "<>"
                "network_interface_ipv4_address": "<>",
                "network_interface_ipv6_address": "<>",
            },
            "..."
        }
    },
    "activity_data": {
        "name": "<the name of the EVENT | ALERT | SYSTEM_ACTIVITY>",
        -- Activity Details to follow per the type of EVENT | ALERT | SYSTEM_ACTIVITY --
    }
}
```

8.4.10 Supported Alerts, Events and System Activity Messages

DOCA Argus monitors workload and system behavior in real time, generating alerts, events, and system activity messages that provide visibility into security-relevant activities, operational state changes, and detected anomalies. These messages are categorized by type, severity, and activity name, with descriptions to help identify their purpose and implications.

The tables in this section outline the supported activities that Argus can detect, covering a broad range of categories including process creation and termination, network connections, execution of binaries and libraries, process memory changes, file descriptor operations, thread creation and termination, container lifecycle events, and key system service milestones or errors.

8.4.10.1 Creation or Modification of System Processes

Type	Severity	Activity Name	Remarks
Event	Info	Process Created	A new process has been detected.
Event	Info	Process Terminated	A process has been terminated.
Event	Warning	Process Zombie	Detects a process in a zombie state.
Alert	High	Process Hidden	Detects a process in a hidden state.

8.4.10.2 Network Connections

Type	Severity	Activity Name	Remarks
Event	Info	Network Connection Created	A new TCP network connection has been created.
Event	Info	Network Connection Terminated	A TCP network connection has been terminated.
Alert	Low	TCP Connection Excessive Data	Monitors a TCP connection's incoming or outgoing data volume that exceeds a configurable threshold (separate thresholds for incoming and outgoing traffic).
Alert	Low	TCP Long-Lasting Connection	Monitors a TCP connection whose total duration exceeds a configurable time threshold.
Event	Info	TCP Network Connection State Change	Monitors changes in the state of TCP network connections (for example, SYN_SENT, SYN_RECEIVED).
Event	Info	TCP Network Connections Status	Provides a periodic (configurable) summary of currently open TCP connections per process, including packet and byte counts. Disabled by default.

Type	Severity	Activity Name	Remarks
Alert	High	Reverse Shell Detected	Detects a process started with stream redirection to a remote connected socket (stdin bound to a remote socket).

8.4.10.3 Executed Binaries and Loaded Libraries (Software Bill of Materials/Process Attestation)

Type	Severity	Activity Name	Remarks
Alert	High	Foreign Binary Executed	Detects execution of a binary not included in the original container image or modified from it. May indicate that an attacker has control of the workload and is executing arbitrary commands.
Alert	High	Binary Executed Not as Intended	Detects execution of a binary from the original container image with command-line arguments and/or from a folder path not matching those in the original container image.
Alert	High	Foreign Binary Executed – File Size Mismatch	Detects execution of a binary whose reported file size differs from the file size of the corresponding binary in the original container image.
Alert	High	Foreign Library Loaded	Detects loading of a library not included in the original container image or modified from it. May indicate that an attacker has control of the workload and is running arbitrary code.
Alert	High	Foreign Library Loaded – File Size Mismatch	Detects loading of a library whose reported file size differs from the file size of the corresponding library in the original container image.

8.4.10.4 Process Memory

Type	Severity	Activity Name	Remarks
Event	Info	Process Memory Created	A new virtual memory area (e.g., heap, stack, executable) has been created. Default: off.
Event	Info	Process Memory Terminated	A virtual memory area is no longer visible (terminated). Default: off.
Event	Warning	New Executable Anonymous Memory Mapped	An executable anonymous memory area has been mapped.
Alert	Medium	Executable Permissions Added	Executable permissions have been added to a memory area.
Alert	Medium	Executable Permissions Removed	Executable permissions have been removed from a memory area.
Event	Info	New File Mapped	A new memory-mapped file has been detected.
Event	Info	File Unmapped	A memory-mapped file has been unmapped.

8.4.10.5 File Descriptors

Type	Severity	Activity Name	Remarks
Event	Info	File Descriptor Open	A new file descriptor has been opened.
Event	Info	File Descriptor Close	A file descriptor has been closed.
Alert	Medium	File Descriptor File Content Change	File Descriptor with write permissions has been closed, and its content may have changed (only for regular files).

8.4.10.6 Threads

Type	Severity	Activity Name	Remarks
Event	Info	Thread Created	A new thread has been created.
Event	Info	Thread Terminated	A thread has been terminated.

8.4.10.7 Containers

Type	Severity	Activity Name	Remarks
Event	Info	Container Started	A new container instance has been detected.
Event	Info	Container Terminated	A container has been terminated.

8.4.10.8 Shell History

Type	Severity	Activity Name	Remarks
Event	Info	Shell Command Executed	A new shell command has been executed.
Alert	High	Shell History Cleared	Shell's history has been cleared. Could be indicator for an attack.
Alert	High	Shell History Disabled	Shell's history has been disabled. Could be indicator for an attack.

Currently, only "bash" processes are supported (i.e., not sh, zsh, etc).

8.4.10.9 System Events

Type	Severity	Activity Name	Remarks
System Activity	Info	Service Initialization Started	The DOCA Argus initialization process has started.
System Activity	Info	Service Initialization Successful	The DOCA Argus initialization process completed successfully.
System Activity	Error	Service Initialization Failed	DOCA Argus failed to initialize.
System Activity	Error	Service Runtime Failure	Critical internal service error; DOCA Argus is offline.
System Activity	Info	Service Gracefully Shutdown	DOCA Argus has been successfully shut down following a user request.
System Activity	Error	Details Gathering Failed	Failed to collect required information.
System Activity	Info	Host Initialization Started	Workload detection process has started.
System Activity	Info	Host Initialization Successful	Workload detection process completed successfully.
System Activity	Error	Host Initialization Failed	Workload detection process failed.
System Activity	Info	OS Identifier Found	Successfully detected the underlying OS of the workload.
System Activity	Info	OS Identifier Discovery Extended	Detection of the workload OS is taking longer than expected.
System Activity	Info	Loading Profile Candidate	Identified an OS profile to use.
System Activity	Info	Profile Verification Successful	Successfully initialized using the identified OS profile.
System Activity	Error	Profile Verification Failed	Initialization using the identified OS profile failed; DOCA Argus will attempt subsequent profile candidates.
System Activity	Error	Profile Parsing Failed	DOCA Argus failed to parse the OS profile.
System Activity	Error	No Matching Profile Found	No matching OS profile has been found.
System Activity	Error	Unable to Determine Target OS	Failed to detect the underlying OS of the workload.
System Activity	Medium	Process Limit Reached	Reached the configured limit for the number of processes to monitor.
System Activity	Medium	File Handles Limit Reached	Reached the configured limit for the number of file handles to monitor.
System Activity	Medium	Process Memory Limit Reached	Reached the configured limit for the number of virtual address descriptors to monitor.

Type	Severity	Activity Name	Remarks
System Activity	Medium	Threads Limit Reached	Reached the configured limit for the number of threads to monitor.

8.4.11 Attributes

The following attributes are currently provided for processes, TCP network connections, file handles, threads, process memory, and SBOM/process attestation.

For requests regarding the extraction of additional attributes, please contact NVIDIA.

8.4.11.1 Processes

Attribute	Description
`process_name`	Command name of the process.
`process_id`	Unique process identifier.
`process_self_exec_id`	Thread-group-change indicator (e.g., incremented on `exec` calls).
`process_hash_sha256`	SHA256 hash of the process' executable.
`process_hash_sha1`	SHA1 hash of the process' executable.
`process_hash_md5`	MD5 hash of the process' executable.
`process_file_size_bytes`	File size, in bytes, of the process' executable.
`process_executable_path`	Absolute path to the process' executable.
`process_current_working_directory`	Absolute path of the folder this process has been executed from.
`process_command_line_arguments`	Command line arguments used to start the process.
`process_creation_time_iso_8601_ns`	Process creation time in iso_8601 format (based on the workload's local time).
`process_parent_process_id`	Parent process identifier.
`process_real_user_id`	Real user ID of the process owner.
`process_real_group_id`	Real group ID of the process owner.
`process_effective_user_id`	Effective user ID of the process owner.
`process_effective_group_id`	Effective group ID of the process owner.
`process_state`	Current state of the process.

Attribute	Description
`process_cpu_clock_cycles`	Number of CPU cycles consumed by the process.
`process_container_id`	Container ID, if the process is part of a container.
`process_pid_namespace`	Namespace for process identifiers.
`process_mount_points_namespace`	Namespace for mount points.
`process_network_namespace`	Namespace for network resources.

8.4.11.2 Threads

Attribute	Description
`thread_id`	Unique thread identifier.
`thread_self_exec_id`	Thread-group-change indicator (e.g., incremented on `exec` calls).
`thread_exit_state`	Thread's exit state.

8.4.11.3 File Descriptors

Attribute	Description
`file_descriptor_index`	File Descriptor FD identifier.
`file_descriptor_name`	A descriptive name for the file descriptor (e.g., the absolute path for a regular file).
`file_descriptor_file_type`	File Descriptor's type.
`file_descriptor_file_mode`	File Descriptor's mode - WRITE_ONLY/READ_WRITE/APPEND/ LARGE_FILE/...
`file_descriptor_inode_number`	File Descriptor's inode number.
`file_descriptor_inode_device_identifier`	File Descriptor's device identifier.
`file_descriptor_inode_permissions`	File Descriptor's File read write execute permissions.
`file_descriptor_inode_uid`	File Descriptor's UID.
`file_descriptor_inode_gid`	File Descriptor's GID.
`file_descriptor_inode_size_bytes`	File's size.
`file_descriptor_inode_deleted`	Indicates whether or not the current file has been deleted.

Attribute	Description
`file_descriptor_inode_hash_sha1`	File's sha1 hash (only for file_descriptor_file_content_change).
`file_descriptor_inode_hash_sha256`	File's sha256 hash (only for file_descriptor_file_content_change).
`file_descriptor_inode_hash_md5`	File's MD5 hash (only for file_descriptor_file_content_change).
`file_descriptor_thread_id_array`	List of identifiers of threads which use this File Descriptor.
`file_descriptor_inode_change_time_iso_8601_ns`	Files change time in iso_8601 format (workload time).
`file_descriptor_inode_modify_time_iso_8601_ns`	Files modification time in iso_8601 format (workload time).
`file_descriptor_inode_access_time_iso_8601_ns`	Files access time in iso_8601 format (workload time).

8.4.11.4 TCP Network Connections

Attribute	Description
`file_descriptor_id`	The unique file descriptor identifier that is associated with the socket.
`connection_state`	The TCP connection state.
`protocol`	The network protocol used.
`source_ip_address`	Source IP address.
`source_port`	Source port number.
`destination_ip_address`	Destination IP address.
`destination_port`	Destination port number.
`tcp_bytes_in`	The amount of data, in bytes, received.
`tcp_bytes_out`	The amount of data, in bytes, sent.
`tcp_segments_in`	The number of TCP segments received.
`tcp_segments_out`	The number of TCP segments sent.
`workload_network_interface_name`	The interface name.
`workload_network_interface_mac_address`	The interface MAC address.

Attribute	Description
`workload_network_interface_ipv4_address`	The IPv4 addresses associated with the interface.
`workload_network_interface_ipv6_address`	The IPv6 addresses associated with the interface.
`tcp_connection_creation_time_iso_8601_ns`	The time the TCP connection has been first observed, in ISO 8601 format (nanoseconds precision).
`tcp_connection_termination_time_iso_8601_ns`	Time when the TCP connection has been terminated, in ISO 8601 format (nanoseconds precision).
`tcp_connection_overall_duration_ns`	The overall duration of the TCP connection, in nanoseconds (calculated based on the observed creation time).
`tcp_average_bytes_in`	The average size, in bytes, of the packets received.
`tcp_average_bytes_out`	The average size, in bytes, of the packets sent.

8.4.11.5 Process Memory

Attribute	Description
`process_id`	Associated process' unique ID.
`virtual_memory_area_start_address`	Start address of the virtual memory area.
`virtual_memory_area_end_address`	End address of the virtual memory area.
`memory_permissions`	Permissions associated with the virtual memory area.
`is_main_process_executable`	Whether the virtual memory belongs to the process' main executable.
`file_path`	Full path (including file name) of the file associated with the memory area.
`file_name`	File name associated with the memory area.

8.4.11.6 Executed Binaries and Loaded Libraries (Attestation)

Attribute	Description
`elf_file_inode_number`	Inode number of the ELF file.
`elf_file_name`	Name of the ELF file.
`elf_file_type`	Type of the ELF file.
`elf_file_path`	File path of the ELF file.

Attribute	Description
`elf_file_hash_sha256`	SHA256 hash of the ELF file.
`elf_file_hash_sha1`	SHA1 hash of the ELF file.
`elf_file_hash_md5`	MD5 hash of the ELF file.
`elf_file_size_bytes`	File size of the ELF file, in bytes.
`is_main_process_executable`	Whether this file is the main executable for the process.

8.4.11.7 Shell History

Attribute	Description
`shell_command_execution_history`	Provides the following two fields.
`command_execution_time_iso_8601_ns`	The time at which the command has been executed, in ISO 8601 format.
`command_line`	The actual executed command.

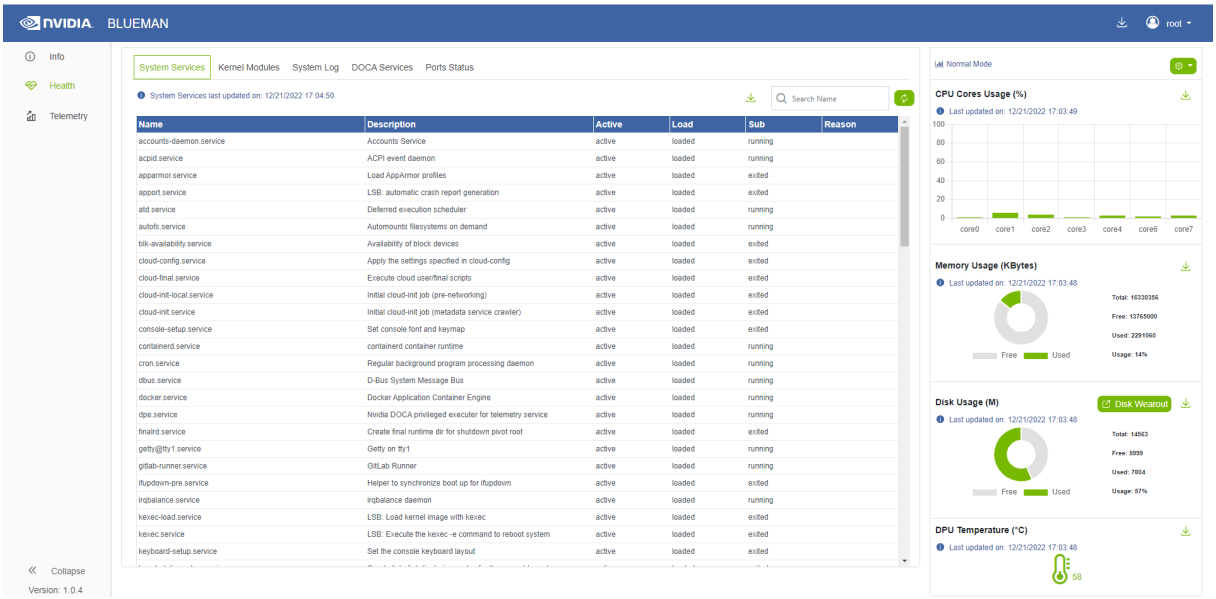
8.5 DOCA BlueMan Service Guide

This guide provides instructions on how to use the DOCA BlueMan service on top of NVIDIA® BlueField® DPU.

8.5.1 Introduction

DOCA BlueMan runs in the DPU as a standalone web dashboard and consolidates all the basic information, health, and telemetry counters into a single interface.

All the information that BlueMan provides is gathered from the DOCA Telemetry Service (DTS), starting from DTS version 1.11.1-doca1.5.1.



8.5.2 Requirements

- BlueField image version 3.9.3.1 or higher
- DTS and the DOCA Privileged Executer (DPE) daemon must be up and running

8.5.2.1 Verifying DTS Status

All the information that BlueMan provides is gathered from DTS.

Verify that the state of the DTS pod is `ready`:

```
$ crictl pods --name doca-telemetry-service
```

Verify that the state of the DTS container is `running`:

```
$ crictl ps --name doca-telemetry-service
```

8.5.2.2 Verifying DPE Status

All the information that DTS gathers for BlueMan is from the the DPE daemon.

Verify that the DPE daemon is `active`:

```
$ systemctl is-active dpe.service
active
```

If the daemon is inactive, activate it by starting the `dpe.service`:

```
$ systemctl start dpe.service
```

8.5.3 Service Deployment

For information about the deployment of DOCA containers on top of the BlueField DPU, refer to the NVIDIA DOCA Container Deployment Guide.

8.5.3.1 DOCA Service on NGC

BlueMan is available on NGC, NVIDIA's container catalog. Service-specific configuration steps and deployment instructions can be found under the service's container page.

8.5.3.2 Default Deployment – BlueField BSP

BlueMan service is located under `/opt/mellanox/doca/services/blueman/`.

The following is a list of the files under the BlueMan directory:

```
doca_blueman_fe_service_<version>-doca<version>_arm64.tar
doca_blueman_conv_service_<version>-doca<version>_arm64.tar
doca_blueman_standalone.yaml
bring_up_doca_blueman_service.sh
```

8.5.3.2.1 Enabling BlueMan Service

8.5.3.2.1.1 Using Script

Run `bring_up_doca_blueman_service.sh`:

```
$ chmod +x /opt/mellanox/doca/services/blueman/bring_up_doca_blueman_service.sh
$ /opt/mellanox/doca/services/blueman/bring_up_doca_blueman_service.sh
```

8.5.3.2.1.2 Manual Procedure

1. Import images to crictl images:

   ```
   $ cd /opt/mellanox/doca/services/blueman/
   $ ctr --namespace k8s.io image import doca_blueman_fe_service_<version>-doca<version>_arm64.tar
   $ ctr --namespace k8s.io image import doca_blueman_conv_service_<version>-doca<version>_arm64.tar
   ```

2. Verify that the DPE daemon is active:

   ```
   $ systemctl is-active dpe.service
   ```

```
active
```

If the daemon is inactive, activate it by starting the `dpe.service`:

```
$ systemctl start dpe.service
```

3. Copy `blueman_standalone.yaml` to `/etc/kubelet.d/`:

```
$ cp doca_blueman_standalone.yaml /etc/kubelet.d/
```

8.5.3.3 Verifying Deployment Success

1. Verify that the DPE daemon is active:

```
$ systemctl is-active dpe.service
```

2. Verify that the state of the DTS container is `running`:

```
$ crictl ps --name doca-telemetry-service
```

3. Verify that the state of the BlueMan service container is `running`:

```
$ crictl ps --name doca-blueman-fe
$ crictl ps --name doca-blueman-conv
```

Configuration

The configuration of the BlueMan back end is located under `/opt/mellanox/doca/services/telemetry/config/blueman_config.ini`. Users can interact with the `blueman_config.ini` file which contains the default range values of the Pass, Warning, and Failed categories which are used in the health page. Changing these values gets reflected in the BlueMan webpage within 60 seconds.

Example of `blueman_config.ini`:

```
;Health Cpu usages Pass, warning, Failed
[Health:CPU_Usages:Pass]
range = 0,80
[Health:CPU_Usages:Warning]
range = 80,90
[Health:CPU_Usages:Failed]
range = 90,100
```

8.5.4 Collected Data

- Info
  - General info – OS name, kernel, part number, serial number, DOCA version, driver, board ID, etc.

        - Installed packages – list of all installed packages on the DPU including their version
        - CPU info – vendor, cores, model, etc.
        - FW info – all the mlxconfig parameters with default/current/next boot data
        - DPU operation mode
    - Health
        - System service
        - Kernel modules
        - Dmesg
        - DOCA services
        - Port status of the PF and OOB
        - Core usage and processes running on each core
        - Memory usage
        - Disk usage
        - Temperature
    - Telemetry – all telemetry counters that come from DTS according to the enabled providers displayed on tables
        - Users have the ability to build graphs of specific counters

8.5.5 Connecting to BlueMan Web Interface

To log into BlueMan, enter the IP address of the DPU's OOB interface (`http://<DPU_OOB_IP>`) to a web browser located in the same network as the DPU.

The login credentials to use are the same pair used for the SSH connection to the DPU.

8.5.6 Troubleshooting

For general troubleshooting, refer to the DOCA Troubleshooting.

For container-related troubleshooting, refer to the "Troubleshooting" section in the NVIDIA DOCA Container Deployment Guide.

The following are additional troubleshooting tips for DOCA BlueMan:

- The following error message in the login page signifies a failure to connect to the DPE daemon: "The service is currently unavailable. Please check server up and running."
    a. Restart the DPE daemon:

    ```
    $ systemctl restart dpe.service
    ```

    b. Verify that DTS is up and running by following the instructions in section "Verifying DTS Status".
- If the message "Invalid Credentials" appears in the login page, verify that the username and password are the same ones used to SSH to the DPU.
- If all of the above is configured as expected and there is still some failure to log in, it is recommended to check if there are any firewall rules that block the connection.
- For other issues, check the `/var/log/syslog` and `/var/log/doca/telemetry/blueman_service.log` log file.

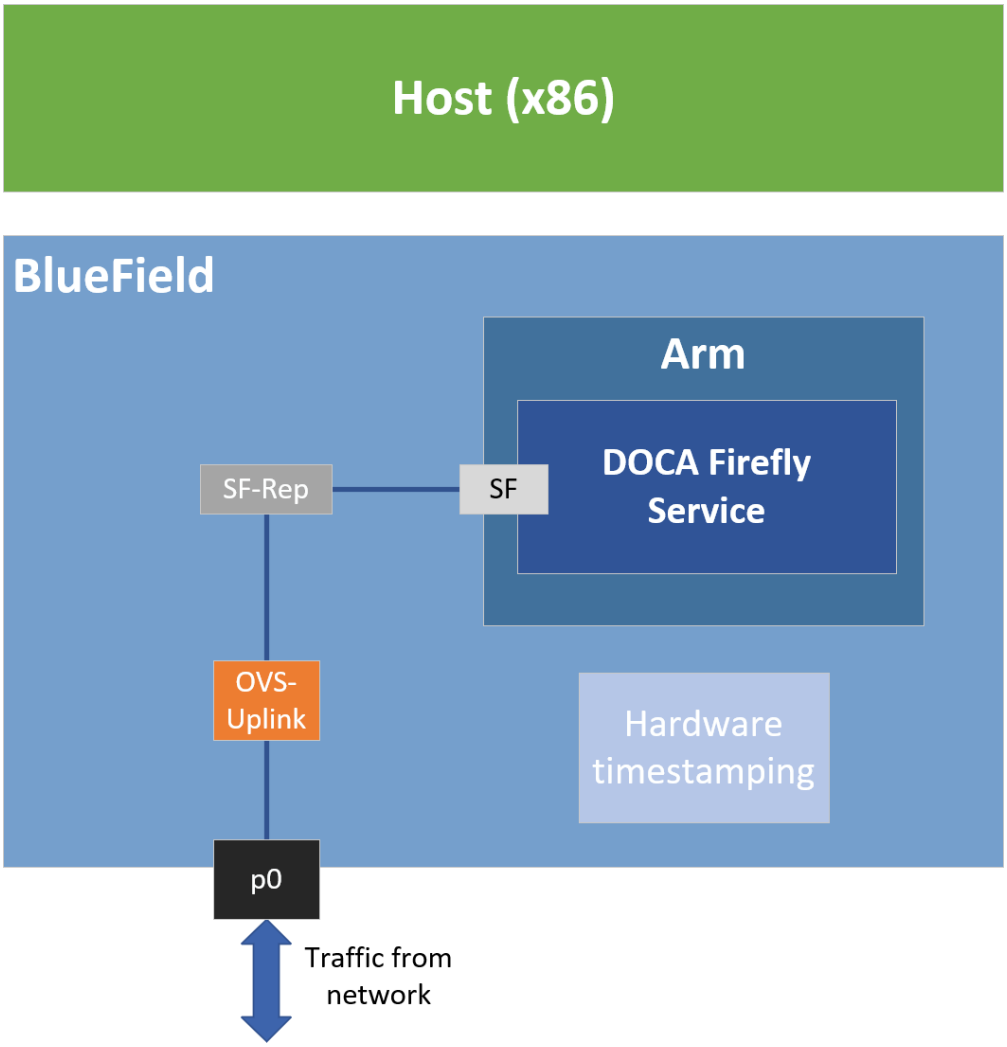
8.6 DOCA Firefly Service Guide

This guide provides instructions on how to use the DOCA Firefly service container on top of NVIDIA® BlueField® DPU.

8.6.1 Introduction

DOCA Firefly Service provides precision time protocol (PTP) based time syncing services to the BlueField DPU.

PTP is a protocol used to synchronize clocks in a network. When used in conjunction with hardware support, PTP is capable of sub-microsecond accuracy, which is far better than is what is normally obtainable with network time protocol (NTP). PTP support is divided between the kernel and user space. The ptp4l program implements the PTP boundary clock and ordinary clock. With hardware time stamping, it is used to synchronize the PTP hardware clock to the master clock.



8.6.2 Requirements

Some of the features provided by Firefly require specific BlueField DPU hardware capabilities:

- PTP – Supported by all BlueField DPUs
- PPS – Requires BlueField DPU with PPS capabilities
- SyncE - Requires converged card BlueField DPUs

Failure to run PPS due to missing hardware support will be noted in the service's output. However, the service will continue to run the timing services it can provide on the provided hardware.

8.6.2.1 Firmware Version

Firmware version must be 24.34.1002 or higher.

8.6.2.2 BlueField BSP Version

Supported BlueField image versions are 3.9.0 and higher.

8.6.2.3 Embedded Mode

8.6.2.3.1 Configuring Firmware Settings on DPU for Embedded Mode

1. Set the DPU to embedded mode (default mode):

```
sudo mlxconfig -y -d 03:00.0 s INTERNAL_CPU_MODEL=1
```

2. Enable the real time clock (RTC):

```
sudo mlxconfig -d 03:00.0 set REAL_TIME_CLOCK_ENABLE=1
```

3. Graceful shutdown and power cycle the DPU to apply the configuration.
4. You may check the DPU mode using the following command:

```
sudo mlxconfig -d 03:00.0 q | grep INTERNAL_CPU_MODEL
# Example output
         INTERNAL_CPU_MODEL                  EMBEDDED_CPU(1)
```

8.6.2.3.2 Ensuring OVS Hardware Offload

DOCA Firefly requires that hardware offload is activated in Open vSwitch (OVS). This is enabled by default as part of the BFB image installed on the DPU.

To verify the hardware offload configuration in OVS:

```
sudo ovs-vsctl get Open_vSwitch . other_config | grep hw-offload
# Example output
        {hw-offload="true"}
```

If inactive:

1. Activate hardware offloading by running:

   ```
   sudo ovs-vsctl set Open_vSwitch . other_config:hw-offload=true;
   ```

2. Restart the OVS service:

   ```
   sudo /etc/init.d/openvswitch-switch restart
   ```

3. Graceful shutdown and power cycle the DPU to apply the configuration.

8.6.2.3.3 Helper Scripts

Firefly's deployment contains a script to help with the configuration steps required for the network interface in embedded mode:

- `scripts/doca_firefly/<firefly-version>/prepare_for_embedded_mode.sh`
- `scripts/doca_firefly/<firefly-version>/set_new_sf.sh`

The latest DOCA Firefly version is `1.7.0`.

Both scripts are included as part of DOCA's container resource which can be downloaded according to the instructions in the NVIDIA DOCA Container Deployment Guide. For more information about the structure of the DOCA container resource, refer to section "Structure of NGC Resource" in the deployment guide.

Due to technical limitations of the NGC resource, both scripts are provided without execute (+x) permissions. This could be resolved by running the following command:

```
chmod +x scripts/doca_firefly/<firefly-version>/*.sh
```

8.6.2.3.3.1 prepare_for_embedded_mode.sh

This script automates all the steps mentioned in section "Setting Up Network Interfaces for Embedded Mode" and configures a freshly installed BFB image to the settings required by DOCA Firefly.

Notes:

- The script deletes all previous OVS settings and creates a single OVS bridge that matches the definitions in section "Setting Up Network Interfaces for Embedded Mode"
- The script should only be run once when connecting to the DPU for the first time or after a power cycle
- The only manual step required after using this script is configuring the IP address for the created network interface (step 5 in section "Setting Up Network Interfaces for Embedded Mode")
- The script automatically uses port 0 (`p0`). Configurations for port 1 should be done manually based on the commands listed in sections "set_new_sf.sh" and "Setting Up Network Interfaces for DPU Mode".

Script arguments:

- SF number (checks if already exists)

Examples:

- Prepare OVS settings using an SF indexed 4:

```
chmod +x ./*.sh
./prepare_for_embedded_mode.sh 4
```

The script makes use of `set_new_sf.sh` as a helper script.

8.6.2.3.3.2 set_new_sf.sh

Creates a new trusted SF and marks it as "trusted".

Script arguments:

- PCIe address
- SF number (checks if already exists)
- MAC address (if absent, a random address is generated)

Examples:

- Create SF with number "4" over port 0 of the DPU:

```
./set_new_sf.sh 0000:03:00.0 4
```

- Create SF with number "5" over port 0 of the DPU and a specific MAC address:

```
./set_new_sf.sh 0000:03:00.0 5 aa:bb:cc:dd:ee:ff
```

- Create SF with number "4" over port 1 of the DPU:

```
./set_new_sf.sh 0000:03:00.1 4
```

The first two examples should work out of the box for a BlueField-2 device and create SF4 and SF5 respectively.

8.6.2.3.4 Setting Up Network Interfaces for DPU Mode

1. Create a trusted SF to be used by the service according to the Scalable Function Setup Guide.

   > ⚠ The following instructions assume that the SF has been created using index 4.

2. Create the required OVS setting as is shown in the architecture diagram:

```
$ sudo ovs-vsctl add-br uplink
$ sudo ovs-vsctl add-port uplink p0
$ sudo ovs-vsctl add-port uplink en3f0pf0sf4
# This port is needed to ensure we have traffic host<->network as well
$ sudo ovs-vsctl add-port uplink pf0hpf
```

3. Verify the OVS settings:

```
sudo ovs-vsctl show
    Bridge uplink
        Port pf0hpf
            Interface pf0hpf
        Port en3f0pf0sf4
            Interface en3f0pf0sf4
        Port p0
            Interface p0
        Port uplink
            Interface uplink
                type: internal
```

4. Enable TX timestamping on the SF interface (not the representor):

```
# tx port timestamp offloading
sudo ethtool --set-priv-flags enp3s0f0s4 tx_port_ts on
```

5. Enable the interface and set an IP address for it:

```
# configure ip for the interface:
sudo ifconfig enp3s0f0s4 <ip-addr> up
```

6. Configure OVS to support TX timestamping over this SF and multicast traffic in general:

```
# Multicast-related definitions
$ sudo ovs-vsctl set Bridge uplink mcast_snooping_enable=true
$ sudo ovs-vsctl set Bridge uplink other_config:mcast-snooping-disable-flood-unregistered=true
$ sudo ovs-vsctl set Port p0 other_config:mcast-snooping-flood=true
$ sudo ovs-vsctl set Port p0 other_config:mcast-snooping-flood-reports=true
# PTP-related definitions
```

```
$ sudo ovs-ofctl add-flow uplink in_port=en3f0pf0sf4,udp,tp_src=319,actions=output:p0
$ sudo ovs-ofctl add-flow uplink in_port=p0,udp,tp_src=319,actions=output:en3f0pf0sf4
$ sudo ovs-ofctl add-flow uplink in_port=en3f0pf0sf4,udp,tp_src=320,actions=output:p0
$ sudo ovs-ofctl add-flow uplink in_port=p0,udp,tp_src=320,actions=output:en3f0pf0sf4
```

If your OVS bridge uses a name other than `uplink`, make sure that the used name is reflected in the `ovs-vsctl` and `ovs-ofctl` commands. For instance:

```
$ sudo ovs-vsctl set Bridge <bridge-name> mcast_snooping_enable=true
```

8.6.2.4 Separated Mode

8.6.2.4.1 Configuring Firmware Settings on DPU for Separated Mode

1. Set the BlueField mode of operation to "Separated":

```
sudo mlxconfig -y -d 03:00.0 s INTERNAL_CPU_MODEL=0
```

2. Enable RTC:

```
sudo mlxconfig -d 03:00.0 set REAL_TIME_CLOCK_ENABLE=1
```

3. Graceful shutdown and power cycle the DPU to apply the configuration.
4. You may check the BlueField's operation mode using the following command:

```
sudo mlxconfig -d 03:00.0 q | grep INTERNAL_CPU_MODEL
# Example output
         INTERNAL_CPU_MODEL                  SEPARATED_HOST(0)
```

8.6.2.4.2 Setting Up Network Interfaces for Separated Mode

1. Make sure that that `p0` is not connected to an OVS bridge:

```
sudo ovs-vsctl show
```

2. Enable TX timestamping on the `p0` interface:

```
# TX port timestamp offloading (assuming PTP interface is p0)
sudo ethtool --set-priv-flags p0 tx_port_ts on
```

3. Enable the interface and set an IP address for it:

```
# Configure IP for the interface
```

```
sudo ifconfig p0 <ip-addr> up
```

8.6.2.5 Host-based Deployment

Host-based deployment requires the same configuration described under section "Separated Mode".

8.6.3 Service Deployment

8.6.3.1 DPU Deployment

For information about the deployment of DOCA containers on top of the BlueField DPU, refer to NVIDIA DOCA Container Deployment Guide.

Service-specific configuration steps and deployment instructions can be found under the service's container page.

> ⚠ DOCA Firefly can also be deployed on DPUs not connected to the Internet. For instructions, refer to the relevant section in the NVIDIA DOCA Container Deployment Guide.

8.6.3.2 Host Deployment

DOCA Firefly has a version adapted for host-based deployments. For more information about the deployment of DOCA containers on top of a host, refer to the NVIDIA BlueField DPU Container Deployment Guide.

The following is the docker command for deploying DOCA Firefly on the host:

```
sudo docker run --privileged --net=host -v /var/log/doca/firefly:/var/log/firefly -v /etc/firefly:/etc/firefly -e
PTP_INTERFACE='eth2' -it nvcr.io/nvidia/doca/doca_firefly:1.7.0-doca3.0.0-host /entrypoint.sh
```

Where:

- Additional YAML configs may be passed as environment variables as additional `-e` key-value pairs as done with `PTP_INTERFACE` above
- The exact container tag should be the desired tag as chosen on DOCA Firefly's NGC page

8.6.4 Configuration

All modules within the service have configuration files that allow customizing various settings, both general and PTP-related.

8.6.4.1 Built-In Config File

Each profile has its own base PTP configuration file for `ptp4l`. For example, the Media profile PTP configuration file is `ptp4l-media.conf`.

The built-in PTP configuration files can be found in section "PTP Profile Default Config Files". For ease-of-use, those files are provided as part of DOCA's container resource as downloaded from NGC and are placed under Firefly's `configs` directory (`scripts/doca_firefly/<firefly version>/configs`).

> ⚠ When using a built-in configuration file, Firefly uses the files as stored within the container itself in the `/etc/linuxptp` directory. The configuration files included in the NGC resource are only provided for ease of access. Modifying them does **not** impact the configuration used in practice by the container. Instead, updates to the configuration should be done as described in the following sections.

8.6.4.2 Custom Config File

Instead of using a profile's base config file, users can create a file of their own, for each of the modules.

To set a custom config file, users should locate their config file in the directory `/etc/firefly` and set the config file name in DOCA Firefly's YAML file.

For example, to set a custom `linuxptp` config file, the user can set the parameter `PTP_CONFIG_FILE` in the YAML file:

```
- name: PTP_CONFIG_FILE
  value: my_custom_ptp.conf
```

In this example, `my_custom_ptp.conf` should be placed at `/etc/firefly/my_custom_ptp.conf`.

⚠ A config file must not define values for the UDS-related ports (`/var/run/ptp4l` and `/var/run/ptp4lro`), as those will impact internal container behavior. Such settings will prompt a warning and will be ignored when preparing the finalized configuration (See more in the next sections).

8.6.4.3 Overriding Specific Config File Parameters

Instead of replacing the entire config file, users may opt to override specific parameters. This can be done using the following variable syntax in the YAML file: `CONF_<TYPE>_<SECTION>_<PARAMETER_NAME>` .

- `TYPE` – either `PTP` , `MONITOR` , `PHC2SYS` , `SYNCE`, or `SERVO`
- `SECTION` – the section in the config file that the parameter should be placed in

  ⚠ If the specified section does not already exist in the config file, a new section is created unless it refers to a PTP network interface that has not been included in the `PTP_INTERFACE` YAML field.

- `PARAMETER_NAME` – the config parameter name as should be placed in the config file

  ⚠ If the parameter name already exists in the config file, then the value is changed according to the value provided in the `.yaml` file. If the parameter name does not already exist in the config file, then it is added.

For example, the following variable in the YAML file definition changes the value of the parameter `priority1` under section `global` in the PTP config file to `64` .

```
- name: CONF_PTP_global_priority1
  value: "64"
```

⚠ Configuring `unicast_master_table` through the YAML file is not supported due to the structure of the table (i.e., multiple entries sharing the same key).

8.6.4.4 Ensuring and Debugging Correctness of Config Files

The previous sections describe 2 layers for the configuration file definitions:

- Basic configuration file – either a built-in config file or a custom config file
- Adding/overriding values to/from the YAML file

In practice, there are slightly more layers in place, and the precedence is as follows (presented in increasing order):

- Default configuration values of the PTP program (ptp4l for instance) – holds values of all available configuration options
- Your chosen configuration file – contains a subset of options
- Definitions from the YAML file – narrower subset
- Firefly mandatory values

When combining the supplied configuration file with the definitions from the YAML file, Firefly goes over those definitions and checks them against a predefined set of configuration options:

- Warning only – warns if a certain value leads to known issues in a supported deployment scenario
- Override – container-internal definitions that should not be set by the user and will be overridden by Firefly

Suitable log messages are provided in either case:

```
# Example for a warning
2023-01-31 11:55:13 - Firefly - Config - INFO    - Missing explicit definition "fault_reset_interval", verifying
default value instead: "4"
2023-01-31 11:55:13 - Firefly - Config - WARNING - Value "4" for definition "fault_reset_interval" will be invalid
in Embedded Mode, expected a value lesser or equal to "1"
2023-01-31 11:55:13 - Firefly - Config - WARNING - Continuing with invalid value
# Example for an override
2023-01-31 11:21:00 - Firefly - Config - WARNING - Invalid value "/var/run/ptp4l2" for definition "uds_address",
expected "/var/run/ptp4l"
2023-01-31 11:21:00 - Firefly - Config - INFO    - Setting definition "uds_address" value to the following: "/var/
run/ptp4l"
```

At the end of this process, an updated configuration file is generated by Firefly to be used later by the various time providers. To avoid accidental modification of a user-supplied configuration file or permission issues, the finalized file is generated within the container under the `/tmp` directory.

For instance, if using a custom configuration file named `my_custom_ptp.conf` under the `/etc/firefly` directory on the DPU, the updated file will reside within the container at the following path: `/tmp/my_custom_ptp.conf`.

For troubleshooting possible issues with the configuration file, one can do one of the following:

- Connect to the container directly as is explained in the debugging finalized configuration file bullet under "Troubleshooting".
- Map the container's `/tmp` directory to the DPU using the built-in support in the YAML file:
    - Before the change:

```
    # Uncomment when debugging the finalized configuration files used - Part #1
```

```
    #- name: debug-firefly-volume
    #  hostPath:
    #    path: /tmp/firefly
    #    type: DirectoryOrCreate
  containers:
    ...
      volumeMounts:
      - name: logs-firefly-volume
        mountPath: /var/log/firefly
      - name: conf-firefly-volume
        mountPath: /etc/firefly
      # Uncomment when debugging the finalized configuration files used - Part #2
      #- name: debug-firefly-volume
      #  mountPath: /tmp
```

- After the change:

```
    # Uncomment when debugging the finalized configuration files used - Part #1
    - name: debug-firefly-volume
      hostPath:
        path: /tmp/firefly
        type: DirectoryOrCreate
  containers:
    ...
      volumeMounts:
      - name: logs-firefly-volume
        mountPath: /var/log/firefly
      - name: conf-firefly-volume
        mountPath: /etc/firefly
      # Uncomment when debugging the finalized configuration files used - Part #2
      - name: debug-firefly-volume
        mountPath: /tmp
```

The finalized configuration file keeps the sections and config options in the same order as they appear in the original file, yet the file is stripped from spare new lines or comment lines. This should be taken into considerations when directly accessing it during a debugging session.

8.6.5 Description

8.6.5.1 Providers

DOCA Firefly Service uses the following third-party providers to provide time syncing services:

- Linuxptp - Version v4.2
  - `PTP` – PTP service, provided by the PTP4L program
  - `PHC2SYS` – OS time calibration, provided by the PHC2SYS program
- Testptp
  - `PPS` - PPS settings service

In addition, DOCA Firefly Service also makes use of the following NVIDIA modules:

- SyncE
  - `SYNCE` – Synchronous Ethernet Deamon (`synced`)
- Firefly
  - `MONITOR` - Firefly PTP Monitor
- Firefly

- `SERVO` - Firefly PTP Servo

Each of the providers can be enabled, disabled, or set to use the setting defined by the configuration profile:

- YAML setting – `<provider name>_STATE`
- Supported values – `enable`, `disable`, `defined_by_profile`

> ⚠ For the default profile settings per provider, refer to the table under section "Profiles".

An example YAML setting for specifically disabling the `phc2sys` provider is the following:

```
- name: PHC2SYS_STATE
  value: "disable"
```

> ⚠ The `defined_by_profile` setting is only available for well-defined profiles. As such, it cannot be used when the `custom` profile is selected. For more information about the profile settings, refer to the table under section "Profiles".

8.6.5.2 Profiles

DOCA Firefly Service includes profiles which represent common use cases for the Firefly service that provide a different default configuration per profile:

	Default	Media	Telco (L2)	Custom
Purpose	Any user that requires PTP	Media productions	Telco networks	Custom configuration for a dedicated user scenario
PTP	Enabled	Enabled	Enabled	No default. Enable/disable should be set by the user.
PTP profile	PTP default profile	SMPTE 2059-2	G.8275.1	Set by the user
PTP Client/ Server [1]	Both	Client-only	Both	Set by the user
PHC2SYS	Enabled	Enabled	Enabled	No default. Enable/disable should be set by the user.
PPS (in/out)	Enabled	Enabled	Enabled	No default. Enable/disable should be set by the user.
PTP Monitor	Disabled	Disabled	Disabled	No default. Enable/disable should be set by the user.
SyncE	Disabled	Disabled	Enabled	No default. Enable/disable should be set by the user.

	Default	Media	Telco (L2)	Custom
Servo	Disabled	Disabled	Disabled	No default. Enable/disable should be set by the user.

1. Client-only is only relevant to a single PTP interface. If more than one PTP interface is provided in the YAML file, both modes are enabled. ↩

8.6.5.3 Outputs

8.6.5.3.1 Container Output

While running, the full output of the DOCA Firefly Service container can be viewed using the following command:

```
sudo crictl logs <CONTAINER-ID>
```

Where `CONTANIER-ID` can be retrieved using the following command:

```
sudo crictl ps
```

For example, in the following output, the container ID is `8f368b98d025b`.

```
$ sudo crictl ps
CONTAINER           IMAGE               CREATED             STATE               NAME                ATTEMPT
    POD ID              POD
8f368b98d025b       289809f312b4c       2 seconds ago       Running             doca-firefly        0
    5af59511b4be4       doca-firefly-some-computer-name
```

The output of the container depends on the services supported by the hardware and enabled by configuration and the selected profile. However, note that any of the configurations runs PTP, so when DOCA FireFly is running successfully expect to see the line "`Running ptp4l`".

The following is an example of the expected container output when running the default profile on a DPU that supports PPS:

```
2023-09-07 14:04:23 - Firefly - Init    - INFO     - Starting DOCA Firefly - Version 1.4.0
2023-09-07 14:04:23 - Firefly - Init    - INFO     - Selected features:

```

8.6.5.3.2 Firefly Output

On top of the container's log, Firefly defines an additional, non-volatile log that can be found in `/var/log/doca/firefly/firefly.log`.

This file contains the same output described in section "Container Output" and is useful for debugging deployment errors should the container stop its execution.

> ⚠ To avoid disk space issues, the `/var/log/doca/firefly/firefly.log` file only contains the log from Firefly's initialization, and not the logs of the rest of the modules (ptp4l, phc2sys, etc.) or that of the PTP monitor. The latter is still included in the container log and can be inspected using the command `sudo crictl logs <CONTAINER-ID>`.

8.6.5.3.3 ptp4l Output

The ptp4l output can be found in the file `/var/log/doca/firefly/ptp4l.log`.

Example output:

```
ptp4l[192710.691]: rms 1 max 1 freq -114506 +/- 0 delay -15 +/- 0
ptp4l[192712.692]: rms 6 max 9 freq -114501 +/- 3 delay -15 +/- 0
ptp4l[192714.692]: rms 7 max 9 freq -114511 +/- 3 delay -13 +/- 0
ptp4l[192716.692]: rms 5 max 7 freq -114502 +/- 1 delay -13 +/- 0
ptp4l[192718.693]: rms 4 max 6 freq -114509 +/- 2 delay -13 +/- 0
```

```
ptp4l[192720.693]: rms 3 max 3 freq -114506 +/- 2 delay -13 +/- 0
ptp4l[192722.694]: rms 4 max 6 freq -114510 +/- 3 delay -12 +/- 0
ptp4l[192724.694]: rms 5 max 7 freq -114510 +/- 5 delay -12 +/- 1
ptp4l[192726.695]: rms 4 max 5 freq -114508 +/- 3 delay -11 +/- 0
ptp4l[192728.695]: rms 6 max 9 freq -114504 +/- 4 delay -11 +/- 0
```

8.6.5.3.4 phc2sys Output

The phc2sys output can be found in the file `/var/log/doca/firefly/phc2sys.log`.

Example output:

```
phc2sys[1873325.928]: reconfiguring after port state change
phc2sys[1873325.928]: selecting CLOCK_REALTIME for synchronization
phc2sys[1873325.928]: selecting enp3s0f0s4 as the master clock
phc2sys[1873325.928]: CLOCK_REALTIME phc offset      1378 s2 freq -165051 delay    255
phc2sys[1873326.928]: CLOCK_REALTIME phc offset      1378 s2 freq -163673 delay    240
phc2sys[1873327.928]: port 62b785.fffe.0c9369-1 changed state
phc2sys[1873327.929]: CLOCK_REALTIME phc offset        14 s2 freq -164624 delay    255
phc2sys[1873328.936]: CLOCK_REALTIME phc offset        89 s2 freq -164545 delay    240
```

8.6.5.3.5 SyncE Output

The SyncE output can be found in the file `/var/log/doca/firefly/synced.log`.

Example output:

```
INFO     [05/09/2023 05:11:01.493414]: SyncE Group #0: is in TRACKING holdover acquired mode on p0, frequency_diff:
0 (ppb)
INFO     [05/09/2023 05:11:02.502963]: SyncE Group #0: is in TRACKING holdover acquired mode on p0, frequency_diff:
-113 (ppb)
INFO     [05/09/2023 05:11:03.512491]: SyncE Group #0: is in TRACKING holdover acquired mode on p0, frequency_diff:
37 (ppb)
```

The verbosity of the output from the `SYNCE` module is limited by default. To set the output to be more verbose, set the `verbose` option to `1` (True).

Before:

```
# Example #4 - Overwrite the value of verbose in the [global] section of the SyncE configuration file.
#- name: CONF_SYNCE_global_verbose
#  value: "1"
```

After:

```
# Example #4 - Overwrite the value of verbose in the [global] section of the SyncE configuration file.
- name: CONF_SYNCE_global_verbose
  value: "1"
```

8.6.5.3.6 Firefly Servo Output

The Firefly servo output can be found in the file `/var/log/doca/firefly/servo.log`.

Example output:

```
2024-03-18 09:04:22 - Firefly - SERVO  - INFO     - offset   +8 +/- 2  freq   -5.66 +/- 0.41  delay -48 +/- 2
2024-03-18 09:04:24 - Firefly - SERVO  - INFO     - offset   +4 +/- 2  freq   -6.35 +/- 0.36  delay -47 +/- 2
2024-03-18 09:04:26 - Firefly - SERVO  - INFO     - offset   +2 +/- 2  freq   -6.75 +/- 0.41  delay -47 +/- 1
2024-03-18 09:04:28 - Firefly - SERVO  - INFO     - offset   +0 +/- 2  freq   -6.97 +/- 0.35  delay -47 +/- 1
2024-03-18 09:04:30 - Firefly - SERVO  - INFO     - offset   +0 +/- 3  freq   -7.30 +/- 0.60  delay -47 +/- 1
2024-03-18 09:04:33 - Firefly - SERVO  - INFO     - offset   +1 +/- 2  freq   -6.93 +/- 0.41  delay -47 +/- 1
2024-03-18 09:04:35 - Firefly - SERVO  - INFO     - offset   +1 +/- 2  freq   -6.81 +/- 0.48  delay -47 +/- 1
2024-03-18 09:04:37 - Firefly - SERVO  - INFO     - offset   +2 +/- 2  freq   -6.76 +/- 0.52  delay -48 +/- 2
```

8.6.5.4 Tx Timestamping Support on DPU Mode

When the BlueField is operating in DPU mode, additional OVS configuration is required as mentioned in step 6 of section "Setting Up Network Interfaces for DPU Mode". This configuration achieves the following:

- Proper support for incoming/outgoing multicast traffic
- Enabling Tx timestamping

Firefly only gets the packet timestamping for outgoing PTP messages (Tx timestamping) when they are offloaded to the hardware. As such, when working with OVS, users must ensure this traffic flow is properly recognized and offloaded. If offloading does not take place, Firefly gets stuck in a fault loop while waiting to receive the Tx timestamp events:

```
ptp4l[2912.797]: timed out while polling for tx timestamp
ptp4l[2912.797]: increasing tx_timestamp_timeout may correct this issue, but it is likely caused by a driver bug
ptp4l[2912.797]: port 1 (enp3s0f0s4): send sync failed
ptp4l[2923.528]: timed out while polling for tx timestamp
ptp4l[2923.528]: increasing tx_timestamp_timeout may correct this issue, but it is likely caused by a driver bug
ptp4l[2923.528]: port 1 (enp3s0f0s4): send sync failed
```

The solution to this issue:

- Activation of hardware offloading in OVS
- OpenFlow rules that ensure OVS properly recognizes the traffic and offloads it to the hardware
- Modification to the `fault_reset_interval` configuration value to ensure timely recovery from the fault induced by the first packet being always treated by software (until the rule is offloaded to hardware). As such, Firefly requires that the `fault_reset_interval` value is 1 or less. Proper warnings are raised if an improper value is detected. The value is updated accordingly in the built-in profiles.

When these configurations are in order, Firefly includes a report for a single fault during boot, but recovers from it and continues as usual:

```
ptp4l[3715.687]: timed out while polling for tx timestamp
ptp4l[3715.687]: increasing tx_timestamp_timeout may correct this issue, but it is likely caused by a driver bug
ptp4l[3715.687]: port 1 (enp3s0f0s4): send delay request failed
```

8.6.5.4.1 Troubleshooting Tx Timestamp Issues

As explained earlier, there are several layers required to ensure Tx timestamping works as necessary by Firefly. The following is a list of commands to debug the state of each layer:

1. Inspect the OpenFlow rules:

```
$ sudo ovs-ofctl dump-flows uplink
cookie=0x0, duration=4075.576s, table=0, n_packets=2437, n_bytes=209582, udp,in_port=en3f0pf0sf4,tp_src=319
actions=output:p0
cookie=0x0, duration=4075.549s, table=0, n_packets=1216, n_bytes=109420, udp,in_port=p0,tp_src=319
actions=output:en3f0pf0sf4
cookie=0x0, duration=4075.521s, table=0, n_packets=13, n_bytes=1242, udp,in_port=en3f0pf0sf4,tp_src=320
actions=output:p0
cookie=0x0, duration=4074.604s, table=0, n_packets=3034, n_bytes=297376, udp,in_port=p0,tp_src=320
actions=output:en3f0pf0sf4
cookie=0x0, duration=4075.856s, table=0, n_packets=184, n_bytes=12901, priority=0 actions=NORMAL
```

2. Inspect hardware TC rules while DOCA Firefly is deployed (the rules age out after 10 seconds without traffic):

```
$ sudo tc -s -d filter show dev en3f0pf0sf4 egress
filter ingress protocol ip pref 4 flower chain 0
filter ingress protocol ip pref 4 flower chain 0 handle 0x1
  eth_type ipv4
  ip_proto udp
  src_port 320
  ip_flags nofrag
  in_hw in_hw_count 1
    action order 1: mirred (Egress Redirect to device p0) stolen
    index 3 ref 1 bind 1 installed 7 sec used 7 sec
    Action statistics:
    Sent 0 bytes 0 pkt (dropped 0, overlimits 0 requeues 0)
    backlog 0b 0p requeues 0
    cookie bec8bd6ede4e86341e9045a6edb58ca2
    no_percpu

filter ingress protocol ip pref 4 flower chain 0 handle 0x2
  eth_type ipv4
  ip_proto udp
  src_port 319
  ip_flags nofrag
  in_hw in_hw_count 1
    action order 1: mirred (Egress Redirect to device p0) stolen
    index 4 ref 1 bind 1 installed 6 sec used 6 sec
    Action statistics:
    Sent 0 bytes 0 pkt (dropped 0, overlimits 0 requeues 0)
    backlog 0b 0p requeues 0
    cookie c568d97efd400de98608fbbf86ccdf3c
    no_percpu
```

> ⚠ If no TC rules are present when Firefly is running, this usually indicates that hardware offloading is disabled at the OVS level, in which case it should be activated as explained under "Ensuring OVS Hardware Offload".

8.6.5.5 PTP

Firefly uses the `ptp4l` utility to handle the Precision Time Protocol (IEEE 1588).

Through the YAML file, users can configure the network interfaces used for the protocol:

```
# Network interfaces to be used (For multiple interfaces use a space (" ") separated list)
- name: PTP_INTERFACE
  # Set according to used interfaces on the local setup
```

```
  value: "p0"
```

Before the deployment of the container, users should configure this field to point at the desired network interface(s) configured in the previous steps.

8.6.5.6 PHC2SYS

Firefly uses the `phc2sys` utility to synchronize the OS's clock to the accurate time stamps received by `ptp4l`.

Through the YAML file, users can configure the command-line arguments used by the `phc2sys` program:

```
- name: PHC2SYS_ARGS
  value: "-a -r"
```

Firefly adds the following command-line arguments on top of the user-selected flags:

- Use of chosen configuration file (empty configuration file by default, or user-supplied file if specified in the YAML file)
- Redirection of output to a log file using the `-m` command line option

`phc2sys` must use the same `domainNumber` setting used by `ptp4l`. If the same `domainNumber` is not set by the user, Firefly does that automatically.

`phc2sys` is only able to accurately sync the clock of the hosting environment (usually the DPU, but may also be the host if deployed there) if other timing services, such as NTP, are disabled.

So, for instance, on Ubuntu 22.04, users must ensure that the NTP timing service is disabled by running:

```
systemctl stop systemd-timesyncd
```

8.6.5.7 SYNCE

Firefly uses the proprietary `synced` utility to implement the Synchronous Ethernet protocol, aimed at ensuring synchronization of the clock's frequency with the reference clock. Once achieved, both clocks are declared as "syntonized".

Through the YAML file, users can configure the network interfaces used for the protocol:

```
# Network interfaces to be used (For multiple interfaces use a space (" ") separated list)
- name: SYNCE_INTERFACE
  # Set according to used interfaces on the local setup
  value: "p0"
```

Before the deployment of the container, one should configure this field to point at the desired network interface(s) configured in the previous steps.

DOCA includes synced support for the `"dpll"` backend (default) which adds support for SFs and VFs. The `"dpll"` backend is the default backend used. If DOCA detects the system does not support it, it will automatically falls back to the `"mft"` backend.

⚠ In versions older than kernel 6.8 or BlueField Platform Software 2.8.0, only PFs are supported and only using the `"mft"` backend.

The backend option can be explicitly set using the YAML file by uncommenting the following lines:

Before

```
# Example #5 - Explicitly specify the used backend in the [global] section of the SyncE configuration file.
#- name: CONF_SYNCE_global_backend
#  # Options are "mft"/"dpll". If nothing is specified in YAML, "dpll" is taken as the default
#  value: "mft"
```

After

```
# Example #5 - Explicitly specify the used backend in the [global] section of the SyncE configuration file.
- name: CONF_SYNCE_global_backend
  # Options are "mft"/"dpll". If nothing is specified in YAML, "dpll" is taken as the default
  value: "mft"
```

The following is an example for the OVS commands required to route the SyncE-related traffic when using a SF on top of the `"dpll"` backend:

```
$ sudo ovs-ofctl add-flow uplink dl_dst=01:80:c2:00:00:02,in_port=en3f0pf0sf4,actions=p0
$ sudo ovs-ofctl add-flow uplink dl_dst=01:80:c2:00:00:02,in_port=p0,actions=en3f0pf0sf4
$ sudo ovs-ofctl add-flow uplink dl_dst=01:80:c2:00:00:02,actions=controller
```

ℹ This example uses the same OVS settings used earlier in the guide:

- `uplink` – bridge name
- `en3f0pf0sf4` – SF representor
- `p0` – PF interface we are working (port 0)

If your deployment uses different values make sure to adjust the above commands accordingly.

If the kernel version does not yet support this feature, and SF/VF are used, the following error is printed:

```
...
mlx5 DPLL kernel support appears to be missing
```

```
Falling back to MFT tools backend
...
```

If this error is shown, only PFs can be used, and `synced` falls back to using the `"mft"` backend.

8.6.5.8 PTP Monitor

PTP monitor periodically queries for various PTP-related information and prints it to the container's log.

The following is a sample output of this tool:

```
gmIdentity:                 48:B0:2D:FF:FE:5C:4D:24 (48b02d.fffe.5c4d24)
portIdentity:               48:B0:2D:FF:FE:5C:53:44 (48b02d.fffe.5c5344-1)
port_state:                 Active
domainNumber:               2
master_offset:              avg: 1    max:    -8  rms:    3
gmPresent:                  true
ptp_stable:                 Recovered
UtcOffset:                  37
timeTraceable:              0
frequencyTraceable:         0
grandmasterPriority1:       128
gmClockClass:               248
gmClockAccuracy:            0x6
grandmasterPriority2:       128
gmOffsetScaledLogVariance: 0xffff
ptp_time (TAI):             Thu Sep  7 11:22:50 2023
ptp_time (UTC adjusted):    Thu Sep  7 11:22:13 2023
system_time (UTC):          Thu Sep  7 11:22:13 2023
ptp_ports:                  48:B0:2D:FF:FE:5C:53:44 (48b02d.fffe.5c5344-1) - Slave
error_count:                1
last_err_time (UTC):        Thu Sep  7 09:55:48 2023
```

Among others, this monitoring provides the following information:

- Details about the Grandmaster the DPU is syncing with
- Current PTP timestamp
- Health information such as connection errors during execution and whether they have been recovered from

PTP monitoring is disabled by default and can be activated by replacing the `disable` value with the IP address for the monitor server to use:

```
- name: MONITOR_STATE
  Value: "<IP address for the monitoring server>"
```

Once activated, the information can be viewed from the container using the following command:

```
sudo crictl logs --tail=<MONITOR_LINE_NUMBER> <CONTAINER-ID>
```

> ⚠ `MONITOR_LINE_NUMBER` is equal to 20 lines + the number of PTP interfaces supplied via the `PTP_INTERFACE` field.

It is recommended to use the following `watch` command to actively monitor the PTP state:

```
sudo watch -n 1 crictl logs --tail=<MONITOR_LINE_NUMBER> <CONTAINER-ID>
```

When triaging deployment issues, additional logging information can be found in the monitor's developer logs at `/var/log/doca/firefly/firefly_monitor_dev.log`.

> ⚠ The monitoring feature connects to ptp4l's local UDS server to query the necessary information. This is why the configuration manager prevents users from modifying the `uds_address` and `uds_ro_address` fields used by ptp4l within the container.

8.6.5.8.1 Configuration

The PTP monitor supports configuration options which are passed through a dedicated configuration file like the rest of DOCA Firefly's modules. The built-in monitor configuration file can be found in the section "PTP Monitor". For ease of use, the file is also provided as part of DOCA's container resource as downloaded from NGC.

"Firefly Modules Configuration Options" contains a complete explanation of each of the configuration options alongside their default values.

To set a custom config file, users should locate their config file in the directory `/etc/firefly` and set the config file name in DOCA Firefly's YAML file.

```
- name: MONITOR_CONFIG_FILE
  value: my_custom_monitor.conf
```

In this example, `my_custom_monitor.conf` should be placed at `/etc/firefly/my_custom_monitor.conf`.

8.6.5.8.2 Time Representations (PTP Time vs System Time)

Under most deployment scenarios, the PTP time shown by the monitor is presented according to the International Atomic Time (TAI) standard, while the system time would most commonly use the Coordinated Universal Time (UTC). Due to the differences between these time representation models, the monitor provides 2 different time readings (each marked accordingly):

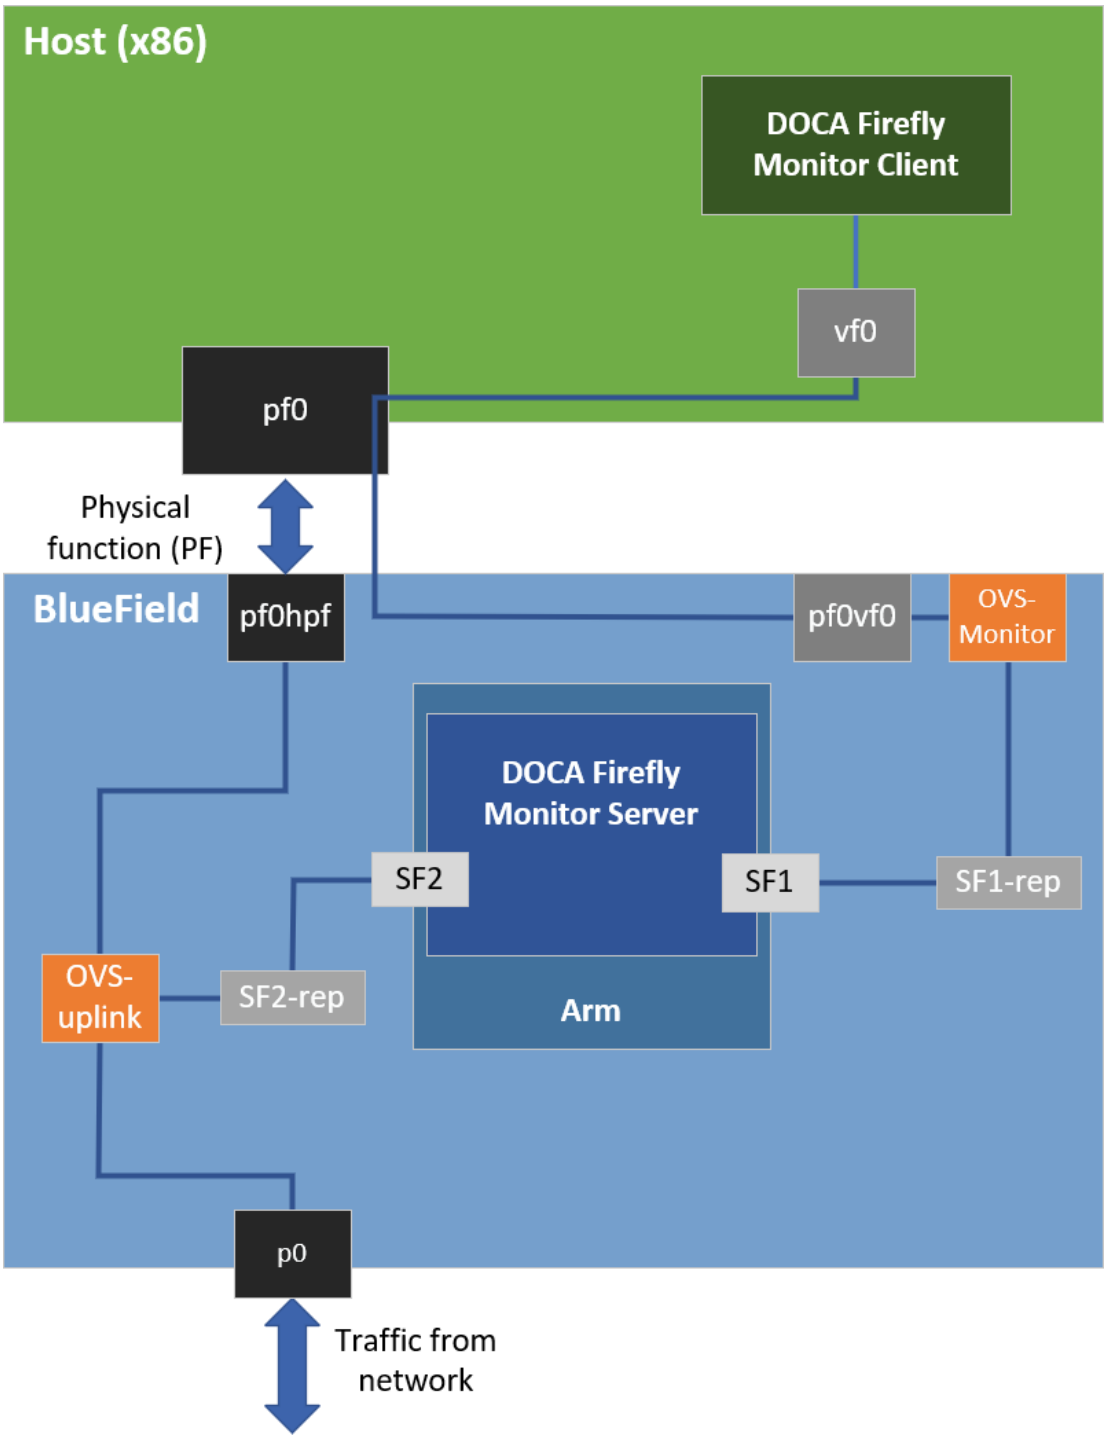
```
...
UtcOffset:                37
...
ptp_time (TAI):           Thu Sep  7 11:22:50 2023
ptp_time (UTC adjusted):  Thu Sep  7 11:22:13 2023
system_time (UTC):        Thu Sep  7 11:22:13 2023
```

This difference (37 seconds in the above example) is intentional and stems from the amount of leap seconds since epoch. This is indicated by the `UtcOffset` field that is also included in the monitor's report.

8.6.5.8.3 Monitor Server

In addition to printing the monitoring data to the container's standard output available through the container logs, the monitoring data is also exposed through a gRPC server that clients can subscribe to. This allows a monitoring client on the host to subscribe to monitor events from the service running on top of the DPU, thus providing better visibility.

The following diagram presents the recommended deployment architecture for connecting the monitoring client (on the host) to the monitor server (on the DPU).



Based on the above, when activating the monitor feature, the user must provide the IP address to be used by the monitor server:

```
- name: MONITOR_STATE
  value: "<IP address for the monitoring server>"
```

Users can choose to only view the monitoring events through the container logs without connecting to the monitoring server. In this case, it is recommended to configure the

local host IP address (127.0.0.1) in the YAML file to avoid exposing it to an unwanted network.

8.6.5.8.4 Monitor Client

The required files for the monitor client are available under the service's dedicated NGC resource "scripts" directory.

To run Monitor Client you need to provide:

```
- name: MONITOR_STATE
  value: "<IP address for the monitoring server>"
- name: MONITOR_CLIENT_TYPE
  value: "vanilla"/"phc2sys"
```

`vanilla` is used for only monitoring the Server, while `phc2sys` is used for also running phc2sys on the host to synchronize the host's system clock with the Server's clock.

> ⚠ The monitor client `vanilla` type can run on both DPU and host, while the `phc2sys` type can only run on the host.

If you are using `phc2sys` you need to provide also the interface the server is running on.

```
- name: MONITOR_CLIENT_PHC2SYS_INTERFACE
  value: "<interface_name>"
```

The monitor phc2sys client output will also include the following additional lines:

```
Host information:
Current system time:         Tue Apr  8 10:28:10 2025
Current phc time (Timezone): Tue Apr  8 10:28:10 2025
Current phc time (UTC):      2025-4-8 10:28:10.409982752 UTC
```

Example command line for executing the monitor client inside a container on host:

```
sudo docker run --privileged --net=host -v /var/log/doca/firefly:/var/log/firefly -v /etc/firefly:/etc/firefly -e
PTP_INTERFACE='eth2' -e MONITOR_STATE='192.168.0.1' -e MONITOR_CLIENT_TYPE='vanilla' -it nvcr.io/nvidia/doca/
doca_firefly:1.5.0-doca2.9.0-host /entrypoint.sh
```

Example command line for executing the python-based monitor client from a Linux host:

```
$ sudo pip3 install click protobuf grpcio
$ ./doca_firefly_monitor_client.py <ip-address-for-the-monitoring-server>
```

> ⚠ Reference source files and the `.proto` file used for Firefly's monitor are placed under the `src/` within the NGC resource.

8.6.5.8.5 Telemetry Export

On top of allowing clients to subscribe to the feed of monitoring events, the PTP Monitor server also supports an active export of the events to DOCA Telemetry Service (DTS). In such a scenario, users should deploy DTS to the machine on which DOCA Firefly is deployed (host/DPU) and then activate "telemetry export" using the following steps:

1. Enable the needed file mounts through the YAML file:

Before	```
	...
	    # Uncomment when using the telemetry features with DTS - Part #1
	    #- name: ipc-sockets-volume
	    # hostPath:
	    # path: /opt/mellanox/doca/services/telemetry/ipc_sockets
	    # type: DirectoryOrCreate
	    #- name: shared-memory
	    # hostPath:
	    # path: /dev/shm/telemetry
	    # type: DirectoryOrCreate
	  containers:
	    - name: doca-firefly
	...
	      # Uncomment when debugging the finalized configuration files used - Part #2
	      #- name: debug-firefly-volume
	      # mountPath: /tmp
	      # Uncomment when using the telemetry features with DTS - Part #2
	      #- name: ipc-sockets-volume
	      # mountPath: /opt/mellanox/doca/services/telemetry/ipc_sockets
	      #- name: shared-memory
	      # mountPath: /dev/shm
	...
	``

After	```
	...
	    # Uncomment when using the telemetry features with DTS - Part #1
	    - name: ipc-sockets-volume
	      hostPath:
	        path: /opt/mellanox/doca/services/telemetry/ipc_sockets
	        type: DirectoryOrCreate
	    - name: shared-memory
	      hostPath:
	        path: /dev/shm/telemetry
	        type: DirectoryOrCreate
	  containers:
	    - name: doca-firefly
	...
	      # Uncomment when debugging the finalized configuration files used - Part #2
	      #- name: debug-firefly-volume
	      # mountPath: /tmp
	      # Uncomment when using the telemetry features with DTS - Part #2
	      - name: ipc-sockets-volume
	        mountPath: /opt/mellanox/doca/services/telemetry/ipc_sockets
	      - name: shared-memory
	        mountPath: /dev/shm
	...
	``

2. Pass a configuration value of `1` to `telemetry_export` through the configuration. This could easily be done directly through the YAML file:

Before	```
	...
	      # Example #7 - Activate the monitor telemetry export feature (export through DTS).
	      #- name: CONF_MONITOR_global_telemetry_export
	      # value: "1"
	...
	``

After	```
	...
	      # Example #7 - Activate the monitor telemetry export feature (export through DTS).
	      - name: CONF_MONITOR_global_telemetry_export
	        value: "1"
	...
	``

Once active, a log message should indicate the availability of the export feature (which uses the DOCA Telemetry Exporter library):

```
...
2024-09-05 06:22:08 - Firefly - MONITOR - INFO     - Monitor records will also be exported via DOCA
Telemetry Exporter
...
```

The following is a sample output of the telemetry export:

```
    "ptp_time_str": "Tue Apr 22 17:26:16 2025",
    "adjusted_ptp_time_str": "Tue Apr 22 17:25:39 2025",
    "sys_time_str": "Tue Apr 22 17:25:39 2025",
    "last_error_time_str": "Tue Apr 22 12:40:47 2025",
    "gm_identity": "18:08:31:FF:FE:5A:F1:EE (180831.fffe.5af1ee)",
    "port_identity": "90:D7:6B:FF:FE:96:92:F8 (90d76b.fffe.9692f8-1)",
    "ptp_ports": "90:D7:6B:FF:FE:96:92:F8 (90d76b.fffe.9692f8-1) - Slave",
    "ptp_stability": 2,
    "ptp_time_raw": 1745342776089236500,
    "adjusted_ptp_time_raw": 1745342739089236500,
    "sys_time_raw": 1745342739,
    "error_count": 1,
    "last_error_time_raw": 1745325647,
    "master_offset_max": 1,
    "master_offset_avg": 1,
    "master_offset_rms": 0,
    "utc_offset": 37,
    "gm_priority1": 127,
    "gm_clock_class": 248,
    "gm_clock_accuracy": 254,
    "gm_priority2": 127,
    "gm_scaled_offset": 65535,
    "domain_number": 0,
    "port_state": 2,
    "source_id": "c-237-153-80-p88-00-0-bf2.mtl.labs.mlnx",
    "timestamp": 1745342739263351,
    "data_type": "Firefly_monitor"
```

- `ptp_ports` - a list of all existing PTP ports and there state according to PTP protocol states.
- `ptp_stability` - represent the stability state of the PTP. It has 3 options:
  1) 0 - PTP is in a stable state
  2) 1 - PTP is currently out of sync
  3) 2 - PTP managed to recover from a sync error
- `error_count` - represent the the number of errors we encountered thus far.
- `port_state` - represent the effective PTP port state of the most active port. It has 3 options:
  1) 0 - PTP port is in an inactive state
  2) 1 - PTP port is active, but uncalibrated
  3) 2 - PTP port is active and calibrated

When locally debugging the telemetry information through DTS, it is important to remember to activate the data writer (storage output), as mentioned in the DOCA Telemetry Service Guide.

> For more information about visualizing the information once exported through DTS, please refer to the example about using Grafana alongside DTS.

8.6.5.9 Firefly Servo

Firefly's Servo module can be seen as an extension to the built-in set of servos offered by `linuxptp`. When active, `linuxptp` is automatically set to "free running" and the control over the physical hardware clock (PHC) is handed over to Firefly's own servo.

The following is a sample output of this tool when using the `l2-telco` profile (16 messages per seconds):

```
2024-03-18 07:46:45 - Firefly - SERVO  - INFO     - Detected new master clock: 48b02d.fffe.5c4d24-1
2024-03-18 07:46:45 - Firefly - SERVO  - INFO     - Transition from servo state IDLE to FREE_RUNNING
2024-03-18 07:46:47 - Firefly - SERVO  - INFO     - Estimated a logSyncInterval of: -4
2024-03-18 07:46:47 - Firefly - SERVO  - INFO     - Measured offset      18691      delay -47
2024-03-18 07:46:48 - Firefly - SERVO  - INFO     - Transition from servo state FREE_RUNNING to LOCKED
2024-03-18 07:46:50 - Firefly - SERVO  - INFO     - offset +164 +/- 164 freq   -1.50 +/- 0.00  delay -48 +/- 1
2024-03-18 07:46:52 - Firefly - SERVO  - INFO     - Transition from servo state LOCKED to LOCKED_STABLE
2024-03-18 07:46:52 - Firefly - SERVO  - INFO     - offset   +0 +/- 1  freq   -1.41 +/- 0.47  delay -48 +/- 1
2024-03-18 07:46:54 - Firefly - SERVO  - INFO     - offset   -8 +/- 4  freq   -4.21 +/- 1.40  delay -47 +/- 1
2024-03-18 07:46:57 - Firefly - SERVO  - INFO     - offset  -12 +/- 2  freq   -5.46 +/- 0.73  delay -47 +/- 1
2024-03-18 07:46:59 - Firefly - SERVO  - INFO     - offset  -13 +/- 2  freq   -6.13 +/- 0.65  delay -47 +/- 1
2024-03-18 07:47:01 - Firefly - SERVO  - INFO     - offset  -13 +/- 3  freq   -6.19 +/- 1.23  delay -47 +/- 2
2024-03-18 07:47:03 - Firefly - SERVO  - INFO     - offset  -19 +/- 2  freq   -8.04 +/- 0.96  delay -47 +/- 1
2024-03-18 07:47:06 - Firefly - SERVO  - INFO     - offset  -14 +/- 3  freq   -6.46 +/- 1.11  delay -47 +/- 1
2024-03-18 07:47:08 - Firefly - SERVO  - INFO     - offset  -16 +/- 2  freq   -7.32 +/- 0.78  delay -48 +/- 2
2024-03-18 07:47:10 - Firefly - SERVO  - INFO     - offset  -15 +/- 2  freq   -7.11 +/- 0.87  delay -47 +/- 2
2024-03-18 07:47:12 - Firefly - SERVO  - INFO     - offset  -14 +/- 1  freq   -6.74 +/- 0.57  delay -47 +/- 2
2024-03-18 07:47:15 - Firefly - SERVO  - INFO     - offset  -12 +/- 3  freq   -6.20 +/- 1.01  delay -48 +/- 1
2024-03-18 07:47:17 - Firefly - SERVO  - INFO     - offset  -13 +/- 2  freq   -6.40 +/- 0.89  delay -47 +/- 1
2024-03-18 07:47:19 - Firefly - SERVO  - INFO     - offset  -11 +/- 2  freq   -5.98 +/- 0.86  delay -48 +/- 1
2024-03-18 07:47:21 - Firefly - SERVO  - INFO     - offset  -10 +/- 2  freq   -5.75 +/- 0.87  delay -46 +/- 1
2024-03-18 07:47:24 - Firefly - SERVO  - INFO     - offset   -8 +/- 1  freq   -5.15 +/- 0.42  delay -47 +/- 1
```

As can be seen, the servo's behavior is similar to that of `linuxptp`'s `ptp4l` and consists of a state machine that tracks the state of the active PTP port (`FREE_RUNNING`, `LOCKED`, `LOCKED_STABLE`, etc).

Firefly's Servo is disabled by default (in all profiles) and can be activated by replacing the `define_by_profile` value with `enable`:

```
# Activation status
- name: SERVO_STATE
  # Options are "enable"/"disable"/"defined_by_profile"
  value: "enable"
```

Once activated, the information can be viewed from the module's log file `/var/log/doca/firefly/servo.log`.

8.6.5.9.1 Firefly Servo Configuration

Firefly's Servo is currently aimed for telco-related deployments, using the `l2-telco` profile including the use of SyncE. As such, the default values in the built-in configuration file are optimized for those scenarios.

The servo supports configuration options which are passed through a dedicated configuration file like the rest of DOCA Firefly's modules. The built-in servo configuration file can be found in the section "Firefly Servo". For ease of use, the file is also provided as part of DOCA's container resource as downloaded from NGC.

"Firefly Modules Configuration Options" contains a complete explanation of each of the configuration options alongside their default values.

To set a custom config file, users should locate their config file in the directory `/etc/firefly` and set the config file name in DOCA Firefly's YAML file.

```
- name: SERVO_CONFIG_FILE
  value: my_custom_servo.conf
```

In this example, `my_custom_servo.conf` should be placed at `/etc/firefly/my_custom_servo.conf`.

8.6.5.9.2 Dynamic Packet Rate Support

The servo has the ability to dynamically detect the packet rate used by the PTP grandmaster clock, so to calibrate itself accordingly incase it differs from the recommended 16 packets per seconds.

```
2024-03-18 07:46:45 - Firefly - SERVO  - INFO     - Transition from servo state IDLE to FREE_RUNNING
2024-03-18 07:46:47 - Firefly - SERVO  - INFO     - Estimated a logSyncInterval of: -4
2024-03-18 07:46:47 - Firefly - SERVO  - INFO     - Measured offset      18691      delay -47
```

In a case the message rate is constant and known in advance, the dynamic estimation can be disabled, in favour of a provided message rate:

```
- name: CONF_SERVO_global_servo_const_log_sync_interval
  value: "-2"
```

In the above example, a fixed message rate of 4 packets per seconds will be used (logSyncInterval of "-2").

> ⚠ While the servo was tested to produce stable results with various packets rates (2, 4, 8, 16, 32, 64, 128), it is only officially recommended for use in deployments using a packet rate of 16 packets per second.

8.6.5.10 VLAN Tagging

DOCA Firefly natively supports VLAN-tagging-enabled network interfaces.

8.6.5.10.1 Separated Mode

The name of the VLAN-enabled network interface should be the one passed through the YAML file in the `PTP_INTERFACE` field.

8.6.5.10.2 Embedded Mode

In addition to passing on the VLAN-enabled interface through the YAML as listed in the previous section, the user is also required to configure the network routing within the DPU to support the VLAN tagging:

1. The following example configures a VLAN tag of 10 to the `enp3s0f0s4` interface:

   ```
   $ sudo ip link add link enp3s0f0s4 name enp3s0f0s4.10 type vlan id 10
   $ sudo ip link set up enp3s0f0s4.10
   $ sudo ifconfig enp3s0f0s4.10 192.168.104.1 up
   ```

   In this example, `enp3s0f0s4.10` is the interface to be passed to DOCA Firefly.
2. Additional commands to route the traffic within the DPU:

   ```
   $ sudo ovs-ofctl add-flow uplink in_port=en3f0pf0sf4,dl_vlan=10,actions=output:p0
   $ sudo ovs-ofctl add-flow uplink in_port=p0,dl_vlan=10,actions=output:en3f0pf0sf4
   ```

8.6.5.11 Multiple Interfaces

DOCA Firefly can support multiple network interfaces through the following YAML file syntax:

```
- name: PTP_INTERFACE
  value: "<space (' ') separated list of interface names>"
```

For example:

```
- name: PTP_INTERFACE
  value: "p0 p1"
```

⚠ The monitoring feature is supported for multiple interfaces only when the `clientOnly` configuration is enabled.

⚠ For Firefly versions lower than 1.7.0, automatic mode (`-a`) for `phc2sys` is not supported when working with multiple interfaces. It is recommended to disable `phc2sys` in this mode.

8.6.6 Troubleshooting

When troubleshooting container deployment issues, it is highly recommended to follow the deployment steps and tips in the "Review Container Deployment" section of the NVIDIA DOCA Container Deployment Guide.

To debug the finalized configuration file used by Firefly, users can connect to the container as follows:

1. Open a shell session on the running container using the container ID:

```
sudo crictl exec -it <container-id> /bin/bash
```

2. Once connected to the container, the finalized configuration file can be found under the `/tmp` directory using the same filename as the original configuration file.

> More information regarding the configuration files can be found under section "Ensuring and Debugging Correctness of Config File".

8.6.6.1 Pod is Marked as "Ready" and No Container is Listed

8.6.6.1.1 Error

When deploying the container, the pod's STATE is marked as `Ready`, an image is listed, however no container can be seen running:

```
$ sudo crictl pods
POD ID              CREATED             STATE               NAME                                NAMESPACE
ATTEMPT             RUNTIME
06bd84c07537e       4 seconds ago       Ready               doca-firefly-my-dpu                 default
0                   (default)

$ sudo crictl images
IMAGE                               TAG                 IMAGE ID            SIZE
k8s.gcr.io/pause                    3.2                 2a060e2e7101d       251kB
nvcr.io/nvidia/doca/doca_firefly    1.1.0-doca2.0.2     134cb22f34611       87.4MB

$ sudo crictl ps
CONTAINER           IMAGE               CREATED             STATE               NAME                ATTEMPT
POD ID              POD
```

8.6.6.1.2 Solution

In most cases, the container did start, but immediately exited. This could be checked using the following command:

```
$ sudo crictl ps -a
CONTAINER           IMAGE               CREATED             STATE               NAME                ATTEMPT
POD ID              POD
```

```
556bb78281e1d       134cb22f34611       7 seconds ago       Exited              doca-firefly            1
          06bd84c07537e       doca-firefly-my-dpu
```

Should the container fail (i.e., state of `Exited`) it is recommended to examine Firefly's main log at `/var/log/doca/firefly/firefly.log`.

In addition, for a short period of time after termination, the container logs could also be viewed using the the container's ID:

```
$ sudo crictl logs 556bb78281e1d
Starting DOCA Firefly - Version 1.1.0
...
Requested the following PTP interface: p10
Failed to find interface "p10". Aborting
```

8.6.6.2 Custom Config File is Not Found

8.6.6.2.1 Error

When DOCA Firefly is deployed using a custom configuration file, a deployment error occurs and the following log message appears:

```
...
2023-09-07 14:04:23 - Firefly - Init    - ERROR    - Custom config file not found: my_file.conf. Aborting
...
```

8.6.6.2.2 Solution

Check the custom file name written in the YAML file and make sure that you properly placed the file with that name under the `/etc/firefly/` directory of the DPU.

8.6.6.3 Profile is Not Supported

8.6.6.3.1 Error

When DOCA Firefly is deployed, a deployment error occurs and the following log message appears:

```
...
2023-09-07 14:04:23 - Firefly - Init    - ERROR    - profile <name> is not supported. Aborting
...
```

8.6.6.3.2 Solution

Verify that the profile selected in the YAML file matches one of the supported profiles as listed in the profiles table.

> ⚠ The profile name is case sensitive. The name must be specified in lower-case letters.

8.6.6.4 PPS Capability is Missing

8.6.6.4.1 Error

When DOCA Firefly is deployed and configured to use the `PPS` module, a deployment error occurs and the following log message appears:

```
...
2023-09-07 14:04:23 - Firefly - Init    - INFO     - Starting PPS configuration
2023-09-07 14:04:23 - Firefly - Init    - WARNING  - [-] PPS capability is missing, seems that the card doesn't
support PPS
2023-09-07 14:04:23 - Firefly - Init    - INFO     - capabilities:
2023-09-07 14:04:23 - Firefly - Init    - INFO     -   50000000 maximum frequency adjustment (ppb)
2023-09-07 14:04:23 - Firefly - Init    - INFO     -   0 programmable alarms

8.6.6.4.2 Solution

This log indicates that the DPU hardware does not support PPS. However, PTP can still run on this hardware, and you should see the line `Running ptp4l` in the container log, indicating that PTP is running successfully.

8.6.6.5 Timed Out While Polling for Tx Timestamp

8.6.6.5.1 Error

When the BlueField is operating in DPU mode, DOCA Firefly gets stuck in a fault loop while waiting to receive the Tx timestamp events:

```
ptp4l[2912.797]: timed out while polling for tx timestamp
ptp4l[2912.797]: increasing tx_timestamp_timeout may correct this issue, but it is likely caused by a driver bug
ptp4l[2912.797]: port 1 (enp3s0f0s4): send sync failed
ptp4l[2923.528]: timed out while polling for tx timestamp
ptp4l[2923.528]: increasing tx_timestamp_timeout may correct this issue, but it is likely caused by a driver bug
```

```
ptp4l[2923.528]: port 1 (enp3s0f0s4): send sync failed
```

DOCA Firefly has a known gap leading to this error appearing once, after which ptp4l recovers from it. This section only covers the case in which there is a fault loop and no recovery occurs.

8.6.6.5.2 Solution

DOCA Firefly's configurations were already adjusted to accommodate for Tx port timestamping. For more information about the reason for this error and for the designed recovery mechanism from it, refer to section "Tx Timestamping Support on DPU Mode".

8.6.6.6 Warning – Time Jumped Backwards

8.6.6.6.1 Error

When using Firefly's Servo module, the following warning log message is encountered on start:

```
 2024-01-01 14:04:23 - Firefly - SERVO   - WARNING  - Clock is going to jump backwards in time - this might have a
system-wide impact
```

8.6.6.6.2 Solution

This warning message indicates that the system's time jumped backwards with a value of at least one minute. This event is logged by Firefly given that such jumps might have system-wide implications. For more information, refer to section "Failed to Reserve Sandbox Name" in the DOCA Troubleshooting.

Such jumps can only happen during Firefly's boot, before the Servo achieves initial time synchronization with the reference clock.

8.6.7 PTP Profile Default Config Files

8.6.7.1 Media Profile

```
#

8.6.8 Firefly Modules Configuration Options

8.6.8.1 PTP Monitor

8.6.8.1.1 monitor-default.conf

```
#
# Default values for all of Firefly's PTP monitor configuration values.
#

[global]
# General
report_interval                     1000
# Debugging & Logging
doca_logging_level                    50
telemetry_export                       0
```

8.6.8.1.2 Configuration Options

- `report_interval` – The time interval (in msecs) for when the monitor should publish a report to all defined output providers (standard output, gRPC clients, etc). Default: 1000 (1 second).
- `doca_logging_level` – Logging level for the module, based on DOCA's logging levels. Default is 50 (INFO). Valid options:
  - 10=DISABLE
  - 20=CRITICAL
  - 30=ERROR
  - 40=WARNING
  - 50=INFO
  - 60=DEBUG
- `telemetry_export` – Indicates whether monitor information should be exported through DOCA Telemetry Service. Valid options:
  - 0=Disabled (default)
  - 1=Enabled

8.6.8.2 Firefly Servo

8.6.8.2.1 servo-default.conf

```
#
# Default values for all of Firefly's servo configuration values
```

```
#

[global]
# Time thresholds
init_offset_from_master_threshold   10000000
offset_from_master_min_threshold       -1500
offset_from_master_max_threshold        1500
init_max_time_adjustment                   0
max_time_adjustment                     1500
step_adjustment_threshold                  0
hold_over_timer                            0
# Sampling Window & servo logic
warmup_period                           1500
sync_filter_length                         6
delay_request_filter_length                6
servo_adjustment_interval                  4
servo_init_adjustment_interval            24
servo_const_log_sync_interval           0xFF
servo_window_min_samples                   2
servo_num_offset_values                    5
servo_pi_cutoff_frequency             0.0159
servo_pi_dumping_factor                 7.85

# Debugging & Logging
summary_interval                        2000
doca_logging_level                        50
free_running                               0
```

8.6.8.2.2 Configuration Options

- `init_offset_from_master_threshold` – Minimal threshold (in nsecs) for switching to PI servo on init. Default is 10000000 (10 msecs).
- `offset_from_master_min_threshold` – Minimal threshold (in nsecs) for declaring time offset from the master clock as "stable". Default is -1500 (-1.5 µsecs).
- `offset_from_master_max_threshold` – Maximal threshold (in nsecs) for declaring time offset from the master clock as "stable". Default is +1500 (+1.5 µsecs).
- `init_max_time_adjustment` – When active, defines the maximal allowed time (step) adjustment (in nsecs) before the servo reaches the "locked" state. Default is 0 (disabled).
- `max_time_adjustment` – When active, defines the maximal allowed reference time adjustment (in nsecs) after the servo has reached the "locked" state. Default is 1500 (1.5 µsecs).
- `step_adjustment_threshold` – When active, defines the thresholds above which a time (step) adjustment (in nsecs) would be allowed, even after the servo has reached the "locked" state. Default is 0 (disabled).
- `hold_over_timer` – When active, defines the time duration (in seconds) in which the servo stays in "hold over" mode, until reverting back to "free running". Default is 0 ("hold over" state is disabled).
- `warmup_period` – Time span (in msecs) during which samples are collected to estimate the `logSyncInterval` value (packet rate). Default is 1500 (1.5 seconds).
- `sync_filter_length` – Number of `SYNC` messages in the servo's history buffer. Default is 6.
- `delay_request_filter_length` – Number of `DELAY_REQUEST` messages in the servo's history buffer. Default is 6 messages.

- `servo_adjustment_interval` – Number of `SYNC` messages after which the PHC is updated once the servo has reached the "locked" state at least once. Default is 4 messages.
- `servo_init_adjustment_interval` – Number of `SYNC` messages after which the PHC is updated before the servo has ever reached the "locked" state. Default is 24 messages.
- `servo_const_log_sync_interval` – Known fixed value to be used as the `logSyncInterval` instead of trying to estimate it at runtime. Default is 0xFF (disabled).
- `servo_window_min_samples` – Minimal number of samples needed for a servo calculation. Default is 2 messages.
- `servo_num_offset_values` – Number of consecutive timestamps within the "offset from master" threshold that are required so to transition from the "locked" state and to the "locked stable" state. Default is 5 offset values.
- `servo_pi_cutoff_frequency` – The PI servo's cutoff frequency value. Default is 0.0159.
- `servo_pi_dumping_factor` – The PI servo's dumping factor value. Default is 7.85.
- `summary_interval` – The time interval (in msecs) for when the servo should publish a report log event. Default is 2000 (2 seconds).
- `doca_logging_level` – Logging level for the module, based on DOCA's logging levels. Default is 50 (INFO). Valid options:
  - 10=DISABLE
  - 20=CRITICAL
  - 30=ERROR
  - 40=WARNING
  - 50=INFO
  - 60=DEBUG
- `free_running` – Tell the servo to only log the operations, without actually adjusting the PHC. Default is 0 (disabled).

8.7 DOCA Flow Inspector Service Guide

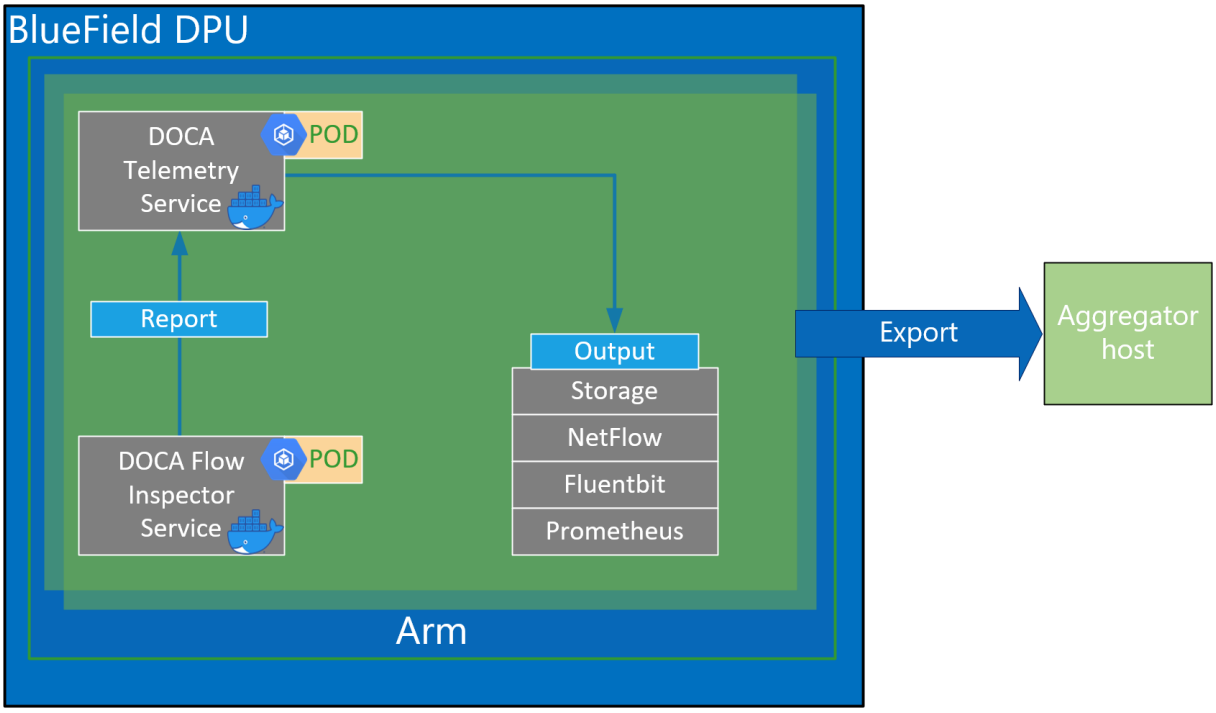
This guide provides instructions on how to use the DOCA Flow Inspector service container on top of NVIDIA® BlueField® DPU.

8.7.1 Introduction

DOCA Flow Inspector service enables real-time data monitoring and extraction of telemetry components. These components can be leveraged by various services, including those focused on security, big data, and other purposes.

DOCA Flow Inspector service is linked to DOCA Telemetry Service (DTS). It receives mirrored packets from the user parses the data, and forwards it to the DTS, which aggregates predefined statistics from various providers and sources. The service utilizes the DOCA Telemetry Exporter API to communicate with the DTS, while the DPDK infrastructure facilitates packet acquisition at a user-space layer.

DOCA Flow Inspector operates within its dedicated Kubernetes pod on BlueField, aimed at receiving mirrored packets for analysis. The received packets are parsed and transmitted, in a predefined structure, to a telemetry collector that manages the remaining telemetry aspects.



8.7.1.1 Service Flow

The DOCA Flow Inspector receives a configuration file in a JSON format which includes which of the mirrored packets should be filtered and which information should be sent to DTS for inspection.

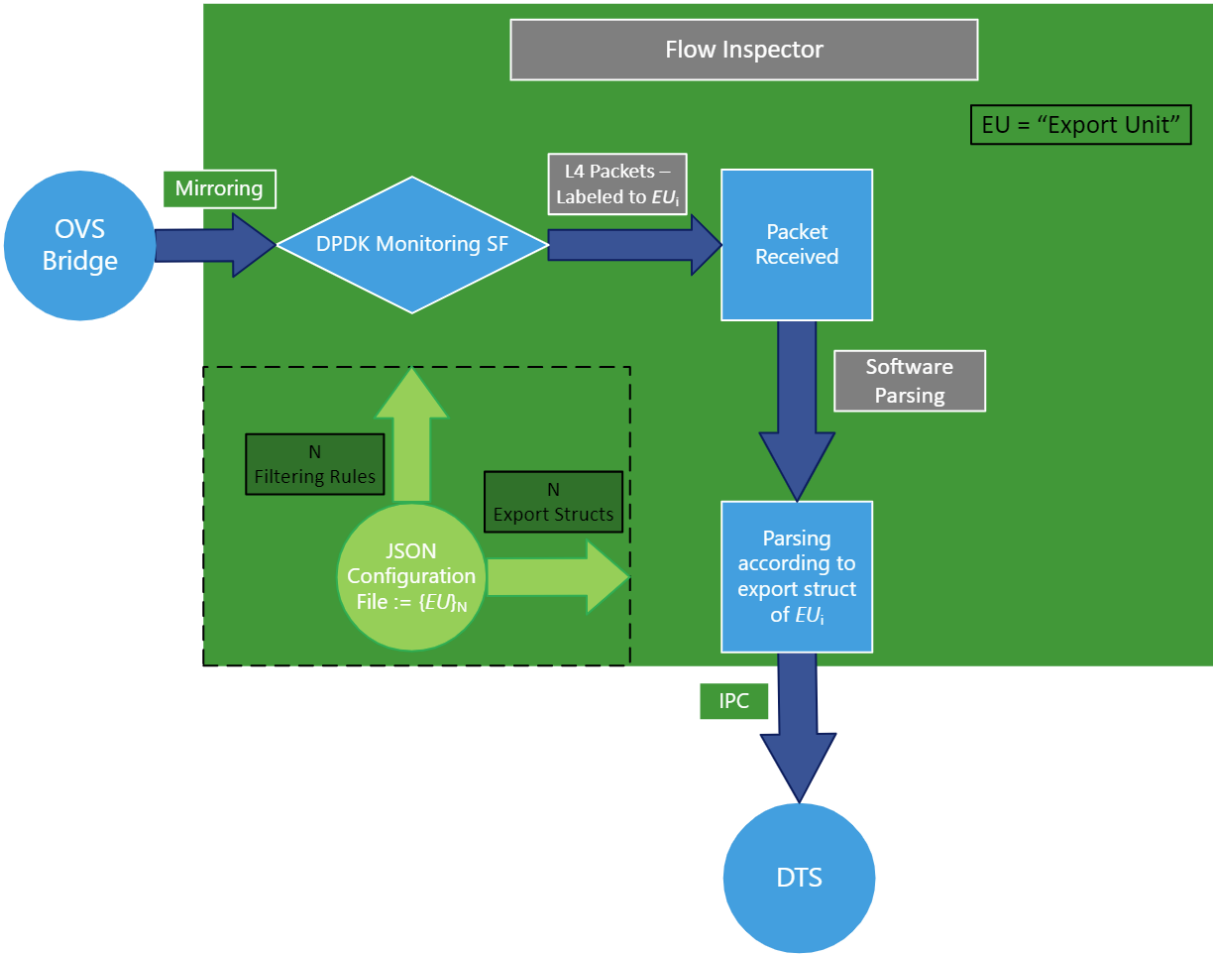
The configuration file can include several export units under the "export-units" attribute. Each one is comprised of a "filter" and an "export". Each packet that matches one filter (based on the protocol and ports in the L4 header) is then parsed to the corresponding

requested struct defined in the export. That information only is sent for inspection. A packet that does not match any filter is dropped.

In addition, the configuration file could contain FI optional configuration flags, see JSON format and example in the Configuration section.

The service watches for changes in the JSON configuration file in runtime and for any change that reconfigures the service.

The DOCA Flow Inspector runs on top of DPDK to acquire L4. The packets are then filtered and HW-marked with their export unit index. The packets are then parsed according to their export unit and export struct, and then forwarded to the telemetry collector using IPC.



Configuration phase:

1. A JSON file is used as input to configure the export units (i.e., filters and corresponding export structs).
2. The filters are translated to HW rules on the SF (scalable function port) using the DOCA Flow library.
3. The connection to the telemetry collector is initialized and all export structures are registered to DTS.

Inspection phase:

1. Traffic is mirrored to the relevant SF.
2. Ingress traffic is received through the configured SF.
3. Non-L4 traffic and packets that do not match any filter are dropped using hardware rules.
4. Packets matching a filter are marked with the export unit index they match and are passed to the software layer in the Arm cores.
5. Packets are parsed to the desired struct by the index of export unit.
6. The telemetry information is forwarded to the telemetry agent using IPC.
7. Mirrored packets are freed.
8. If the JSON file is changed, run the configuration phase with the updated file.

8.7.2 Requirements

Before deploying the flow inspector container, ensure that the following prerequisites are satisfied:

1. Create the needed files and directories. Folders should be created automatically. Make sure the `.json` file resides inside the folder:

   ```
   $ touch /opt/mellanox/doca/services/flow_inspector/bin/flow_inspector_cfg.json
   ```

   Validate that DTS's configuration folders exist. They should be created automatically when DTS is deployed.

   ```
   $ sudo mkdir -p /opt/mellanox/doca/services/telemetry/config
   $ sudo mkdir -p /opt/mellanox/doca/services/telemetry/ipc_sockets
   $ sudo mkdir -p /opt/mellanox/doca/services/telemetry/data
   ```

2. Allocate huge pages as needed by DOCA Flow:

   ```
   $ echo '1024' | sudo tee -a /sys/kernel/mm/hugepages/hugepages-2048kB/nr_hugepages
   $ sudo mkdir /mnt/huge
   $ sudo mount -t hugetlbfs -o pagesize=2M nodev /mnt/huge
   ```

   Deploy a scalable function according to BlueField Scalable Function User Guide and mirror packets accordingly using the Open vSwitch command.
   For example:

   a. Mirror packets from `p0` to `sf4`:

   ```
   $ ovs-vsctl add-br ovsbr1
   $ ovs-vsctl add-port ovsbr1 p0
   $ ovs-vsctl add-port ovsbr1 en3f0pf0sf4
   $ ovs-vsctl -- --id=@p1 get port en3f0pf0sf4 \
               -- --id=@p2 get port p0 \
               -- --id=@m create mirror name=m0 select-dst-port=@p2 select-src-port=@p2 output-
   port=@p1 \
               -- set bridge ovsbr1 mirrors=@m
   ```

   b. Mirror packets from `pf0hpf` or `p0` that pass through `sf4`:

   ```
   $ ovs-vsctl add-br ovsbr1
   ```

```
$ ovs-vsctl add-port ovsbr1 pf0hpf
$ ovs-vsctl add-port ovsbr1 p0
$ ovs-vsctl add-port ovsbr1 en3f0pf0sf4
$ ovs-vsctl -- --id=@p1 get port en3f0pf0sf4 \
           -- --id=@p2 get port pf0hpf \
           -- --id=@m create mirror name=m0 select-dst-port=@p2 select-src-port=@p2 output-
port=@p1 \
           -- set bridge ovsbr1 mirrors=@m
$ ovs-vsctl -- --id=@p1 get port en3f0pf0sf4 \
           -- --id=@p2 get port p0 \
           -- --id=@m create mirror name=m0 select-dst-port=@p2 select-src-port=@p2 output-
port=@p1 \
           -- set bridge ovsbr1 mirrors=@m
```

The output of last command (creating the mirror) should output a sequence of letters and numbers similar to the following:

```
0d248ca8-66af-427c-b600-af1e286056e1
```

⚠ The designated SF must be created as a trusted function. Additional details can be found in the BlueField Scalable Function User Guide.

8.7.3 Service Deployment

For information about the deployment of DOCA containers on top of the BlueField DPU, refer to NVIDIA DOCA Container Deployment Guide.

DTS is available on NGC, NVIDIA's container catalog. Service-specific configuration steps and deployment instructions can be found under the service's container page.

⚠ The order of running DTS and DOCA Flow Inspector is important. You must launch DTS, wait a few seconds, and then launch DOCA Flow Inspector.

8.7.4 Configuration

8.7.4.1 JSON Input

The DOCA Flow Inspector configuration file should be placed under `/opt/mellanox/doca/services/flow_inspector/bin/<json_file_name>.json` and be built in the following format:

```
{
    /* Optional param, time period to check for changes in JSON config file (in seconds) and flush telemetry buffer
if enabled (default is 60 seconds) */
    "config-sample-rate": <time>,

    /* Optional param, telemetry buffer size in bytes (default is 60KB) */
    "telemetry-buffer-size": <size>,

    /* Optional param, enable periodic telemetry buffer flush and defining the period time (in seconds) */
    "telemetry-flush-rate": <numeric value in seconds>,

    /* Mandatory param, Flow Inspector export units */
```

```
    "export-units":
    [

        /* Export Unit 0 */
        {
            "filter":
            {     "protocols": [<L4 protocols separated by comma>], # What L4 protocols are allowed
                  "ports":
                    [
                            [<source port>, <destination port>],
                            [<source ports range>, <destination ports range>],
                            <... more pairs of source, dest ports>
                    ]
            },
            "export":
            {
                    "fields": [<fields to be part of export struct, separated by comma>] # the Telemetry event will
contain these fields.

            }
        },
        <... More Export Units>
    ]
}
```

8.7.4.1.1 Export Unit Attributes

Allowed protocols:

- `"TCP"`
- `"UDP"`

Port range:

- It is possible to insert a range of ports for both source and destination
- Range should include borders `[start_port-end_port]`

Allowed ports:

- All ports in range `0` - `65535` as a string
- Or `*` to indicate any ports

Allowed fields in export struct:

- `timestamp` – timestamp indicating when it was received by the service
- `host_ip` – the IP of the host running the service
- `src_mac` – source MAC address
- `dst_mac` – destination MAC address
- `src_ip` – source IP
- `dst_ip` – destination IP
- `protocol` – L4 protocol
- `src_port` – source port
- `dst_port` – destination port
- `flags` – additional flags (relevant to TCP only)
- `data_len` – data payload length
- `data_short` – short version of data (payload sliced to first 64 bytes)
- `data_medium` – medium version of data (payload sliced to first 1500 bytes)

- `data_long` – long version of data (payload sliced to first 9*1024 bytes)

JSON example:

```
{

    /* Optional param, time period to check for changes in JSON config file (in seconds) and flush telemetry buffer
if enabled (default is 60 seconds) */
    "config-sample-rate": 30,

    /* Optional param, telemetry maximum buffer size in bytes */
    "telemetry-buffer-size": 70000,

    /* Optional param, enable periodic telemetry buffer flush and defining the period time (in seconds) */
    "telemetry-flush-rate": 1.5,

   /* Mandatory param, Flow Inspector export units */
    "export-units":
    [

        /* Export Unit 0 */
        {
            "filter":
            {
                "protocols": ["tcp", "udp"],
                "ports":
                    [
                        ["*","433-460"],
                        ["20480","28341"],
                        ["28341","20480"],
                        ["68", "67"],
                        ["67", "68"]
                    ]
            },
            "export":
            {
                "fields": ["timestamp", "host_ip", "src_mac", "dst_mac", "src_ip", "dst_ip", "protocol",
"src_port",
                    "dst_port", "flags", "data_len", "data_long"]
            }
        },

        /* Export Unit 1 */
        {
            "filter":
            {
                "protocols": ["tcp"],
                "ports":
                    [
                        ["5-10","422"],
                        ["80","80"]
                    ]
            },
            "export":
            {
                "fields": ["timestamp","dst_ip", "host_ip", "data_len", "flags", "data_medium"]
            }
        }
    ]
}
```

If a packet header contains L4 ports or L4 protocol which are not specified in any filter, they are filtered out.

8.7.4.2 Yaml File

The `.yaml` file downloaded from NGC can be easily edited according to your needs.

```
env:
  # Set according to the local setup
  - name: SF_NUM_1
    value: "2"    # Additional EAL flags, if needed
  - name: EAL_FLAGS
    value: ""    # Service-Specific command line arguments
  - name: SERVICE_ARGS
    value: "--policy /flow_inspector/flow_inspector_cfg.json -l 60"
```

- The `SF_NUM_1` value can be changed according to the SF used in the OVS configuration and can be found using the command in BlueField Scalable Function User Guide.
- The `EAL_FLAGS` value must be changed according to the DPDK flags required when running the container.
- The `SERVICE_ARGS` are the runtime arguments received by the service:
  - `-l` , `--log-level <value>` – sets the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>
  - `-p` , `--policy <json_path>` – sets the JSON path inside the container

8.7.4.3 Verifying Output

Enabling write to data in the DTS allows debugging the validity of the DOCA Flow Inspector.

To allow DTS to write locally, uncomment the following line in `/opt/mellanox/doca/services/telemetry/config/dts_config.ini` :

```
#output=/data
```

> Any changes in `dts_config.ini` necessitate restarting the pod for the new settings to apply.

The schema folder contains JSON-formatted metadata files which allow reading the binary files containing the actual data. The binary files are written according to the naming convention shown in the following example:

> Requires installing the `tree` runtime utility (`apt install tree`).

```
$ tree /opt/mellanox/doca/services/telemetry/data/
/opt/mellanox/doca/services/telemetry/data/
    {year}
        {mmdd}
             {hash}
                  {source_id}
                      {source_tag}{timestamp}.bin
                  {another_source_id}
                       {another_source_tag}{timestamp}.bin
    schema
        schema_{MD5_digest}.json
```

New binary files appear when:

- The service starts
- When the binary file's max age/size restriction is reached
- When JSON file is changed and new schemas of telemetry are created

- An hour passes

If no schema or no data folders are present, refer to the Troubleshooting section in DOCA Telemetry Service Guide.

> ⚠ `source_id` is usually set to the machine hostname. `source_tag` is a line describing the collected counters, and it is often set as the provider's name or name of user-counters.

Reading the binary data can be done from within the DTS container using the following command:

```
crictl exec -it <Container-ID> /opt/mellanox/collectx/bin/clx_read -s /data/schema /data/path/to/datafile.bin
```

The data written locally should be shown in the following format assuming a packet matching Export Unit 1 from the example has arrived:

```
{
    "timestamp": 1656427771076130,
    "host_ip": "10.237.69.238",
    "src_ip": "11.7.62.4",
    "dst_ip": "11.7.62.5",
    "data_len": 1152,
    "data_short": "Hello World"
}
```

8.7.5 Troubleshooting

When troubleshooting container deployment issues, it is highly recommended to follow the deployment steps and tips in the "Review Container Deployment" section of the NVIDIA DOCA Container Deployment Guide.

8.7.5.1 Pod is Marked as "Ready" and No Container is Listed

8.7.5.1.1 Error

When deploying the container, the pod's STATE is marked as `Ready`, an image is listed, however no container can be seen running:

```
$ sudo crictl pods
POD ID              CREATED             STATE               NAME
NAMESPACE           ATTEMPT             RUNTIME
3162b71e67677       4 seconds ago       Ready               doca-flow-inspector-my-dpu                      default
0                   (default)

$ sudo crictl images
IMAGE                                TAG                 IMAGE ID            SIZE
k8s.gcr.io/pause                     3.2                 2a060e2e7101d       487kB
nvcr.io/nvidia/doca/doca_flow_inspector   1.1.0-doca2.0.2     2af1e539eb7ab       86.8MB

$ sudo crictl ps
```

```
CONTAINER           IMAGE               CREATED             STATE               NAME                ATTEMPT
POD ID              POD
```

8.7.5.1.2 Solution

In most cases, the container did start, but immediately exited. This could be checked using the following command:

```
$ sudo crictl ps -a
CONTAINER           IMAGE               CREATED             STATE               NAME                ATTEMPT
POD ID              POD
556bb78281e1d       2af1e539eb7ab       6 seconds ago       Exited              doca-flow-inspector      1
          3162b71e67677       doca-flow-inspector-my-dpu
```

Should the container fail (i.e., state of `Exited`), it is recommended to examine the Flow Inspector's main log at `/var/log/doca/flow_inspector/flow_inspector_fi_dev.log`.

In addition, for a short period of time after termination, the container logs could also be viewed using the container's ID:

```
$ sudo crictl logs 556bb78281e1d
...
2023-10-04 11:42:55 - flow_inspector - FI     - ERROR    - JSON file was not found <config-file-path>.
```

8.7.5.2 Pod is Not Listed

8.7.5.2.1 Error

When placing the container's YAML file in the Kubelet's input folder, the service pod is not listed in the list of pods:

```
$ sudo crictl pods
POD ID              CREATED             STATE               NAME
NAMESPACE           ATTEMPT             RUNTIME
```

8.7.5.2.2 Solution

In most cases, the pod does not start due to the absence of the requested hugepages. This can be verified using the following command:

```
$ sudo journalctl -u kubelet -e. . .
Oct 04 12:12:19 <my-dpu> kubelet[2442376]: I1004 12:12:19.905064 2442376 predicate.go:103] "Failed to admit pod,
unexpected error while attempting to recover from admission failure" pod="default/doca-flow-inspector-<my-dpu>"
 err="preemption: error finding a set of pods to preempt: no set of running pods found to reclaim resources: [(res:
hugepages-2Mi, q: 104563999874), ]"
```

8.8 DOCA HBN Service Guide

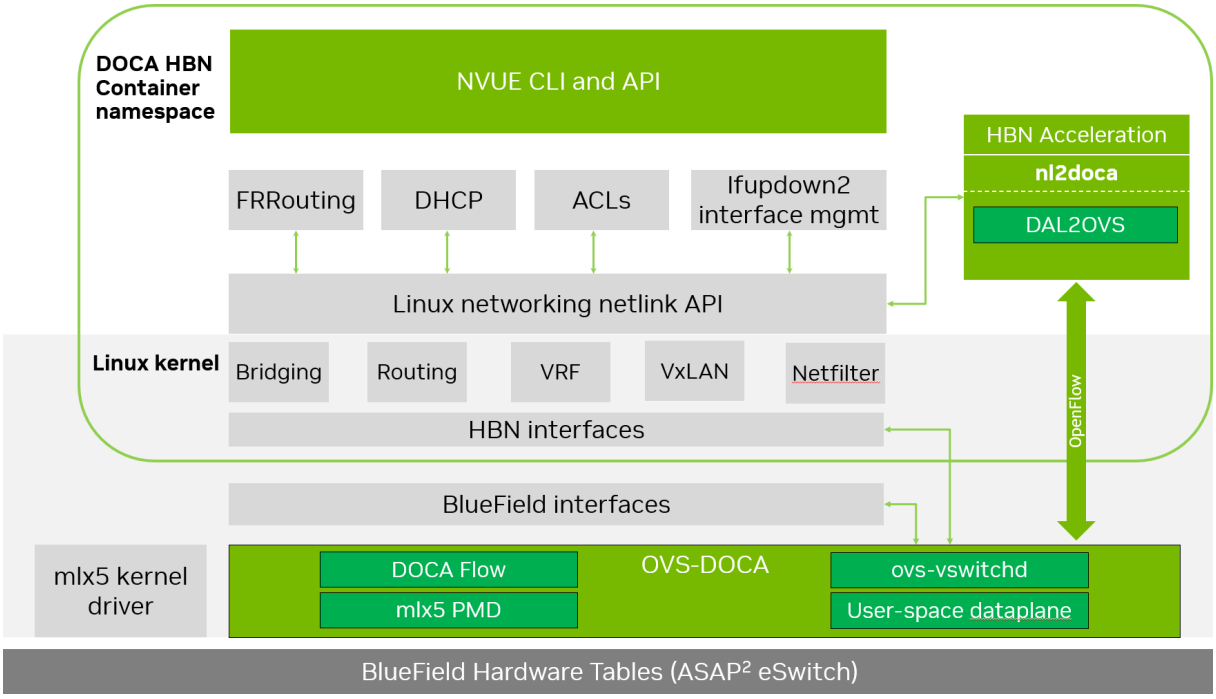
This guide provides instructions on how to use the DOCA HBN Service container on top of NVIDIA® BlueField® networking platform.

8.8.1 Introduction

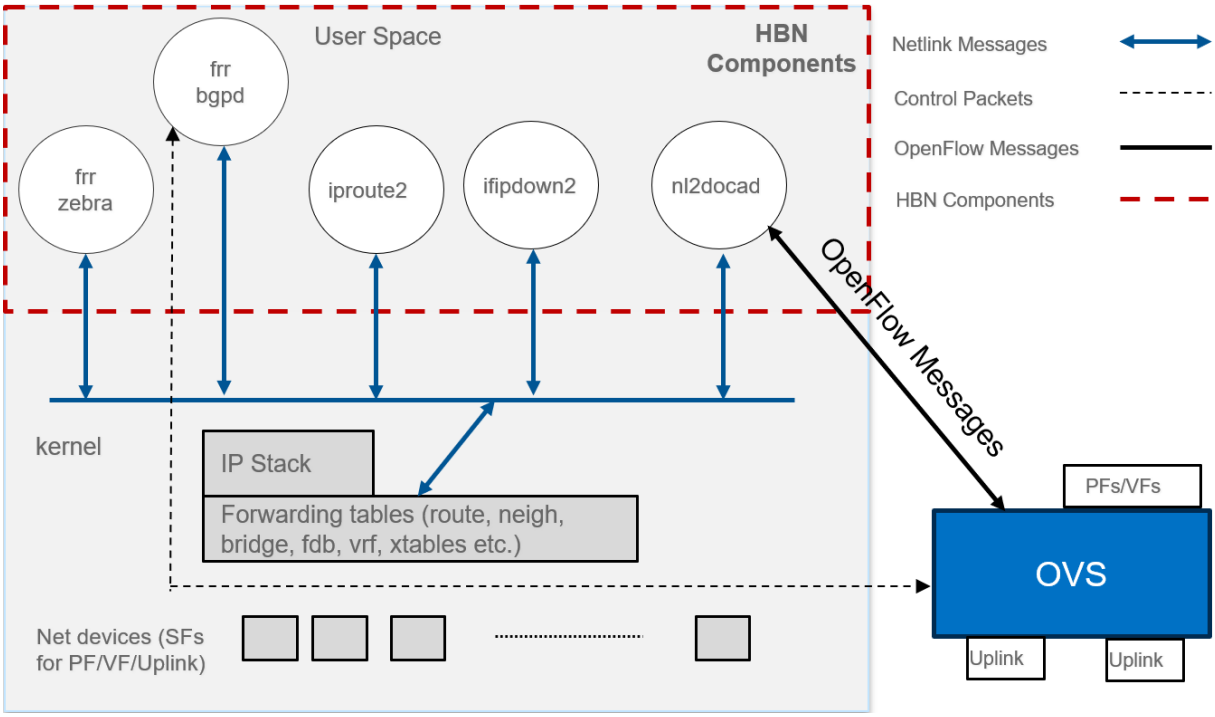
Host-based Networking (HBN) is a DOCA service that allows network architects to design networks based on layer-3 (L3) protocols. HBN enables routing to run on the server side by using BlueField as a BGP router. The HBN solution encapsulates a set of network functions inside a container, which is deployed as a service pod on BlueField's Arm cores.

The HBN solution packages a set of network functions inside a container which, itself, is packaged as a service pod to be run on BlueField Arm. At the core of HBN is the Linux networking BlueField acceleration driver Netlink-to-DOCA, or nl2docad. This daemon seamlessly accelerates Linux networking using DOCA APIs to program specific packet processing rules in BlueField hardware.

The driver mirrors the Linux kernel routing and bridging tables into the BlueField hardware tables by discovering the configured Linux networking objects using the Linux Netlink API. Dynamic network flows, as learned by the Linux kernel networking stack, are also programmed by the driver into BlueField hardware by listening to Linux kernel networking events.



The following diagram captures an overview of HBN and the interactions between various components of HBN.



- ifupdown2 is the interface manager which pushes all the interface related states to kernel
- The routing stack is implemented in FRR and pushes all the control states (EVPN MACs and routes) to kernel via netlink
- Kernel maintains the whole network state and relays the information using netlink. The kernel is also involved in the punt path and handling traffic that does not match any rules in the eSwitch.
- nl2docad listens for the network state via netlink and invokes the DOCA interface to accelerate the flows in BlueField hardware tables. nl2docad also offloads these flows to eSwitch.

8.8.2 Service Function Chaining

HBN is a "bump-in-the-wire" service and requires specific network configuration on BlueField called service function chaining (SFC). SFC configuration is used to redirect network traffic, which is originated from or forwarded to the host or BlueField itself via the HBN data plane.

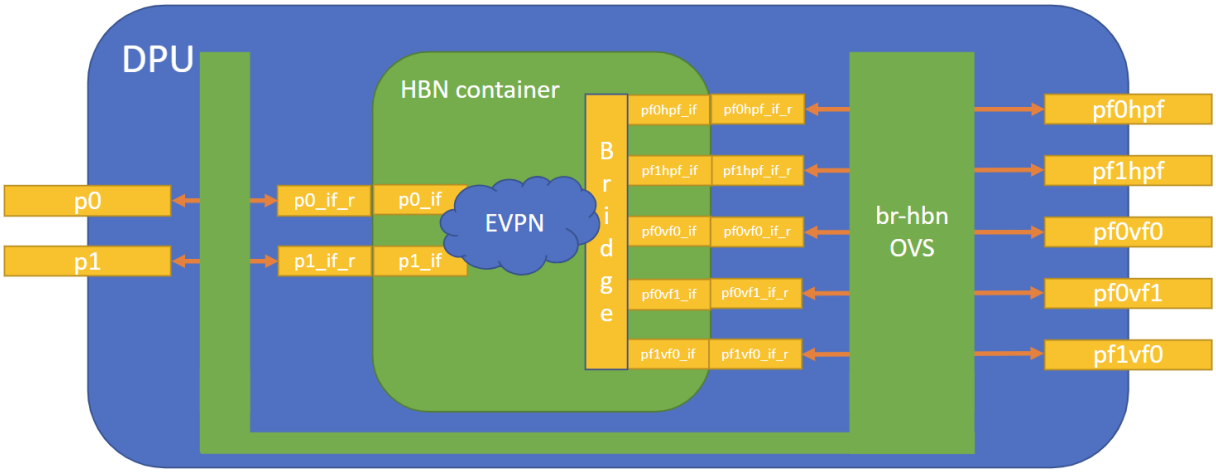
The diagram below shows the fully detailed default configuration for HBN with SFC.

In this setup, the HBN container is configured to use sub-function ports (SFs) instead of the actual uplinks, PFs and VFs. To illustrate, for example:

- Uplinks – use `p0_if` instead of `p0`

- PF – use `pf0hpf_if` instead of `pf0hpf`
- VF – use `pf0vf0_if` instead of `pf0vf0`

The indirection layer between the SF and the actual ports is managed via a `br-hbn` OVS bridge automatically configured when the BFB image is installed on BlueField with HBN enabled. This indirection layer allows other services to be chained to existing SFs and provide additional functionality to transit traffic.



8.8.3 HBN Service Release Notes

The following subsections provide information about new features, interoperability, known issues, and bug fixes.

8.8.3.1 Changes and New Features

HBN 3.3.0 offers the following new features and updates:

- Introduced resource scaling profiles to optimize CPU and memory usage. These profiles define specific resource limits based on scale targets, enabling efficient coexistence with other DPU services on NVIDIA® BlueField®-2 and NVIDIA® BlueField®-3 platforms

You can upgrade to this version from the previous HBN version.

8.8.3.2 Supported Platforms and Interoperability

8.8.3.2.1 Supported BlueField Networking Platforms

This version has been validated on the following NVIDIA BlueField networking platforms:

- BlueField-2 DPUs:
  - BlueField-2 P-Series DPU 25GbE Dual-Port SFP56; PCIe Gen4 x8; Crypto Enabled; 16GB on-board DDR; 1GbE OOB management; HHHL
  - BlueField-2 P-Series DPU 25GbE Dual-Port SFP56; integrated BMC; PCIe Gen4 x8; Secure Boot Enabled; Crypto Enabled; 16GB on-board DDR; 1GbE OOB management; FHHL
  - BlueField-2 P-Series DPU 25GbE Dual-Port SFP56; integrated BMC; PCIe Gen4 x8; Secure Boot Enabled; Crypto Enabled; 32GB on-board DDR; 1GbE OOB management; FHHL
  - BlueField-2 P-Series DPU 100GbE Dual-Port QSFP56; integrated BMC; PCIe Gen4 x16; Secure Boot Enabled; Crypto Enabled; 32GB on-board DDR; 1GbE OOB management; FHHL
- BlueField-3 DPUs:
  - BlueField-3 B3210E E-Series FHHL DPU; 100GbE (default mode) / HDR100 IB; Dual-port QSFP112; PCIe Gen5.0 x16 with x16 PCIe extension option; 16 Arm cores; 32GB on-board DDR; integrated BMC; Crypto Enabled
  - BlueField-3 B3220 P-Series FHHL DPU; 200GbE (default mode)/NDR200 IB; Dual-port QSFP112; PCIe Gen5.0 x16 with x16 PCIe extension option; 16 Arm cores; 32GB on-board DDR; integrated BMC; Crypto Enabled
  - BlueField-3 B3240 P-Series Dual-slot FHHL DPU; 400GbE/NDR IB (default mode); Dual-port QSFP112; PCIe Gen5.0 x16 with x16 PCIe extension option; 16 Arm cores; 32GB on-board DDR; integrated BMC; Crypto Enabled
- BlueField-3 SuperNICs:
  - BlueField-3 B3210L E-series FHHL SuperNIC, 100GbE (default mode)/ HDR100 IB, Dual port QSFP112, PCIe Gen4.0 x16, 8 Arm cores, 16GB on-board DDR, integrated BMC, Crypto Enabled
  - BlueField-3 B3220L E-Series FHHL SuperNIC, 200GbE (default mode)/ NDR200 IB, Dual-port QSFP112, PCIe Gen5.0 x16, 8 Arm cores, 16GB on-board DDR, integrated BMC, Crypto Enabled
  - BlueField-3 B3140L E-Series FHHL SuperNIC, 400GbE/NDR IB (default mode), Single-port QSFP112, PCIe Gen5.0 x16, 8 Arm cores, 16GB on-board DDR, integrated BMC, Crypto Enabled
  - BlueField-3 B3140H E-series HHHL SuperNIC, 400GbE (default mode)/NDR IB, Single-port QSFP112, PCIe Gen5.0 x16, 8 Arm cores, 16GB on board DDR, integrated BMC, Crypto Enabled

⚠ HBN does not support BlueField platforms with 8GB on-board DDR memory.

8.8.3.2.2 Supported BlueField OS

This version supports DOCA 3.3.0 (BSP 4.14.0) on Ubuntu 22.04 OS.

8.8.3.2.3 Verified Scalability Limits

This version has been tested to sustain the following maximum scalability limits:

Limit	BlueField-2	BlueField-3	Comments
VTEP peers (BlueFields per control plane) in the fabric	8K [1]	8K [1]	Number of BlueFields (VTEPs) within a single overlay fabric (reachable in the underlay)
L2 VNIs/Overlay networks per BlueField	20	20	Total number of L2 VNIs in the fabric for L2 VXLAN use-case assuming every interface is associated with its own VLAN + L2 VNI
L3 VNIs/Overlay networks per BlueField	20 for up to 4K VTEPs 10 for up to 8K VTEPs	20 for up to 4K VTEPs 10 for up to 8K VTEPs	Total number of L3 VNIs in the fabric for L3 VXLAN use-case assuming every interface is associated with its own VLAN + L2 VNI + L3 VNI + VRF
BlueFields per a single L2 VNI network	8K	8K	Total number of DPUs, configured with the same L2 VNI (3 real DPUs, 2000 emulated VTEPs)
BlueFields per a single L3 VNI network	8K	8K	Total number of DPUs, configured with the same L3 VNI (3 real DPUs, 2000 emulated VTEPs)
Maximum number of local MAC/ARP entries per BlueField	20	20	Max total number of MAC/ARP entries learned from the host on the DPU
Maximum number of local BGP routes per BlueField	200	200	Max total number of BGP routes advertised by the host to the BlueField (BGP peering with the host): 100 IPv4 + 100 IPv6
Maximum number of remote L3 LPM routes (underlay)	8K	8K	IPv4 or IPv6 underlay LPM routes per BlueField (default + host routes + LPM)
Maximum number of EVPN type-2 entries	16K	16K	Remote overlay MAC/IP entries for compute peers stored on a single BlueField (L2 EVPN)
Maximum number of EVPN type-5 entries	32K	80K	Remote overlay L3 LPM entries for compute peers stored on a single BlueField (L3 EVPN)
Maximum number of next-hops in ECMP next-hop group	16	16	Max number of next-hops in ECMP next-hop group (for overlay ECMP)
Maximum number of PFs on the host side	2	2	Total number of PFs visible to the host

Limit	BlueField-2	BlueField-3	Comments
Maximum number of VFs on the host side	16	16	Total number of VFs created on the host
Maximum number of SFs on the BlueField side	2	2	Total number of SF devices created on BlueField Arm

1. Tested with 4 VNIs

8.8.3.3 Known Issues

The following table lists known issues and limitations for this release of HBN.

4835913	Description: When the HBN container undergoes a forced restart (e.g., during a sudden host reboot), the standard graceful cleanup procedure may fail to execute. This failure leaves stale rules in the host's `iptables`. When the container subsequently restarts, these unexpected legacy rules conflict with the new setup, breaking the container's network configuration and routing.
	Workaround: Manually remove the IP Address Management (IPAM) container's IPv4 and IPv6 resource addresses to clear the conflicting network state before starting the container again.
	Keywords: Container restart; iptables; network configuration
	Reported in HBN Version: 3.4.0
4667419	Description: On systems running the Ubuntu 24.04 BFB image, restarting the HBN container may fail. This can result in `containerd` service errors or internal assertion failures (e.g., in the `nl2doca` service), preventing the container from functioning correctly.
	Workaround: When manually restarting the HBN container, you must introduce delays to allow for proper cleanup and initialization. Follow this sequence: 1. Remove `/etc/kubelet.d/doca_hbn.yaml` to stop the container. 2. Wait 150 seconds to ensure the container is fully stopped and resources are released. 3. Copy the file back to `/etc/kubelet.d/doca_hbn.yaml`. 4. Wait an additional 150 seconds before applying any new configurations or operations.
	Keywords: Restart; containerd; service
	Reported in HBN Version: 3.2.0
4703270	Description: Ubuntu 24.04 BFB image may intermittently see error logs on the terminal stating `Systemd Manager Object Allocation Failure - Permission Denied`.
	Workaround: N/A
	Keywords: Systemd; permission denied
	Reported in HBN Version: 3.2.0
4414582	Description: In L3 EVPN scenarios with 16k overlay and 4k underlay routes, OVS may get stuck or abnormally terminate.
	Workaround: Set: `ovs-vsctl set Open_vSwitch . other_config:doca-congestion-threshold=60`
	Keywords: L3 EVPN; 16k overlay; 4k underlay; OVS
	Reported in HBN Version: 2.5.0
4255661	Description: ARP packets between DPU and Outside Global which are forwarded using HBN are not hardware-offloaded.
	Workaround: N/A
	Keywords: ARP; outside world/global, HW offload
	Reported in HBN Version: 2.5.0
4255708	Description: When several ports are configured as part of a bridge and later reconfigured as L3 interfaces, only one port (the 1st port that was enslaved previously to bridge) is correctly reprogrammed as an L3 interface in nl2doca. The remaining ports continue to appear as bridged ports in nl2doca.
	Workaround: Restart the HBN container after unconfiguring the bridge ports and before reconfiguring them as L3 interfaces
	Keywords: Bridge port, L3 port
	Reported in HBN Version: 2.5.0
4193046	Description: When LLDP is enabled on BlueField, it might not work on uplink ports when the HBN service is running. This might happen if LLDP is running without an interface filter configuration.
	Workaround: Configure LLDP to run only on interfaces where LLDP is required, using a configuration file, `/etc/lldpd.d/ports.conf`, for the `lldpd` daemon. The interfaces can be specified using a regular expression, if required. For example: • To run LLDP only on the uplinks (`p0` and `p1`), configure it as follows: `$ cat /etc/lldpd.d/ports.conf`

4835913	Description: When the HBN container undergoes a forced restart (e.g., during a sudden host reboot), the standard graceful cleanup procedure may fail to execute. This failure leaves stale rules in the host's `iptables`. When the container subsequently restarts, these unexpected legacy rules conflict with the new setup, breaking the container's network configuration and routing.
	Workaround: Manually remove the IP Address Management (IPAM) container's IPv4 and IPv6 resource addresses to clear the conflicting network state before starting the container again.
	Keywords: Container restart; iptables; network configuration

	Keywords: Bridge port, L3 port
	Reported in HBN Version: 2.5.0
4193046	Description: When LLDP is enabled on BlueField, it might not work on uplink ports when the HBN service is running. This might happen if LLDP is running without an interface filter configuration.
	Workaround: Configure LLDP to run only on interfaces where LLDP is required, using a configuration file, `/etc/lldpd.d/ports.conf`, for the `lldpd` daemon. The interfaces can be specified using a regular expression, if required. For example: • To run LLDP only on the uplinks (`p0` and `p1`), configure it as follows: `$ cat /etc/lldpd.d/ports.conf`

4835913	Description: When the HBN container undergoes a forced restart (e.g., during a sudden host reboot), the standard graceful cleanup procedure may fail to execute. This failure leaves stale rules in the host's `iptables`. When the container subsequently restarts, these unexpected legacy rules conflict with the new setup, breaking the container's network configuration and routing.
	Workaround: Manually remove the IP Address Management (IPAM) container's IPv4 and IPv6 resource addresses to clear the conflicting network state before starting the container again.
	Keywords: Container restart; iptables; network configuration
	Reported in HBN Version: 3.4.0
4667419	Description: On systems running the Ubuntu 24.04 BFB image, restarting the HBN container may fail. This can result in `containerd` service errors or internal assertion failures (e.g., in the `nl2doca` service), preventing the container from functioning correctly.
	Workaround: When manually restarting the HBN container, you must introduce delays to allow for proper cleanup and initialization. Follow this sequence: 0. Remove `/etc/kubelet.d/doca_hbn.yaml` to stop the container. 0. Wait 150 seconds to ensure the container is fully stopped and resources are released. 0. Copy the file back to `/etc/kubelet.d/doca_hbn.yaml`. 0. Wait an additional 150 seconds before applying any new configurations or operations.
	Keywords: Restart; containerd; service

	Reported in HBN Version: 3.2.0
4414582	Description: In L3 EVPN scenarios with 16k overlay and 4k underlay routes, OVS may get stuck or abnormally terminate.
	Workaround: Set: `ovs-vsctl set Open_vSwitch . other_config:doca-congestion-threshold=60`
	Keywords: L3 EVPN; 16k overlay; 4k underlay; OVS
	Reported in HBN Version: 2.5.0
4255661	Description: ARP packets between DPU and Outside Global which are forwarded using HBN are not hardware-offloaded.
	Workaround: N/A
	Keywords: ARP; outside world/global, HW offload
	Reported in HBN Version: 2.5.0
4255708	Description: When several ports are configured as part of a bridge and later reconfigured as L3 interfaces, only one port (the 1st port that was enslaved previously to bridge) is correctly reprogrammed as an L3 interface in nl2doca. The remaining ports continue to appear as bridged ports in nl2doca.
	Workaround: Restart the HBN container after unconfiguring the bridge ports and before reconfiguring them as L3 interfaces
	Keywords: Bridge port, L3 port
	Reported in HBN Version: 2.5.0
4193046	Description: When LLDP is enabled on BlueField, it might not work on uplink ports when the HBN service is running. This might happen if LLDP is running without an interface filter configuration.
	Workaround: Configure LLDP to run only on interfaces where LLDP is required, using a configuration file, `/etc/lldpd.d/ports.conf`, for the `lldpd` daemon. The interfaces can be specified using a regular expression, if required. For example: • To run LLDP only on the uplinks (`p0` and `p1`), configure it as follows: `$ cat /etc/lldpd.d/ports.conf`

4835913	Description: When the HBN container undergoes a forced restart (e.g., during a sudden host reboot), the standard graceful cleanup procedure may fail to execute. This failure leaves stale rules in the host's `iptables`. When the container subsequently restarts, these unexpected legacy rules conflict with the new setup, breaking the container's network configuration and routing.
	Workaround: Manually remove the IP Address Management (IPAM) container's IPv4 and IPv6 resource addresses to clear the conflicting network state before starting the container again.
	Keywords: Container restart; iptables; network configuration
	Reported in HBN Version: 3.4.0
4667419	Description: On systems running the Ubuntu 24.04 BFB image, restarting the HBN container may fail. This can result in `containerd` service errors or internal assertion failures (e.g., in the `nl2doca` service), preventing the container from functioning correctly.
	Workaround: When manually restarting the HBN container, you must introduce delays to allow for proper cleanup and initialization. Follow this sequence: 0. Remove `/etc/kubelet.d/doca_hbn.yaml` to stop the container. 0. Wait 150 seconds to ensure the container is fully stopped and resources are released. 0. Copy the file back to `/etc/kubelet.d/doca_hbn.yaml`. 0. Wait an additional 150 seconds before applying any new configurations or operations.

	Reported in HBN Version: 2.5.0
4193046	Description: When LLDP is enabled on BlueField, it might not work on uplink ports when the HBN service is running. This might happen if LLDP is running without an interface filter configuration.
	Workaround: Configure LLDP to run only on interfaces where LLDP is required, using a configuration file, `/etc/lldpd.d/ports.conf`, for the `lldpd` daemon. The interfaces can be specified using a regular expression, if required. For example: • To run LLDP only on the uplinks (`p0` and `p1`), configure it as follows: `$ cat /etc/lldpd.d/ports.conf`

4835913	Description: When the HBN container undergoes a forced restart (e.g., during a sudden host reboot), the standard graceful cleanup procedure may fail to execute. This failure leaves stale rules in the host's `iptables`. When the container subsequently restarts, these unexpected legacy rules conflict with the new setup, breaking the container's network configuration and routing.
	Workaround: Manually remove the IP Address Management (IPAM) container's IPv4 and IPv6 resource addresses to clear the conflicting network state before starting the container again.
	Keywords: Container restart; iptables; network configuration
	Reported in HBN Version: 3.4.0
4667419	Description: On systems running the Ubuntu 24.04 BFB image, restarting the HBN container may fail. This can result in `containerd` service errors or internal assertion failures (e.g., in the `nl2doca` service), preventing the container from functioning correctly.
	Workaround: When manually restarting the HBN container, you must introduce delays to allow for proper cleanup and initialization. Follow this sequence: 0. Remove `/etc/kubelet.d/doca_hbn.yaml` to stop the container. 0. Wait 150 seconds to ensure the container is fully stopped and resources are released. 0. Copy the file back to `/etc/kubelet.d/doca_hbn.yaml`. 0. Wait an additional 150 seconds before applying any new configurations or operations.
	Keywords: Restart; containerd; service

4703270	Description: Ubuntu 24.04 BFB image may intermittently see error logs on the terminal stating `Systemd Manager Object Allocation Failure - Permission Denied`.
	Workaround: N/A
	Keywords: Systemd; permission denied
	Reported in HBN Version: 3.2.0
4414582	Description: In L3 EVPN scenarios with 16k overlay and 4k underlay routes, OVS may get stuck or abnormally terminate.
	Workaround: Set: `ovs-vsctl set Open_vSwitch . other_config:doca-congestion-threshold=60`
	Keywords: L3 EVPN; 16k overlay; 4k underlay; OVS
	Reported in HBN Version: 2.5.0
4255661	Description: ARP packets between DPU and Outside Global which are forwarded using HBN are not hardware-offloaded.
	Workaround: N/A
	Keywords: ARP; outside world/global, HW offload
	Reported in HBN Version: 2.5.0
4255708	Description: When several ports are configured as part of a bridge and later reconfigured as L3 interfaces, only one port (the 1st port that was enslaved previously to bridge) is correctly reprogrammed as an L3 interface in nl2doca. The remaining ports continue to appear as bridged ports in nl2doca.
	Workaround: Restart the HBN container after unconfiguring the bridge ports and before reconfiguring them as L3 interfaces
	Keywords: Bridge port, L3 port
	Reported in HBN Version: 2.5.0
4193046	Description: When LLDP is enabled on BlueField, it might not work on uplink ports when the HBN service is running. This might happen if LLDP is running without an interface filter configuration.
	Workaround: Configure LLDP to run only on interfaces where LLDP is required, using a configuration file, `/etc/lldpd.d/ports.conf`, for the `lldpd` daemon. The interfaces can be specified using a regular expression, if required. For example: • To run LLDP only on the uplinks (`p0` and `p1`), configure it as follows: `$ cat /etc/lldpd.d/ports.conf`

8.8.3.4 Bug Fixes

The following table lists the known issues which have been fixed for this release of HBN.

8.8.4 HBN Service Deployment

8.8.4.1 HBN Service Requirements

> For HBN hardware and software requirements, refer to the HBN Service Release Notes.

The following subsections describe specific prerequisites for the BlueField before deploying the DOCA HBN Service.

8.8.4.1.1 Enabling BlueField DPU Mode

HBN requires BlueField to work in either DPU mode or zero-trust mode of operation. Information about configuring BlueField modes of operation can be found under "BlueField Modes of Operation".

8.8.4.1.2 Enabling SFC

HBN requires SFC configuration to be activated on the BlueField before running the HBN service container. SFC allows for additional services/containers to be chained to HBN and provides additional data manipulation capabilities. SFC can be configured in 3 modes:

1. HBN-only mode – In this mode, one OVS bridge is created, `br-hbn`. All HBN-specific ports are added to this bridge. This is the default mode of operation. This mode is configured by setting `ENABLE_BR_HBN=yes` in `bf.cfg` and leaving `ENABLE_BR_SFC` to default.
2. Dual bridge mode – In this mode, 2 OVS bridges are created, `br-hbn` and `bf-sfc`. All HBN-specific ports are added to `bf-sfc` bridge and all these ports are patched into the `br-hbn` bridge. `bf-sfc` can be used to add various custom steering flows to direct traffic across different ports in the bridge. In this mode,

both `ENABLE_BR_SFC` and `ENABLE_BR_HBN` are set as to `yes`. `BR_HBN_XXX` parameters are not set and all ports are under `BR_SFC_XXX` variables.

3. Mixed mode – this is similar to the dual bridge model, except that ports can be assigned to either of the bridges (i.e., some ports in `br-hbn` and some in `br-sfc` bridge). In this mode, ports are under `BR_SFC_XXX` and `BR_HBN_XXX`.
   The use of the bridge `br-sfc` allows defining deployment-specific rules before or after HBN pipeline. User can add OpenFlow rules directly to `bf-sfc` bridge. If `ENABLE_BR_SFC_DEFAULT_FLOWS` is set to `yes`, make sure user rules are inserted at higher priority to make it effective.

The following table describes various `bf.cfg` parameters used to configure these modes as well as other parameters which assign ports to various bridges:

Parameter	Description	Mandatory	Default Value	Example
`ENABLE_BR_HBN`	Setting this parameter to `yes` enables the `br-hbn` bridge ⚠ This setting is necessary to work with HBN.	Yes	`no`	`ENABLE_BR_HBN=yes`
`ENABLE_BR_SFC`	Setting this parameter to `yes` enables the `br-sfc` bridge ℹ This is only needed when the second OVS bridge is required for custom steering flows.	No	`no`	`ENABLE_BR_SFC=no`
`BR_HBN_UPLINKS`	Uplinks added to `br-hbn` directly	No	`p0,p1`	`BR_HBN_UPLINKS="p0,p1"`
`BR_SFC_UPLINKS`	Uplinks added to `br-sfc` directly	No	`""`	`BR_SFC_UPLINKS=""`
`BR_HBN_REPS`	PFs and VFs added to `br-hbn` directly	No	`""`	`BR_HBN_REPS="pf0hpf,pf1hpf,pf0vf0-pf0vf12,pf1vf0-pf1vf4"`
`BR_SFC_REPS`	PFs and VFs added to `br-sfc` directly	No	`""`	`BR_SFC_REPS=""`
`BR_HBN_SFS`	DPU ports added to `br-hbn` directly. These ports are mostly service ports present on the DPU which require using HBN network offload services.	No	`""`	`BR_HBN_SFS=svc1,svc2`

Parameter	Description	Mandatory	Default Value	Example
`BR_SFC_SFS`	DPU ports added to `br-sfc` directly	No	`""`	`BR_SFC_SFS=svc1,svc2`
`BR_HBN_SFC_PATCH_PORTS`	Patch ports added to `br-sfc`. These are general purpose ports meant for muxing or demuxing of traffic across various PF/VF ports.	No		`BR_HBN_SFC_PATCH_PORTS=patch1`
`LINK_PROPAGATION`	Mapping of how link propagation should work. If nothing is provided, each uplink/PF/VF port reflects its status in its corresponding HBN port. For example, the status of p0 is reflected in `p0_if`.	No	Uplink/PF/VF to the corresponding HBN port	`LINK_PROPAGATION=""`
`ENABLE_BR_SFC_DEFAULT_FLOWS`	Provides default connectivity in the `br-sfc` bridge so each port can send traffic to its corresponding output port	No	`no`	`ENABLE_BR_SFC_DEFAULT_FLOWS=yes`
`HUGEPAGE_SIZE`	Sets the huge page size for DOCA-OVS to use. Only 2048 is tested for HBN, which is also the default value.	No	`2048`	`HUGEPAGE_SIZE=2048`

`HUGEPAGE_COUNT`	Sets the number of huge pages needed for the HBN application. The current default limit is 2048. When HBN is running with other services, this must be modified accordingly.
	The recommended upper limit for memory allocated to huge pages for HBN depends on the total memory available on the BlueField-3 DPU (assuming the default `HUGEPAGE_SIZE` of 2048 kB).
	• BlueField-3 with 16GB Memory:
	  • Recommended Limit: 5GB
	  • Configuration: `HUGEPAGE_COUNT=2560`
	• BlueField-3 with 32GB Memory:
	  • Recommended Limit: 10GB
	  • Configuration: `HUGEPAGE_COUNT=5120`
		No	`2048`	`HUGEPAGE_COUNT=2048`

Refer to section "HBN Deployment Configuration" for more information about port connectivity in each mode.

The following subsections provide additional information about SFC and instructions on enabling it during BlueField DOCA image installation.

8.8.4.1.2.1 Deploying BlueField DOCA Image with SFC from Host

For DOCA image installation on BlueField, the user should follow the instructions under DOCA Installation Guide for Linux with the following extra notes to enable BlueField for HBN setup:

1. Make sure link type is set to ETH under the "Installing Software on Host" section.
2. Add the following parameters to the `bf.cfg` configuration file:
    a. This configuration example is relevant for "HBN-only mode". Set the appropriate variables and values depending on your deployment model.
    b. Enable HBN specific OVS bridge on BlueField Arm by setting ENABLE_BR_HBN=yes.
    c. Define the uplink ports to be used by HBN `BR_HBN_UPLINKS='<port>'`.

    > ⚠ Must include both ports (i.e., `p0,p1`) for dual-port BlueField devices and only `p0` for single-port BlueField devices.

    d. Include PF and VF ports to be used by HBN. The following example sets both PFs and 8 VFs on each uplink: `BR_HBN_REPS='pf0hpf,pf1hpf,pf0vf0-pf0vf7,pf1vf0-pf1vf7'`.
    e. (Optional) Include SF devices to be created and connected to HBN bridge on the BlueField Arm side by setting `BR_HBN_SFS='pf0dpu1,pf0dpu3'`.

    > ℹ If nothing is provided, `pf0dpu1` and `pf0dpu3` are created by default.

    > ✖ While older formats of `bf.cfg` still work in this release, they will be deprecated over the next 2 releases. So, its advisable to move to the new format to avoid any upgrade issues in future releases. The following is an example for the old `bf.cfg` format:
    >
    > ```
    > ENABLE_SFC_HBN=yes
    > NUM_VFs_PHYS_PORT0=12 # <num VFs supported by HBN on Physical Port 0> (valid range:
    > 0-127) Default 14
    > NUM_VFs_PHYS_PORT1=2  # <num VFs supported by HBN on Physical Port 1> (valid range:
    > 0-127) Default 0
    > ```

3. Then run:

```
bfb-install -c bf.cfg -r rshim0 -b <BFB-image>
```

4. Once SFC deployment is done, it creates 3 set of files:

- `/etc/mellanox/hbn.conf` – this file can be used to redeploy SFC without the need to pass through `bf.cfg` again to modify interface mapping
- `/etc/mellanox/sfc.conf` – this file provides a view of how various ports are connected in different bridges
- `/etc/mellanox/mlnx-sf.conf` – this file includes all the HBN ports to be created and corresponding commands to create the port

8.8.4.1.2.2 Deploying BlueField DOCA Image with SFC Using PXE Boot

To enable HBN SFC using a PXE installation environment with BFB content, use the following configuration for PXE:

```
bfnet=<IFNAME>:<IPADDR>:<NETMASK> or <IFNAME>:dhcp
bfks=<URL of the kickstart script>
```

The kickstart script (bash) should include the following lines:

```
cat >> /etc/bf.cfg << EOF

ENABLE_BR_HBN=yes
BR_HBN_UPLINKS='p0,p1'
BR_HBN_REPS='pf0hpf,pf1hpf,pf0vf0-pf0vf7,pf1vf0-pf1vf7'
BR_HBN_SFS='pf0dpu1,pf0dpu3'
EOF
```

The `/etc/bf.cfg` generated above is sourced by the BFB `install.sh` script.

It is recommended to verify the accuracy of the BlueField's clock post-installation. This can be done using the following command:

```
$ date
```

Please refer to the known issues listed in the "DOCA Release Notes" for more information.

8.8.4.1.2.3 Redeploying SFC from BlueField

Redeploying SFC from BlueField can be done after the DPU has already been deployed using `bf.cfg` and either port mapping or bridge configuration needs to be change.

To redeploy SFC from BlueField:

1. Edit `/etc/mellanox/hbn.conf` by adding or removing entries in each segment as necessary.
2. Rerun the SFC install script:

   ```
   /opt/mellanox/sfc-hbn/install.sh -c -r
   ```

   This generates a new set of `sfc.conf` and `mlnx-sf.conf` and reloads the DPU.

Configuration and reload can be split into 2 steps by removing the `-r` option and rebooting BlueField post configuration.

After the BlueField reloads, the command `ovs-vsctl show` should show all the new ports and bridges configured in OVS.

8.8.4.1.2.4 Deploying HBN with Other Services

When the HBN container is deployed by itself, BlueField Arm is configured with 3k huge pages. If it is deployed with other services, the actual number of huge-pages must be adjusted based on the requirements of those services. For example, SNAP or NVMesh may need approximately 1k to 5k huge pages. So, if HBN is running with either of these services on the same BlueField, the total number of hugepages must be set to the sum of the hugepage requirement of all the services.

For example, if NVMesh needs 3k hugepages, 6k total hugepages must be set when running with HBN. To do that, add the following parameters to the `bf.cfg` configuration file alongside other desired parameters.

```
HUGEPAGE_COUNT=6144
```

Memory Requirements

These configurations must only be applied to BlueField-3 platforms equipped with 32GB of onboard RAM. Attempting these settings on 16GB systems may result in memory exhaustion or instability for services running on the BlueField Arm cores.

Service Coexistence Limits

When running HBN alongside other DOCA services, the system is qualified to support a maximum of 16 VFs.

8.8.4.2 Scaling Profiles

To address the scaling needs of Network Cloud Providers (NCPs) while optimizing DPU resources (CPU and memory) and enabling coexistence with other DPU services (such as SNAP, AppShield, or OVN), HBN provides pre-defined Scaling Profiles. These profiles specify resource limits for each scale target to ensure balanced performance and efficient consumption.

The following table details the available profiles and their corresponding resource limits based on the DPU platform and memory configuration.

Profiles are strictly hardware-dependent. Attempting to apply a BlueField-3 specific profile (e.g., 32GB RAM variants) to BlueField-2 hardware is not supported. If an incompatible profile is selected, the system logs an error and automatically defaults to the `rp_4k_16k` profile to maintain system stability.

8.8.4.2.1 Scaling Profiles and Resource Limits

Profile Name	Supported Platforms	DPU VTEPs	Underlay Routes	L2 EVPN Routes	L3 EVPN Routes	VRFs / L3 VNIs	Max CPU (HBN)	Max CPU (OVS)	Max RAM (HBN)	Max RAM (OVS)	Hugepage Size	Hugepage Count
`default`	• BlueField-2 (16GB / 32GB) • BlueField-3 (16GB / 32GB)	4K	6K	16K	16K	20	1	1	3GB	3GB	2048	1600
`rp_4k_16k`	• BlueField-2 (16GB / 32GB) • BlueField-3 (16GB / 32GB)	4K	6K	16K	16K	20	1	1	3GB	3GB	2048	1600
`rp_8k_40k`	BlueField-2 (16GB/ 32GB)	8K	10K	16K	40K	10	2	1	4GB	4GB	2048	2000
`rp_8k_80k`	BlueField-3 (32GB)	8K	10K	16K	80K	10	1	1	4GB	4GB	2048	2000
`rp_16k_128k`	BlueField-3 (32GB)	16K	18K	16K	128K	5	2	2	6GB	6GB	2048	3000

8.8.4.2.2 Profile Configuration

8.8.4.2.2.1 Initial Setup

The profile is initially selected via the `bf.cfg` configuration file using the parameter `HBN_PROFILE`. The naming convention follows the format `rp_<vtep_num>_<l3_routes>`.

- Default behavior: If no profile is selected, the `default` profile is applied (equivalent to `rp_4K_16K`).
- Invalid profile: If a user selects a non-existent profile, the error is logged and the system defaults to `default`.

8.8.4.2.2.2 Flexible Profile

Users requiring custom resource allocation can use the flexible profile.

1. Set the profile name to `flexible_profile`.
2. Edit the `/etc/mellanox/hbn_profiles/flexible_profile.yaml` file to define custom values for `hbn_cpu`, `memory`, `ovs_cpu`, `huge_pages_size`, and `huge_pages_count`.

   > Unlike standard profiles, flexible mode supports fractional values (e.g., `HBN_CPU_CORE="0.5"`).

   > When using the `flexible_profile`, you must explicitly configure all required parameters. If any parameter is missing or unused, the system will automatically fall back to the `default` profile.

8.8.4.2.3 Changing Profiles

To switch profiles on a running system, update the `hbn.conf` file.

- File location: `hbn.conf` is found under `/etc/mellanox/hbn.conf`.

  > Do not edit `resources_profiles.yaml` directly as it is not editable. Instead, update the profile name in `hbn.conf` only.

- Effect: The `hbn-profile.path` unit monitors this file. When a change is detected, it triggers `hbn-profile.service`. This service retrieves values from either

`resources_profiles.yaml` (for standard profiles) or `flexible_profile.yaml` (for flexible profiles) and applies them.

> **Container Restart**
>
> If the HBN container does not restart automatically after the profile change, it must be restarted manually.

> **OVS Restart**
>
> Changes to `OVS_CPU` settings require a manual OVS restart for the configuration to take effect. Use the command `systemctl restart openvswitch-switch.service`.

8.8.4.2.4 System Behavior and Services

8.8.4.2.4.1 HBN Profile Service

The `hbn-profile.service` manages resource application. The `hbn-profile.path` unit monitors `hbn.conf`, `flexible_profile.yaml` and the HBN container YAML file `/etc/kubelet.d/doca_hbn.yaml` using `inotify` mechanisms.

> **Overwrite Protection**
>
> If a user manually updates the container YAML file, the service will overwrite those changes with the values defined in `hbn.conf`.

8.8.4.2.4.2 OVS Resource Limitation

This feature also limits resources for OVS to ensure accurate consumption estimates.

- CPU: The service configures CPU core limits via the OVS CLI using `other_config:pmd-cpu-mask`.
- Memory: Huge pages are allocated according to the profile.

8.8.4.3 Launching HBN Service

8.8.4.3.1 HBN Service Container Deployment

HBN service is available on NGC, NVIDIA's container catalog. For information about the deployment of DOCA containers on top of the BlueField, refer to NVIDIA DOCA Container Deployment Guide.

8.8.4.3.1.1 Downloading HBN Container Resource File

Pull the latest DOCA container resource as a `*.zip` file from NGC and extract it to the `<resource>` folder. The HBN resource from NGC is available here

8.8.4.3.1.2 Running HBN Preparation Script

The HBN script (`hbn-dpu-setup.sh`) performs the following steps on BlueField Arm which are required for HBN service to run:

1. Sets up interface MTU if needed.
2. Sets up mount points between BlueField Arm and HBN container for logs and configuration persistency.
3. Sets up various paths as needed by supervisord and other services inside container.
4. Enables the REST API access if needed.
5. Creates or updates credentials

The script is located in `<resource>/scripts/doca_hbn/<hbn_version>/` folder, which is downloaded as part of the DOCA Container Resource.

Optional

To achieve the desired configuration on HBN's first boot, before running preparation script, users can update default NVUE or flat (network interfaces and FRR) configuration files, which are located in `<resource>/scripts/doca_hbn/<hbn_version>/` .

- For NVUE-based configuration:
  - `etc/nvue.d/startup.yaml`
- For flat-files based configuration:
  - `etc/network/interfaces`
  - `etc/frr/frr.conf`
  - `etc/frr/daemons`

Run the following commands to execute the `hbn-dpu-setup.sh` script:

```
cd <resource>/scripts/doca_hbn/2.4.0/
chmod +x hbn-dpu-setup.sh
sudo ./hbn-dpu-setup.sh
```

The following is the help menu for the `hbn-dpu-setup.sh` script:

```
./hbn-dpu-setup.sh -h
usage: hbn-dpu-setup.sh
hbn-dpu-setup.sh -m|--mtu <MTU> Use <MTU> bytes for all HBN interfaces (default 9216)
hbn-dpu-setup.sh -u|--username <username> User creation
hbn-dpu-setup.sh -p|--password <password> Password for --username <username>
hbn-dpu-setup.sh -e|--enable-rest-api-access Enable REST API from external IPs
hbn-dpu-setup.sh -h|--help
```

Enabling REST API Access

To enable the REST API access:

1. Change the default password for the `nvidia` username:

   ```
   ./hbn-dpu-setup.sh -u nvidia -p <new-password>
   ```

2. Enable REST API:

   ```
   ./hbn-dpu-setup.sh --enable-rest-api-access
   ```

3. Perform BlueField system-level reset.

8.8.4.3.1.3 Spawning HBN Container

HBN container `.yaml` configuration is called `doca_hbn.yaml` and it is located in `<resource>/configs/<doca_version>/` directory. To spawn the HBN container, simply copy the `doca_hbn.yaml` file to the `/etc/kubelet.d` directory:

```
cd <resource>/configs/2.9.0/
sudo cp doca_hbn.yaml /etc/kubelet.d/
```

Kubelet automatically pulls the container image from NGC and spawns a pod executing the container. The DOCA HBN Service starts executing right away.

8.8.4.3.1.4 Verifying HBN Container is Running

To inspect the HBN container and verify if it is running correctly:

1. Check HBN pod and container status and logs:
   a. Examine the currently active pods and their IDs (it may take up to 20 seconds for the pod to start):

      ```
      sudo crictl pods
      ```

   b. View currently active containers and their IDs:

      ```
      sudo crictl ps
      ```

   c. Examine logs of a given container:

```
sudo crictl logs
```

d. Examine kubelet logs if something did not work as expected:

```
sudo journalctl -u kubelet@mgmt
```

2. Log into the HBN container:

```
sudo crictl exec -it $(crictl ps | grep hbn | awk '{print $1;}') bash
```

3. While logged into HBN container, verify that the `frr`, `nl2doca`, and `neighmgr` services are running:

```
(hbn-container)$ supervisorctl status frr
(hbn-container)$ supervisorctl status nl2doca
(hbn-container)$ supervisorctl status neighmgr
```

4. Users may also examine various logs under `/var/log` inside the HBN container.

8.8.4.3.2 HBN Deployment Configuration

The HBN service comes with four types of configurable interfaces:

- Two uplinks (`p0_if`, `p1_if`)
- Two PF port representors (`pf0hpf_if`, `pf1hpf_if`)
- User-defined number of VFs (i.e., `pf0vf0_if`, `pf0vf1_if`, ..., `pf1vf0_if`, `pf1vf1_if`, ...)
- DPU interfaces to connect to services running on BlueField, outside of the HBN container (`pf0dpu1_if` and `pf0dpu3_if`)

The `*_if` suffix indicates that these are sub-functions and are different from the physical uplinks (i.e., PFs, VFs). They can be viewed as virtual interfaces from a virtualized BlueField.

Each of these interfaces is connected outside the HBN container to the corresponding physical interface, see section "Service Function Chaining" (SFC) for more details.

The HBN container runs as an isolated namespace and does not see any interfaces outside the container (`oob_net0`, real uplinks and PFs, `*_if_r` representors).

8.8.4.3.2.1 HBN-only Deployment Configuration

This is the default deployment model of HBN. In this model, only one OVS bridge is created.

The following is a sample `bf.cfg` and the resulting OVS and port configurations:

- Sample `bf.cfg`:

bf.cfg

```
BR_HBN_UPLINKS="p0,p1"
BR_HBN_REPS="pf0hpf,pf1hpf,pf0vf0-pf0vf12,pf1vf0-pf1vf1"
BR_HBN_SFS="svc1,svc2"
```

- Generated `hbn.conf`:

8.8.4.3.3 HBN Deployment Considerations

8.8.4.3.3.1 SF Interface State Tracking

When HBN is deployed with SFC, the interface state of the following network devices is propagated to their corresponding SFs:

- Uplinks – `p0` , `p1`
- PFs – `pf0hpf` , `pf1hpf`
- VFs – `pf0vfX` , `pf1vfX` where `X` is the VF number

For example, if the p0 uplink cable gets disconnected:

- `p0` transitions to DOWN state with `NO-CARRIER` (default behavior on Linux); and
- `p0` state is propagated to `p0_if` whose state also becomes DOWN with NO-CARRIER

After `p0` connection is reestablished:

- `p0` transitions to UP state; and
- `p0` state is propagated to `p0_if` whose state becomes UP

Interface state propagation only happens in the uplink/PF/VF-to-SF direction.

A daemon called `sfc-state-propagation` runs on BlueField, outside of the HBN container, to sync the state. The daemon listens to netlink notifications for interfaces and transfers the state to SFs.

8.8.4.3.3.2 SF Interface MTU

In the HBN container, all the interfaces MTU are set to 9216 by default. MTU of specific interfaces can be overwritten using flat-files configuration or NVUE.

On BlueField side (i.e., outside of the HBN container), the MTU of the uplinks, PFs and VFs interfaces are also set to 9216. This can be changed by modifying `/etc/systemd/network/30-hbn-mtu.network` or by adding a new configuration file in the `/etc/systemd/network` for specific directories.

To reload this configuration, run:

```
systemctl restart systemd-networkd
```

8.8.4.3.3.3 Connecting to DOCA Services to HBN on BlueField Arm

There are various SF ports (named `pf0dpuX_if`, where X is [0..n]) on BlueField Arm, which can be used to run any services on BlueField and use HBN to provide network connectivity. These ports can have a flexible naming convention based on the service name. For example, to support OVN service, it can create an interface named `ovn` which can be used by the OVN service running on the BlueField Arm, and it will get a corresponding HBN port named `ovn_if`. These interfaces are created using either `BR_SFC_SFS` or `BR_HBN_SFS` based on which the bridge needs the service interface and mode of service deployment.

Traffic between BlueField and the outside world is hardware-accelerated when the HBN side port is an L3 interface or access-port using switch virtual interface (SVI). So, it is treated the same way as PF or VF ports from a traffic handling standpoint.

> There are 2 SF port pairs created by default on BlueField Arm side so there can be 2 separate DOCA services running at same time.

8.8.4.3.3.4 Disabling BlueField Uplinks

The uplink ports must be always kept administratively up for proper operation of HBN. Otherwise, the NVIDIA® ConnectX® firmware would bring down the corresponding representor port which would cause data forwarding to stop.

⚠ Change in operational status of uplink (e.g., carrier down) would result in traffic being switched to the other uplink.

When using ECMP failover on the two uplink SFs, locally disabling one uplink does not result in traffic switching to the second uplink. Disabling local link in this case means to set one uplink admin DOWN directly on BlueField.

To test ECMP failover scenarios correctly, the uplink must be disabled from its remote counterpart (i.e., execute admin DOWN on the remote system's link which is connected to the uplink).

8.8.4.3.3.5 HBN NVUE User Credentials

The preconfigured default user credentials are as follows:

Username	`nvidia`
Password	`nvidia`

NVUE user credentials can be added post installation:

1. This can be done by specifying additional `--username` and `--password` to the HBN startup script (refer to "Running HBN Preparation Script"). For example:

   ```
   sudo ./hbn-dpu-setup.sh -u newuser -p newpassword
   ```

2. After executing this script, respawn the container or start the `decrypt-user-add` script inside running HBN container:

   ```
   supervisorctl start decrypt-user-add
   decrypt-user-add: started
   ```

   The script creates a new user in the HBN container:

   ```
   cat /etc/passwd | grep newuser
   newuser:x:1001:1001::/home/newuser:/bin/bash
   ```

8.8.4.3.3.6 HBN NVUE Interface Classification

Interface	Interface Type	NVUE Type
`p0_if`	Uplink representor	swp
`p1_if`	Uplink representor	swp
`lo`	Loopback	loopback
`pf0hpf_if`	Host representor	swp
`pf1hpf_if`	Host representor	swp
`pf0vfx_if` (where `x` is 0-255)	VF representor	swp

Interface	Interface Type	NVUE Type
`pf1vfx_if` (where `x` is 0-255)	VF representor	swp

8.8.4.3.3.7 HBN Files Persistence

The following directories are mounted from BlueField Arm to the HBN container namespace and are persistent across HBN service restarts and BlueField reboots:

	BlueField Arm Mount Point	HBN Container Mount Point
Configuration file mount points	`/var/lib/hbn/etc/network/`	`/etc/network/`
	`/var/lib/hbn/etc/frr/`	`/etc/frr/`
	`/var/lib/hbn/etc/nvue.d/`	`/etc/nvue.d/`
	`/var/lib/hbn/etc/supervisor/conf.d/`	`/etc/supervisor/conf.d/`
	`/var/lib/hbn/var/lib/nvue/`	`/var/lib/nvue/`
Support and log file mount points	`/var/lib/hbn/var/support/`	`/var/support/`
	`/var/log/doca/hbn/`	`/var/log/hbn/`

8.8.4.3.3.8 SR-IOV Support in HBN

Creating SR-IOV VFs on Host

The first step to use SR-IOV is to create Virtual Functions (VFs) on the host server.

VFs can be created using the following command:

```
sudo echo N > /sys/class/net/<host-rep>/device/sriov_numvfs
```

Where:

- `<host-rep>` is one of the two host representors (e.g., `ens1f0` or `ens1f1`)
- 0≤`N`≤16 is the desired total number of VFs
  - Set `N`=0 to delete all the VFs on 0≤N≤16
  - `N`=16 is the maximum number of VFs supported on HBN across all representors

Automatic Creation of VF Representors and SF Devices on BlueField

VFs created on the host must have corresponding VF representor devices and SF devices for HBN on BlueField side. For example:

- `ens1f0vf0` is the first SR-IOV VF device from the first host representor; this interface is created on the host server

- `pf0vf0` is the corresponding VF representor device to `ens1f0vf0`; this device is present on the BlueField Arm side and automatically created at the same time as `ens1f0vf0` is created by the user on the host side
- `pf0vf0_if` is the corresponding SF device for `pf0vf0` which is used to connect the VF to HBN pipeline

The creation of the SF device for VFs is done ahead of time when provisioning the BlueField and installing the DOCA image on it, see section "Enabling SFC" to see how to select how many SFs to create ahead of time.

The SF devices for VFs (i.e., `pfXvfY`) are pre-mapped to work with the corresponding VF representors when these are created with the command from the previous step.

8.8.4.3.3.9 Management VRF

Two management VRFs are automatically configured for HBN when BlueField is deployed with SFC:

- The first management VRF is outside the HBN container on BlueField. This VRF provides separation between out-of-band (OOB) traffic (via `oob_net0` or `tmfifo_net0`) and data-plane traffic via uplinks and PFs.
- The second management VRF is inside the HBN container and provides similar separation. The OOB traffic (via `eth0`) is isolated from the traffic via the `*_if` interfaces.

MGMT VRF on BlueField Arm

The management (mgmt) VRF is enabled by default when the BlueField is deployed with SFC (see section "Enabling SFC"). The mgmt VRF provides separation between the OOB management network and the in-band data plane network.

The uplinks and PFs/VFs use the default routing table while the `oob_net0` (OOB Ethernet port) and the `tmifo_net0` netdevices use the mgmt VRF to route their packets.

When logging in either via SSH or the console, the shell is by default in mgmt VRF context. This is indicated by a mgmt added to the shell prompt:

```
root@bf2:mgmt:/home/ubuntu#
root@bf2:mgmt:/home/ubuntu# ip vrf identify
mgmt.
```

When logging into the HBN container with `crictl`, the HBN shell will be in the default VRF. Users must switch to MGMT VRF manually if OOB access is required. Use `ip vrf exec` to do so.

```
root@bf2:mgmt:/home/ubuntu# ip vrf exec mgmt bash
```

The user must run `ip vrf exec mgmt` to perform operations requiring OOB access (e.g., apt-get update).

Network devices belonging to the mgmt VRF can be listed with the `vrf` utility:

```
root@bf2:mgmt:/home/ubuntu# vrf link list

VRF: mgmt
--------------------
tmfifo_net0      UP             00:1a:ca:ff:ff:03 <BROADCAST,MULTICAST,UP,LOWER_UP>
oob_net0         UP             08:c0:eb:c0:5a:32 <BROADCAST,MULTICAST,UP,LOWER_UP>

root@bf2:mgmt:/home/ubuntu# vrf help
vrf <OPTS>

VRF domains:
    vrf list

Links associated with VRF domains:
    vrf link list [<vrf-name>]

Tasks and VRF domain asociation:
    vrf task exec <vrf-name> <command>
    vrf task list [<vrf-name>]
    vrf task identify <pid>

    NOTE: This command affects only AF_INET and AF_INET6 sockets opened by the
          command that gets exec'ed. Specifically, it has *no* impact on netlink
          sockets (e.g., ip command).
```

To show the routing table for the default VRF, run:

```
root@bf2:mgmt:/home/ubuntu# ip route show
```

To show the routing table for the mgmt VRF, run:

```
root@bf2:mgmt:/home/ubuntu# ip route show vrf mgmt
```

MGMT VRF Inside HBN Container

Inside the HBN container, a separate mgmt VRF is present. Similar commands as those listed under section "MGMT VRF on BlueField Arm" can be used to query management routes.

The `*_if` interfaces use the default routing table while the `eth0` (OOB) uses the mgmt VRF to route out-of-band packets out of the container. The OOB traffic gets NATed through the `oob_net0` interface on BlueField Arm, ultimately using the BlueField OOB's IP address.

When logging into the HBN container via `crictl`, the shell enters the default VRF context by default. Switching to the mgmt VRF can be done using the command `ip vrf exec mgmt <cmd>`.

Existing Services in MGMT VRF on BlueField Arm

On the BlueField Arm, outside the HBN container, a set of existing services run in the mgmt VRF context as they need OOB network access:

- containerd

- kubelet
- ssh
- docker

These services can be restarted and queried for their status using the command `systemctl` while adding `@mgmt` to the original service name. For example:

- To restart containerd:

```
root@bf2:mgmt:/home/ubuntu# systemctl restart containerd@mgmt
```

- To query containerd status:

```
root@bf2:mgmt:/home/ubuntu# systemctl status containerd@mgmt
```

The original version of these services (without `@mgmt`) are not used and must not be started.

Running New Service in MGMT VRF on BlueField Arm

If a service needs OOB access to run, it can be added to the set of services running in mgmt VRF context. Adding such a service is only possible on the BlueField Arm (i.e., outside the HBN container).

To add a service to the set of mgmt VRF services:

1. Add it to `/etc/vrf/systemd.conf` (if it is not present already). For example, NTP is already listed in this file.
2. Run the following:

```
root@bf2:mgmt:/home/ubuntu# systemctl daemon-reload
```

3. Stop and disable to the non-VRF version of the service to be able to start the mgmt VRF one:

```
root@bf2:mgmt:/home/ubuntu# systemctl stop ntp
root@bf2:mgmt:/home/ubuntu# systemctl disable ntp
root@bf2:mgmt:/home/ubuntu# systemctl enable ntp@mgmt
root@bf2:mgmt:/home/ubuntu# systemctl start ntp@mgmt
```

8.8.5 HBN Service Configuration

To start configuring HBN, log in to the HBN container:

```
sudo crictl exec -it $(crictl ps | grep hbn | awk '{print $1;}') bash
```

8.8.5.1 General Network Configuration

8.8.5.1.1 Flat Files Configuration

Add network interfaces and FRR configuration files to HBN. For more more information refer to the Cumulus Linux FRRouting guide.

- `/etc/network/interfaces`
- `/etc/frr/frr.conf`; `/etc/frr/daemons`

8.8.5.2 NVUE Configuration

This section assumes familiarity with NVIDIA user experience (NVUE) Cumulus Linux. The following sections elaborate on HBN-specific aspects of NVUE.

8.8.5.2.1 NVUE Service

HBN installs NVUE by default and enables NVUE service at boot.

8.8.5.2.2 NVUE REST API

HBN enables the REST API with only localhost access by default. To enable REST API access, refer to Enable REST API Access.

You can run cURL commands from the command line. Use the default HBN username, `nvidia`, and password which you must be update when enabling the REST API using the HBN preparation script.

To change the default password for the `nvidia` user or to add additional users for NVUE access, refer to section HBN NVUE User Credentials.

REST API example:

```
curl -u 'nvidia:nvidia' --insecure https://<mgmt_ip>:8765/nvue_v1/vrf/default/router/bgp
{
  "configured-neighbors": 2,
  "established-neighbors": 2,
  "router-id": "10.10.10.201"
}
```

8.8.5.2.2.1 NVUE REST API Management Through CLI

- To enable the REST API service:

```
nv set system api state enabled
```

- To disable the REST API service:

```
nv set system api state disabled
```

- To bind the REST API service to a specific address:

```
nv set system api listening-address <localhost|ipv4|ipv6|0.0.0.0>
```

For information about using the NVUE REST API, refer to the NVUE API documentation.

8.8.5.2.3 NVUE REST API in DOCA Platform Framework

For information on DOCA Platform Framework (DPF), refer to DOCA Framework.

This section explains how to configure external access to the HBN NVUE REST API in a DOCA Platform Framework (DPF) environment.

By default, the NVUE REST API is only accessible from within the cluster (i.e., via `localhost`). To expose the API to external networks, you must configure Kubernetes NodePort and set the appropriate listening address.

8.8.5.2.3.1 Enabling External Access to the NVUE REST API

1. Configure NodePort in DPUService – Add the following section under `spec.serviceConfiguration.helmChart.values` in your `DPUServiceConfiguration` YAML:

```
service:
  type: NodePort
  nodePort: 30765
```

2. Set the API listening address – To bind the API to all available HBN IP addresses (for example, for external access), configure the following:

```
configuration:
  startupYAMLJ2: |
    - set:
        system:
          api:
            listening-address:
              0.0.0.0: {}
```

3. Verify API accessibility – Use `curl` to confirm that the NVUE REST API is reachable:

```
curl -k -u 'username:password' https://<node-ip>:<nodePort>/nvue_v1/interface/
```

4. Check service status – To check the NodePort service status:

```
kubectl get svc -n <your-namespace>
```

8.8.5.2.3.2 Example: Combined `DPUServiceConfiguration` and `DPUServiceTemplate`

The following is a sample manifest to deploy HBN with the NVUE REST API enabled:

```
---
apiVersion: svc.dpu.nvidia.com/v1alpha1
kind: DPUServiceConfiguration
metadata:
  name: doca-hbn
  namespace: dpf-operator-system
spec:
  deploymentServiceName: "doca-hbn"
  serviceConfiguration:
    helmChart:
      values:
        service:
          nodePort: 30765
          type: NodePort
        configuration:
          user:
            create: true
            password:
              secretKey: password
              secretName: hbn-user-password
            username: nvidia
          perDPUValuesYAML: |
            - hostnamePattern: "*"
          startupYAMLJ2: |
            - header:
                model: bluefield
                nvue-api-version: nvue_v1
                rev-id: 1.0
                version: HBN 3.1.0
            - set:
                system:
                  api:
                    listening-address:
                      0.0.0.0: {}
```

8.8.5.2.3.3 Security Considerations

Authentication

- Always use valid username/password authentication.
- Use HTTPS to secure all REST API communications.
- The default credentials are `nvidia:nvidia`.
- It is strongly recommended to change the default credentials using the user creation procedure described below.

User Creation/Update Procedure for NVUE REST API

> ⚠ The user should not interact directly with the DPU cluster in DPF.

1. Create a password secret on the host cluster:

```
kubectl -n dpf-operator-system create secret generic hbn-user-password \
  --from-literal=password=<new-password>
```

2. Propagate the secret to the DPU cluster (label the secret so that it is made available to the DPU):

```
kubectl -n dpf-operator-system label secret hbn-user-password \
  dpu.nvidia.com/image-pull-secret=""
```

3. Update the user configuration in the helm values your service YAML:

```
configuration:
  user:
    create: true
    username: "your-username"
    password:
      secretName: "hbn-user-password" #Must match the secret name from Step 1
      secretKey: "password"           #Must match the key in the secret
    # Optional settings
    shell: "/bin/bash"
    homeDir: "/home/your-username"
    additionalGroups: ["group1", "group2"]
    uid: "1000"
    gid: "1000"
```

User Creation Configuration Options

The following options can be used to configure user creation or update in the `spec.serviceConfiguration.helmChart.values.configuration.user` section.

Option	Required	Description
`create`	Yes	Enables user creation or update. Default is `false`.
`username`	Yes	Username for the new user, or existing user in case of an update
`password.secretName`	Yes	Name of the Kubernetes secret that stores the password
`password.secretKey`	Yes	Key within the secret that contains the password value
`shell`	No	Shell assigned to the user (e.g., `/bin/bash`)
`homeDir`	No	Path to the user's home directory
`additionalGroups`	No	List of additional groups to assign the user to (e.g., `["group1", "group2"]`)
`uid`	No	User ID
`gid`	No	Group ID

8.8.5.2.4 NVUE CLI

For information about using the NVUE CLI, refer to the NVUE CLI documentation

8.8.5.2.5 NVUE Startup Configuration File

When the network configuration is saved using NVUE, HBN writes the configuration to the `/etc/nvue.d/startup.yaml` file.

The startup configuration is applied by following the supervisor daemon at boot time. `nvued-startup` will appear in an `EXITED` state after applying the startup configuration:

```
# supervisorctl status nvued-startup
nvued-startup                    EXITED    Apr 17 10:04 AM
```

`nv config apply startup` applies the yaml configuration saved at `/etc/nvue.d/`. `nv config save` saves the running configuration to `/etc/nvue.d/startup.yaml`.

8.8.5.3 HBN Configuration Examples

8.8.5.3.1 HBN Default Configuration

After a fresh HBN installation, the default `/etc/network/interfaces` file should contain only the declaration of a loopback interface:

```
source /etc/network/interfaces.d/*.intf

auto lo
iface lo inet loopback
```

FRR configuration files are also present in `/etc/frr/` but configurations are not enabled.

8.8.5.3.2 Layer-3 Routing

8.8.5.3.2.1 Next-hop IDs and Next-hop Groups

In HBN, route programming utilizes next-hop IDs to specify a route's next-hop. For routes with multiple paths, next-hop groups are used to identify equal-cost multi-path (ECMP) next-hop sets. This grouping enables the system to efficiently process and modify route and next-hop objects, improving scalability, network convergence, and performance. You may notice changes in the display of route information in the output of kernel operational commands.

8.8.5.3.2.2 Native Routing with BGP and ECMP

HBN supports unicast routing with BGP and ECMP for IPv4 and IPv6 traffic. ECMP is achieved by distributing traffic using hash calculation based on the source IP, destination IP, and protocol type of the IP header.

For TCP and UDP packets, the source and destination ports are also included.

ECMP Example

ECMP is implemented any time routes have multiple paths over uplinks or host ports. For example, 20.20.20.0/24 has 2 paths using both uplinks, so a path is selected based on a hash of the IP headers.

```
# ip route show 20.20.20.0/24
20.20.20.0/24 nhid 106 proto bgp metric 20
# ip nexthop show group id 106
id 106 group 105/107 proto zebra
# ip nexthop show id 105
id 105 via fe80::202:ff:fe00:7 dev p0_if scope link proto zebra
# ip nexthop show id 107
id 107 via fe80::202:ff:fe00:c dev p1_if scope link proto zebra
```

HBN supports up to 64 paths for ECMP

Sample NVUE Configuration for Native Routing with Host-facing Ports as Access

```
nv set interface lo ip address 10.10.10.1/32
nv set interface lo ip address 2010:10:10::1/128
nv set interface vlan100 type svi
nv set interface vlan100 vlan 100
nv set interface vlan100 base-interface br_default
nv set interface vlan100 ip address 2030:30:30::1/64
nv set interface vlan100 ip address 30.30.30.1/24
nv set bridge domain br_default vlan 100
nv set interface pf0hpf_if,pf1hpf_if bridge domain br_default access 100
nv set vrf default router bgp router-id 10.10.10.1
nv set vrf default router bgp autonomous-system 65501
nv set vrf default router bgp path-selection multipath aspath-ignore on
nv set vrf default router bgp address-family ipv4-unicast enable on
nv set vrf default router bgp address-family ipv4-unicast redistribute connected enable on
nv set vrf default router bgp address-family ipv6-unicast enable on
nv set vrf default router bgp address-family ipv6-unicast redistribute connected enable on
nv set vrf default router bgp neighbor p0_if remote-as external
nv set vrf default router bgp neighbor p0_if type unnumbered
nv set vrf default router bgp neighbor p0_if address-family ipv4-unicast enable on
nv set vrf default router bgp neighbor p0_if address-family ipv6-unicast enable on
nv set vrf default router bgp neighbor p1_if remote-as external
nv set vrf default router bgp neighbor p1_if type unnumbered
nv set vrf default router bgp neighbor p1_if address-family ipv4-unicast enable on
nv set vrf default router bgp neighbor p1_if address-family ipv6-unicast enable on
```

Sample NVUE Configuration for Native Routing with Host-facing Ports as Trunk

```
nv set interface lo ip address 10.10.10.1/32
nv set interface lo ip address 2010:10:10::1/128
nv set interface vlan100 type svi
nv set interface vlan100 vlan 100
nv set interface vlan100 base-interface br_default
nv set interface vlan100 ip address 2030:30:30::1/64
nv set interface vlan100 ip address 30.30.30.1/24
nv set bridge domain br_default vlan 100
nv set interface pf0hpf_if,pf1hpf_if bridge domain br_default
nv set vrf default router bgp router-id 10.10.10.1
nv set vrf default router bgp autonomous-system 65501
nv set vrf default router bgp path-selection multipath aspath-ignore on
nv set vrf default router bgp address-family ipv4-unicast enable on
nv set vrf default router bgp address-family ipv4-unicast redistribute connected enable on
nv set vrf default router bgp address-family ipv6-unicast enable on
nv set vrf default router bgp address-family ipv6-unicast redistribute connected enable on
nv set vrf default router bgp neighbor p0_if remote-as external
nv set vrf default router bgp neighbor p0_if type unnumbered
nv set vrf default router bgp neighbor p0_if address-family ipv4-unicast enable on
nv set vrf default router bgp neighbor p0_if address-family ipv6-unicast enable on
nv set vrf default router bgp neighbor p1_if remote-as external
nv set vrf default router bgp neighbor p1_if type unnumbered
nv set vrf default router bgp neighbor p1_if address-family ipv4-unicast enable on
nv set vrf default router bgp neighbor p1_if address-family ipv6-unicast enable on
```

Sample Flat Files Configuration for Native Routing with Host-facing Ports as Access

Example `/etc/network/interfaces` configuration:

```
auto lo

Direct Routing on Host-facing Interfaces

Host-facing interfaces (PFs and VFs) are not limited to being part of the bridge for routing. HBN supports L3-only configuration with direct routing on host-facing PFs and VFs.

Sample NVUE Configuration

```
nv set interface pf0hpf_if ip address 30.30.11.1/24
nv set interface pf0hpf_if ip address 2030:30:11::1/64
nv set interface pf0vf0_if ip address 30.30.13.1/24
nv set interface pf0vf0_if ip address 2030:30:13::1/64
```

Sample Flat File Configuration

```
auto pf0hpf_if
iface pf0hpf_if
    address 2030:30:11::1/64
    address 30.30.11.1/24

auto pf0vf0_if
iface pf0vf0_if
    address 2030:30:13::1/64
    address 30.30.13.1/24
```

8.8.5.3.2.3 BGP Peering with the Host

HBN supports the ability to establish a BGP session between the host and the HBN service running on BlueField Arm and allow the host to announce arbitrary route prefixes through the BlueField into the underlay fabric. The host can use any standard BGP protocol stack implementation to establish BGP peering with HBN.

Traffic to and from endpoints on the host gets offloaded.

> ⚠ Both IPv4 and IPv6 unicast AFI/SAFI are supported.

It is possible to apply route filtering for these prefixes to limit the potential security impact in this configuration.

Sample NVUE Configuration for Host BGP Peering

The following code block shows configuration to peer to host at `45.3.0.4` and `2001:cafe:1ead::4`. The BGP session can be established using IPv4 or IPv6 address.

> ⚠ Either of these sessions can support IPv4 unicast and IPv6 unicast AFI/SAFI.

NVUE configuration for peering with host:

```
nv set vrf default router bgp autonomous-system 63642
nv set vrf default router bgp enable on
nv set vrf default router bgp neighbor 45.3.0.4 nexthop-connected-check off
nv set vrf default router bgp neighbor 45.3.0.4 peer-group dpu_host
nv set vrf default router bgp neighbor 45.3.0.4 type numbered
nv set vrf default router bgp neighbor 2001:cafe:1ead::4 nexthop-connected-check off
nv set vrf default router bgp neighbor 2001:cafe:1ead::4 peer-group dpu_host
nv set vrf default router bgp neighbor 2001:cafe:1ead::4 type numbered
nv set vrf default router bgp peer-group dpu_host address-family ipv4-unicast enable on
nv set vrf default router bgp peer-group dpu_host address-family ipv6-unicast enable on
nv set vrf default router bgp peer-group dpu_host remote-as external
```

Sample Flat Files Configuration for Host BGP peering

The following block shows configuration to peer to host at `45.3.0.4` and `2001:cafe:1ead::4`. The BGP session can be established using IPv4 or IPv6 address.

`frr.conf` file:

```
router bgp 63642
 bgp router-id 27.0.0.4
 bgp bestpath as-path multipath-relax
 neighbor dpu_host peer-group
 neighbor dpu_host remote-as external
 neighbor dpu_host advertisement-interval 0
 neighbor dpu_host timers 3 9
 neighbor dpu_host timers connect 10
 neighbor dpu_host disable-connected-check
 neighbor fabric peer-group
 neighbor fabric remote-as external
 neighbor fabric advertisement-interval 0
 neighbor fabric timers 3 9
 neighbor fabric timers connect 10
 neighbor 45.3.0.4 peer-group dpu_host
 neighbor 2001:cafe:1ead::4 peer-group dpu_host
 neighbor p0_if interface peer-group fabric
 neighbor p1_if interface peer-group fabric
 !
 address-family ipv4 unicast
    neighbor dpu_host activate
 !
 address-family ipv6 unicast
    neighbor dpu_host activate
```

Sample FRR configuration on the Host

Any BGP implementation can be used on the host to peer to HBN and advertise endpoints. The following is an example using FRR BGP:

Sample FRR configuration on the host:

```
bf2-s12# sh run
Building configuration...

Current configuration:
!
frr version 7.2.1
frr defaults traditional
hostname bf2-s12
no ip forwarding
no ipv6 forwarding
!
router bgp 1000008
!
router bgp 1000008 vrf v_200_2000
 neighbor 45.3.0.2 remote-as external
 neighbor 2001:cafe:1ead::2 remote-as external
 !
 address-family ipv4 unicast
  redistribute connected
 exit-address-family
 !
 address-family ipv6 unicast
  redistribute connected
  neighbor 45.3.0.2 activate
  neighbor 2001:cafe:1ead::2 activate
 exit-address-family
!
```

```
line vty
!
end
```

Sample interfaces configuration on the host:

```
root@bf2-s12:/home/cumulus# ifquery -a
auto lo
iface lo inet loopback
    address 27.0.0.7/32
    address 2001:c000:10ff:f00d::7/128

auto v_200_2000
iface v_200_2000
    address 60.1.0.1
    address 60.1.0.2
    address 60.1.0.3
    address 2001:60:1::1
    address 2001:60:1::2
    address 2001:60:1::3
    vrf-table auto
auto ens1f0np0
iface ens1f0np0
    address 45.3.0.4/24
    address 2001:cafe:1ead::4/64
    gateway 45.3.0.1
    gateway 2001:cafe:1ead::1
    vrf v_200_2000
    hwaddress 00:03:00:08:00:12
    mtu 9162
```

8.8.5.3.2.4 VRF Route Leaking

VRFs are typically used when multiple independent routing and forwarding tables are desirable. However, users may want to reach destinations in one VRF from another VRF, as in the following cases:

- To make a service, such as a firewall available to multiple VRFs
- To enable routing to external networks or the Internet for multiple VRFs, where the external network itself is reachable through a specific VRF

Route leaking can be used to reach remote destinations as well as directly connected destinations in another VRF. Multiple VRFs can import routes from a single source VRF, and a VRF can import routes from multiple source VRFs. This can be used when a single VRF provides connectivity to external networks or a shared service for other VRFs. It is possible to control the routes leaked dynamically across VRFs with a route map.

When route leaking is used:

- The `redistribute` command (not `network` command) must be used in BGP to leak non-BGP routes (connected or static routes)
- It is not possible to leak routes between the default and non-default VRF

> **Kernel limitation**
>
> 3769309 – Ping or other IP traffic from a locally connected host in vrfX to a local interface IP address on the BlueField/HBN in vrfY does not work, even if VRF route-leaking is enabled between these two VRFs.

In the following example commands, routes in the BGP routing table of VRF `BLUE` dynamically leak into VRF `RED`:

```
nv set vrf RED router bgp address-family ipv4-unicast route-import from-vrf list BLUE
```

```
nv config apply
```

The following example commands delete leaked routes from VRF `BLUE` to VRF `RED`:

```
nv unset vrf RED router bgp address-family ipv4-unicast route-import from-vrf list BLUE
nv config apply
```

To exclude certain prefixes from the import process, configure the prefixes in a route map.

The following example configures a route map to match the source protocol BGP and imports the routes from VRF `BLUE` to VRF `RED`. For the imported routes, the community is 11:11 in VRF `RED`.

```
nv set vrf RED router bgp address-family ipv4-unicast route-import from-vrf list BLUE
nv set router policy route-map BLUEtoRED rule 10 match type ipv4
nv set router policy route-map BLUEtoRED rule 10 match source-protocol bgp
nv set router policy route-map BLUEtoRED rule 10 action permit
nv set router policy route-map BLUEtoRED rule 10 set community 11:11
nv set vrf RED router bgp address-family ipv4-unicast route-import from-vrf route-map BLUEtoRED
nv config
```

To check the status of the VRF route leaking, run:

- NVUE command:

  ```
  nv show vrf <vrf-name> router bgp address-family ipv4-unicast route-import
  ```

- Vtysh command:

  ```
  show ip bgp vrf <vrf-name> ipv4|ipv6 unicast route-leak command.
  ```

- For example:

  ```
  nv show vrf RED router bgp address-family ipv4-unicast route-import
                  operational   applied
  --------------  ------------  ---------
  from-vrf
    enable                      on
    route-map                   BLUEtoRED
    [list]        BLUE          BLUE
  [route-target]  10.10.10.1:3
  ```

To show more detailed status information, the following NVUE commands are available:

- `nv show vrf <vrf-name> router bgp address-family ipv4-unicast route-import from-vrf`
- `nv show vrf <vrf-name> router bgp address-family ipv4-unicast route-import from-vrf list`
- `nv show vrf <vrf-name> router bgp address-family ipv4-unicast route-import from-vrf list <leak-vrf-id>`

To view the BGP routing table, run:

- NVUE command:

```
nv show vrf <vrf-name> router bgp address-family ipv4-unicast
```

- Vtysh command:

```
show ip bgp vrf <vrf-name> ipv4|ipv6 unicast
```

To view the FRR IP routing table, run:

- Vtysh command:

```
show ip route vrf <vrf-name>
```

- Or:

```
net show route vrf <vrf-name>
```

> These commands show all routes, including routes leaked from other VRFs.

8.8.5.3.2.5 VLAN Subinterfaces

A VLAN subinterface is a VLAN device on an interface. The VLAN ID appends to the parent interface using dot (`.`) VLAN notation which is a standard way to specify a VLAN device in Linux.

For example:

- A VLAN with ID 100 which is a subinterface of `p0_if` is annotated as `p0_if.100`
- The subinterface `p0_if.100` only receives packets that have a VLAN 100 tag on port `p0_if`
- Any packets transmitted from `p0_if.100` would have VLAN tag 100

In HBN, VLAN subinterfaces can be created on uplink ports as well as on the host-facing PF and VF ports. A VLAN subinterface only receives traffic tagged for that VLAN.

> VLAN subinterfaces are L3 interfaces and should not be added to a bridge.

In the following example, uplink subinterface on `p0_if` with VLAN ID 10 and a host facing subinterface on VF ports `pf1vf0_if` with VLAN ID 999 are created. The host-facing subinterface is also assigned with IPv4 and IPv6 addresses.

Subinterface configuration using NVUE commands:

```
nv set interface p0_if.10 base-interface p0_if
nv set interface p0_if.10 type sub
nv set interface p0_if.10 vlan 10

nv set interface pf1vf0_if type swp
nv set interface pf1vf0_if.999 base-interface pf1vf0_if
nv set interface pf1vf0_if.999 type sub
nv set interface pf1vf0_if.999 vlan 999
nv set interface pf1vf0_if ip address 30.30.14.1/24
```

```
nv set interface pf1vf0_if ip address 2030:30:14::1/64
```

Same configuration using sample flat file in `/etc/network/interfaces`:

subinterface configuration e/n/i file

```
auto p0_if.10
iface p0_if.10

auto pf1vf0_if.999
iface pf1vf0_if.999
    address 2030:30:40::1/64
    address 30.30.40.1/24
```

8.8.5.3.3 Ethernet Virtual Private Network – EVPN

HBN supports VXLAN with EVPN control plane for intra-subnet bridging (L2) services for IPv4 and IPv6 traffic in the overlay. For the underlay, only IPv4 or BGP unnumbered configuration is supported.

> ⚠ HBN supports VXLAN encapsulation only over uplink parent interfaces.

8.8.5.3.3.1 Single VXLAN Device

With a single VXLAN device, a set of VXLAN network identifiers (VNIs) represents a single device model. The single VXLAN device has a set of attributes that belong to the VXLAN construct. Individual VNIs include VLAN-to-VNI mapping which allows users to specify which VLANs are associated with which VNIs. A single VXLAN device simplifies the configuration and reduces the overhead by replacing multiple traditional VXLAN devices with a single VXLAN device.

Users may configure a single VXLAN device automatically with NVUE, or manually by editing the `/etc/network/interfaces` file. When users configure a single VXLAN device with NVUE, NVUE creates a unique name for the device in the following format using the bridge name as the hash key: `vxlan<id>`.

This example configuration performs the following steps:

1. Creates a single VXLAN device (vxlan21).
2. Maps VLAN 10 to VNI 10 and VLAN 20 to VNI 20.
3. Adds the VXLAN device to the default bridge.

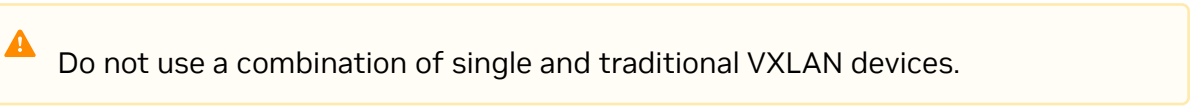
```
cumulus@leaf01:~$ nv set bridge domain bridge vlan 10 vni 10
cumulus@leaf01:~$ nv set bridge domain bridge vlan 20 vni 20
cumulus@leaf01:~$ nv set nve vxlan source address 10.10.10.1
cumulus@leaf01:~$ nv config apply
```

Alternately, edit the `/etc/network/interfaces` files, then run the `ifreload -a` command to apply the SVD configuration:

```
auto lo
iface lo inet loopback
    vxlan-local-tunnelip 10.10.10.1

auto vxlan21
iface vxlan21
    bridge-vlan-vni-map 10=10 20=20
    bridge-learning off

auto bridge
iface bridge
    bridge-vlan-aware yes
    bridge-ports vxlan21 pf0hpf_if pf1hpf_if
    bridge-vids 10 20
    bridge-pvid 1
```



8.8.5.3.3.2 Sample Switch Configuration for EVPN

The following is a sample NVUE config for underlay switches (NVIDIA Spectrum with Cumulus Linux) to enable EVPN deployments with HBN. It assumes that the uplinks on all BlueField devices are connected to ports `swp1-4` on the switch.

```
nv set evpn enable on
nv set router bgp enable on

nv set vrf default router bgp address-family ipv4-unicast enable on
nv set vrf default router bgp address-family ipv4-unicast redistribute connected enable on

nv set vrf default router bgp address-family l2vpn-evpn enable on
nv set vrf default router bgp autonomous-system 63640
nv set vrf default router bgp enable on
nv set vrf default router bgp neighbor swp1 peer-group fabric
nv set vrf default router bgp neighbor swp1 type unnumbered
nv set vrf default router bgp neighbor swp2 peer-group fabric
nv set vrf default router bgp neighbor swp2 type unnumbered
nv set vrf default router bgp neighbor swp3 peer-group fabric
nv set vrf default router bgp neighbor swp3 type unnumbered
nv set vrf default router bgp neighbor swp4 peer-group fabric
nv set vrf default router bgp neighbor swp4 type unnumbered
nv set vrf default router bgp path-selection multipath aspath-ignore on
nv set vrf default router bgp peer-group fabric address-family ipv4-unicast enable on
nv set vrf default router bgp peer-group fabric address-family ipv6-unicast enable on
nv set vrf default router bgp peer-group fabric address-family l2vpn-evpn add-path-tx off
nv set vrf default router bgp peer-group fabric address-family l2vpn-evpn enable on
nv set vrf default router bgp peer-group fabric remote-as external
nv set vrf default router bgp router-id 27.0.0.10

nv set interface lo ip address 2001:c000:10ff:f00d::10/128
nv set interface lo ip address 27.0.0.10/32
nv set interface lo type loopback
nv set interface swp1,swp2,swp3,swp4 type swp
```

8.8.5.3.3.3 Layer-2 EVPN

Sample NVUE Configuration for L2 EVPN with Host-facing Ports as Access

The following is a sample NVUE configuration which has L2-VNIs (`2000` , `2001`) for EVPN bridging on BlueField.

```
nv set bridge domain br_default encap 802.1Q
nv set bridge domain br_default type vlan-aware
nv set bridge domain br_default vlan 200 vni 2000 flooding enable auto
nv set bridge domain br_default vlan 200 vni 2000 mac-learning off
nv set bridge domain br_default vlan 201 vni 2001 flooding enable auto
nv set bridge domain br_default vlan 201 vni 2001 mac-learning off

nv set evpn enable on
nv set nve vxlan arp-nd-suppress on
nv set nve vxlan enable on
nv set nve vxlan mac-learning off
nv set nve vxlan source address 27.0.0.4
nv set router bgp enable on
nv set system global anycast-mac 44:38:39:42:42:07
nv set vrf default router bgp address-family ipv4-unicast enable on
nv set vrf default router bgp address-family ipv4-unicast redistribute connected enable on
```

```
nv set vrf default router bgp address-family l2vpn-evpn enable on
nv set vrf default router bgp autonomous-system 63642
nv set vrf default router bgp enable on
nv set vrf default router bgp neighbor p0_if peer-group fabric
nv set vrf default router bgp neighbor p0_if type unnumbered
nv set vrf default router bgp neighbor p1_if peer-group fabric
nv set vrf default router bgp neighbor p1_if type unnumbered
nv set vrf default router bgp path-selection multipath aspath-ignore on
nv set vrf default router bgp peer-group fabric address-family ipv4-unicast enable on
nv set vrf default router bgp peer-group fabric address-family ipv4-unicast policy outbound route-map
MY_ORIGIN_ASPATH_ONLY
nv set vrf default router bgp peer-group fabric address-family ipv6-unicast enable on
nv set vrf default router bgp peer-group fabric address-family ipv6-unicast policy outbound route-map

8.8.5.3.3.4 Layer-3 EVPN with Symmetric Routing

In distributed symmetric routing, each VXLAN endpoint (VTEP) acts as a layer-3 gateway, performing routing for its attached hosts. However, both the ingress VTEP and egress VTEP route the packets (similar to traditional routing behavior of routing to a next-hop router). In a VXLAN encapsulated packet, the inner destination MAC address is the router MAC address of the egress VTEP to indicate that the egress VTEP is the next hop and that it must also perform the routing.

All routing happens in the context of a tenant (VRF). For a packet that the ingress VTEP receives from a locally attached host, the SVI interface corresponding to the VLAN determines the VRF. For a packet that the egress VTEP receives over the VXLAN tunnel, the VNI in the packet has to specify the VRF. For symmetric routing, this is a VNI corresponding to the tenant and is different from either the source VNI or the destination VNI. This VNI is a layer-3 VNI or interconnecting VNI. The regular VNI, which maps a VLAN, is the layer-2 VNI.

Refer to the Cumulus Linux Symmetric Routing.

HBN uses a one-to-one mapping between an L3 VNI and a tenant (VRF).

The VRF to L3 VNI mapping must be consistent across all VTEPs.

An L3 VNI and an L2 VNI cannot have the same ID.

In an EVPN symmetric routing configuration, when the switch announces a type-2 (MAC/IP) route, in addition to containing two VNIs (L2 and L3 VNIs), the route also contains separate route targets (RTs) for L2 and L3. The L3 RT associates the route with the tenant VRF. By default, this is auto-derived using the L3 VNI instead of the L2 VNI. However, this is configurable.

Sample NVUE Configuration for L3 EVPN with Host-facing Ports as Access

If using NVUE to configure EVPN symmetric routing, the following is a sample configuration using NVUE commands:

```
nv set bridge domain br_default vlan 111 vni 1000111
```

```
nv set bridge domain br_default vlan 112 vni 1000112

8.8.5.3.3.5 Multi-hop eBGP Peering for EVPN (Route Server in Symmetric EVPN Routing)

eBGP multi-hop peering for EVPN support in a route server-like role in EVPN topology, allows the deployment of EVPN on any cloud that supports IP transport.

Route servers and BF/HBN VTEPs are connected via the IP cloud. That is:

- Switches in the cloud provider need not be EVPN-aware
- Switches in the provider fabric provide IPv4 and IPv6 transport and do not have to support EVPN

Sample Route Server Configuration for EVPN

The following is a sample configuration of an Ubuntu server running FRR 9.0 stable, configured as EVPN route server and an HBN VTEP that is peering to two spine switches for IP connectivity and 3 Route servers for EVPN overlay control.

```
root@sn1:/home/cumulus# uname -a
Linux sn1 5.15.0-88-generic #98-Ubuntu SMP Mon Oct 2 15:18:56 UTC 2023 x86_64 x86_64 x86_64 GNU/Linux

Total number of neighbors 3
doca-hbn-service-bf2-s12-1-ipmi#
```

The command output shows that the HBN has BGP sessions with spine switches exchanging IPv4/IPv6 unicast. BGP sessions with route servers `sn1`, `sn2`, and `sn3` only exchanging L2VPN EVPN AFI/SAFI.

8.8.5.3.3.6 Downstream VNI (DVNI)

Downstream VNI (symmetric EVPN route leaking) allows users to leak remote EVPN routes without having the source tenant VRF locally configured. A common use case is where upstream switches learn the L3VNI from downstream leaf switches and impose the learned L3VNI to the traffic VXLAN routed to the associated VRF. This eliminates the need to configure L3VNI-SVI interfaces on all leaf switches and enables shared service and hub-and-spoke scenarios.

To configure access to a shared service in a specific VRF, users must:

1. Configure route-target import statements, effectively leaking routes from remote tenants to the shared VRF.
2. Import shared VRF's route-target at the remote nodes.

The route target import or export statement takes the following format:

```
route-target import|export <asn>:<vni>
```

For example:

```
route-target import 65101:6000
```

For route target import statements, users can use `route-target import ANY:<vni>` for NVUE commands or `route-target import *:<vni>` in the `/etc/frr/frr.conf` file. `ANY` in NVUE commands or the asterisk (`*`) in the `/etc/frr/frr.conf` file use any ASN (autonomous system number) as a wildcard.

The NVUE commands are as follows:

1. To configure a route import statement:

   ```
   nv set vrf <vrf> router bgp route-import from-evpn route-target <asn>:<vni>
   ```

2. To configure a route export statement:

   ```
   nv set vrf <vrf> router bgp route-export from-evpn route-target <asn>:<vni>
   ```

Important considerations when implementing DVNI configuration:

- EVPN symmetric mode supports downstream VNI with L3 VNIs and single VXLAN devices only
- You can configure multiple import and export route targets in a VRF
- You cannot leak (import) overlapping tenant prefixes into the same destination VRF

If symmetric EVPN configuration is using automatic import/export (which is often the case), when DVNI is configured, automatic import of a tenant's VNI is disabled which isolates the VRF from the tenant. To avoid this issue, add `route-import from-evpn route-target auto` to the command line.

DVNI Configurations for Shared Internet Service

Configuration example here considers a scenario where External/Internet connectivity is available via a firewall (FW), which is connected to a shared VRF (`vrf external` in this example).

The routes on super spine switches have `external` VRF configured in which the route-targets from remote tenants are imported.

On BlueField devices with HBN, a local tenant VRF imports route-target corresponding to the shared `external` VRF.

L3VNI:

Tenant	L3VNI	
tenant1	30001	On HBN VTEPs
tenant2	30002	On HBN VTEPs
tenant3	30003	On HBN VTEPs
tenant4	30004	On HBN VTEPs
tenant5	30005	On HBN VTEPs
tenant6	30006	On HBN VTEPs
external	60000	Configured on superspines and connects to external world

On BlueField devices with HBN, every tenant VRF on HBN one must import VNI of shared `external` VRF:

```
nv set vrf tenant1 router bgp route-import from-evpn route-target ANY:60000
nv set vrf tenant1 router bgp route-import from-evpn route-target auto
nv set vrf tenant2 router bgp route-import from-evpn route-target ANY:60000
nv set vrf tenant2 router bgp route-import from-evpn route-target auto
nv set vrf tenant3 router bgp route-import from-evpn route-target ANY:60000
nv set vrf tenant3 router bgp route-import from-evpn route-target auto
nv set vrf tenant4 router bgp route-import from-evpn route-target ANY:60000
nv set vrf tenant4 router bgp route-import from-evpn route-target auto
nv set vrf tenant5 router bgp route-import from-evpn route-target ANY:60000
nv set vrf tenant5 router bgp route-import from-evpn route-target auto
nv set vrf tenant6 router bgp route-import from-evpn route-target ANY:60000
nv set vrf tenant6 router bgp route-import from-evpn route-target auto
root@doca-hbn-service-bf3-s06-1-ipmi:/tmp#
```

On super spine switches (SS1 in this example), every remote tenant VRF that needs access to shared services has to be leaked to the shared `external` VRF.

```
nv set vrf external router bgp route-import from-evpn route-target ANY:30001
nv set vrf external router bgp route-import from-evpn route-target ANY:30002
nv set vrf external router bgp route-import from-evpn route-target ANY:30003
nv set vrf external router bgp route-import from-evpn route-target ANY:30004
nv set vrf external router bgp route-import from-evpn route-target ANY:30005
nv set vrf external router bgp route-import from-evpn route-target ANY:30006
nv set vrf external router bgp route-import from-evpn route-target auto
root@superspine1:mgmt:/home/cumulus#
```

All super spines in this case need this configuration.

DVNI Leaked Routes in VRF Table of HBN

> Each super spine here is advertising reachability providing 4-way overlay ECMP.

8.8.5.3.3.7 Gateway Application Using Downstream VNI and Subinterface

A DPU running the HBN service can be deployed in the role of a border gateway using a combination of HBN features, specifically, EVPN symmetric routing, downstream VNI, VRF route-leaking, and VLAN sub-interfaces. Such a border gateway can do the northbound traffic handoff (to external networks or the Internet) for one or more tenants. In this gateway configuration, the BlueField's uplinks must carry both the tenant traffic which would be in the "overlay" and VXLAN-encapsulated, as well as traffic to and from the external network or Internet, which would be direct-routed in the "underlay". This is accomplished by configuring and running VXLAN-EVPN on the uplink interfaces while configuring and using additional VLAN sub-interfaces on those same uplinks for the traffic to and from external networks. These VLAN sub-interfaces would be configured into an Internet or external VRF for separation from the VXLAN-encapsulated traffic which is carried over the default VRF.

With a BlueField running HBN able to act as a border gateway, there is no longer a dependence on physical switches and routers to terminate VXLAN traffic and perform this role, hence the requirements on the underlying network is simply to provide end-to-

end IP/UDP connectivity and facilitate the setup of overlay networks on top. Additionally, multiple border gateways can be easily deployed in the network, including dedicated gateways per tenant or shared gateways for groups of tenants.

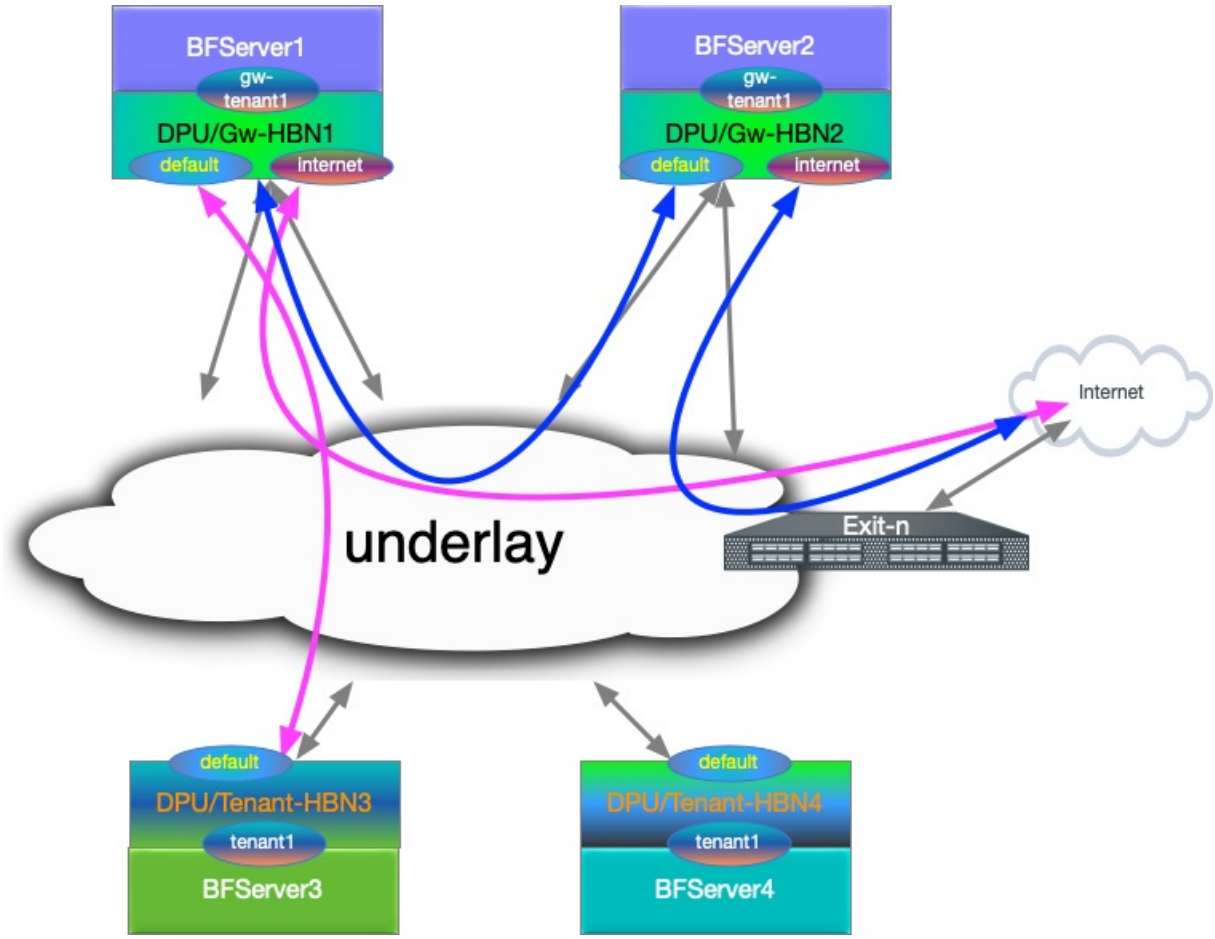
> ⚠ Since HBN currently does not support network address translation (NAT), a dedicated border gateway must be deployed per tenant, for those tenants that have overlapping IP addresses.

For more details and configuration of some of the key features that together enable the border gateway functionality, refer to sections on Downstream VNIs and VLAN Subinterfaces.

Gateway Application Example

The following topology diagram and associated configuration snippets show two different use cases of border gateway deployment:

- `tenant1` is an example of a tenant hosted on a server(s) with a non-gateway BlueField, using a dedicated border gateway on BlueField Gw-HBN1 for Internet connectivity. Traffic flow to and from the Internet for this tenant is marked in pink.
- `gw_tenant1` is an example of a tenant hosted on a server(s) with a gateway BlueField. In this case, the border gateway for this tenant is provided by BlueField Gw-HBN2. Traffic flow to and from the Internet for this tenant is depicted in blue.



L3 VNI Origin Map

HBN	VRF	L3 VNI
`gw-hbn1` and `gw-hbn2`	`internet1`	`10000`
`gw-hbn1` and `gw-hbn2`	`gw_tenant1`	`30000`
`tenant-hbn3` and `tenant-hbn4`	`tenant1`	`20000`

Configuration Snippet for Internet VRF

- Internet VRF is established in BGP sessions using sub-interface features with underlay switches (i.e., `p0_if.60` and `p1_if.60`)
- The Internet VRF also imports all the tenant VRFs (local and remote) using the downstream VNI feature with from-EVPN syntax

```
nv set interface p0_if.60,p1_if.60,vlan10 ip vrf internet1
nv set vrf internet1 evpn enable on
nv set vrf internet1 evpn vni 10000
    nv set vrf internet1 loopback ip address 6.2.0.1/32
nv set vrf internet1 loopback ip address 2001:cafe:feed::1/128
nv set vrf internet1 router bgp address-family ipv4-unicast enable on
nv set vrf internet1 router bgp address-family ipv4-unicast redistribute connected enable on
nv set vrf internet1 router bgp address-family ipv4-unicast route-export to-evpn enable on
nv set vrf internet1 router bgp address-family ipv6-unicast enable on
nv set vrf internet1 router bgp address-family ipv6-unicast redistribute connected enable on
nv set vrf internet1 router bgp address-family ipv6-unicast route-export to-evpn enable on
nv set vrf internet1 router bgp address-family l2vpn-evpn enable on
```

```
nv set vrf internet1 router bgp autonomous-system 65552
nv set vrf internet1 router bgp enable on
nv set vrf internet1 router bgp neighbor p0_if.60 capabilities source-address internet1
nv set vrf internet1 router bgp neighbor p0_if.60 peer-group l3_pg1
nv set vrf internet1 router bgp neighbor p0_if.60 type unnumbered
nv set vrf internet1 router bgp neighbor p1_if.60 capabilities source-address internet1
nv set vrf internet1 router bgp neighbor p1_if.60 peer-group l3_pg1
nv set vrf internet1 router bgp neighbor p1_if.60 type unnumbered
nv set vrf internet1 router bgp peer-group l3_pg1 address-family ipv4-unicast enable on
nv set vrf internet1 router bgp peer-group l3_pg1 address-family ipv6-unicast enable on
nv set vrf internet1 router bgp peer-group l3_pg1 remote-as external
nv set vrf internet1 router bgp route-export to-evpn route-target 65552:10000
nv set vrf internet1 router bgp route-import from-evpn route-target ANY:20000
nv set vrf internet1 router bgp route-import from-evpn route-target ANY:30000
nv set vrf internet1 router bgp route-import from-evpn route-target auto
nv set vrf internet1 router bgp router-id 27.0.0.5
```

Configuration Snippet for Gateway Local Tenant

- `gw_tenant` is stretched across 2 gateway and connected using L3 VNI
- `gw_tenant` has multiple SVIs, which are represented as `vlan30` and `vlan31` SVIs
- Internet L3 VNI is imported using DVNI. The example also explicitly adds route targets using auto.

`gw_tenant` VRF:

```
nv set interface vlan30-31 ip vrf gw_tenant1
nv set vrf gw_tenant1 evpn enable on
nv set vrf gw_tenant1 evpn vni 30000
nv set vrf gw_tenant1 loopback ip address 15.3.0.1/32
nv set vrf gw_tenant1 loopback ip address 2001:bad:c0de::1/128
nv set vrf gw_tenant1 router bgp address-family ipv4-unicast enable on
nv set vrf gw_tenant1 router bgp address-family ipv4-unicast redistribute connected enable on
nv set vrf gw_tenant1 router bgp address-family ipv4-unicast route-export to-evpn enable on
nv set vrf gw_tenant1 router bgp address-family ipv6-unicast enable on
nv set vrf gw_tenant1 router bgp address-family ipv6-unicast redistribute connected enable on
nv set vrf gw_tenant1 router bgp address-family ipv6-unicast route-export to-evpn enable on
nv set vrf gw_tenant1 router bgp address-family l2vpn-evpn enable on
nv set vrf gw_tenant1 router bgp autonomous-system 65552
nv set vrf gw_tenant1 router bgp enable on
nv set vrf gw_tenant1 router bgp route-export to-evpn route-target 65552:30000
nv set vrf gw_tenant1 router bgp route-import from-evpn route-target ANY:10000
nv set vrf gw_tenant1 router bgp route-import from-evpn route-target auto
nv set vrf gw_tenant1 router bgp router-id 27.0.0.5
```

Configuration Snippet for Remote Tenant

- `tenant1` is stretched across 2 remote HBN VTEP and connected using L3 VNI
- `tenant1` is importing Internet L3 VNI routes in `tenant1` and adding its own using route-target auto

Tenant VRF:

```
nv set interface vlan20-21 ip vrf tenant1
nv set vrf tenant1 evpn enable on
nv set vrf tenant1 evpn vni 20000
nv set vrf tenant1 loopback ip address 15.1.0.1/32
nv set vrf tenant1 loopback ip address 2001:c001:c0de::1/128
nv set vrf tenant1 router bgp address-family ipv4-unicast enable on
nv set vrf tenant1 router bgp address-family ipv4-unicast redistribute connected enable on
nv set vrf tenant1 router bgp address-family ipv4-unicast route-export to-evpn enable on
nv set vrf tenant1 router bgp address-family ipv6-unicast enable on
nv set vrf tenant1 router bgp address-family ipv6-unicast redistribute connected enable on
nv set vrf tenant1 router bgp address-family ipv6-unicast route-export to-evpn enable on
nv set vrf tenant1 router bgp address-family l2vpn-evpn enable on
nv set vrf tenant1 router bgp autonomous-system 6300656
nv set vrf tenant1 router bgp enable on
nv set vrf tenant1 router bgp route-export to-evpn route-target 6300656:20000
nv set vrf tenant1 router bgp route-import from-evpn route-target ANY:10000
nv set vrf tenant1 router bgp route-import from-evpn route-target auto
nv set vrf tenant1 router bgp router-id 27.0.0.17
```

HBN Accelerated Routing Plan

The following subsections pick a few IP endpoints from the code snippets above and examine their route distribution.

- The gateway devices have a remote tenant
- Internet route is injected using the default originator from the exit node

Gateway-1 Route Info

- BGP sharing the uplink via a sub-interface feature in the Internet VRF.

```
gateway1 - External Routes Internet VRF
```

```
root@doca-hbn-service # ip -4 route show default vrf internet1
default nhid 248 proto bgp metric 20

root@doca-hbn-service-bf2-s12-1-ipmi:~# ip -6 route show default vrf internet1
default nhid 248 proto bgp metric 20 pref medium

root@doca-hbn-service # ip nexthop get id 248 ; ip nexthop get id 249 ; ip nexthop get id 250
id 248 group 249/250 proto zebra
id 249 via fe80::202:ff:fe00:1d dev p0_if.60 scope link proto zebra
id 250 via fe80::202:ff:fe00:26 dev p1_if.60 scope link proto zebra
```

- Local Tenant routing information: The Internet is reached using L3 VNI via a peer gateway.

```
gateway1 - External Routes gw_tenant VRF
```

```
root@hbn:/# ip -4 route show vrf gw_tenant1  default
default  encap ip id 10000 src 0.0.0.0 dst 27.0.0.7 ttl 0 tos 0 via 27.0.0.7 dev vxlan48 proto bgp metric
20 onlink

root@hbn:/# ip -6 route show vrf gw_tenant1  default
default  encap ip id 10000 src 0.0.0.0 dst 27.0.0.7 ttl 0 tos 0 via ::ffff:27.0.0.7 dev vxlan48 proto bgp
metric 20 onlink pref medium
```

- Remote tenant routing reachability via `gateway1` using DVNI CFG.
- Considering an IP endpoint from the remote `tenant1` VRF on Tenant-HBN3.

```
gateway1 - Routes Internet VRF
```

```
root@hbn:/# ip -4 route show vrf internet1  15.1.0.1/32
15.1.0.1  encap ip id 20000 src 0.0.0.0 dst 27.0.0.17 ttl 0 tos 0 via 27.0.0.17 dev vxlan48 proto bgp
metric 20 onlink

root@hbn:/# ip -6 route show vrf internet1  2001:c001:c0de::1/128
2001:c001:c0de::1  encap ip id 20000 src 0.0.0.0 dst 27.0.0.17 ttl 0 tos 0 via ::ffff:27.0.0.17 dev vxlan48
proto bgp metric 20 onlink pref medium
```

Tenant-HBN3 Route Info

- IP endpoint as `gateway1` VRF loopback and DVNI handoff for the VNI is reaching the `gateway1` node.

```
tenant-hbn3 - Routes tenant VRF
```

```
root@hbn:/# ip -4 route show vrf tenant1 6.2.0.1/32
6.2.0.1  encap ip id 10000 src 0.0.0.0 dst 27.0.0.5 ttl 0 tos 0 via 27.0.0.5 dev vxlan48 proto bgp metric
20 onlink
```

```
root@hbn:/# ip -6 route show vrf tenant1 2001:cafe:feed::1/128
2001:cafe:feed::1  encap ip id 10000 src 0.0.0.0 dst 27.0.0.5 ttl 0 tos 0 via ::ffff:27.0.0.5 dev vxlan48
proto bgp metric 20 onlink pref medium
```

- Internet VRF default route is reaching the remote tenant VRF.

tenant-hbn3 external - Routes tenant VRF

```
root@hbn:/# ip -4 route show vrf tenant1 default
default proto bgp metric 20
    nexthop  encap ip id 10000 src 0.0.0.0 dst 27.0.0.5 ttl 0 tos 0 via 27.0.0.5 dev vxlan48 weight 1
 onlink
    nexthop  encap ip id 10000 src 0.0.0.0 dst 27.0.0.7 ttl 0 tos 0 via 27.0.0.7 dev vxlan48 weight 1
 onlink

root@hbn:/# ip -6 route show vrf tenant1 default
default proto bgp metric 20 pref medium
    nexthop  encap ip id 10000 src 0.0.0.0 dst 27.0.0.5 ttl 0 tos 0 via ::ffff:27.0.0.5 dev vxlan48 weight
1 onlink
    nexthop  encap ip id 10000 src 0.0.0.0 dst 27.0.0.7 ttl 0 tos 0 via ::ffff:27.0.0.7 dev vxlan48 weight
1 onlink
```

Gateway and Tenant Complete Configuration Example

8.8.5.3.4 Access Control Lists

Access Control Lists (ACLs) are a set of rules that are used to filter network traffic. These rules are used to specify the traffic flows that must be permitted or blocked at networking device interfaces. There are two types of ACLs:

- Stateless ACLs – rules that are applied to individual packets. They inspect each packet individually and permit/block the packets based on the packet header information and the match criteria specified by the rule.
- Stateful ACLs – rules that are applied to traffic sessions/connections. They inspect each packet with respect to the state of the session/connection to which the packet belongs to determine whether to permit/block the packet.

8.8.5.3.4.1 Stateless ACLs

HBN supports configuration of stateless ACLs for IPv4 packets, IPv6 packets, and Ethernet (MAC) frames. The following examples depict how stateless ACLs are configured for each case, with NVUE and with flat files (`cl-acltool`).

Stateless ACLs can be bound to host representor ports (for e.g., pf0hpf_if, pf0vf0_if, etc.) and sub-interfaces of host representor ports (pf0hpf_if.500, pf0vf0_if.999, etc).

NVUE Examples for Stateless ACLs

NVUE IPv4 ACLs Example

The following is an example of an ingress IPv4 ACL that permits DHCP request packets ingressing on the `pf0vf1_if.999` interface towards the DHCP server:

```
root@hbn01-host01:~# nv set acl acl1_ingress type ipv4
root@hbn01-host01:~# nv set acl acl1_ingress rule 100 match ip protocol udp
root@hbn01-host01:~# nv set acl acl1_ingress rule 100 match ip dest-port 67
root@hbn01-host01:~# nv set acl acl1_ingress rule 100 match ip source-port 68
root@hbn01-host01:~# nv set acl acl1_ingress rule 100 action permit
```

Bind the ingress IPv4 ACL to host representor port `pf0vf1_if.999` of BlueField in the inbound direction:

```
root@hbn01-host01:~# nv set interface pf0vf1_if.999 acl acl1_ingress inbound
root@hbn01-host01:~# nv config apply
```

The following is an example of an egress IPv4 ACL that permits DHCP reply packets egressing out of the `pf0vf1_if.999` port towards the DHCP client:

```
root@hbn01-host01:~# nv set acl acl2_egress type ipv4
root@hbn01-host01:~# nv set acl acl2_egress rule 200 match ip protocol udp
root@hbn01-host01:~# nv set acl acl2_egress rule 200 match ip dest-port 68
root@hbn01-host01:~# nv set acl acl2_egress rule 200 match ip source-port 67
root@hbn01-host01:~# nv set acl acl2_egress rule 200 action permit
```

Bind the egress IPv4 ACL to host representor port `pf0vf1_if.999` of BlueField in the outbound direction:

```
root@hbn01-host01:~# nv set interface pf0vf1_if.999 acl acl2_egress outbound
root@hbn01-host01:~# nv config apply
```

NVUE IPv6 ACLs Example

The following is an example of an ingress IPv6 ACL that permits traffic with matching `dest-ip` and `protocol tcp` ingress on port `pf0hpf_if` :

```
root@hbn01-host01:~# nv set acl acl5_ingress type ipv6
root@hbn01-host01:~# nv set acl acl5_ingress rule 100 match ip protocol tcp
root@hbn01-host01:~# nv set acl acl5_ingress rule 100 match ip dest-ip 48:2034::80:9
root@hbn01-host01:~# nv set acl acl5_ingress rule 100 action permit
```

Bind the ingress IPv6 ACL to host representor port `pf0hpf_if` of BlueField in the inbound direction:

```
root@hbn01-host01:~# nv set interface pf0hpf_if acl acl5_ingress inbound
root@hbn01-host01:~# nv config apply
```

The following is an example of an egress IPv6 ACL that permits traffic with matching `source-ip` and `protocol tcp` egressing out of port `pf0hpf_if`:

```
root@hbn01-host01:~# nv set acl acl6_egress type ipv6
root@hbn01-host01:~# nv set acl acl6_egress rule 101 match ip protocol tcp
root@hbn01-host01:~# nv set acl acl6_egress rule 101 match ip source-ip 48:2034::80:9
root@hbn01-host01:~# nv set acl acl6_egress rule 101 action permit
```

Bind the egress IPv6 ACL to host representor port `pf0hpf_if` of BlueField in the outbound direction:

```
root@hbn01-host01:~# nv set interface pf0hpf_if acl acl6_egress outbound
root@hbn01-host01:~# nv config apply
```

NVUE MAC ACLs Example

The following is an example of an ingress MAC ACL that permits traffic with matching `source-mac` and `dest-mac` ingressing to port `pf0hpf_if`:

```
root@hbn01-host01:~# nv set acl acl3_ingress type mac
root@hbn01-host01:~# nv set acl acl3_ingress rule 1 match mac source-mac 00:00:00:00:00:0a
root@hbn01-host01:~# nv set acl acl3_ingress rule 1 match mac dest-mac 00:00:00:00:00:0b
root@hbn01-host01:~# nv set interface pf0hpf_if acl acl3_ingress inbound
```

Bind the ingress MAC ACL to host representor port `pf0hpf_if` of BlueField in the inbound direction:

```
root@hbn01-host01:~# nv set interface pf0hpf_if acl acl3_ingress inbound
root@hbn01-host01:~# nv config apply
```

The following is an example of an egress MAC ACL that permits traffic with matching `source-mac` and `dest-mac` egressing out of port `pf0hpf_if`:

```
root@hbn01-host01:~# nv set acl acl4_egress type mac
root@hbn01-host01:~# nv set acl acl4_egress rule 2 match mac source-mac 00:00:00:00:00:0b
root@hbn01-host01:~# nv set acl acl4_egress rule 2 match mac dest-mac 00:00:00:00:00:0a
root@hbn01-host01:~# nv set acl acl4_egress rule 2 action permit
```

Bind the egress MAC ACL to host representor port `pf0hpf_if` of BlueField in the outbound direction:

```
root@hbn01-host01:~# nv set interface pf0hpf_if acl acl4_egress outbound
root@hbn01-host01:~# nv config apply
```

Flat Files (cl-acltool) Examples for Stateless ACLs

For the same examples cited above, the following are the corresponding ACL rules which must be configured under `/etc/cumulus/acl/policy.d/<rule_name.rules>` followed by invoking `cl-acltool -i`. The rules in `/etc/cumulus/acl/policy.d/<rule_name.rules>` are configured using Linux iptables/ip6tables/ebtables.

Flat Files IPv4 ACLs Example

The following example configures an ingress IPv4 ACL rule matching with DHCP request under `/etc/cumulus/acl/policy.d/<rule_name.rules>` with the ingress interface as the host representor of BlueField followed by invoking `cl-acltool -i`:

```
[iptables]
## ACL acl1_ingress in dir inbound on interface pf1vf1_if.999 ##
-t filter -A FORWARD -m physdev --physdev-in pf1vf1_if.999 -p udp --sport 68 --dport 67 -j ACCEPT
```

The following example configures an egress IPv4 ACL rule matching with DHCP reply under `/etc/cumulus/acl/policy.d/<rule_name.rules>` with the egress interface as the host representor of BlueField followed by invoking `cl-acltool -i`:

```
[iptables]
## ACL acl2_egress in dir outbound on interface pf1vf1_if.999 ##
-t filter -A FORWARD -m physdev --physdev-out pf1vf1_if.999 -p udp --sport 67 --dport 68 -j ACCEPT
```

Flat File IPv6 ACLs Example

The following example configures an ingress IPv6 ACL rule matching with `dest-ip` and `tcp` protocol under `/etc/cumulus/acl/policy.d/<rule_name.rules>` with the ingress interface as the host representor of BlueField followed by invoking `cl-acltool -i`:

```
[ip6tables]
## ACL acl5_ingress in dir inbound on interface pf0hpf_if ##
-t filter -A FORWARD -m physdev --physdev-in pf0hpf_if -d 48:2034::80:9 -p tcp -j ACCEPT
```

The following example configures an egress IPv6 ACL rule matching with `source-ip` and `tcp` protocol under `/etc/cumulus/acl/policy.d/<rule_name.rules>` with the egress interface as the host representor of BlueField followed by invoking `cl-acltool -i`:

```
[ip6tables]
## ACL acl6_egress in dir outbound on interface pf0hpf_if ##
-t filter -A FORWARD -m physdev --physdev-out pf0hpf_if -s 48:2034::80:9 -p tcp -j ACCEPT
```

Flat Files MAC ACLs Example

The following example configures an ingress MAC ACL rule matching with `source-mac` and `dest-mac` under `/etc/cumulus/acl/policy.d/<rule_name.rules>` with the ingress interface as the host representor of BlueField followed by invoking `cl-acltool -i`:

```
[ebtables]
## ACL acl3_ingress in dir inbound on interface pf0hpf_if ##
-t filter -A FORWARD -m physdev --physdev-in pf0hpf_if -s 00:00:00:00:00:0a/ff:ff:ff:ff:ff:ff -d 00:00:00:00:00:0b/
ff:ff:ff:ff:ff:ff -j ACCEPT
```

The following example configures an egress MAC ACL rule matching with `source-mac` and `dest-mac` under `/etc/cumulus/acl/policy.d/<rule_name.rules>` with egress interface as host representor of BlueField followed by invoking `cl-acltool -i`:

```
[ebtables]
## ACL acl4_egress in dir outbound on interface pf0hpf_if ##
-t filter -A FORWARD -m physdev --physdev-out pf0hpf_if -s 00:00:00:00:00:0b/ff:ff:ff:ff:ff:ff -d
00:00:00:00:00:0a/ff:ff:ff:ff:ff:ff -j ACCEPT
```

8.8.5.3.4.2 Stateful ACLs

Stateful ACLs facilitate monitoring and tracking traffic flows to enforce per-flow traffic filtering (unlike stateless ACLs which filter traffic on a per-packet basis). HBN supports stateful ACLs using reflexive ACL mechanism. Reflexive ACL mechanism is used to allow initiation of connections from "within" the network to "outside" the network and allow only replies to the initiated connections from "outside" the network (or vice versa).

HBN supports stateful ACL configuration for IPv4 traffic. Stateful ACL configuration is supported for TCP, UDP, and ICMP protocols.

Stateful ACLs can be bound to host representor ports (for e.g., pf0hpf_if, pf0vf0_if, etc.) and sub-interfaces of host representor ports (pf0hpf_if.500, pf0vf0_if.999, etc).

Stateful ACLs can be applied for native routed traffic (north-south underlay routed traffic in EVPN deployments), EVPN bridged traffic (east-west overlay bridged/L2 traffic in EVPN deployments) and EVPN routed traffic (east-west overlay routed traffic in EVPN deployments). Stateful ACLs applied for native routed traffic are called "Native-L3 stateful ACLs". Stateful ACLs applied for EVPN bridged traffic and EVPN routed traffic are called "EVPN-L2 stateful ACLs" and "EVPN-L3 stateful ACLs", respectively.

Stateful ACLs in HBN are enabled by default. To enable stateful ACL functionality, use the following NVUE commands:

```
root@hbn03-host00:~# nv set system reflexive-acl enable
root@hbn03-host00:~# nv config apply
```

If using flat-file configuration (and not NVUE), edit the file `/etc/cumulus/nl2docad.d/acl.conf` and set the knob `rflx.reflexive_acl_enable` to `TRUE`. To apply this change, execute:

```
root@hbn03-host00:~# supervisorctl start nl2doca-reload
```

NVUE Example for Stateful ACLs

The following is an example of allowing HTTP (TCP) connection originated by the host, where BlueField is hosted, to an HTTP server (with the IP address 11.11.11.11) on an external network. Two sets of ACLs matching with CONNTRACK state must be

configured for a CONNTRACK entry to be established in the kernel which would be offloaded to hardware:

- Configure an ACL rule matching TCP/HTTP connection/flow details with CONNTRACK state of NEW, ESTABLISHED and bind it to the SVI in the inbound direction.
- Configure an ACL rule matching TCP/HTTP connection/flow details with CONNTRACK state of ESTABLISHED and bind it to the SVI in the outbound direction.

Stateful ACLs should be bound to a physical interface. In this example, the physical interface is `pf1vf7_if`.

1. Configure the ingress ACL rule:

```
root@hbn03-host00:~# nv set acl allow_tcp_conn_from_host rule 11 action permit
root@hbn03-host00:~# nv set acl allow_tcp_conn_from_host rule 11 match conntrack new
root@hbn03-host00:~# nv set acl allow_tcp_conn_from_host rule 11 match conntrack established
root@hbn03-host00:~# nv set acl allow_tcp_conn_from_host rule 11 match ip dest-ip 11.11.11.11/32
root@hbn03-host00:~# nv set acl allow_tcp_conn_from_host rule 11 match ip dest-port 80
root@hbn03-host00:~# nv set acl allow_tcp_conn_from_host rule 11 match ip protocol tcp
root@hbn03-host00:~# nv set acl allow_tcp_conn_from_host type ipv4
```

2. Bind this ACL to the physical interface in the inbound direction:

```
root@hbn03-host00:~# nv set interface pf1vf7_if acl allow_tcp_conn_from_host inbound
root@hbn03-host00:~# nv config apply
```

3. Configure the egress ACL rule:

```
root@hbn03-host00:~# nv set acl allow_tcp_resp_from_server rule 21 action permit
root@hbn03-host00:~# nv set acl allow_tcp_resp_from_server rule 21 match conntrack established
root@hbn03-host00:~# nv set acl allow_tcp_resp_from_server rule 21 match ip protocol tcp
root@hbn03-host00:~# nv set acl allow_tcp_resp_from_server type ipv4
root@hbn03-host00:~# nv config apply
```

4. Bind this ACL to the physical interface in the outbound direction:

```
root@hbn03-host00:~# nv set interface pf1vf7_if acl allow_tcp_resp_from_server outbound
root@hbn03-host00:~# nv config apply
```

Flat Files (cl-acltool) Example for Stateful ACLs

For the same NVUE example for stateful ACLs cited above (HTTP server at IP address 11.11.11.11 on an external network), the following are the corresponding ACL rules which must be configured under `/etc/cumulus/acl/policy.d/<rule_name.rules>` followed by invoking `cl-acltool -i` to install the rules in BlueField hardware.

1. Configure an ingress ACL rule matching with TCP flow details and CONNTRACK state of NEW, ESTABLISHED under `/etc/cumulus/acl/policy.d/stateful_acl.rules` with the ingress interface as the SVI followed by invoking `cl-acltool -i`:

```
[iptables]
## ACL allow_tcp_conn_from_host in dir inbound on interface pf1vf7_if ##
-t filter -A FORWARD -m physdev --physdev-in pf1vf7_if -p tcp -d 11.11.11.11/32 --dport 80 -m conntrack --
ctstate EST,NEW -j ACCEPT -m mark --mark 0xdead
```

2. Configure an egress ACL rule matching the TCP flow and CONNTRACK state of ESTABLISHED, RELATED under `/etc/cumulus/acl/policy.d/stateful_acl.rules` file with the egress interface as SVI followed by invoking `cl-acltool -i` :

```
[iptables]
## ACL allow_tcp_resp_from_server in dir outbound on interface pf1vf7_if ##
-t filter -A FORWARD -m physdev --physdev-out  pf1vf7_if  -p tcp -s 11.11.11.11/32 --sport 80 -m conntrack
--ctstate EST -j ACCEPT -m mark --mark 0xdead
```

8.8.5.3.5 Network Address Translation

Network address translation (NAT) allows a network to use one set of IP addresses for internal traffic and another set for external traffic. Besides preventing the depletion of IPv4 addresses, NAT enables the use of private address space internally while still providing access to the Internet. NAT essentially consists of a set of rules for translating between public and private IP addresses and ports. Both static and dynamic NAT rules are configured on outbound or inbound uplink interfaces or sub-interfaces of uplink ports. These NAT rules should be applied on all public egress and ingress facing uplink interfaces and their sub-interfaces.

HBN supports Source NAT (SNAT), which allows traffic from the private network to reach public networks by changing the packet's source address. HBN also supports Destination NAT (DNAT), which allows incoming traffic from public networks to reach private networks by changing the packet's destination address. HBN SNAT and DNAT are supported for IPv4 and three protocols: ICMP, TCP, and UDP.

SNAT and DNAT can be configured in two types:

- Static NAT – Provides a permanent mapping between one private IP address and a single public address. Static NAT is stateless and does not use connection tracking. Static NAT is enabled by default and supports port address translation (PAT) with a one-to-one mapping between private and public ports. The static NAT mapping rules are not flushed or timed out from rule tables.
- Dynamic NAT – This is a stateful NAT which uses the OVS connection tracking infrastructure to monitor NAT connections. Dynamic NAT is disabled by default, and users must enable dynamic mode before setting up dynamic NAT rules (see section "Dynamic NAT Configuration"). Dynamic NAT maps private IP addresses to a range of public addresses and supports port ranges for PAT. Users are responsible for managing the pool of IP addresses and ports used in the configuration of dynamic NAT and PAT. It is recommended to use a NAT IP address range that is a power of two.

8.8.5.3.5.1 Source NAT (SNAT)

Static SNAT Configuration

Static NAT is enabled by default and is stateless.

NVUE Examples for Static SNAT

NVUE ICMP Example

The following is an example of an SNAT rule translating ICMP packets matching source IP 30.30.30.2 to source IP 100.100.100.2:

```
nv set acl acl_1 rule 1 action source-nat translate-ip 100.100.100.1
nv set acl acl_1 rule 1 match ip protocol icmp
nv set acl acl_1 rule 1 match ip source-ip 30.30.30.2
nv set acl acl_1 type ipv4
```

Bind the egress ICMP NAT ACL uplink port `p0_if` and `p1_if` of BlueField in the outbound direction:

```
nv set interface p0_if acl acl_1 outbound
nv set interface p1_if acl acl_1 outbound
```

NVUE UDP with PAT Example

The following is an example of an SNAT rule translating UDP packets matching source IP 21.1.0.18 and source port 10011 to source IP 199.5.1.1 and source port 11011:

```
nv set acl stnatpat rule 1 action source-nat translate-ip 199.5.1.1
nv set acl stnatpat rule 1 action source-nat translate-port 11011
nv set acl stnatpat rule 1 match ip protocol udp
nv set acl stnatpat rule 1 match ip source-ip 21.1.0.18
nv set acl stnatpat rule 1 match ip source-port 10011
nv set acl stnatpat type ipv4
```

Bind the egress UDP NAT ACL to uplink port `p0_if.10` and `p1_if.10` of BlueField in the outbound direction:

```
nv set interface p0_if.10,p1_if.10 acl stnatpat outbound
```

Flat Files (cl-acltool) Example for Static SNAT

```
[iptables]

## ACL acl_1 in dir outbound on interface p0_if ##
-t nat -A POSTROUTING  -m physdev --physdev-out p0_if -s 30.30.30.2 -p icmp  -j SNAT --to-source 100.100.100.1 -m
mark --mark 0xdead

## ACL acl_1 in dir outbound on interface p1_if ##
-t nat -A POSTROUTING  -m physdev --physdev-out p1_if -s 30.30.30.2 -p icmp  -j SNAT --to-source 100.100.100.1 -m
mark --mark 0xdead

## ACL stnatpat in dir outbound on interface p0_if.10 ##
-t nat -A POSTROUTING -o p0_if.10 -s 21.1.0.18 -p udp --sport 10011  -j SNAT --to-source 199.5.1.1:11011 -m mark --
mark 0xdead

## ACL stnatpat in dir outbound on interface p1_if.10 ##
-t nat -A POSTROUTING -o p1_if.10 -s 21.1.0.18 -p udp --sport 10011  -j SNAT --to-source 199.5.1.1:11011 -m mark --
mark 0xdead
```

Dynamic NAT Configuration

Dynamic NAT is stateful and relies on underlying connection tracking.

Enabling NVUE Dynamic NAT

```
nv set system nat mode dynamic
```

NVUE Examples for Dynamic SNAT

NVUE Dynamic SNAT with TCP

The following is an example of an SNAT rule translating TCP packets matching source IP 21.1.0.0/16 to an IP range of 199.10.0.1 to 199.10.255.254:

```
nv set acl dnat1 rule 1 action source-nat translate-ip 199.10.0.1 to 199.10.255.254
nv set acl dnat1 rule 1 match ip protocol tcp
nv set acl dnat1 rule 1 match ip source-ip 21.1.0.0/16
nv set acl dnat1 type ipv4
```

Bind the egress TCP NAT to uplink sub-interfaces `p0_if.10` and `p1_if.10`:

```
nv set interface p0_if.10,p1_if.10 acl dnat1 outbound
```

NVUE Dynamic SNAT with TCP and PAT

The following is an example of an SNAT rule translating TCP packets matching source IP 30.30.30.0/29 and source port 5000 to an IP range 100.100.100.8 to 100.100.100.15 and source port 10000:

```
nv set acl acl_2 rule 1 action source-nat translate-ip 100.100.100.8 to 100.100.100.15
nv set acl acl_2 rule 1 action source-nat translate-port 10000
nv set acl acl_2 rule 1 match ip protocol  tcp
nv set acl acl_2 rule 1 match ip source-ip 30.30.30.0/29
nv set acl acl_2 rule 1 match ip source-port  5000
nv set acl acl_2 type ipv4
```

Bind the egress TCP NAT to uplink sub-interfaces `p0_if` and `p1_if`:

```
nv set interface p0_if,p1_if acl acl_2 outbound
```

Flat Files (cl-acltool) Example for Dynamic SNAT

```
## ACL dnat1 in dir outbound on interface p0_if.10 ##
-t nat -A POSTROUTING -o p0_if.10 -s 21.1.0.0/16 -p tcp  -j SNAT --to-source 199.10.0.1-199.10.255.254 -m mark --
mark 0xdead
## ACL dnat1 in dir outbound on interface p1_if.10 ##
-t nat -A POSTROUTING -o p1_if.10 -s 21.1.0.0/16 -p tcp -j SNAT --to-source 199.10.0.1-199.10.255.254 -m mark --
mark 0xdead

## ACL acl_2 in dir outbound on interface p0_if ##
-t nat -A POSTROUTING  -m physdev --physdev-out p0_if -s 30.30.30.0/29 -p tcp --sport 5000  -j SNAT --to-source
100.100.100.8-100.100.100.15:10000 -m mark --mark 0xdead
## ACL acl_2 in dir outbound on interface p1_if ##
-t nat -A POSTROUTING  -m physdev --physdev-out p1_if -s 30.30.30.0/29 -p tcp --sport 5000  -j SNAT --to-source
100.100.100.8-100.100.100.15:10000 -m mark --mark 0xdead
```

The following is an example where a pool of private IP addresses is translated to a public address using a unique port number from the available range:

```
nv set acl dnatpat1 rule 1 action source-nat translate-ip 199.9.1.1
nv set acl dnatpat1 rule 1 match ip protocol tcp
nv set acl dnatpat1 rule 1 match ip source-ip 21.1.0.0/16
nv set acl dnatpat1 rule 1 action source-nat translate-port 10001-24000
nv set acl dnatpat1 type ipv4
nv set interface p0_if.10,p1_if.10 acl dnatpat1 outbound
```

8.8.5.3.5.2 Destination NAT (DNAT)

Static DNAT Configuration

Static NAT is enabled by default and is stateless.

NVUE Examples for Static DNAT

NVUE ICMP Example

The following is an example of an SNAT rule translating ICMP packets matching incoming destination IP 100.100.100.1 to destination IP 30.30.30.2

```
nv set acl acl_1 rule 1 action dest-nat translate-ip 30.30.30.2
nv set acl acl_1 rule 1 match ip protocol icmp
nv set acl acl_1 rule 1 match ip dest-ip  100.100.100.1
nv set acl acl_1 type ipv4
```

Bind the ingress ICMP NAT ACL to uplink port p0_if and p1_if of BlueField in the inbound direction:

```
nv set interface p0_if acl acl_1 inbound
nv set interface p1_if acl acl_1 inbound
```

NVUE UDP with PAT example

Flat Files (cl-acltool) Example for Static DNAT

```
## ACL acl_1 in dir inbound on interface p0_if ##
-t nat -A PREROUTING  -m physdev --physdev-in p0_if -d 100.100.100.1 -p icmp  -j DNAT --to-destination 30.30.30.2
 -m mark --mark 0xdead

## ACL acl_1 in dir inbound on interface p1_if ##
-t nat -A PREROUTING  -m physdev --physdev-in p1_if -d 100.100.100.1 -p icmp  -j DNAT --to-destination 30.30.30.2
 -m mark --mark 0xdead
```

Dynamic DNAT configuration

This is common configuration for DNAT and SNAT so please see section "Dynamic NAT Configuration".

Enabling NVUE Dynamic DNAT

NVUE Examples for Dynamic DNAT

NVUE Dynamic DNAT with TCP and PAT

The following is an example of an DNAT rule translating TCP packets matching destination IP 100.100.100.1/29 and destination port 5000 to an IP range 30.30.30.1 to 30.30.30.6 and translated destination port 1234:

```
nv set acl acl_3 rule 1 action dest-nat translate-ip 30.30.30.1 to 30.30.30.6
nv set acl acl_3 rule 1 action dest-nat translate-port 1234
nv set acl acl_3 rule 1 match ip protocol  tcp
nv set acl acl_3 rule 1 match ip dest-ip 100.100.100.1/29
nv set acl acl_3 rule 1 match ip dest-port  5000
nv set acl acl_3 type ipv4
```

Bind the ingress TCP NAT ACL to uplink sub-interfaces `p0_if` and `p1_if`:

```
nv set interface p0_if acl acl_6 inbound
nv set interface p1_if acl acl_6 inbound
```

Flat Files (cl-acltool) Example for Dynamic DNAT

```
## ACL acl_6 in dir inbound on interface p0_if ##
-t nat -A PREROUTING  -m physdev --physdev-in p0_if -d 100.100.100.1/29 -p udp  -j DNAT --to-destination
30.30.30.1-30.30.30.6 -m mark --mark 0xdead

## ACL acl_6 in dir inbound on interface p1_if ##
-t nat -A PREROUTING  -m physdev --physdev-in p1_if -d 100.100.100.1/29 -p udp  -j DNAT --to-destination
30.30.30.1-30.30.30.6 -m mark --mark 0xdead
```

More examples of dynamic DNAT with NVUE

In practice multiple rules can be combined as well as multiple dnat acl can be applied to same uplink ports.

ICMP

```
nv set acl dyndnaticmp rule 1 action dest-nat translate-ip 21.1.0.19 to 21.1.0.20
nv set acl dyndnaticmp rule 1 match ip dest-ip 199.101.6.0/30
nv set acl dyndnaticmp rule 1 match ip protocol icmp
nv set acl dyndnaticmp rule 2 action dest-nat translate-ip 120.19.0.19 to 120.19.0.20
nv set acl dyndnaticmp rule 2 match ip dest-ip 199.101.6.4/30
nv set acl dyndnaticmp rule 2 match ip protocol icmp
nv set acl dyndnaticmp rule 3 action dest-nat translate-ip 21.1.0.15 to 21.1.0.16
nv set acl dyndnaticmp rule 3 match ip dest-ip 199.101.6.8/30
nv set acl dyndnaticmp rule 3 match ip protocol icmp
nv set acl dyndnaticmp type ipv4
```

TCP

```
nv set acl dyndnattcp rule 1 action dest-nat translate-ip 21.1.0.19 to 21.1.0.20
nv set acl dyndnattcp rule 1 match ip dest-ip 199.101.7.0/30
nv set acl dyndnattcp rule 1 match ip protocol tcp
nv set acl dyndnattcp rule 2 action dest-nat translate-ip 120.19.0.19 to 120.19.0.20
nv set acl dyndnattcp rule 2 match ip dest-ip 199.101.7.4/30
nv set acl dyndnattcp rule 2 match ip protocol tcp
nv set acl dyndnattcp rule 3 action dest-nat translate-ip 21.1.0.15 to 21.1.0.16
nv set acl dyndnattcp rule 3 match ip dest-ip 199.101.7.8/30
nv set acl dyndnattcp rule 3 match ip protocol tcp
nv set acl dyndnattcp type ipv4
```

UDP

```
nv set acl dyndnatudp rule 1 action dest-nat translate-ip 21.1.0.19 to 21.1.0.20
nv set acl dyndnatudp rule 1 match ip dest-ip 199.101.8.0/30
nv set acl dyndnatudp rule 1 match ip protocol udp
nv set acl dyndnatudp rule 2 action dest-nat translate-ip 120.19.0.19 to 120.19.0.20
nv set acl dyndnatudp rule 2 match ip dest-ip 199.101.8.4/30
nv set acl dyndnatudp rule 2 match ip protocol udp
nv set acl dyndnatudp rule 3 action dest-nat translate-ip 21.1.0.15 to 21.1.0.16
nv set acl dyndnatudp rule 3 match ip dest-ip 199.101.8.8/30
nv set acl dyndnatudp rule 3 match ip protocol udp
nv set acl dyndnatudp type ipv4
```

Applying these to uplink ports

```
nv set interface p0_if.10,p1_if.10 acl dyndnaticmp inbound
nv set interface p0_if.10,p1_if.10 acl dyndnattcp inbound
nv set interface p0_if.10,p1_if.10 acl dyndnatudp inbound
```

8.8.5.3.6 Bidirectional Forwarding Detection (BFD) for BGP

BFD functionality is derived from the upstream FRRouting (FRR) suite, which includes a dedicated daemon called bfdd.
HBN supports BFD for BGP from 3.0.0 release. Single-Hop (UDP port 3784) and Multi-Hop (UDP port 4784) BFD supports are present for both IPv4 and IPv6. Asynchronous Mode (Periodically send BFD Control Packets to one another) is the default and only mode supported. *BFD Echo Function is **NOT** supported.*

8.8.5.3.6.1 BFD Configuration

BFD configuration has two parts , BFD profile configuration and BFD profile attachment to client like BGP.

BFD Profile Configuration

We have follwing profile settings for BFD sessions and it is present under "nv set/unset/ show router bfd profile <profile-name> " command.

Sr. No.	Command	Details	Range	Default
1.	detect-multiplier		1-255	3
2.	receive-interval	Configures the minimum interval that this system is capable of receiving control packets.	10-4294967ms	300ms
3.	transmit-interval	The minimum transmission interval (less jitter) that this system wants to use to send BFD control packets.	10-4294967ms	300 ms
4.	shutdown	Enables or disables the peer.	on/off	off
5.	passive-mode	Mark session as passive: a passive session will not attempt to start the connection and will wait for control packets from peer before it begins replying.	on/off	off
6.	minimum-ttl	For multi hop sessions only: configure the minimum expected TTL for an incoming BFD control packet.	1-254	254

```
nv set router bfd profile pf1 detect-multiplier 21
nv set router bfd profile pf1 min-rx-interval 100
nv set router bfd profile pf1 min-tx-interval 100
```

```
nv set router bfd profile pf1 minimum-ttl 253
nv set router bfd profile pf1 passive-mode on
nv set router bfd profile pf1 shutdown on
```

BGP Configuration for BFD

Apply BFD profile with BGP neighbor/peer-group. This will create/update BFD session for the respective BGP neighbor/peer-group.

```
nv set vrf default router bgp neighbor p0_if.100 bfd profile pf1
nv set vrf default router bgp neighbor 6000::23 bfd profile pf1
nv set vrf default router bgp peer-group EBGP_MHOP_V4 bfd profile pf1
```

8.8.5.3.6.2 BFD Show Commands

Following commands can be used to display BFD sessions.

```
root@doca-hbn-service-bf3-s13-1-ipmi:/etc/cumulus/sougatab/frr-bfd-upgrade-debs# nv show vrf default router bfd
peers --view=brief

MHop - Multihop, Local - Local, Peer - Peer, Interface - Interface, State -

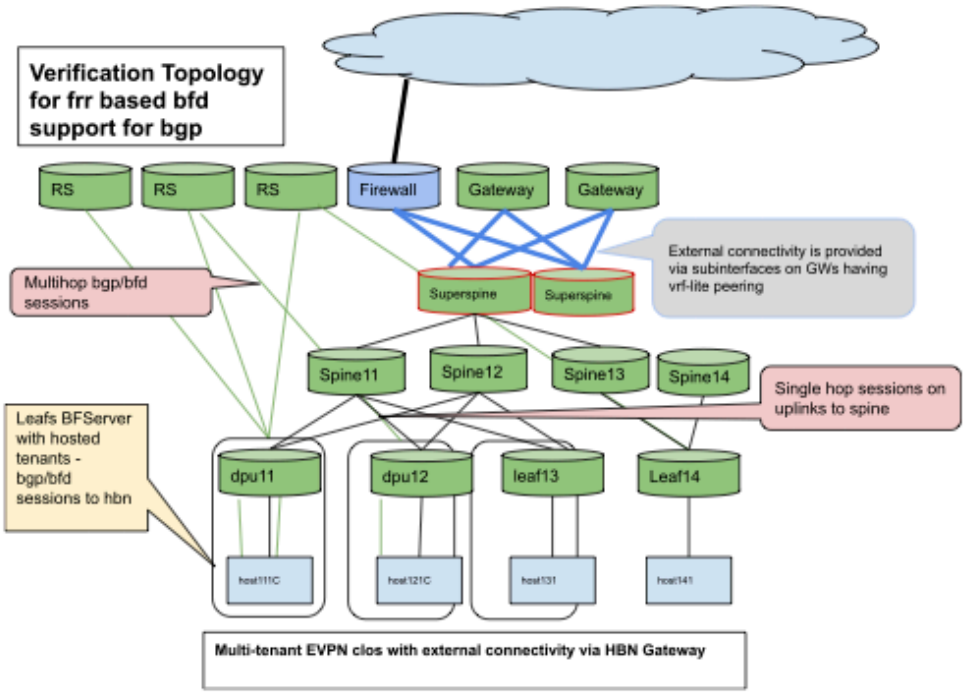
8.8.5.3.6.4 Example topology with hbn, route server and BF Host using BFD



In this example HBN running on dpu11 peers with

- route servers using multihop BFD in default vrf for EVPN
- host11C using singlehop BFD in each tenant vrf
    - tenant1 uses svi for bgp/bfd session

- tenant2 uses subinterface to peer to host

8.8.5.3.6.5 Configuration

DPU1 HBN configuration

HBN (DPU1)

8.8.5.3.7 Control plane policing (CoPP)

Control plane policing is a mechanism to guard the control plane. This is achieved by policing the traffic coming towards the control plane. Control plane constitutes of routers, management protocol handlers and system services. CoPP ensures only necessary traffic reaches to the control plane without exceeding predefined packet rate. CoPP uses filtering and rate limiting traffic coming towards control plane. This prevents overloading of CPU and other system resources with excessive packets i.e. Denial of service (DoS) attacks. The excess traffic is rate limited and dropped according to predefined or user defined configurations. CoPP configuration is applied globally to the control plane.

We have following separate policers for each protocol or group of packets. Unit of each value is in packet per second.

Sr. No.	Policer Name	Protocol	Default State	Default Rate	Default Burst
1.	arp	ARP, RARP	Enabled	800	800
2.	bgp	BGP	Enabled	2000	2000
3.	bfd	BFD	Enabled	2000	2000
4.	icmp	ICMP, ICMPv6	Enabled	1000	1000
5.	icmp6-neigh	IPv6 NDP	Enabled	1000	1000
6.	dhcp	DHCPv4, DHCPv6	Enabled	2000	2000
7.	ip2me	All other IPv4 or IPv6 traffic destined for HBN	Enabled	1000	1000
8.	catch-all	All other traffic not matched by above rules	Enabled	100	100

We enabled the CoPP configuration on HBN by default with predefined values.

8.8.5.3.7.1 CoPP configuration

Enabling a policer

In this example we are enabling a bgp policer.

```
nv set system control-plane policer bgp enable on
```

Updating a policer

In this example we are changing the rate and burst of the bgp policer.

```
nv set system control-plane policer bgp rate 3000
nv set system control-plane policer bgp burst 3000
```

Disabling a policer

```
nv set system control-plane policer bgp enable off
```

8.8.5.3.7.2 CoPP show commands

CoPP summary

Following CLI shows the summary of all the policers. This includes the configurations and respective statistics

```
nv show system control-plane policer
```

Corresponding sample output

```
Policer      State  Policer Rate  Policer Burst  To CPU Pkts  To CPU Bytes  Violated Packets  Violated Bytes

8.8.5.3.8 DHCP Relay on HBN

DHCP is a client server protocol that automatically provides IP hosts with IP addresses and other related configuration information. A DHCP relay (agent) is a host that

forwards DHCP packets between clients and servers. DHCP relays forward requests and replies between clients and servers that are not on the same physical subnet.

DHCP relay can be configured using either flat file (supervisord configuration) or through NVUE.

8.8.5.3.8.1 Configuration

HBN is a non-systemd based container. Therefore, the DHCP relay must be configured as explained in the following subsections.

Flat File Configuration (Supervisord)

The HBN initialization script installs default configuration files on BlueField in `/var/lib/hbn/etc/supervisor/conf.d/`. BlueField directory is mounted to `/etc/supervisor/conf.d` which achieves configuration persistence.

By default, DHCP relay is disabled. Default configuration applies to one instance of DHCPv4 relay and DHCPv6 relay in the default VRF.

NVUE Configuration

The user can use NVUE to configure and maintain DHCPv4 and DHCPv6 relays with CLI and REST API. NVUE generates all the required configurations and maintains the relay service.

DHCPv4 Relay Configuration

NVUE Example

The following configuration starts a relay service which listens for the DHCP messages on `p0_if`, `p1_if`, and `vlan482` and relays the requests to DHCP server 10.89.0.1 with `gateway-interface` as `lo`.

```
nv set service dhcp-relay default gateway-interface lo
nv set service dhcp-relay default interface p0_if
nv set service dhcp-relay default interface p1_if
nv set service dhcp-relay default interface vlan482 downstream
nv set service dhcp-relay default server 10.89.0.1
```

Flat Files Example

```
[program: isc-dhcp-relay-default]
command = /usr/sbin/dhcrelay --nl -d -i p0_if -i p1_if -id vlan482 -U lo 10.89.0.1
autostart = true
autorestart = unexpected
startsecs = 3
startretries = 3
exitcodes = 0
stopsignal = TERM
stopwaitsecs = 3
```

Where:

Option	Description
`-i`	Network interface to listen on for requests and replies

Option	Description
`-iu`	Upstream network interface
`-id`	Downstream network interface
`-U [address]%%ifname`	Gateway IP address interface. Use `%%` for `IP%%ifname`. `%` is used as an escape character.
`--loglevel-debug`	Debug logging. Location: `/var/log/syslog`.
`-a`	Append an agent option field to each request before forwarding it to the server with default values for `circuit-id` and `remote-id`
`-r remote-id`	Set a custom remote ID string (max of 255 chars). To use this option, you must also enable the `-a` option.
`--use-pif-circuit-id`	Set the underlying physical interface which receives the packet as the `circuit-id`. To use this option you must also enable the `-a` option.

DHCPv4 Relay Option 82

NVUE Example

The following NVUE command is used to enable option 82 insertion in DHCP packets with default values:

```
nv set service dhcp-relay default agent enable on
```

To provide a custom `remote-id` (e.g., host10) using NVUE:

```
nv set service dhcp-relay default agent remote-id host10
```

To use the underlying physical interface on which the request is received as `circuit-id` using NVUE:

```
nv set service dhcp-relay default agent use-pif-circuit-id enable on
```

Flat Files Example

```
[program: isc-dhcp-relay-default]
command = /usr/sbin/dhcrelay --nl -d -i p0_if -i p1_if -id vlan482 -U lo -a --use-pif-circuit-id -r host10
10.89.0.1
autostart = true
autorestart = unexpected
startsecs = 3
startretries = 3
exitcodes = 0
stopsignal = TERM
stopwaitsecs = 3
```

DHCPv6 Relay Configuration

NVUE Example

The following NVUE command starts the DHCPv6 Relay service which listens for DHCPv6 requests on `vlan482` and sends relayed DHCPv6 requests towards `p0_if` and `p1_if`.

```
nv set service dhcp-relay6 default interface downstream vlan482
nv set service dhcp-relay6 default interface upstream p0_if
nv set service dhcp-relay6 default interface upstream p1_if
```

Flat Files Example

```
[program: isc-dhcp-relay6-default]
command = /usr/sbin/dhcrelay --nl -6 -d -l vlan482 -u p0_if -u p1_if
autostart = true
autorestart = unexpected
startsecs = 3
startretries = 3
exitcodes = 0
stopsignal = TERM
stopwaitsecs = 3
```

Where:

Option	Description
`-l [address]%%ifname[#index]`	Downstream interface. Use `%%` for `IP%%ifname`. `%` is used as escape character.
`-u [address]%%ifname`	Upstream interface. Use `% %` for `IP%%ifname`. `%` is used as escape character.
`-6`	IPv6
`--loglevel-debug`	Debug logging located at `/var/log/syslog`

8.8.5.3.8.2 DHCP Relay and VRF Considerations

DHCP relay can be spawned inside a VRF context to handle the DHCP requests in that VRF. There can only be 1 instance each of DHCPv4 relay and DHCPv6 relay per VRF. To achieve that, the user can follow these guidelines:

- DHCPv4 on default VRF:

  ```
  /usr/sbin/dhcrelay --nl -i <interface> -U [address]%%<interface> <server_ip>
  ```

- DHCPv4 on VRF:

  ```
  /usr/sbin/ip vrf exec <vrf> /usr/sbin/dhcrelay --nl -i <interface> -U [address]%%<interface> <server_ip>
  ```

- DHCPv6 on default VRF:

  ```
  /usr/sbin/dhcrelay --nl -6 -l <interface> -u <interface>
  ```

- DHCPv6 on VRF:

  ```
  /usr/sbin/ip vrf exec <vrf> /usr/sbin/dhcrelay --nl -6 -l <interface> -u <interface>
  ```

8.8.6 HBN Service Troubleshooting

8.8.6.1 HBN Container Stuck in init-sfs

The HBN container starts as `init-sfs` and should transition to `doca-hbn` within 2 minutes as can be seen using `crictl ps`. But sometimes it may remain as `init-sfs`.

This can happen if interface `p0_if` is missing. Run the command `ip -br link show dev p0_if` in BlueField and inside the container to check if `p0_if` is present or not. If its missing, make sure the firmware is upgraded to the latest version. Perform BlueField system-level reset for the new firmware to take effect.

8.8.6.2 Host-side PF/VF Down After BlueField Reboot

In general, the host can use any interface manager to manage host interfaces belonging to BlueField. When the host uses an interface manager other than Netplan or NetworkManager, some ports may remain down after BlueField reboot.

Apply the following workaround if interfaces stay down:

1. Restart openibd:

```
systemctl restart openibd
```

2. Recreate SR-IOV interfaces if they are needed.
3. Replay interface config. For example:
    - If using ifupdown2:

```
ifreload -a
```

    - If using Netplan:

```
netplan apply
```

8.8.6.3 BGP Session not Establishing

One of the main causes of a BGP session not getting established is a mismatch in MTU configuration. Make sure the MTU on all interfaces is the same. For example, if BGP is failing on `p0`, check and verify that there is a matching MTU value for `p0`, `p0_if_r`, `p0_if`, and the remote peer of `p0`.

8.8.6.4 Generating Support Information

The HBN container image can be collected from `/etc/image-version` using the `hbn-support` command inside container:

```
root@bf2:/tmp# hbn-support
Please send /var/support/hbn_support_doca-hbn-service-bf2-s15-1-ipmi_20240820_211214.txz to Cumulus support.
```

The generated dump would be available under `/var/support` in the HBN container and should contain any process core dump and log files. The generated cores can be found under `/var/support/core` and collected by `hbn-support`. The `/var/support` directory is also mounted on the BlueField Arm side at `/var/lib/hbn/var/support`.

For BlueField, the BFB version can be checked from `/etc/mlnx-release`.

The firmware version can be collect from `mlxfwmanager`.

BlueField support dump can be collect using the `sos` command:

```
root@bf2:/tmp/#sos report -a --all-logs --batch
```

Example output:

```
sos report (version 4.8.0)

This command will collect system configuration and diagnostic
information from this Ubuntu system.
...
...
  Finished running plugins

Creating compressed archive...

Your sos report has been generated and saved in:
        /tmp/sosreport-bf2-s15-1-ipmi-2024-08-20-cpdvegw.tar.xz

Please send this file to your support representative.
```

8.8.6.5 SFC Troubleshooting

To troubleshoot flows going through SFC interfaces, the first step is to disable the `nl2doca` service in the HBN container:

```
root@bf2:/tmp# supervisorctl stop nl2doca
nl2doca: stopped
```

Stopping `nl2doca` effectively stops hardware offloading and switches to software forwarding. All packets would appear on `tcpdump` capture on BlueField interfaces.

`tcpdump` can be performed on SF interfaces as well as VLAN, VXLAN, and uplinks to determine where a packet gets dropped or which flow a packet is taking.

8.8.6.6 General nl2doca Troubleshooting

The following steps can be used to make sure the nl2doca daemon is up and running:

1. Make sure there are no errors in the nl2doca log file at `/var/log/hbn/nl2docad.log`.
2. To check the status of the nl2doca daemon under supervisor, run:

```
supervisorctl status nl2doca
```

3. Use `ps` to check that the actual nl2doca process is running:

```
ps -eaf | grep nl2doca
root          18       1  0 06:31 ?        00:00:00 /bin/bash /usr/bin/nl2doca-docker-start
root        1437      18  0 06:31 ?        00:05:49 /usr/sbin/nl2docad
```

4. The core file should be in `/var/support/core/`.
5. Check if the `/cumulus/nl2docad/run/stats/punt` is accessible. Otherwise, nl2doca may be stuck and should be restarted:

```
supervisorctl restart nl2doca
```

8.8.6.7 nl2doca Offload Troubleshooting

If a certain traffic flow does not work as expected, disable nl2doca (i.e., disable hardware offloading):

```
supervisorctl stop nl2doca
```

With hardware offloading disabled, you can confirm it is an offloading issue if the traffic starts working. If it is not an offloading issue, use `tcpdump` on various interfaces to see where the packet gets dropped.

Offloaded entries can be checked in following files, which contain the programming status of every IP prefix and MAC address known to system.

- Bridge entries are available in the file `/cumulus/nl2docad/run/software-tables/17`. It includes all the MAC addresses in the system including local and remote MAC addresses.
  Example format:

```
- flow-entry: 0xaaab0cef4190
      flow-pattern:
        fid: 112
```

```
        dst mac: 00:00:5e:00:01:01
      flow-actions:
        SET VRF: 2
        OUTPUT-PD-PORT: 20(TO_RTR_INTF)
        STATS:
          pkts: 1719
          bytes: 191286
```

- Router entries are available in the file `/cumulus/nl2docad/run/software-tables/18`. It includes all the IP prefixes known to the system.
  Example format for Entry with ECMP:

```
Entry with ECMP:
- flow-entry: 0xaaaada723700
  flow-pattern:
     IPV6: LPM
     VRF: 0
     destination-ip: ::/0
  flow-actions :
     ECMP: 2
     STATS:
        pkts: 0
        bytes: 0

Entry without ECMP: - flow-entry: 0xaaaada7e1400
    flow-pattern:
       IPV4: LPM
       VRF: 0
       destination-ip: 60.1.0.93/32
    flow-actions :
        SET FID: 200
        SMAC: 00:04:4b:a7:88:00
        DMAC: 00:03:00:08:00:12
        OUTPUT-PD-PORT: 19(TO_BR_INTF)
   STATS:
       pkts: 0
       bytes: 0
```

- ECMP entries are available in the file `/cumulus/nl2docad/run/software-tables/19`. It includes all the next hops in the system.
  Example format:

```
- ECMP: 2
  ref-count: 2
  num-next-hops: 2
  entries:
  - { index: 0, fid: 4100, src mac: 'b8:ce:f6:99:49:6a', dst mac: '00:02:00:00:00:0a' }
  - { index: 1, fid: 4101, src mac: 'b8:ce:f6:99:49:6b', dst mac: '00:02:00:00:00:0e' }
```

To check counters for packets going to the kernel, run:

```
cat /cumulus/nl2docad/run/stats/punt
PUNT miss pkts:3154 bytes:312326
PUNT miss drop pkts:0 bytes:0
PUNT control pkts:31493 bytes:2853186
PUNT control drop pkts:0 bytes:0
ACL PUNT pkts:68 bytes:7364
ACL drop pkts:0 bytes:0
```

For a specific type of packet flow, programming can be referenced in block specific files. The typical flow is as follows:

For example, to check L2 EVPN ENCAP flows for remote MAC `8a:88:d0:b1:92:b1` on port `pf0vf0_if`, the basic offload flow should look as follows: RxPort (`pf0vf0_if`) -> BR (Overlay) -> RTR (Underlay) -> BR (Underlay) -> TxPort (one of the uplink `p0_if` or `p1_if` based on ECMP hash).

Step-by-step procedure:

1. Navigate to the interface file `/cumulus/nl2docad/run/software-tables/20`.

2. Check for the RxPort (`pf0vf0_if`):

```
Interface: pf0vf0_if
    PD PORT: 6
    HW PORT: 16
    NETDEV PORT: 11
    Bridge-id: 61
    Untagged FID: 112
```

   FID 112 is given to the receive port.
3. Check the bridge table file `/cumulus/nl2docad/run/software-tables/17` with destination MAC `8a:88:d0:b1:92:b1` and FID 112:

```
flow-pattern:
      fid: 112
        dst mac: 8a:88:d0:b1:92:b1
      flow-actions:
        VXLAN ENCAP:
          ENCAP dst ip: 6.0.0.26
          ENCAP vni id: 1000112
        SET VRF: 0
        OUTPUT-PD-PORT: 20(TO_RTR_INTF)
        STATS:
          pkts: 100
          bytes: 10200
```

4. Check the router table file `/cumulus/nl2docad/run/software-tables/18` with destination IP `6.0.0.26` and VRF 0:

```
flow-pattern:
        IPV4: LPM
        VRF: 0
        ip dst: 6.0.0.26/32
      flow-actions :
        ECMP: 1
        OUTPUT PD PORT: 2(TO_BR_INTF)
        STATS:
          pkts: 300
          bytes: 44400
```

5. Check the ECMP table file `/cumulus/nl2docad/run/software-tables/19` with ECMP 1:

```
- ECMP: 1
      ref-count: 7
      num-next-hops: 2
      entries:
        - { index: 0, fid: 4100, src mac: 'b8:ce:f6:99:49:6a', dst mac: '00:02:00:00:00:2f' }
        - { index: 1, fid: 4115, src mac: 'b8:ce:f6:99:49:6b', dst mac: '00:02:00:00:00:33' }
```

6. The ECMP hash calculation picks one of these paths for next-hop rewrite. Check bridge table file for them (`fid=4100, dst mac: 00:02:00:00:00:2f` or `fid=4115, dst mac: 00:02:00:00:00:33`):

```
flow-pattern:
        fid: 4100
        dst mac: 00:02:00:00:00:2f
flow-actions:
    OUTPUT-PD-PORT: 36(p0_if)
    STATS:
       pkts: 1099
       bytes: 162652
```

   This will show the packet going out on the uplink.

8.8.6.8 NVUE Troubleshooting

To check the status of the NVUE daemon, run:

```
supervisorctl status nvued
```

To restart the NVUE daemon, run:

```
supervisorctl restart nvued
```

8.9 DOCA Management Service Guide

This guide explains how to use the DOCA Management Service (DMS) with the NVIDIA® BlueField® networking platform or NVIDIA® ConnectX® SmartNICs.

DOCA Management Service is currently in beta stage, with General Availability (GA) support for SPC-X use cases.

Follow the security best practices outlined in this guide to ensure proper protection when using this service.

8.9.1 Introduction

DOCA Management Service (DMS) is a centralized solution for configuring and operating BlueField and ConnectX devices.

Networking management in Cloud and AI Cloud environments is often fragmented, relying on incompatible tools and complex syntax. DMS addresses this by providing a unified API that simplifies secure local and remote configuration through intent-based models and standard protocols.

8.9.1.1 Data Modeling and Framework

DMS uses a methodical management framework inspired by OpenConfig. It provides a structured "dictionary" for device configurations, ensuring that diverse hardware features are managed through a consistent, hierarchical model rather than disparate scripts.

8.9.1.1.1 Unified Configuration Dictionary

DMS leverages YANG (Yet Another Next Generation) as its modeling language. This allows hardware parameters, firmware settings, and operational states to be mapped into a predictable, tree-like schema.

- Logic-based abstraction: YANG abstracts the complexity of underlying tools (like `mlxconfig` or OS scripts), representing them as intuitive paths (e.g., `/interfaces/interface/config/mtu`).
- Structured paths: DMS follows the OpenConfig convention of separating Configuration (desired state) and State (actual operational data) into distinct branches.
- Standardized transport: All interactions occur over gRPC, ensuring high-performance and secure communication.

⚠ DMS does not currently support telemetry streaming via the gNMI Subscribe mechanism.

8.9.1.1.2 Management Protocols

DMS implements two primary gRPC-based interfaces to handle different types of management tasks.

Interface	Purpose	Scope
gNMI (network management)	Data configuration	Used for `Get` and `Set` operations on device parameters (MTU, RoCE, QoS).
gNOI (network operations)	System tasks	Used for operational actions such as OS installation, reboots, and file transfers.

⚠
- DMS does not seek full OpenConfig alignment but uses it as a framework
- Telemetry streaming via gNMI Subscribe is not supported
- DMS can run on the host (managing BlueField/ConnectX) or directly on the BlueField Arm cores (DPU mode)

8.9.2 Security Considerations

DMS provides multiple layers of security to protect the infrastructure:

8.9.2.1 Architecture Security

8.9.2.1.1 Process Separation

DMS uses a two-process architecture to minimize security risks (detailed in the "Process Separation" section):

- dmsd (Frontend) – Handles client communication with limited privileges
- dmspe (Backend) – Executes privileged operations in an isolated process

This separation ensures that even if the frontend is compromised, privileged operations remain protected. The frontend process runs with minimal permissions and only communicates with the backend through a controlled interface, limiting the attack surface.

8.9.2.1.2 User Group Authorization

Only users in the `dmsgroup` are authorized to execute DMS commands, providing an additional access control layer.

8.9.2.2 Authentication and Encryption

DMS supports multiple authentication methods with varying security levels. The table below provides a quick overview; for detailed configuration examples and usage, see section "Manual Launch & Authentication Modes".

Method	Security Level	Best For	Description
Local testing	Low	Development only	No authentication. Server binds to localhost only.
PAM	Medium	Unix user authentication	Uses system user accounts. Requires `allowed_users` list.
Credentials	Medium	Simple deployments	Static username/password authentication.
Certificate (TLS)	High	Production deployments	Mutual TLS with certificates. Provides encryption and strong authentication.

TLS Encryption is strongly recommended for all production deployments to protect data in transit.

8.9.2.3 Network Exposure Risks and Mitigations

8.9.2.3.1 Risks

- Exposing DMS on external networks without proper authentication may allow unauthorized access
- Weak or default passwords can be exploited by attackers
- Unencrypted traffic can be intercepted (man-in-the-middle attacks)

8.9.2.3.2 Mitigations

The following security mitigations are recommended. For practical command examples, refer to section "Security Best Practices".

- Use Certificate (TLS) for production
- Enable TLS encryption for all external interfaces (see section "Mode 4: TLS with Certificates" for TLS configuration)
- For PAM authentication: use the `allowed_users` list to restrict which Unix users can connect (see section "Mode 2: PAM Authentication")
- Use strong, unique passwords or passfile instead of command-line passwords
- Bind to `localhost` (127.0.0.1) for local-only access
- Deploy DMS on the DPU for better isolation from the host network

8.9.2.4 Customer Responsibilities

To ensure secure DMS operation:

1. Use TLS in production – Always enable certificate-based authentication
2. Restrict network access – Configure firewall rules to restrict access to the dmsd listening port (configured via the `-bind_address` flag; see the "General Flags" section for port configuration details). Only allow connections from trusted management networks or specific client IP addresses.
3. Limit user access – Add only necessary users to `dmsgroup` (see the requirement to add user to dmsgroup)
4. Secure credentials – Use `--passfile` and restrict file permissions (chmod 600)
5. Monitor logs – Regularly review dmsd logs for suspicious activity
6. Keep software updated – Apply DOCA updates to address security fixes

> Refer to the "Security Best Practices" for more information.

8.9.3 Prerequisites

To operate the DMS, DOCA must be installed on the system where DMS will run.

- DMS on Host – The DOCA for Host package must be installed on the host system. It should be installed using either the `doca-networking` or `doca-all` profile. See the "Host Deployment (Non-DPU)" section for full details.
- DMS on DPU (BlueField Arm) – A compatible DOCA image must be installed on the BlueField Arm processor. See the "Running on the DPU (Arm)" section for full details.
- DMS in POD (Kubernetes) – Kubernetes must be installed and configured on the system. The system must have appropriate container runtime support (Docker or Kubelet). See the "POD Deployment (Kubernetes)" section for full details.

Consult the DOCA Installation Guide for Linux to correctly set up the required DOCA components prior to deploying DMS

Supported operating systems are Linux-based environments.

8.9.4 Service Deployment

DMS consists of the below components:

- `dmsd` – Server (Frontend) – DMS server frontend that handles client communication. Can run on the BlueField Arm or on the host with an NVIDIA PCIe device.
- `dmspe` – Privileged Backend – Executes privileged operations in an isolated process for security (see the "Process Separation" section).
- `dmsc` – Client – DOCA-provided OpenConfig client. Customers can choose to use this client, any other open-source client, or develop their own (gRPC-based) client.
- Yang files – Yang model files contain the data model used to configure the device, using NVIDIA-specific extension to common OpenConfig YANG Models.
- Configuration files - DMS uses configuration files for authentication (password files, user access lists), security (TLS certificates and keys), and service settings (YAML configuration files, service files). These files manage access control, encryption, and operational parameters.

8.9.4.1 DMS Operational Modes

DMS consists of two main processes that work together to provide secure management capabilities:

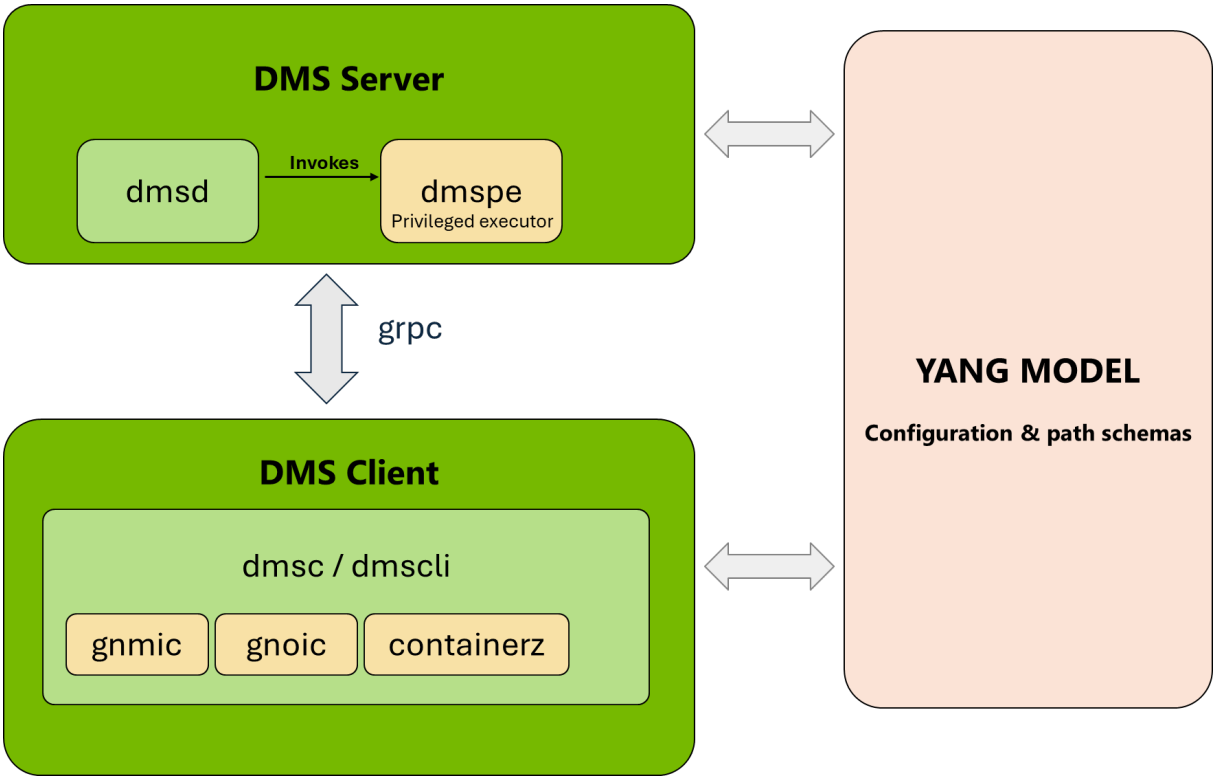
8.9.4.1.1 dmsd (Frontend Process)

Acts as the frontend service responsible for managing communication with clients. It handles incoming requests and prepares them for secure execution. The dmsd process is user-facing and responds to client requests, then communicates with the privileged backend when elevated permissions are required.

8.9.4.1.2 dmspe (Privileged Backend Process)

Responsible for executing privileged commands that require elevated permissions. These commands are executed securely to ensure system integrity. The dmspe process operates as a back-end service, silently executing commands on behalf of dmsd with the necessary privileges.

The following diagram illustrates the DMS architecture and component interactions:

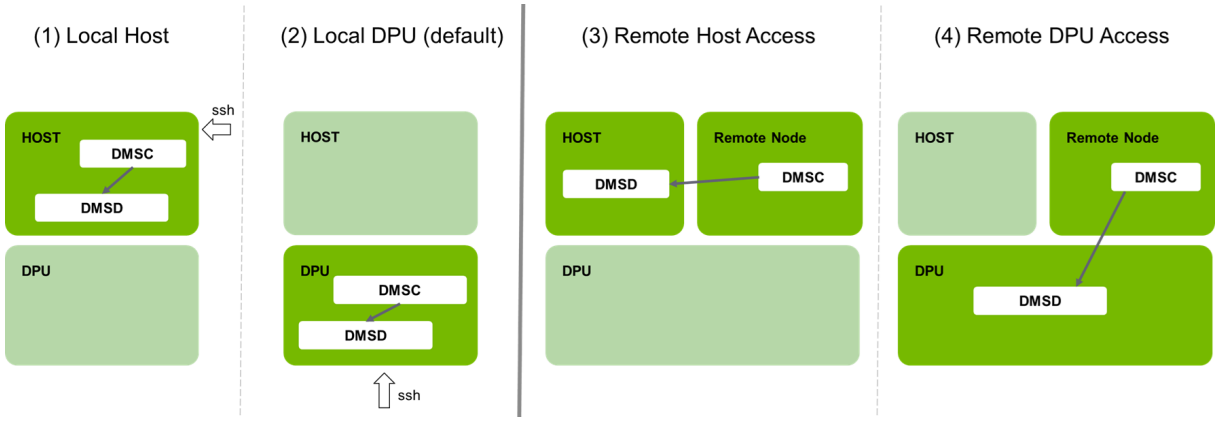


The DMS architecture supports flexible deployment.

The DMS client (Dmsc) can operate from various locations relative to the server components (Dmsd frontend and Dmspe backend).

The supported modes of operation are:

- 1. Local Host – Both the DMS client (`dmsc`) and server components (`dmsd` frontend with `dmspe` backend) are deployed on the Host.
- 2. Local DPU (Default) – Both the DMS client and server components are deployed on the DPU (BlueField Arm).
- 3. Remote Client (Host Server) – The DMS server components are deployed on the Host, while the DMS client is deployed remotely, connecting over the management network.
- 4. Remote Client (DPU Server) – The DMS server components are deployed on the DPU, while the DMS client is deployed remotely.
- 5. Host with ConnectX NIC (non-DPU) – DMS server components run on the Host, managing a ConnectX NIC without a DPU.
- 6. Host with Multiple NICs/DPUs – A single DMS server on the Host manages multiple network devices simultaneously.
- 7. Containerized Deployment – DMS server components run in a container on the Host (see the Containerz deployment instructions).
- 8. POD Deployment – DMS server components run in a Kubernetes pod, enabling orchestrated deployment



8.9.4.2 Process Separation

DMS implements process separation to enhance security and performance by isolating privileged operations from client-facing services. This architecture ensures that:

- Client-facing operations (handled by dmsd frontend) remain non-privileged and user-facing
- Privileged operations (handled by dmspe backend) are executed in an isolated, secure process

- System integrity is maintained by limiting the attack surface and preventing unauthorized access to elevated permissions

The detailed architecture and process descriptions are provided in section "DMS Operational Modes".

8.9.5 Running the DMS Server

8.9.5.1 Prerequisites

To operate the DMS, the underlying DOCA framework must be properly installed and configured based on your deployment target.

> **OS Compatibility**
>
> DMS is strictly supported on Linux-based environments.

8.9.5.1.1 Host Deployment (Non-DPU)

When running DMS on the host server to manage connected PCIe devices, the following setup is required:

- The DOCA for Host package must be installed using either the `doca-networking` or `doca-all` profile.
- You must execute the `install_dmspe.sh` script to install the backend with the correct execution permissions.
- Only users within the `dmsgroup` are authorized to execute DMS commands. Add your user and apply the changes:

```
sudo usermod -a -G dmsgroup $USER
newgrp dmsgroup
```

8.9.5.1.2 DPU Deployment (BlueField Arm)

When running DMS directly on the BlueField Arm cores, the necessary backend permissions are set automatically, so no installation script is required.

- A compatible DOCA image must be installed on the BlueField Arm processor.
- You must still ensure your user is a member of the `dmsgroup` to execute commands.

8.9.5.1.3 POD Deployment (Kubernetes)

When orchestrating DMS via Kubernetes, the user group requirements are handled automatically within the container environment.

- A Kubernetes cluster must be configured with a compatible container runtime (Docker or Kubelet).
- The POD must be deployed using the provided `dms.yaml` file.
- The container requires privileged access to interact with the underlying hardware devices.

8.9.5.2 DMS Daemon Launch Options

The `dmsd` frontend server can be launched automatically via SystemD or manually from the command line for custom authentication testing.

8.9.5.2.1 Option 1: SystemD Service (Recommended)

On the DPU, `dmsd` comes pre-installed with the BlueField BFB-Bundle and runs automatically as a `systemd` service bound to `localhost:9339`.

> ⚠ It does not run as a SystemD service automatically on the host.

By default, the service uses PAM authentication. You can interact with it using the built-in `dmscli` wrapper, which defaults to the OS root password.

SystemD management commands:

- View current configuration:

```
systemctl cat dmsd.service
```

- Edit service flags (e.g., change auth mode):

```
sudo systemctl edit --full dmsd.service
```

- Apply changes and restart:

```
sudo systemctl daemon-reload && sudo systemctl restart dmsd.service
```

- Verify the process is running:

```
ps -ef | grep dms
```

The template service file is located at `/opt/mellanox/doca/services/dms/dmsd.service/dmsd.service`.

8.9.5.2.2 Option 2: Manual Launch & Authentication Modes

When launching `dmsd` manually, you must define the authentication mode using the `--auth` flag. Below are the four supported operational modes, ranging from local testing to production-grade security.

8.9.5.2.2.1 Authentication Modes Overview

Mode	Security Level	Best For	Description
Mode 1: Local Testing	Low	Development only	No authentication. The server binds strictly to localhost (`127.0.0.1`) with TLS disabled.
Mode 2: PAM	Medium	Unix user authentication	Uses the system's Pluggable Authentication Modules (PAM) to verify against local Unix accounts. Requires an `allowed_users` list.
Mode 3: Credentials	Medium	Simple deployments	Authenticates using a predefined, static username and password configured on the server.
Mode 4: Certificate (TLS)	High	Production deployments	Uses mutual TLS (mTLS) with certificates. Provides full encryption and strong mutual authentication.

For a complete breakdown of all `dmsc` client arguments and their default values, please refer to the "DMS Client Flags" section.

Password Handling

Important note on password handling:

- Interactive prompt: By default, if a password is required, the client prompts the user to enter it interactively.
- Passfile (`--passfile`): For automation or secure deployments, passwords can be provided using the `--passfile /path/to/file` parameter instead.
- Server requirement: If using a passfile on the server side, the `dmsd` server process must have read permissions to that specific file.

8.9.5.2.2.2 CLI Command Reference

Use the following server and client command templates to launch and interact with DMS in your chosen mode.

> ⚠ Replace `<server_ip>` with your actual target IP address. For PAM and Credentials modes, the client will be prompted interactively for the password unless `--passfile` is used.

Mode	Target	Execution Command
Mode 1: Local Testing	Server	`dmsd -bind_address 127.0.0.1:9339 -auth cert -tls_enabled=false`
	Client	`dmsc -a 127.0.0.1:9339 -i get --path /state/system/platform`
Mode 2: PAM	Server	`dmsd -bind_address 0.0.0.0:9339 -auth pam -allowed_users root,admin -tls_enabled=false`
	Client	`dmsc -a <server_ip>:9339 -u root -i get --path /state/system/platform`
Mode 3: Credentials	Server	`dmsd -bind_address 0.0.0.0:9339 -auth credentials -username admin -password secret -tls_enabled=false`
	Client	`dmsc -a <server_ip>:9339 -u admin -i get --path /state/system/platform`
Mode 4: Certificate	Server	`dmsd -bind_address 0.0.0.0:9339 -auth cert -tls_ca /tmp/ca.crt -tls_cert /tmp/target.crt -tls_key /tmp/target.key`
	Client	`dmsc -a <server_ip>:9339 --tls-ca /tmp/ca.crt --tls-cert /tmp/client.crt --tls-key /tmp/client.key get --path /state/system/platform`

8.9.5.2.3 Advanced Launch Configurations

The following examples demonstrate how to start the `dmsd` daemon manually for specialized environments, alternate authentication methods, and specific hardware targeting.

8.9.5.2.3.1 Shadow File Authentication (Remote Host)

This method allows for a zero-touch setup by reusing an existing OS user's credentials, reading the hashed password directly from the shadow file.

```
/opt/mellanox/doca/services/dms/dmsd \
  --bind_address <ip>:<port> \
  --auth shadow \
  --username my_username \
  --shadow /etc/shadow
```

8.9.5.2.3.2 Credentials with Inline Password (Localhost)

While standard credential modes prompt for a password interactively, you can explicitly pass it inline for automation scripts.

> ⚠ For production automation, using `--passfile` is recommended over plaintext inline passwords.

```
/opt/mellanox/doca/services/dms/dmsd \
  --bind_address localhost:9339 \
  --auth credentials \
  --username my_username \
  --password my_password
```

8.9.5.2.3.3 Targeting a Specific PCIe Device

If your host contains multiple NVIDIA DPUs or network devices, you must specify the exact PCIe address for the DMS daemon to bind to.

```
/opt/mellanox/doca/services/dms/dmsd \
  --bind_address localhost:9339 \
  --auth credentials \
  --username my_username \
  --password my_password \
  --target_pci 0000:08:00
```

8.9.5.2.3.4 Targeting Multiple PCIe Devices

You can manage multiple DPUs simultaneously from a single server instance by providing a comma-separated list of their PCIe addresses.

```
/opt/mellanox/doca/services/dms/dmsd \
  --bind_address localhost:9339 \
  --auth credentials \
  --username my_username \
  --password my_password \
  --target_pci 0000:08:00,0000:09:00
```

8.9.5.2.4 Security Best Practices

To ensure proper protection of your infrastructure, always adhere to the following guidelines:

Do	Do Not
Use Mode 4 (TLS with certificates) in all production environments.	Use `-tls_enabled=false` or `-noauth` over public or production networks.
Use the `--passfile` flag (with `chmod 600` permissions) to supply credentials securely.	Put plaintext passwords directly on the command line using the `-password` flag in production.
Restrict the `-allowed_users` list to only the specific administrators who need access.	Expose the server on `0.0.0.0` without strict authentication and firewall configurations.

8.9.5.3 DMS Server Flags (`dmsd`)

To view the complete list of flags dynamically, run `dmsd --help`.

8.9.5.3.1 General & Provisioning Flags

Flag	Description	Default
`--bind_address <string>`	Binds the server to an IP and port (e.g., `localhost:9339` or `0.0.0.0:9339`).	`:9339`
`-v <value>`	Sets the log level for V logs.	N/A
`--target_pci <string>`	Specifies target PCIe addresses. Auto-selects if only one device is present.	N/A
`--image_folder <string>`	Defines the image installation directory for OS provisioning.	`/tmp/dms`
`--chunk_size_ack <uint>`	Chunk size (in bytes) required to trigger a transfer response.	`12000000`
`--exec_timeout <uint>`	Maximum execution timeout (in seconds) for unresponsive commands.	`0` (Unlimited)
`--init_config <string>`	Path to a JSON file containing gNMI requests to automatically run on startup.	N/A

8.9.5.3.2 Authentication & Security Flags

Flag	Description
`--auth <string>`	Sets the authentication mode. Valid options: `shadow`, `credentials`, `cert`.
`--noauth`	Disables authentication entirely (Requires `shadow` or `credentials` mode).
`--username <string>`	Specifies the username (Required for `shadow` and `credentials` modes).

Flag	Description
`--password <string>`	Specifies the plaintext password (Used in `credentials` mode).
`--shadow <string>`	Path to the system shadow file (Used in `shadow` mode).
`--ca <string>`	Path to the Certificate Authority (CA) validation certificate.
`--tls_cert_file <string>`	Path to the server's public TLS certificate.
`--tls_key_file <string>`	Path to the server's private TLS key.

8.9.5.3.3 Authentication Method Flags

The `--auth <string>` flag specifies one of the following three authentication methods, each with its own set of required flags:

8.9.5.3.3.1 Shadow

- Zero-touch setup – no need to create a dedicated DMS user (reuses existing OS user)
- The server reads the hashed password from the shadow file in real time for each client request
- Required flags: `--username <string>` and `--shadow <string>`
    - Example:

```
--auth shadow --username root --shadow /etc/shadow
```

- To disable authentication:

```
--noauth
```

8.9.5.3.3.2 Credentials

- Requires the admin to define a strong password.
- Required flags: `--username <string>` and optionally `--password <string>`
    - Example:

```
--auth credentials --username root --password 123456
```

- To prompt for password input interactively at startup, leave the `--password` flag empty.
- To disable authentication:

```
--noauth
```

8.9.5.3.3.3 Certificate (TLS)

- The most secure option, using Transport Layer Security (TLS) for both encryption and mutual authentication.
- Authentication is based on digital certificates, ensuring only trusted clients can connect.
    - Required flags:
      `--auth cert`
      `--ca <path/to/ca.crt>`
      `--tls_key_file <path/to/target.key>`
      `--tls_cert_file <path/to/target.crt>`
    - Example:

      ```
      --auth cert --ca /path/to/certs/ca.crt --tls_key_file /path/to/certs/target.key --tls_cert_file /
      path/to/certs/target.crt
      ```

- To disable TLS:

  ```
  --tls_enabled=false
  ```

8.9.5.3.4 Security Flags

8.9.5.3.4.1 TLS Encryption and Authentication

DMS uses TLS (Transport Layer Security) by default to secure communication. TLS is a widely adopted cryptographic protocol that provides the following guarantees:

- Encryption – Protects transmitted data from eavesdropping.
- Authentication – Verifies the identity of the server and optionally the client via digital certificates.
- Integrity – Ensures transmitted data is not tampered with.

TLS relies on a public/private key pair and a digital certificate issued by a Certificate Authority (CA). These elements ensure secure, authenticated communication.

DMS supports TLS for both gNMI and gNOI interfaces, and works with either self-signed or CA-signed certificates.

To enable TLS, both server and client must provide:

- `--ca <string>` – Path to the CA certificate used to validate the remote party's certificate.
- `--tls_cert_file <string>` – Path to the public certificate presented during the TLS handshake.

- `--tls_key_file <string>` – Path to the corresponding private key used to sign the handshake and decrypt messages.

  > ⚠ The private key must be protected. If compromised, it can be used to impersonate the server or client.

8.9.5.3.4.2 TLS Communication Modes

Mutual TLS Authentication (mTLS)

Both the server and client present certificates and verify each other during the TLS handshake.

```
# Server:
/opt/mellanox/doca/services/dms/dmsd <flags> --auth cert \
  --ca /path/to/certs/client_ca.crt \
  --tls_cert_file /path/to/certs/target.crt \
  --tls_key_file /path/to/certs/target.key

# Client:
/opt/mellanox/doca/services/dms/dmsc <flags> \
  --tls-ca /path/to/certs/target_ca.crt \
  --tls-cert /path/to/certs/client.crt \
  --tls-key /path/to/certs/client.key <command>
```

Highlights:

- Provides the highest level of security.
- Ensures both sides are authenticated and trusted.
- All traffic is encrypted.

TLS (Server Authentication Only)

Only the server presents its certificate during the handshake. The client verifies the server but does not present a certificate.

```
# Server:
/opt/mellanox/doca/services/dms/dmsd <flags> --auth cert \
  --tls_cert_file /path/to/certs/target.crt \
  --tls_key_file /path/to/certs/target.key

# Client:
/opt/mellanox/doca/services/dms/dmsc <flags> \
  --tls-ca /path/to/certs/target_ca.crt \
  --skip-verify <command>
```

Highlights:

- Client authenticity is not verified.
- Use `--skip-verify` if a root CA is not provided.
- Traffic remains encrypted.

Insecure Mode (No TLS)

TLS is disabled entirely on both server and client. No encryption or authentication is performed.

- Server:

```
/opt/mellanox/doca/services/dms/dmsd <flags> --auth cert --tls_enabled=false
```

- Client:

```
/opt/mellanox/doca/services/dms/dmsc <flags> --insecure <command>
```

To achieve insecure communication (no encryption), configure:

- Server – use `--tls_enabled=false` param
- Client – use `--insecure` flag'

Highlights:

- Not recommended for production.
- Use only in fully isolated, trusted environments for testing or development.

8.9.5.4 Logging

DMS generates comprehensive logs for troubleshooting and system monitoring. Understanding exactly where these logs are stored and how they are generated is critical for maintaining system health.

Log Rotation & Disk Space

DMS does not automatically rotate log files. By default, logging is enabled for all components, meaning these files will grow continuously over time. If you do not manually implement log rotation policies (e.g., using `logrotate`), DMS logs will eventually consume all available disk space, potentially causing system failure.

8.9.5.4.1 Log Components and Locations

There is no single "end-to-end" log file for DMS. You must check the specific component logs based on your deployment type:

Component	Log Location / Command	Deployment Type	Description
Wrapper Script	`/var/log/dms/dms_wrapper.log`	Containerized / POD only	Contains initialization messages from the `entrypoint.sh` script, version info, and startup statuses.
`dmsd` (Frontend)	`journalctl -u dmsd`	Systemd	Captured automatically by `journald`. Reads from the binary database.
`dmsd` (Frontend)	`kubectl logs` or `docker logs`	Containerized	Logs are piped directly to standard out/error (`stdout` / `stderr`).

Component	Log Location / Command	Deployment Type	Description
`dmspe` (Backend)	`journalctl | grep dmspe`	All (Recommended)	The backend uses `syslog` exclusively. Use this command to filter journald for backend execution logs.
`dmspe` (Backend)	`/var/log/syslog`	Legacy Systems	If `rsyslog` is configured, messages are written here. ⚠ This file may not exist on modern systems using only journald.

8.9.5.4.2 Example Log Rotation Configuration

To prevent the wrapper logs from filling your storage, save the following configuration to `/etc/logrotate.d/dms`:

```
/var/log/dms/*.log {
    daily
    rotate 7
    compress
    delaycompress
    missingok
    notifempty
    create 0644 root root
}
```

8.9.5.5 Configuration Persistency

DMS can automatically restore device configurations when the service restarts by utilizing the `-init_config` flag. This mechanism ensures that your infrastructure configurations persist reliably across service interruptions or scheduled restarts.

8.9.5.5.1 State Restoration Mechanism

1. When DMS receives gNMI `Set` requests, it automatically records the desired state to the specified `init_config` file.

   ⚠ This behavior can be disabled using the `-disable_recording_init_config` flag.

2. On startup, the DMS daemon reads the `init_config` file and automatically applies all stored configurations.

This workflow ensures that device configurations are always restored to their last successfully configured state following a reboot or service restart.

8.9.5.5.2 Configuration File Characteristics

- The configuration file stores gNMI `Set` requests in standard JSON format.
- If the specified file does not exist at startup, DMS will automatically generate an empty JSON file (`{}`).
- The file is updated in real-time whenever a `Set` request is processed, keeping the persistent state synchronized with runtime changes.

8.9.5.5.3 Disabling Automatic Recording

If you need strict, immutable control over your startup configurations, you can prevent DMS from automatically recording new `Set` requests by passing the `-disable_recording_init_config` flag at launch.

This is useful when administrators want to manually curate the JSON configuration file, and it prevents runtime changes from surviving a service reboot.

8.9.5.5.4 Execution Example

To set up configuration persistency, launch the `dmsd` server and point the `-init_config` flag to your desired JSON file path.

```
dmsd -bind_address 0.0.0.0:9339 -auth pam -init_config /opt/mellanox/doca/services/dms/dms_config.json
```

Upon any subsequent restart, DMS will automatically apply the configurations saved in `dms_config.json` .

8.9.6 Running the DMS Client

Client Binaries: dmsc vs. dmscli

This guide references both `dmsc` and `dmscli` :

- `dmsc` is the core DMS client binary used for executing standard, single-line CLI commands (e.g., `dmsc <flags> get...`).
- `dmscli` is a convenience wrapper script built around `dmsc` . Running `dmscli` automatically drops you into the interactive `prompt` mode with built-in autocomplete functionality. It is equivalent to running `dmsc prompt` .

To see the full list of flags, use the help flag (i.e., `dmsc --help`, `dmsc -h`).

8.9.6.1 DMS Client Flags (`dmsc`)

General and security flags:

Flag	Description	Default
`--address <string>`	Address and port of the target `dmsd` server.	`:9339`
`--target <string>`	Target PCIe address (Mandatory if the server manages multiple devices).	N/A
`-u`, `--username <string>`	Username for authentication.	N/A
`-p`, `--password <string>`	Password for authentication.	N/A
`-d`, `--debug`	Enables debug mode output.	Disabled
`--tls-ca <string>`	Path to the server's CA certificate.	N/A
`--tls-cert <string>`	Path to the client's public TLS certificate.	N/A
`--tls-key <string>`	Path to the client's private TLS key.	N/A
`--skip-verify`	Skips verifying the server's certificate during handshake (Connection remains encrypted).	Disabled
`--insecure`	Disables TLS entirely. Connects over plain, unencrypted TCP.	Disabled

8.9.6.2 gNMI Command

The gRPC Network Management Interface (gNMI) is a standardized protocol used to configure and monitor network devices via gRPC and Protocol Buffers. It enables structured interaction using standardized models like OpenConfig.

8.9.6.2.1 Supported Core Commands

- Get – Retrieves real-time device data (e.g., operational state, configurations).
- Set – Modifies device configurations immediately.
- Capabilities – Queries the device's capabilities, including supported models, versions, and encodings.

> ⚠ DMS does not currently support the gNMI `Subscribe` command (streaming telemetry data).

For an interactive shell experience with autocomplete, use the `dmscli` wrapper. Run `dmscli prompt` and authenticate using the `dmsd` user password (which defaults to the OS root password).

8.9.6.2.2 Executing Get Requests

Get requests retrieve data in real-time without relying on a cache. You must provide the specific YANG XPath for the parameter you wish to query.

You can query exact parameters or request an entire subtree.

If you fail to provide a mandatory parameter for decoding a leaf, that leaf is skipped. If the first leaf fails, the entire request fails.

Syntax (querying a specific interface MTU):

```
/opt/mellanox/doca/services/dms/dmsc <flags> get --path /interfaces/interface[name=p0]/config/mtu
```

Example JSON response:

```
[
  {
    "source": "localhost:9339",
    "timestamp": 1712485149723248511,
    "time": "2024-04-07T10:19:09.723248511Z",
    "updates": [
      {
        "Path": "interfaces/interface[name=p0]/config/mtu",
        "values": {
          "interfaces/interface/config/mtu": "1500"
        }
      }
    ]
  }
]
```

8.9.6.2.3 Executing Set Requests

Set requests execute immediately, invoking the underlying OS tools to apply the configuration.

Syntax Requirement

When passing inline updates, you must separate the path, data type, and value using the `:::` delimiter. Currently, only the `--update` flag is supported for Set operations.

Syntax (updating MTU to 9216):

```
/opt/mellanox/doca/services/dms/dmsc <flags> set --update /interfaces/interface[name=p0]/config/mtu:::int:::9216
```

Example JSON response:

```
{
  "source": "localhost:9339",
  "time": "1970-01-01T00:00:00Z",
  "results": [
    {
      "operation": "UPDATE",
      "path": "interfaces/interface[name=p0]/config/mtu"
    }
  ]
}
```

While most updates execute immediately, certain leaves require a system reboot to take effect. See the gNOI system reboot section for details.

8.9.6.2.3.1 Bulk Configurations via JSON

To apply multiple configurations simultaneously, you can pass a JSON file containing a list of commands using the `--request-file` flag.

```
/opt/mellanox/doca/services/dms/dmsc <flags> set --request-file req.json
```

Example `req.json` structure:

```
{
  "updates": [
    {
      "path": "/interfaces/interface[name=p0]/config/mtu",
      "value": 9216,
      "encoding": "uint"
    },
    {
      "path": "/interfaces/interface[name=p0]/config/enabled",
      "value": true,
      "encoding": "bool"
    }
  ]
}
```

8.9.6.2.4 Supported Get/Set Paths Reference

To dynamically list all supported paths on your specific device, run the following command:

```
/opt/mellanox/doca/services/dms/dmsc --file /opt/mellanox/doca/service/dms/yang path --types --descr
```

Availability Modes

The table below indicates hardware compatibility for each path. These paths work across all DMS operational modes, provided the underlying hardware supports the feature:

- Local Host: Client and server on Host
- Local DPU (default): Client and server on DPU
- Remote Client (Host Server): Server on Host, client remote
- Remote Client (DPU Server): Server on DPU, client remote

- Host with ConnectX NIC: Host managing ConnectX NIC without DPU
- Host with Multiple NICs/DPUs: Single Host server managing multiple devices
- Containerized Deployment: DMS in container on Host
- POD Deployment: DMS in Kubernetes pod

The "Hardware" column indicates which hardware types support each path, regardless of the operational mode used.

The tables below outline the primary configuration paths available across DMS.

- Configuration Paths (`/config/...`): Support both `Get` and `Set` operations.
- State Paths (`/state/...`): Support `Get` only (read-only operational data).
- Command Paths (`/nvidia/command/...`): Support `Get` only to trigger execution.

8.9.6.2.4.1 Core Interface Settings

Base paths prefix: `/interfaces/interface[name=*]` .

Configuration Path	Type	Description	Hardware
`/config/enabled`	`boolean`	Enables or disables the interface administratively.	All modes
`/config/mtu`	`uint16`	Sets the MTU size in octets.	All modes
`/config/name`	`string`	Specifies the device-specific name of the interface.	All modes
`/config/type`	`identityref`	Defines the specific type of the interface.	All modes
`/name`	`leafref`	References the interface name.	All modes
`/ethernet/nvidia/config/inter-packet-gap`	`uint8`	Configures the inter-packet gap in 4-byte units.	DPU only
`/ethernet/nvidia/config/rate-limit`	`uint16`	Sets the port bandwidth rate limit in permille units.	DPU only
`/state/admin-status`	`enum`	Retrieves the desired administrative state of the interface.	All modes
`/state/oper-status`	`enum`	Retrieves the current operational state of the interface.	All modes

8.9.6.2.4.2 Quality of Service (QoS)

Base paths prefix: `/interfaces/interface[name=*]/nvidia/qos` .

Configuration Path	Type	Description	Hardware
`/config/pfc`	`boolean`	Enables Priority Flow Control (PFC).	All modes
`/config/priority-to-tc`	`string`	Maps priorities to traffic classes (requires exactly 8 entries).	All modes
`/config/priority[id=*]/id`	`prio`	Sets the specific Priority ID (0-7).	All modes
`/config/trust-mode`	`identityref`	Sets the interface QoS trust mode (PCP, DSCP).	All modes

8.9.6.2.4.3 RoCE Configuration

Base paths prefix: `/interfaces/interface[name=*]/nvidia/roce` (unless marked global).

Configuration Path	Type	Description	Hardware
`/adp-retx-profiles*`	`json`	Configures adaptive-retransmission timeouts via JSON.	CX, DPU
`/config/adaptive-retransmission`	`boolean`	Enables RoCE adaptive retransmission.	CX, DPU
`/config/adaptive-routing-force`	`boolean`	Forces adaptive routing even if not negotiated.	CX, DPU
`/config/cc-per-plane`	`boolean`	Enables Congestion Control per plane.	CX, DPU
`/config/rt-resp-dscp`	`uint8`	Defines the fixed DSCP value for RTT response packets.	CX, DPU
`/config/rt-resp-dscp-mode`	`identityref`	Defines the method for setting DSCP in RTT responses.	CX, DPU
`/config/slow-restart`	`boolean`	Enables slow restart during network congestion.	CX, DPU
`/config/slow-restart-idle`	`boolean`	Enables slow restart when the network is idle.	CX, DPU
`/config/tos`	`tos`	Sets the Type of Service (ToS) value for RoCE traffic.	CX, DPU
`/config/tx-window`	`boolean`	Enables the transmission window.	CX, DPU
(Global) `/nvidia/roce/config/adaptive-routing`	`boolean`	Globally enables RoCE adaptive routing.	CX, DPU
(Global) `/nvidia/roce/config/cc-steering-ext`	`string`	Controls the 2-bit CC steering extension.	CX, DPU
(Global) `/nvidia/roce/config/multipath-dscp`	`identityref`	Sets the DSCP bit for multipath on transmit.	CX, DPU

Configuration Path	Type	Description	Hardware
(Global) `/nvidia/roce/config/tx-sched-locality-mode`	`identityref`	Configures the transmission scheduler adaptation to locality.	CX, DPU

8.9.6.2.4.4 Congestion Control (CC) Settings

Base paths prefix: `/interfaces/interface[name=*]/nvidia/cc` (unless marked global).

Configuration Path	Type	Description	Hardware
`/config/priority[id=*]/id`	`leafref`	References the CC priority configuration entry ID.	CX, DPU
`/config/priority[id=*]/np_enabled`	`boolean`	Enables CC Notification Point (NP) for the priority.	CX, DPU
`/config/priority[id=*]/rp_enabled`	`boolean`	Enables CC Reaction Point (RP) for the priority via DOCA SDK.	CX, DPU
`/slot[id=*]/config/counter_enable`	`boolean`	Enables the counter for the specified CC algorithm slot.	CX, DPU
`/slot[id=*]/config/enabled`	`boolean`	Enables execution of the CC algorithm slot.	CX, DPU
`/slot[id=*]/config/id`	`algo`	Sets the CC algorithm slot ID.	CX, DPU
`/slot[id=*]/id`	`leafref`	References the CC algorithm slot ID.	CX, DPU
`/slot[...]/param[...]/config/id`	`algo`	Sets the CC algorithm parameter ID.	CX, DPU
`/slot[...]/param[...]/config/value`	`algo`	Sets the parameter value within the CC algorithm slot.	CX, DPU
`/slot[...]/param[...]/id`	`leafref`	References the CC algorithm parameter ID.	CX, DPU
(Global) `/nvidia/cc/config/user-programmable`	`boolean`	Globally enables user-programmable CC functionality.	CX, DPU

8.9.6.2.4.5 System and Device Management

Base paths prefix: `/nvidia`.

Configuration Path	Type	Description	Hardware
`/command[run=*]/run`	`string`	Executes the specified command.	All modes
`/device/config/module[...]/module-id`	`int`	Retrieves the module ID for port splitting (read-only).	DPU only
`/device/config/module[...]/port[...]/port-id`	`int`	Retrieves the port ID for port splitting (read-only).	DPU only
`/device/config/module[...]/port[...]/lanes`	`string`	Sets or retrieves the lanes for port splitting.	DPU only
`/mode/config/mode`	`identityref`	Sets the operational mode of the DPU (NIC, DPU, SEPARATED).	DPU only
`/physical-functions/config/num-of-pf`	`int`	Sets/gets the number of PFs for multiplane and port splitting.	CX, DPU
`/interfaces/interface[name=*]/virtual-functions/vf[netdev-name=*]/config/data-direct`	`boolean`	Enables data direct options for VFs.	DPU only

8.9.6.3 gNOI Commands

gNOI (gRPC Network Operations Interface) is a protocol for operational tasks such as installing software, managing certificates, and troubleshooting. It complements gNMI by focusing on administrative and system-level functions.

Within DMSc, gNOI support is provided by the GNOIC project. For full documentation, refer to the GNOIC project documentation.

To invoke a gNOI command, run:

```
/opt/mellanox/doca/services/dms/dmsc -a localhost --port 9339 --tls-cert client.crt --tls-key client.key <command>
```

To use interactive mode with autocompletion, enter:

```
/opt/mellanox/doca/services/dms/dmsc prompt
```

> ⚠ All commands are blocked by default unless explicitly enabled. gNOI commands are currently supported only on the host system—not on the BlueField.

8.9.6.3.1 OS Commands

The OS command suite facilitates the lifecycle management of device software, supporting the provisioning of DOCA images (BFB bundles) on BlueField DPUs and firmware updates for both DPUs and ConnectX NICs.

8.9.6.3.1.1 Install

This command transfers and authenticates the specified package file to the target device.

If the file already exists in the server's image folder (default: `/tmp/dms`) with the expected version and extension, the server intelligently skips the transfer phase and proceeds directly to authentication.

Syntax examples:

- Install a BFB image:

```
/opt/mellanox/doca/services/dms/dmsc <flags> os install --version 2_9_0 --pkg DOCA_2.9.0_Ubuntu.bfb
```

- Install a configuration file:

```
/opt/mellanox/doca/services/dms/dmsc <flags> os install --version 0_0_1.cfg --pkg bf.cfg
```

- Install firmware:

```
/opt/mellanox/doca/services/dms/dmsc <flags> os install --version 24_29_0046.fw --pkg fw-BlueField.bin
```

8.9.6.3.1.2 Activate

Deploys the staged BFB bundles or firmware to the active hardware.

The `activate` command deploys BFB bundles and/or firmware to the hardware.

```
/opt/mellanox/doca/services/dms/dmsc <flags> os activate --version <version_string>
```

Syntax examples:

- Activate all files matching a version prefix:

```
/opt/mellanox/doca/services/dms/dmsc <flags> os activate --version 2_9_0
```

- Activate specific files by name (semicolon-separated):

```
/opt/mellanox/doca/services/dms/dmsc <flags> os activate --version "2_9_0.bfb;0_0_1.cfg;24_29_0046.fw"
```

- Auto-detect and install the appropriate firmware:

```
/opt/mellanox/doca/services/dms/dmsc <flags> os activate --version auto
```

Important activation behaviors:

- Auto mode: Using `--version auto` automatically triggers the `mlnx-fw-updater.pl` script, which detects the connected device type and installs the correct firmware version.
- Host requirement: Deploying BFB bundles is strictly supported only when the command is run from the host system.
- Automatic reset: Activating firmware automatically triggers a firmware reset upon completion.

8.9.6.3.1.3 Verify

Retrieves the currently installed firmware and BFB bundle versions from the target device.

> ⚠ The BFB bundle version is only displayed if it was originally installed via DMS.

```
/opt/mellanox/doca/services/dms/dmsc <flags> os verify
```

The response includes the firmware and BFB versions, separated by a semicolon:

```
+-----------------+-------------------------------------------------------------+-----------------------------+
|   Target Name   |                          Version                            | Activation Fail Msg         |
+-----------------+-------------------------------------------------------------+-----------------------------+
| 127.0.0.1:19999 | FW: 32.42.1000;BFB: bf-bundle-2.8.0-98_24.07-ubuntu-22.04_dev |                             |
+-----------------+-------------------------------------------------------------+-----------------------------+
```

8.9.6.3.2 System

Manage system-level state transitions, such as rebooting the BlueField Arm or firmware.

8.9.6.3.2.1 Reboot Status

Queries the target to determine if a reboot is currently in progress.

```
/opt/mellanox/doca/services/dms/dmsc <flags> system reboot-status [--reboot_status_check <mode>]
```

> ℹ Returns `false` if active, or `true` if rebooting.

Reboot status check modes:

Value	Description
`fast`	Default. Performs a quick but imprecise check. Any configuration change may trigger a reboot response.
`strict`	Performs a slower but highly accurate status check.

Value	Description
`none`	Skips the firmware reboot check entirely.

8.9.6.3.2.2 Reboot

Triggers a reboot of the device. This command is non-blocking and returns immediately to the client.

```
/opt/mellanox/doca/services/dms/dmsc <flags> system reboot --delay <seconds> [--subcomponent <component>] [--method
<type>]
```

This command is non-blocking and returns immediately after it is issued.

Flag	Description
`--delay <uint>`	Seconds to wait before executing the reset
`--subcomponent`	Specifies the component to reset (currently supports: `ARM`)
`--method`	Specifies the reset method (supported values: `WARM`, `POWERDOWN`)

⚠ If `subcomponent` and `method` are not specified, the system executes the lowest-level reset available.

8.9.6.3.3 Factory-reset

Performs a factory reset on the target node by restoring all PFs to their default out-of-the-box configurations.

Standard execution:

```
/opt/mellanox/doca/services/dms/dmsc <flags> factory-reset start
```

Alias execution:

```
/opt/mellanox/doca/services/dms/dmsc <flags> reset start
```

⚠ Resetting to a "Golden Image" (a pre-configured, ideal-state version) is not currently supported.

8.9.6.3.4 File

The `file` command suite performs operational file transfers and metadata queries directly on the target device.

8.9.6.3.4.1 Stat

Retrieves metadata (such as permissions, size, and modification dates) for a specified file or directory.

- Single file query:

```
/opt/mellanox/doca/services/dms/dmsc <flags> file stat --path /path/to/file
```

- Directory query with recursive listing:

```
/opt/mellanox/doca/services/dms/dmsc <flags> file stat --path /path/to/dir --recursive
```

Example output:

```
+----------------+---------------------+----------------------+------------+------------+------+
|  Target Name   |        Path         |     LastModified     |    Perm    |   Umask    | Size |
+----------------+---------------------+----------------------+------------+------------+------+
| 127.0.0.1:9339 | /path/to/dir/file_1 | 2025-04-10T09:05:37Z | -rw-r--r-- | -----w--w- | 0    |
|                | /path/to/dir/file_2 | 2025-04-10T09:05:37Z | -rw-r--r-- | -----w--w- | 0    |
+----------------+---------------------+----------------------+------------+------------+------+
```

8.9.6.3.4.2 Get

Streams the contents of a file from the remote target device down to the client.

Server Prerequisite

The `dmsd` server must be explicitly started with the `--allow_list_read` flag specifying permitted directories.

```
/opt/mellanox/doca/services/dms/dmsd <flags> --allow_list_read <dir1>,<dir2>,<dir3>
```

Client command:

```
/opt/mellanox/doca/services/dms/dmsc <flags> file get --file /tmp/debug/<file_to_get>
```

8.9.6.3.4.3 Put

Streams a file from the client up to the remote target device.

Server Prerequisite

The `dmsd` server must be explicitly started with the `--allow_list_write` flag specifying permitted directories.

```
/opt/mellanox/doca/services/dms/dmsd <flags> --allow_list_write <dir1>,<dir2>,<dir3>
```

Client command:

```
/opt/mellanox/doca/services/dms/dmsc <flags> file put --file /tmp/debug/file_to_send --dst /tmp/output/
path_on_remote_host
```

8.9.6.3.5 mlxconfig

The `mlxconfig` suite enables deep hardware configuration by allowing administrators to set and retrieve native device parameters.

> **Server Prerequisite**
>
> This feature is disabled by default for safety. To use it, the `dmsd` server daemon must be explicitly started with the `--enable_mlxconfig` flag.

8.9.6.3.5.1 Set

Applies `KEY=VALUE` parameter pairs to the target device.

> Some commands may require a firmware reset or system reboot to take effect.

Examples:

- Setting a single param:

```
/opt/mellanox/doca/services/dms/dmsc <flags> mlxconfig set LINK_TYPE_P1=1
```

- Setting multiple parameters:

```
/opt/mellanox/doca/services/dms/dmsc <flags> mlxconfig set LINK_TYPE_P1=1 LINK_TYPE_P2=1
```

8.9.6.3.5.2 Query

Retrieves the configuration parameter values from the device.

Examples:

- Standard query (returns the nextboot value):

```
/opt/mellanox/doca/services/dms/dmsc <flags> mlxconfig query LINK_TYPE_P1 LINK_TYPE_P2
```

- Verbose query (Returns default, current, and nextboot values):

```
/opt/mellanox/doca/services/dms/dmsc <flags> mlxconfig query -v LINK_TYPE_P1
```

8.9.6.3.5.3 Reset

Restores all `mlxconfig` parameters to their default values.

```
/opt/mellanox/doca/services/dms/dmsc <flags> mlxconfig reset
```

> To see the complete list of supported parameters dynamically, run `/opt/mellanox/doca/services/dms/dmsc -a <server>:<port> --insecure mlxconfig query` (requires that the server be started with the `--enable_mlxconfig` flag).

8.9.6.3.6 Containerz

The Containerz suite supports the remote management and monitoring of containers on either the host or the DPU. Behavior adapts automatically based on whether the server is using the Docker or Kubelet backend.

This deployment model follows the DOCA container methodology described in the DOCA Container Deployment Guide.

8.9.6.3.6.1 Container Lifecycle Management

These operations control the execution states of your containers.

- Launch a container.
  - In Docker mode, the image must exist locally:

    ```
    /opt/mellanox/doca/services/dms/dmsc <flags> containerz container start --image <image_name>
    ```

  - In Kubelet mode, provide the path to the pod's YAML manifest:

    ```
    /opt/mellanox/doca/services/dms/dmsc <flags> containerz container start --image /path/to/yaml/file.yaml
    ```

- Display all currently running containers:

  ```
  /opt/mellanox/doca/services/dms/dmsc <flags> containerz container list
  ```

- Halt a running container but leave it available for restart:

  ```
  /opt/mellanox/doca/services/dms/dmsc <flags> containerz container stop --instance <container_name>
  ```

  > In Kubelet mode, this deletes the manifest YAML from the directory.

- Stop and permanently delete the specified container:

```
/opt/mellanox/doca/services/dms/dmsc <flags> containerz container remove --instance <container_name>
```

8.9.6.3.6.2 Image Management

These commands handle the staging, pushing, and removal of container images on the target device.

- Download an image from a remote registry directly to the device:

```
/opt/mellanox/doca/services/dms/dmsc <flags> containerz image pull --image ubuntu
```

- Stream a local container image (in `.tar` format) from the client to the target device over gRPC:

```
/opt/mellanox/doca/services/dms/dmsc <flags> containerz image push --file /path/to/tarfile.tar
```

- Display all container images currently stored on the device:

```
/opt/mellanox/doca/services/dms/dmsc <flags> containerz image list
```

- Delete a specific container image from the device's storage:

```
/opt/mellanox/doca/services/dms/dmsc <flags> containerz image remove --image ubuntu
```

8.9.6.3.6.3 Volume Operations

Manages persistent storage volumes mapped to your containers.

> ⚠ In Kubelet mode, all volumes are strictly created under `/var/dms/volume`.

- Create a new named storage volume:

```
/opt/mellanox/doca/services/dms/dmsc <flags> containerz volume create --name my_volume
```

- Display all named volumes and their current mount points:

```
/opt/mellanox/doca/services/dms/dmsc <flags> containerz volume list
```

- Delete a specific volume by its name:

```
/opt/mellanox/doca/services/dms/dmsc <flags> containerz volume remove --name my_volume
```

8.10 DOCA Pipeline Language Services Guide

This page outlines the DOCA Pipeline Language (DPL) approach to packet processing programmability for NVIDIA BlueField. DPL introduces a software development solution based on a domain-specific programming language (DSL), supported by a set of DOCA services.

For more details, refer to the DPL Developer Container.

8.10.1 Introduction

DPL is derived from the P4-16 language specification.

P4 is an open-source, domain-specific programming language (DSL) designed for programming and customizing network data planes. It provides a high-level abstraction for programmable packet processing, allowing developers to add, modify, and extend networking functionalities.

For fixed-function devices, P4 serves as a documentation tool, offering a structured description of the data plane's functional blocks.

8.10.1.1 Key Features of P4

- High-level abstraction: Simplifies the programming of complex network data planes with clear and concise syntax
- Programmable packet processing: Enables customization of packet processing and traffic management
- Documentation of fixed functions: Offers a standardized method for documenting the fixed functional blocks of network devices

8.10.1.2 P4 Compiler

A P4 compiler (p4c) is a critical component in the P4 ecosystem. It automatically generates the data plane program and corresponding control plane interface, ensuring seamless coordination between the data plane and control plane.

Key benefits of a compiler:

- Automatic generation: Streamlines development by automatically generating essential components and optimizing resource usage

- Custom pipeline behavior: Allows developers to extend data plane functionality with customized pipeline behaviors
- Dynamically loadable pipelines: Supports hot-swappable pipelines, enabling updates without rebuilding or redeploying an entire application
- Control plane integration: Facilitates communication between the data plane and control plane via an open-source API, ensuring effective management of customized pipelines

8.10.1.3 Focus on NVIDIA's DOCA Pipeline Language

The remainder of this document focuses on NVIDIA's implementation of the DOCA Pipeline Language (DPL). While DPL's syntax is derived from P4-16, its pipeline semantics align with NVIDIA's DPU architecture rather than standard P4 execution models. For example, while P4 semantics imply a staged pipeline based on a feed-forward RMT (Reconfigurable Match-Action Table) architecture, NVIDIA's DPU architecture follows a run-to-completion dRMT (disaggregated RMT) model, offering greater flexibility and enhanced capabilities.

8.10.1.4 DPL Highlights

DPL introduces a unique programming paradigm distinct from traditional SDKs, APIs, libraries, drivers, or utilities. It is a specialized programming language with a runtime system, designed for rapid development, testing, and deployment of packet-processing pipelines. DPL is a ready-to-use, customizable solution as part of DOCA Services.

8.10.1.4.1 Key Features of DPL

- DPL Services: A system-level solution that includes a compiler, runtime agent, and debugging tools, enabling rapid programming of the DPU pipeline
- Optimized for NVIDIA devices: Specifically designed and fine-tuned for programming network data planes on NVIDIA hardware
- Advanced networking functionality: Leverages DPL's capabilities to enhance and extend networking features on NVIDIA DPUs
- Comprehensive documentation: Provides detailed descriptions of BlueField's fixed functional blocks within the DPU data plane
- A P4Runtime compatible server utilizing the open-source APIs with vendor specific extensions

8.10.1.4.2 Developer Resources

The DPL programming guide serves as a comprehensive resource for developers who want to use DPL for programming network data planes. By utilizing the DPL `p4c` compiler and the P4-16 specification, developers can:

- Enhance network device functionality and efficiency
- Meet the evolving demands of modern network infrastructures
- Ensure seamless integration and optimization within NVIDIA's DPU ecosystem

8.10.2 Prerequisites

The DPL compiler can run on any Linux OS that supports Docker. Language specifications, runtime APIs, and tutorials are available at the P4 GitHub Repository.

8.10.2.1 Development Environment Requirements

To set up the development environment, the following components are required:

- Host computer with Ubuntu 22.04 or later with Docker installed (required for the DOCA development container)
- Server with root/hypervisor access to install the DPL Runtime Service package
- One or more BlueField-3 devices, installed in the target server for DPL execution

8.10.2.2 Suggested Workflow

The suggested workflow is as follows:

1. Coding

1. Use the DPL programming guide and sample applications to create a DPL program remotely.
2. The program is compiled using `dplp4c`, iterating until it successfully produces a binary.

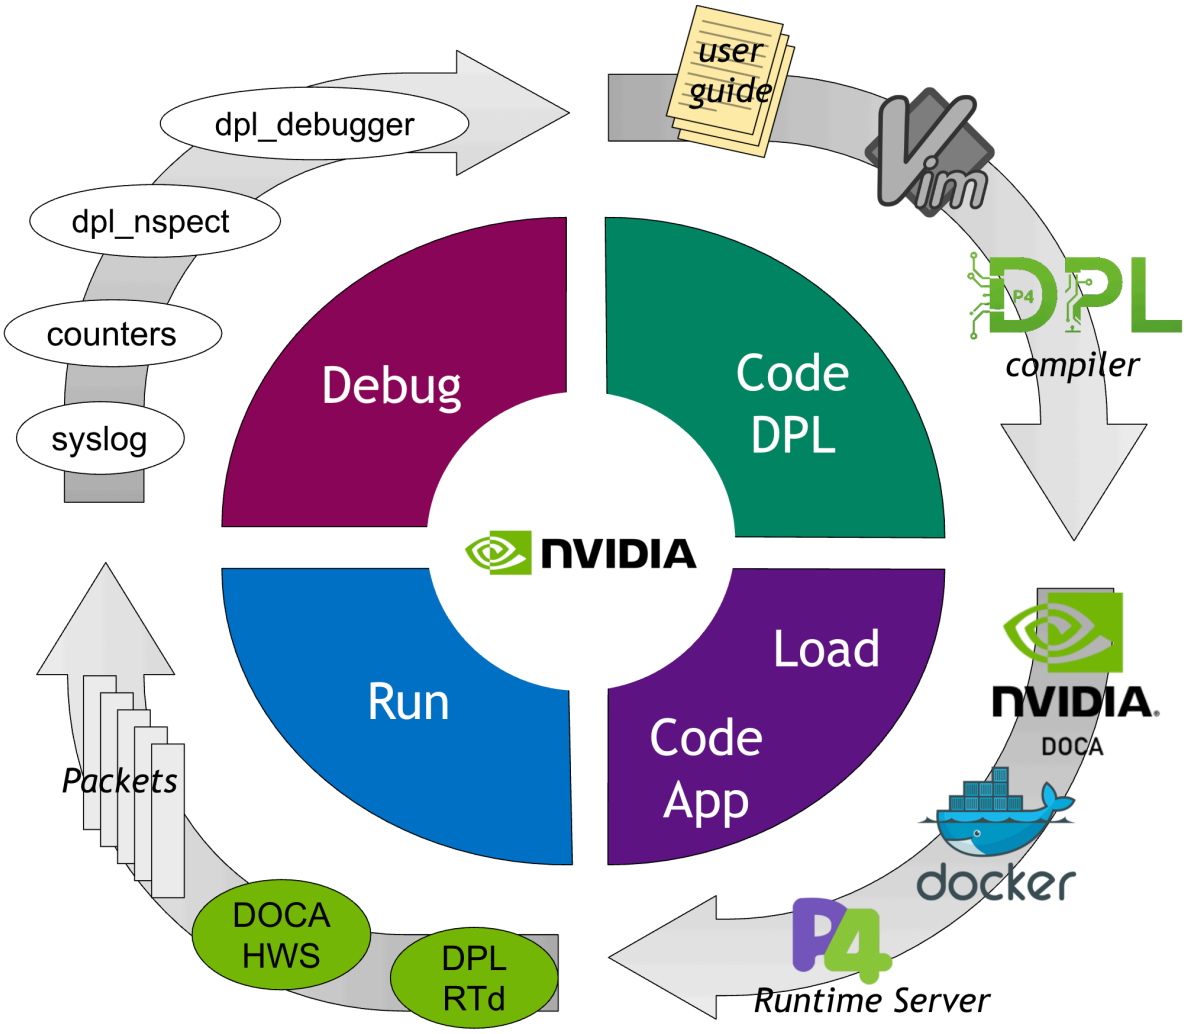
- Loading

1. The compiled binary is transferred to the BlueField system.
2. Using the P4Runtime API (via an open-source or proprietary P4Runtime controller), the pipeline is sent from the remote machine to the DPL Service running on BlueField.
3. The user checks for P4Runtime error messages.

- Running

1. Inspect the logs for any DPL Service error messages.
2. Use the `dpl_nspect` tool to verify that P4 tables and entries are present in the hardware.
3. Use the `dpl_debugger` tool to understand the packet processing pipeline, which shows the state of packets and their metadata.

This process is repeated until the DPL application is fully verified.



8.10.3 DPL Programming Model

P4, and by extension DPL, is a domain-specific language (DSL) designed for programming network data planes. It enables customized packet processing, allowing developers to define how packets are handled at different pipeline stages.

However, P4 programs are not universally portable across different architectures. Instead, they are typically compatible within the same target architecture family.

The BlueField programmable pipeline follows a hybrid model that leverages both hardware and software processing capabilities. It consists of three main stages:

1. Parsing
2. Match-action processing (Steering)
3. Forwarding database (FDB)

8.10.3.1 Parsing

The BlueField native parser is the first stage of the packet processing pipeline. It is responsible for identifying and extracting packet headers, progressing through the protocol stack until the entire frame is parsed.

Key features:

- Pre-defined protocol headers and standard transitions based on IETF specifications
- On-demand reparsing at any stage, which eliminates the need for reinjection or a final deparser stage

8.10.3.1.1 Flex Parsing

Flex parsing allows developers to integrate custom protocol headers into BlueField's hardware parsing engine. It consists of four components:

- Flex Arc In: Defines the transition from a native header to a Flex header
- Flex Header: Specifies header characteristics such as length and next protocol location
- Flex Sampler: Extracts specific bytes from the hardware, enabling their use in control blocks or table keys
- Flex Arc Out: Defines the transition from a Flex header back to a native header (or another Flex header)

The DPL compiler automatically generates Flex parsing components based on the developer's defined parse nodes and transitions.

8.10.3.1.2 Operational Mode

- The DPL parser operates in a hybrid mode with a default native parser
- The compiler automatically integrates native headers and fields into DPL constructs
- The Flex parse graph consists of:
    - Nodes (either native or flex)
    - Arcs (transitions)

- Samplers for custom parsing operations

This design eliminates the need to redefine and reimplement standard IETF protocols and headers.

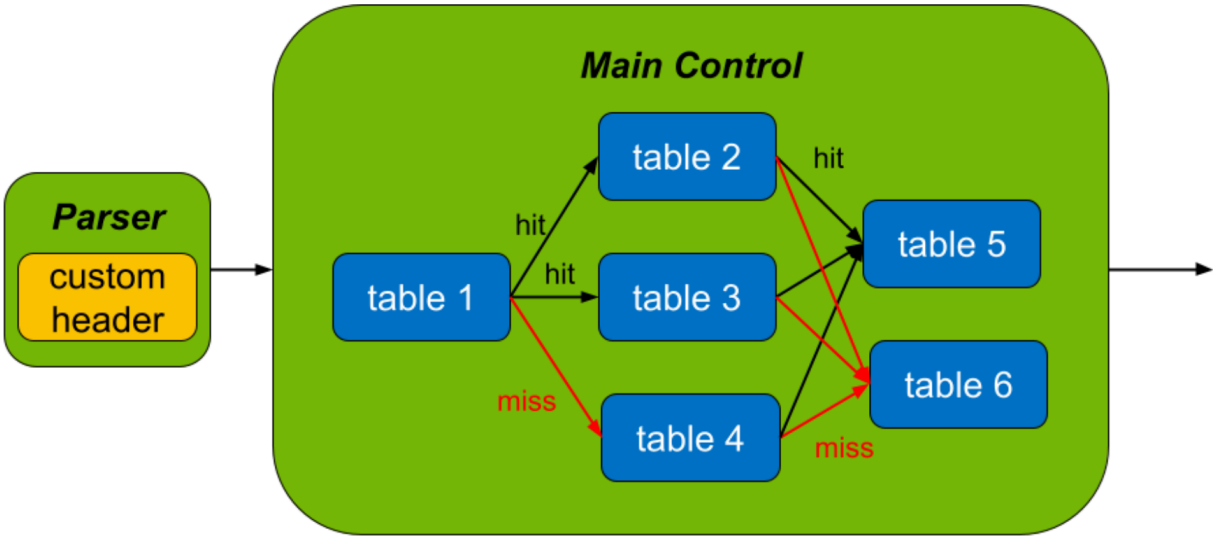
8.10.3.2 Match-Action Processing (Steering)

After parsing, packet processing decisions are made based on match-action tables, commonly referred to as "Steering".

Key Features:

- Match fields: Define packet attributes for classification (for example, source/destination MAC, VLAN, IP, and protocol headers)
- Tables: Store rules for packet handling and decision-making
- Actions: Define processing rules (for example, forwarding, header modification, dropping packets)
- Programmability: Allows dynamic updates to match-action rules based on network conditions
- Efficient processing: Packet handling occurs directly in hardware, reducing latency
- P4Runtime integration: DPL tables are populated via the P4Runtime API, supporting SDN controllers

> In this document, the terms "flow tables" and "P4 tables" are interchangeable.



8.10.3.3 Forwarding Database

The Forwarding Database (FDB) is the final stage within the embedded switch (eSwitch). It enables accurate and efficient packet routing within the network infrastructure. It is responsible for:

- Storing and managing MAC addresses
- Ensuring efficient packet forwarding based on network topology
- Maintaining records of port locations for destination-based forwarding

8.10.3.4 BlueField DPU Pipeline Behavior

The BlueField pipeline is designed for flexibility, allowing developers to customize packet processing to meet specific application needs.

Key characteristics:

- Extended parser support: Developers can expand the native parser using Flex Parsing
- Immediate execution model: No deferred actions; all modifications take effect immediately.
- Mid-pipeline reparsing: Packet headers are reparsed immediately after modification, ensuring correct metadata updates
- No deparser control in TA: Unlike traditional architectures, BlueField does not require a separate deparser step

8.10.3.5 DPL Services

Rather than providing a traditional SDK or driver-level APIs, DPL offers a high-level, services-based approach to programming the DPU pipeline.

The DPL Services consist of 2 packages that form the DPL solution. The services are provided as containers and are deployed separately.

See the following sections on each service:

- DPL System for a high-level overview of the components that make up the DPL Services
- DPL Runtime Service for instructions on deploying and configuring the backend DPL Runtime Service which interacts with the hardware.
- DPL Development Container for information about the DPL language, the compiler tools, and methodology building DPL programs

See also:

- DOCA Pipeline Language Developer Tools to learn about the various tools and methods for debugging DPL programs

8.10.4 DPL Release Notes

8.10.4.1 Changes and New Features

This section describes the changes and new features in this software release.

General Features & Enhancements

- Added support for modifying action parameters for both default and non-default entries.

DPL Development Container

- Running and working with the container changed. See DPL Installation Guide.

8.10.4.2 Capabilities and Limitations

8.10.4.2.1 General Constraints

- P4 Controller support: Only one P4 Controller can be connected to the DPL Runtime daemon at a time.
- Table and counter object sizes:
  - Must be a power of 2.
  - Must be smaller than 2^{23}.
  - A P4 table of size *N* allows for *N-1* regular entries and 1 default entry.

8.10.4.2.2 Supported RPC Messages

The following RPC messages are supported by the DPL Runtime daemon:

RPC Message	Support Details & Limitations
Write RPC	• Atomicity: Only `CONTINUE_ON_ERROR` is supported • Batching: Supported
Read RPC	Batching: Supported
Pipeline Config	`SetForwardingPipelineConfig` and `GetForwardingPipelineConfig` are supported.

RPC Message	Support Details & Limitations
StreamChannel RPC	Supported updates: `PacketIn`, `PacketOut`, `IdleTimeoutNotification`, `StreamError`.

8.10.4.2.3 Entity & Operation Support Matrix (Write/Read RPC)

Instead of listing operations and entities separately, developers can consult this matrix to see exactly what operations are permitted on which entity types.

Entity Type	Read RPC	Write RPC: INSERT	Write RPC: DELETE	Write RPC: MODIFY
TableEntry	Supported	Regular entries only	Regular entries only	Default entry only
CounterEntry (Direct/ Indirect)	Supported	Unsupported	Unsupported	Supported
MeterEntry (Direct/ Indirect)	Supported	Unsupported	Unsupported	Supported

8.10.4.2.4 Metering Limits

This table defines the maximum thresholds based on the selected mode.

Mode	Max CIR	Max CBurst	Max PIR	Max PBurst
Bytes	255,000,000,000	2,147,483,648	510,000,000,000	4,294,967,296
Packets [1]	1,992,187,500	16,777,216	3,984,375,000	33,554,432

1. Packets mode, 1 packet equals 128 bytes

8.10.4.2.5 Unsupported Features

The following P4 Runtime features are currently not supported in this release:

Category	Unsupported Items
RPC Messages	`Capabilities` RPC
StreamChannel Updates	• `MasterArbitrationUpdate` • `DigestList` / `DigestListAck` • `google.protobuf.Any`

Category	Unsupported Items
Entities	• `ExternEntry` • `ActionProfileMember` • `ActionProfileGroup` • `PacketReplicationEngineEntry` • `ValueSetEntry` • `RegisterEntry` • `DigestEntry`

8.10.4.3 Bug Fixes

Reference	Issue
P4DT-800	Description: Programs using comparison operators are not supported and will result in an error.
P4DT-859	Description: DPL Development scripts fail with the community edition of docker installed from `docker.ce`, instead use the official release installed from `docker.io`.
4540834	Description: Entries insertion/deletion rate may degrade when using tables with idle timeout or delayed counters.
	Discovered in version: 1.2.0

8.10.4.4 DPL Runtime Daemon Known Issues

The following are known limitations of the DPL Runtime daemon service.

Reference	Issue
4259599	Description: Packets received with double VLAN tags (Dot1AD followed by Dot1Q) are processed with the tags in reversed order. This causes the hardware to misinterpret the inner and outer VLAN structure.
	Workaround: Disable RX VLAN offload on the affected VF network device using the following command: `ethtool -K <vf_netdev> rxvlan off`
	Reported in version: 1.2.0
4437411	Description: Packets with broadcast MAC `ff:ff:ff:ff:ff:ff` transmitted from VFs are not supported by DPL actions `nv_add_entry` and `nv_send_to_controller`.
	Workaround: N/A
	Reported in version: 1.2.0

Reference	Issue
4439323	Description: Modifying eSwitch multiport mode (enable/disable) while DPL RT Service is active causes system hang.
	Workaround: Stop the DPL RT Service before changing `esw_multiport` settings.
	Reported in version: 1.2.0
1141	Description: Debugging packets from the second wire port P1 is not supported.
	Workaround: Use wire port P0 for debugging packets.
	Reported in version: N/A

8.10.4.5 DPL Compiler Known Issues

The following are known limitations of the DPL Compiler.

Reference	Issue
DPLCOMP-1848	Description: The fields `ipv4.protocol` and `ipv6.next_header` cannot be used as match keys in an `nv_add_entry` table.
	Workaround: Use a constant value (e.g., `NV_TCP_PROTOCOL`) to define the protocol context instead of using the protocol field as a variable key.
	Reported in version: 1.3.0
DPLCOMP-2052	Description: Multiple flex parser nodes with same field layout (bit offset and length for the selection field) may fail to load.
	Workaround: None
	Reported in version 1.5.0
DPLCOMP-2060	Description: Sliced LPM key with a mask of all 1s fails to load.
	Workaround: None
	Reported in version 1.5.0
DPLCOMP-1149	Description: Cycles in flex parser graph result in load failure with syndrome 0x178645
	Workaround: None
	Reported in version 1.3.0
DPLCOMP-2071	Description: Building with debug points enabled (--debug-mode=auto or extern) or when the program explicitly calls the nv_send_debug_pkt() extern, a validation error: "<variable name>" is read without initialization due to a compiler optimization in at least one code path" may be incorrectly triggered.
	Workaround: Disable debugging
	Reported in version 1.5.0

8.10.5 DPL System

This document provides a high-level overview of the NVIDIA® DOCA Pipeline Language (DPL) solution, which enables programmable packet processing on NVIDIA® BlueField® DPUs and SuperNICs using P4-based semantics.

8.10.5.1 Introduction

DPL is a domain-specific programming framework based on the P4-16 language. While reusing P4 syntax, DPL introduces NVIDIA-specific semantics and architecture tailored for the BlueField platform. Rather than relying on C-based APIs, developers use DPL to define packet parsing, matching, and processing behavior directly in a high-level, declarative manner. This speeds up development and simplifies pipeline optimization.

A deployed DPL program is dynamically controlled using P4Runtime, an open-source, gRPC-based control plane interface and with a custom shared memory interface for high performance situations. This allows rules and configurations to be updated at runtime without recompilation. Although DPL is compatible with any P4Runtime-compliant controller, future support for vendor-specific extensions is planned. The DPL compiler also generates optimized, ready-to-use APIs that simplify integration with custom control applications (for example, DPDK-based implementations). These generated APIs link the user's application to a low-latency, BlueField-optimized interface that exposes control and data-plane operations in a structured manner, enhancing rule insertion rates, configuration update performance, and overall usability.

The DPL toolkit includes:

- A compiler for building BlueField optimized pipelines
- A runtime service to manage hardware deployment and control-plane interaction
- Debugging and inspection developer tools for introspecting the pipeline

Together, these components deliver a complete programmable pipeline platform optimized for BlueField devices.

8.10.5.2 BlueField Network Configuration

BlueField-3 combines a ConnectX networking ASIC with an embedded Arm subsystem, providing high-performance networking and programmable packet processing. It supports offloading and acceleration of SDN, storage, and security functions.

8.10.5.2.1 DOCA Device Types

DPL supports two kinds of DOCA devices:

- Local device – A PF, VF, or SF that is locally exposed to the system (host or BlueField).
- Netdev representor – A proxy network interface on BlueField for a device on the host side. Representors allow the DPU to control and inspect traffic flowing to/from host-side devices.

8.10.5.2.2 Representor Naming

- Uplink Representor – `p<port_number>`
- PF Representor – `pf<port_number>hpf`
- VF Representor – `pf<port_number>vf<function_number>`
- SF Representor – `en<domain>f<function>pf<port_number>sf<function_number>`

> ⚠ The host function's MTU must be smaller than that of both its uplink and representor.

8.10.5.3 DPL Architecture

In DPU mode, the BlueField owns NIC resources, and all host traffic flows through a virtual switch on the Arm subsystem before reaching the host.

Key characteristics:

- Host-side NIC drivers load only after the BlueField completes NIC configuration
- BlueField allocates all NIC memory (ICM)
- BlueField configures the embedded switch, and all host traffic is intercepted

A compiled DPL pipeline executes within the embedded switch (eSwitch) and consists of:

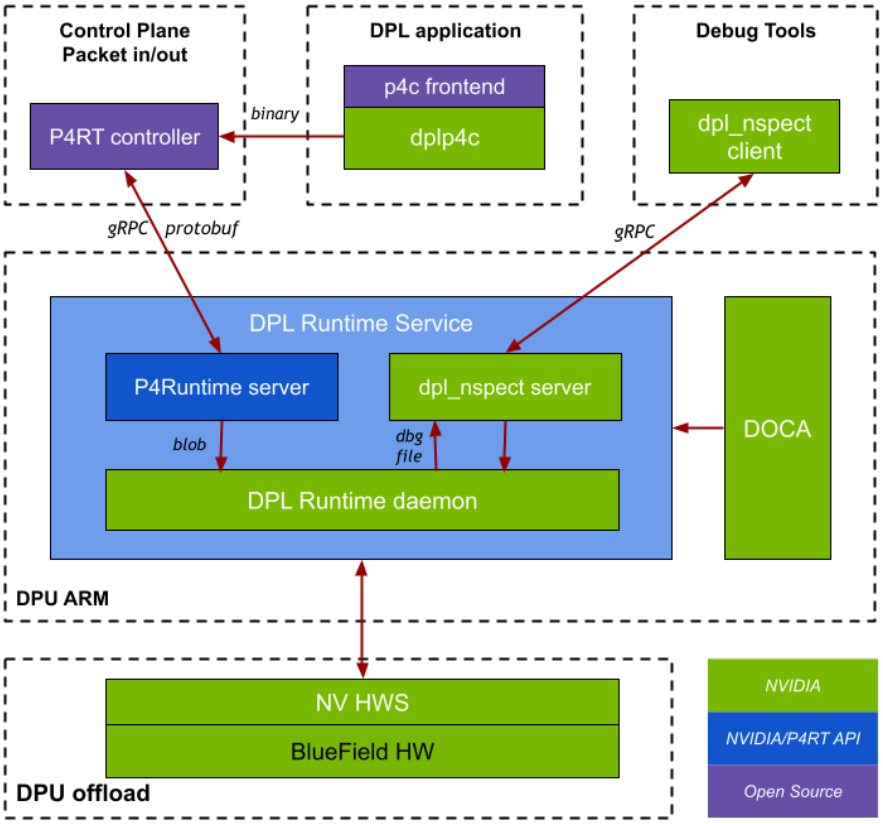
- A programmable packet parser (parse graph)
- Match/action tables

- Packet actions (e.g., forward, drop, modify, encrypt)

  - `pf0hpf` and `pf1hpf` are the representors facing the x86 host
  - `pf0` and `pf1` are the representors facing the network

8.10.5.4 DPL Components

The DPL solution on the BlueField DPU consists of multiple components working in tandem. These components are outlined below and shown in the following diagram:



8.10.5.4.1 DPL Compiler

The compiler, typically run from a host development system, generates:

- P4Info file – Target-independent protobuf description used by controllers
- Device config (`.dplconfig`) – Binary blob for loading into BlueField hardware
- Optional debug file – Used by inspection debug tools

> P4 language reference: P4-16 v1.2.4 Documentation.

8.10.5.4.2 P4Runtime Controller

The P4Runtime Controller manages real-time updates and control of the pipeline. It must conform to P4Runtime v1.3.0 and communicates with BlueField using gRPC over TCP (default port 9559). Capabilities include:

- Installing/removing rules
- Querying table state
- Handling packet-in/out traffic

8.10.5.4.3 DPL Nspect

DPL Nspect is a host-side CLI tool for:

- Viewing table contents
- Debugging DPL pipelines
- Tracing packet path and action outcomes

It communicates with the runtime service's internal debug server.

8.10.5.4.4 DPL Runtime Service

8.10.5.4.4.1 DPL Runtime Daemon

The runtime daemon (`dpl_rtd`) runs on the BlueField and:

- Hosts the gRPC P4Runtime server
- Processes incoming controller commands
- Loads compiled pipeline artifacts
- Interfaces with the DOCA HWS driver
- Manages parse graphs, match tables, and state
- Provides debug and monitoring services

8.10.5.4.4.2 P4Runtime Server

Implements gRPC endpoints for standard P4Runtime protocol messages. Converts P4Info operations into hardware actions using the DOCA HWS driver. The server is hosted within the DPL Runtime Service.

8.10.5.4.4.3 DPL Nspect Server

A backend service in the runtime daemon that handles debug and monitoring traffic. Communicates with the Nspect client and debugger tools over gRPC.

8.10.5.4.5 NV HWS Driver

The NV HWS Driver provides low-level APIs for pipeline construction and table management in BlueField hardware. The DPL compiler and runtime interface with this driver to install flows, modify match criteria, and define actions.

8.10.5.4.6 eSwitch Management

Developers are free to manage the eSwitch using tools like:

- OVS (e.g., DOCA OVS)
- DPDK-based apps
- DOCA management interfaces

DPL does not constrain how virtual interfaces or bridges are configured.

8.10.6 DPL Runtime Service

This page explains how to deploy, configure, and operate the DOCA Pipeline Language (DPL) Runtime Service on NVIDIA® BlueField® DPUs and SuperNICs. The service enables runtime management of data plane pipelines compiled using DPL.

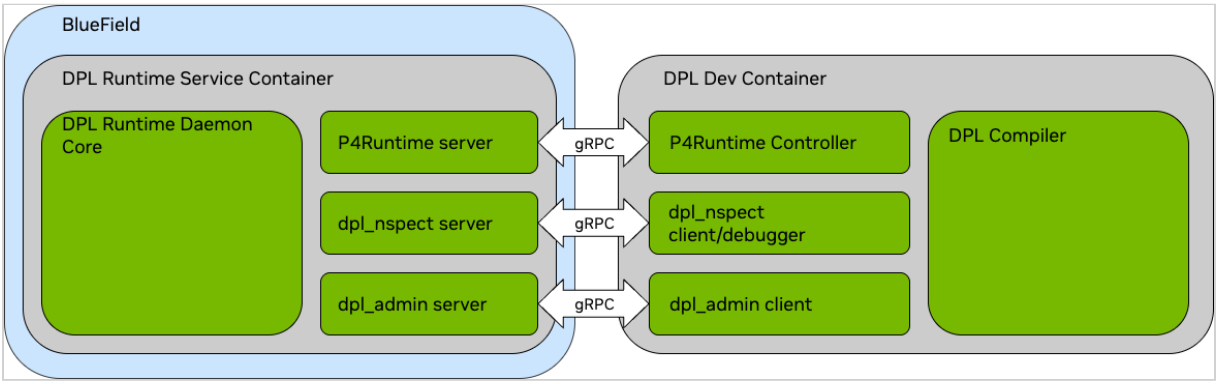
8.10.6.1 Introduction

The DPL Runtime Service programs and manages the DPU / NIC datapath at runtime. It supports dynamic rule insertion, packet monitoring, and forwarding logic using both standard and proprietary APIs.

The service consists of the following core components:

Component	Description
Runtime core	Manages requests from all interfaces and programs hardware resources
P4Runtime server	gRPC server implementing the P4Runtime 1.4.1 API for remote pipeline configuration and table control.
Nspect server	Provides runtime visibility and debugging through the `dpl_nspect` client
Admin server	Offers administrative and configuration control over the daemon via gRPC

High-level system illustration:



8.10.6.2 Requirements

8.10.6.2.1 Supported Platforms

DPU:

DPL is supported on the following BlueField SKUs:

NVIDIA SKU	Legacy OPN	PSID	Description
900-9D3B6-00CV-AA0	N/A	MT_0000000884	BlueField-3 B3220 P-Series FHHL DPU; 200GbE (default mode) / NDR200 IB; Dual-port QSFP112; PCIe Gen5.0 x16 with x16 PCIe extension option; 16 Arm cores; 32GB on-board DDR; integrated BMC; Crypto Enabled
900-9D3B6-00SV-AA0	N/A	MT_0000000965	BlueField-3 B3220 P-Series FHHL DPU; 200GbE (default mode) / NDR200 IB; Dual-port QSFP112; PCIe Gen5.0 x16 with x16 PCIe extension option; 16 Arm cores; 32GB on-board DDR; integrated BMC; Crypto Disabled
900-9D3B6-00CC-AA0	N/A	MT_0000001024	BlueField-3 B3210 P-Series FHHL DPU; 100GbE (default mode) / HDR100 IB; Dual-port QSFP112; PCIe Gen5.0 x16 with x16 PCIe extension option; 16 Arm cores; 32GB on-board DDR; integrated BMC; Crypto Enabled
900-9D3B6-00SC-AA0	N/A	MT_0000001025	BlueField-3 B3210 P-Series FHHL DPU; 100GbE (default mode) / HDR100 IB; Dual-port QSFP112; PCIe Gen5.0 x16 with x16 PCIe extension option; 16 Arm cores; 32GB on-board DDR; integrated BMC; Crypto Disabled

The following NVIDIA DPUs are supported with DOCA on the host:

- BlueField-3 devices

SuperNIC:

DPL is supported on the following NIC SKUs:

NVIDIA SKU	Legacy OPN	PSID	Description
900-9X91Q-00CN-ST0	N/A	-	NVIDIA ConnectX-9 C9240 HHHL SuperNIC, Dual-port 400GbE (default) / 400Gb/s IB, QSFP112, PCIe 6 x16 with x16 PCIe SocketDirect extension option, Crypto Enabled, Secure Boot Enabled, Tall bracket

8.10.6.2.2 Hardware Prerequisites

DPU:

For the the system requirements, see DPU's hardware user guide.

SuperNIC:

For the the system requirements, see Adapter's user guide.

8.10.6.2.3 Software Prerequisites

DPU:
